Abstract

This paper presents the application of optimal control problem in modeling of stirred tank heater temperature control. The analysis of the open loop system shows that the system is not efficient without a controller. Linear Quadratic Gaussian (LQG) and Linear Quadratic Integral (LQI) controllers are used to increase the performance of the system. Comparison of the closed loop system with the proposed controllers have been done with Matlab/Simulink Toolbox and a promising results have been analyzed.

Keywords: Stirred tank heater, Linear Quadratic Gaussian, Linear Quadratic Integral

1. Introduction

Mixing Vessels play an essential function in chemical processes. Its utilities are varied and range from blending chemicals to converting temperatures of fluids. In the look at of stirred tank heaters, we are able to use it typically as an instrument for varying the temperature of fluid present in the tank. We normally use a steam enters and leave the tank through a pipe. Here, we use the steam to increase the temperature of the tank. The objective is to control the output temperature of the tank at desired value for the operating condition.

2. Mathematical Modeling of the Stirred Tank Heater

The stirred tank heater system is shown in Figure 1 below.
The material balance on this system will be:

\[
\frac{dm}{dt} = F_0 \rho_0 - F_1 \rho_1 \Rightarrow A \frac{d(h \rho)}{dt} = F_0 \rho_0 - F_1 \rho_1 \quad (1)
\]

Assuming constant cross-sectional area, A. The energy balance is:

\[
\frac{dE}{dt} = F_0 \rho_0 \dot{H}_0 - F_1 \rho_1 \dot{H}_1 + Q = F_0 \rho_0 \dot{H}_0 - F_1 \rho_1 \dot{H} + Q \quad (2)
\]

Remember, within the tank:

\[
\frac{dE}{dt} = \frac{d(U + K + P)}{dx} \approx \frac{dU}{dt} \approx \frac{dH}{dt} \quad (3)
\]

So

\[
\frac{dH}{dt} = \frac{d(\rho V \dot{H})}{dt} = F_0 \rho_0 \dot{H}_0 - F_1 \rho_1 \dot{H} + Q \quad (4)
\]

If we assume that the enthalpy can be expressed as:

\[
\dot{H} = \dot{C}_p (T - T_{ref}) + \dot{H}_{ref} \quad (5)
\]

Then with

\[ T_{ref} = 0 \]
\[ \dot{H}_{ref} = 0 \]

Then Equation (4) becomes
\[
\frac{d\left(\rho V \hat{C}_p T\right)}{dt} = F_0 \rho_0 \hat{C}_p T_0 - F_i \rho_i \hat{C}_p T + Q \tag{6}
\]

Rearranging Equation (6) becomes

\[
\frac{d\left(\rho VT\right)}{dt} = F_0 \rho_0 T_0 - F_i \rho_i T + \frac{Q}{\hat{C}_p} \tag{7}
\]

If we assume, then: \( \rho = \text{constant} \) and

\[
V = A \frac{dh}{dt} = F_0 - F_i
\]

Then Equation (7) becomes

\[
\rho A \frac{d(hT)}{dt} = F_0 \rho T_0 - F_i \rho T + \frac{Q}{\hat{C}_p} \tag{8}
\]

Rearranging Equation (8) becomes

\[
T A \frac{dh}{dt} + h A \frac{dT}{dt} = F_0 T_0 - F_i T + \frac{Q}{\rho \hat{C}_p} \tag{9}
\]

Inserting the material balance:

\[
T \left(F_0 - F_i\right) + h A \frac{dT}{dt} = F_0 T_0 - F_i T + \frac{Q}{\rho \hat{C}_p} \tag{10}
\]

Rearranging Equation (10) becomes

\[
h A \frac{dT}{dt} = F_0 (T_0 - T) + \frac{Q}{\rho \hat{C}_p}
\]

Where

\[
H = h(t)
\]

If we make the assumption that \( \frac{dh}{dt} = 0 \) then \( V = hA = \text{constant} \) and \( F_0 = F_i \) so

\[
V \frac{dT}{dt} = F_0 (T_0 - T) + \frac{Q}{\rho \hat{C}_p} \tag{11}
\]

If we are using steam for the heating medium, then we could relate the rate of heat added, \( Q \), to the steam temperature, \( T_s \), as:
\[ Q = UA(T_s - T) \]

Then Equation (11) becomes
\[ V \frac{dT}{dt} = F_0(T_0 - T) + \frac{UA(T_s - T)}{\rho C_p} \quad (12) \]

Then arranging Equation (12) yields
\[ \frac{dT}{dt} + aT = \frac{1}{\tau_f} T_0 + KT \quad (13) \]

Where
\[ \frac{1}{\tau_f} = \frac{F_0}{V}, \quad K = \frac{UA}{\rho V C_p} \quad \text{and} \quad a = \frac{1}{\tau_f} + K \]

Letting \( x_1 = T, \dot{x}_1 = \frac{dT}{dt}, u_1 = T_0 \) and \( u_2 = T_s \) yields to the state space form
\[ \dot{T} = -aT + \begin{bmatrix} \frac{1}{\tau_f} & K \end{bmatrix} \begin{bmatrix} T_0 \\ T_s \end{bmatrix} \quad (14) \]
\[ y = T \]

For
\[ \tau_f = 0.2 \text{sec}, K = 0.4 \quad \text{and} \quad a = 5.4 \]

The state space representation becomes
\[ \dot{T} = -5.4T + \begin{bmatrix} 5 & 0.4 \end{bmatrix} \begin{bmatrix} T_0 \\ T_s \end{bmatrix} \quad (15) \]
\[ y = T \]

3. Proposed Controllers Design

3.1 LQG optimal controller Design

LQG computes an optimal controller to stabilize the plant \( G(s) \)
\[ \dot{x} = Ax + Bu + \xi \quad (16) \]
\[ y = Cx + Du + \theta \]

And minimize the quadratic cost function
The block diagram of a stirred tank heater system with LQG controller is shown in Figure 2 below.

