## Supplemental Figures and Tables

**Figure S1. Estimation flowchart including data inputs, database inputs, modeling processes, and results.**

**Figure S2. Prevalence of daily smoking for men (A) and women (B), aged 15-19, in 2015.** ATG=Antigua and Barbuda; VCT= Saint Vincent and the Grenadines; BRB=Barbados; COM=Comoros; DMA=Dominica; GRD=Grenada; MDV=Maldives; MUS=Mauritius; LCA=Saint Lucia; TTO=Trinidad and Tobago; TLS=Timor-Leste; SYC=Seychelles; W Africa=Western Africa; E Med.=Eastern Mediterranean; MLT=Malta; SGP=Singapore; MHL=Marshall Islands; KIR=Kiribati; SLB=Solomon Islands; FSM=Federated States of Micronesia; VUT=Vanuatu; WSM=Samoa; FJI=Fiji; TON=Tonga.

**Figure S3. Percent change in age-standardized smoking prevalence from 1990 to 2015, for men (A) and women (B).** Countries without a statistically significant change from 1990 to 2015 are indicated in grey.

**Figure S4. Prevalence of daily smoking across birth cohorts over time, at the global level and by super region, for men (A) and women (B).** Birth cohorts are colour-coded by five-year intervals, with the most recent birth cohort in red (2005) to the least recent birth cohort in dark blue (1910). Each dot represents the prevalence of daily smoking for a given birth cohort and age group.

**Figure S5. Leading 30 level 3 global causes for DALYs attributable to smoking for males (A) and females (B), 1990, 2005, and 2015 with percentage change in the number of DALYs, and all-age, and age-standardised rates.** Causes are connected by arrows between time periods. For the time period 1990 to 2005 and for 2005 to 2015, three measures of change are shown: percent change in the number of DALYs, percent change in the all-age DALY rate and percent change in the age-standardised DALY rate. Changes that are statistically significant are shown in bold. DALYs=disability-adjusted life-years.

**Figure S6. Rankings of smoking as a risk factor for all-cause, all-age attributable DALYs for both sexes combined in 1990 (A) and 2005 (B).** DALYs = disability-adjusted life-years. ATG=Antigua and Barbuda; VCT= Saint Vincent and the Grenadines; BRB=Barbados; COM=Comoros; DMA=Dominica; GRD=Grenada; MDV=Maldives; MUS=Mauritius; LCA=Saint Lucia; TTO=Trinidad and Tobago; TLS=Timor-Leste; SYC=Seychelles; W Africa=Western Africa; E Med.=Eastern Mediterranean; MLT=Malta; SGP=Singapore; MHL=Marshall Islands; KIR=Kiribati; SLB=Solomon Islands; FSM=Federated States of Micronesia; VUT=Vanuatu; WSM=Samoa; FJI=Fiji; TON=Tonga.

**Table S1. Geographies estimated, SDI value, and SDI level.** SDI = Socio-demographic Index. SDI values and levels reflect 2015 estimates for the component factors: total fertility rate, mean educational attainment, and lag-distributed income per capita.

**Table S2. Citations for sources used in relative risk estimation.**

**Table S3. Number of data points extracted for each frequency-type indicator.** Data points are location-, year-, age-, sex-specific. Columns are different frequencies of tobacco use captured. Rows are different types of tobacco captured.

**Table S4. Crosswalking coefficients, model fit, and number of data points using each crosswalk.** Data points are location-, year-, age-, sex-specific. \*Used to crosswalk data from sources that did not have

data on any of the five other frequency-type combinations with crosswalk models with R-squared values > 0.8.

**Table S5. Strength of evidence supporting a causal relationship between smoking and 38 included outcomes.** Prospective observational studies with a significant association in the opposite direction is missing if there were no prospective observational studies or the strength of evidence was assessed through a pooled analysis. Biologic plausibility indicates whether any biological or mechanistic pathway exists that could potentially explain the relationship between smoking and the outcome. Analogy indicates whether smoking is associated with another outcome from the same category and whether any evidence exists that smoking can cause the current outcome through the same biological or mechanistic pathway.

**Table S6. Citations for evidence used in assessing causal relationships between smoking and 38 included outcomes.**

**Table S7. Relative-risk estimates, by age and sex, for 38 included outcomes.**

**Table S8. All-cause all-age (30+) deaths and DALYs and all-cause age-standardized mortality and DALY rates (per 100) in 2015 for men and women.** 95% uncertainty intervals are reported in parentheses: (lower, upper).

## Geographies estimated and Socio-demographic Index

Consistent with the protocol of the Global Burden of Disease Study 2015, we estimated smoking prevalence from 1980-2015 for 195 countries and territories (Table S1), both sexes, and 15 five-year age groups (age group 10-14 through age group 80+). We estimated smoking attributable burden for the same 195 countries and territories from 1990-2015, both sexes, and 11 five-year age groups (age group 30-34 through age group 80+). Additionally, we calculated aggregate estimates by geography and level of development. Geographic aggregates (regions, super regions, and global) are consistent with the previously published GBD location hierarchy.<sup>1</sup> Aggregation by level of development used the Socio-demographic Index (SDI) level method used throughout GBD estimation to create five levels of development- high, high-middle, middle, low-middle, and low- to which there is a one-to-one map for all 195 countries and territories presented in this work.