Figure 2: Block diagram of a stirred tank heater system with LQG controller

The solution of the LQG problem is a combination of the solutions of Kalman filtering and full state feedback problems based on the so-called separation principle.

The plant noise and measurement noise are white and Gaussian with joint correlation function

$$E\left\{ \begin{bmatrix} \xi(t) \\ \theta(t) \end{bmatrix} \begin{bmatrix} \xi(t) \\ \theta(t) \end{bmatrix}^T \right\} = \begin{bmatrix} \Xi & N_f \\ N_f^T & \Theta \end{bmatrix} \delta(t-\tau) \quad (18)$$

The input variables $W$ and $V$ are

$$W = \begin{bmatrix} Q & N_c \\ N_c^T & R \end{bmatrix} ; \quad V = \begin{bmatrix} \Xi \\ N_f \end{bmatrix}$$

The final negative-feedback controller becomes:

$$F(s) := \begin{bmatrix} A - K_f C_2 - B_2 K_c + K_f D_2 K_c & K_f \\ K_c & 0 \end{bmatrix}$$

For the Gaussian noises $\Xi$ and $\Theta$:

$$\Xi = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad \Theta = \begin{bmatrix} 5 & 0 \\ 0 & 5 \end{bmatrix}$$

The value of $Q$ and $R$ is chosen as

$$J_{LQG} = \lim_{T \to \infty} E \left\{ \int_0^T \begin{bmatrix} x^T u^T \end{bmatrix} \begin{bmatrix} Q & N_c \\ N_c^T & R \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} dt \right\} \quad (17)$$
\[ Q = 0.1 \text{ and } R = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \]

The LQG controller becomes

\[ \dot{L}_1 = -5.72L_1 + \begin{bmatrix} 0.09181 \\ 0.04534 \\ 0.003627 \end{bmatrix} \]

\[ y = \begin{bmatrix} -0.04534 \\ -0.003627 \end{bmatrix} L_1 \]

### 3.2 Linear Quadratic Integral Controller Design

LQI computes an optimal state-feedback control law for the tracking loop. Block diagram of a stirred tank heater system with LQI controller is shown in Figure 3 below.

![Figure 3 Block diagram of a stirred tank heater system with LQI controller](image)

For a plant \( \text{sys} \) with the state-space equations

\[ \dot{x} = Ax + Bu \quad (19) \]

\[ y = Cx + Du \]

The state-feedback control is of the form

\[ u = -K[x, x_i] \quad (20) \]

Where \( x_i \) is the integrator output. This control law ensures that the output \( y \) tracks the reference command \( r \). For MIMO systems, the number of integrators equals the dimension of the output \( y \). LQI calculates the optimal gain matrix \( K \), given a state-space model \( \text{SYS} \) for the plant and weighting matrices \( Q, R, N \). The value of \( Q, R \) and \( N \) is chosen as
\[ Q = 1 ; R = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \text{ and } N = \begin{bmatrix} 1 & 0 \end{bmatrix} \]

The LQI optimal gain matrix becomes

\[ K = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \]

### 4. Result and Discussion

#### 4.1 Open Loop Response of the Stirred Tank Heater

The open loop response of the stirred tank heater system for a 10 °C input temperature and a step (from 0 to 25 °C) steam temperature simulation result is shown in Figure 4 below.

Figure 4 Open loop response

The result shows that the output temperature is 11 °C for a steam temperature of 25 °C. This system is not efficient because to produce an 11 °C the system uses excess steam temperature.

#### 4.2 Comparison of the Closed Loop Response of the Stirred Tank Heater with LQG and LQI Controllers for a Step Steam Temperature Input

Comparison of the closed loop response of the stirred tank heater with LQG and LQI controllers for a 5 °C input temperature and a step (from 0 to 25 °C) steam temperature simulation result is shown in Figure 5 below.
The simulation result shows that both the proposed controllers improved the output temperature but the stirred tank heater with LQG controller performance is better because the system improves the settling time and the percentage overshoot.

**4.3 Comparison of the Closed Loop Response of the Stirred Tank Heater with LQG and LQI Controllers for a Random Steam Temperature Input**

Comparison of the closed loop response of the stirred tank heater with LQG and LQI controllers for a $5 \, ^{\circ}C$ input temperature and a random (between 10 to $25 \, ^{\circ}C$) steam temperature simulation result is shown in Figure 6 below.
The simulation result shows that the stirred tank heater with LQG controller performance is better than the stirred tank heater with LQI controller in improving the output temperature, settling time and the percentage overshoot.

5. Conclusion

In this paper, the modeling and design of stirred tank heater temperature control have been done successfully. The analysis and simulation of the open loop stirred tank heater proved that the system is not efficient and to improve the output temperature a feedback controller is needed. In this paper, an optimal control method is used to improve the system. Linear Quadratic Gaussian and Linear Quadratic Integral controllers are used. Comparison of the closed loop response of the stirred tank heater with LQG and LQI controllers have been done for a step and random steam temperature input signal. For the step input signal the simulation result proved that both the proposed controllers improved the output temperature but the stirred tank heater with LQG controller performance is better because the system improves the settling time and the percentage overshoot while for the random input signal the simulation result proved that the stirred tank heater with LQG controller performance is better than the stirred tank heater with LQI controller in improving the output temperature, settling time and the percentage overshoot. Finally, the comparative simulation results proved that the stirred tank heater with LQG controller performance is better than the stirred tank heater with LQI controller.