Full details of calculation of SDI level were previously published.<sup>1</sup> Briefly, SDI is a composite indicator including total fertility rate, mean educational attainment, measured as number years of schooling completed among individuals ages 15+, and lag-distributed income per capita. Calculation of the composite indicator followed the methodology used in construction of the Human Development Index.<sup>2</sup> SDI values are included in Table S1, along with the geography's SDI level. SDI levels reflect 2015 values for the component indicators.

## Age-standardisation

For age-standardised rates we used the GBD population standard.<sup>1</sup>

## Data and modeling flowchart

Figure S1 shows the full estimation process, from data inputs to results.

## Inclusion criteria

We included nationally representative survey data sources that captured information on primary tobacco use among individuals over age 10. We included only self-reported smoking data and excluded data from questions asking about others' smoking behaviors. We included data that was collected between 1 January 1980 and 31 December 2015 in any of the 195 geographies included in this study.

For consumption estimation, we included nationally representative supply-side data on tobacco availability from sources covering multiple countries. Data were included if they were collected between 1 January 1960 and 31 December 2015 and covered one of the 195 geographies included in this study.

## Data sources

A complete list of sources is available from the GBD 2015 Data Input Sources Tool (<http://ghdx.healthdata.org/gbd-2015/data-input-sources>).

## Consumption

We estimated country-wide consumption of tobacco as grams per capita using four supply-side data sources: 1) the United Nations Food and Agriculture Organization (FAO),<sup>3</sup> which covered 171 countries and territories from 1961-2013 and reported data as domestic supply in tonnes of tobacco; 2) the US Department of Agriculture (USDA),<sup>4</sup> which covered 153 countries from 1960 to 2005 and reported data as domestic consumption of manufactured cigarettes; 3) Euromonitor,<sup>5</sup> which covered 80 countries from 1998-2015 and reported data as sales of cigarettes including manufactured, roll-your-own, and

illicit sales; and 4) sales data (personal correspondence from Christopher Tan, MBA, September 2013), which covered 18 countries from 1997 to 2012.

### Prevalence

We searched the Global Health Data Exchange (GHDx) database for primary data sources with the keyword “Tobacco Use” on 1 May 2015 and again on 16 February 2016 to ensure all available data sources were captured. Of the 3,318 sources identified in the GHDx, 2,224 sources met inclusion criteria and were included.

In addition to the primary data sources identified through the GHDx, we supplemented with secondary database estimates from the WHO InfoBase Database and International Smoking Statistics Database for sources for which primary data are unavailable. We included 281 sources from the WHO InfoBase and 313 sources from the International Smoking Statistics Database.

### Smoking Impact Ratio

The Smoking Impact Ratio (SIR) is computed using four estimates: 1) lung cancer mortality rates in a reference population of smokers, 2) lung cancer mortality rates in a reference population of never-smokers, 3) lung cancer mortality rates among never smokers in a population of interest, and 4) observed lung cancer mortality rates in a population of interest. We used available prospective cohort studies to estimate values 1, 2, and 3. A list of included prospective cohorts is available in the GBD 2015 Data Input Sources Tool (<http://ghdx.healthdata.org/gbd-2015/data-input-sources>). We used lung cancer mortality rate estimates from GBD 2015 for value 4.<sup>6</sup>

### Burden

Inputs to calculate attributable burden included GBD 2015 deaths and DALYs for the 38 outcomes included in this analysis. Estimates are publically available through the GBD Results Tool: <http://ghdx.healthdata.org/gbd-results-tool>.

### Relative risk

Relative risk estimates were derived from prospective cohort studies. Sources used in relative risk estimation are reported in Table S2.

### Consumption data preparation

To prepare the supply-side tobacco consumption data for modeling, first we converted sources reporting data in units of cigarettes to units of grams of tobacco by equating one cigarette to one gram of tobacco. Next, we transformed all data to per capita estimates using GBD population estimates. Data reported for aggregated former geographies, such as the Soviet Union and the Socialist Federal Republic of Yugoslavia, were split using the ratios derived from four years after dissolution. Since FAO data were reported as availability of tobacco, not as sales or consumption, we assumed that there was noise resulting from compensation for overstock or understock. Since our metric of interest was consumption, we smoothed FAO data by taking a four-year historical average. To enforce consistency between prevalence and consumption, we assumed that grams per daily smoker per day would not exceed 30 and would not be less than five. Data outside these thresholds were considered to be outliers and were dropped. We controlled for differences between sources by crosswalking data from each source to the average of data from other sources paired by country-year. Uncertainty of data was estimated by calculating the standard deviation of data over a 10-year rolling window by source.

## Consumption modeling

We used spatiotemporal Gaussian process regression (ST-GPR) to model supply-side tobacco consumption. We updated the mean function used previously by Ng. et al to the following:

$$m_{g,a,s}(t) = X\beta + h(r_{g,t})$$

where  $h(r_{g,t})$  is a smoothing function for residuals from the mixed effects model that draws strength across geography and time, and  $X\beta$  is the estimate produced by the following mixed effects model, fit using restricted maximum likelihood in R:

$$\log(\text{consumption})_{g,t} = \beta_0 + \beta_1 \text{education}_{g,t} + \alpha_s + \alpha_r + \alpha_g + \epsilon_{g,t}$$

where  $\text{education}_{g,t}$  is the mean years of education completed among individuals over age 15 in geography  $g$  at time  $t$ , and  $\alpha_s$ ,  $\alpha_r$ , and  $\alpha_g$  are super region, region, and geography random intercepts, respectively. The linear model component ( $X\beta$ ) was fit using random effects, but predictions were made based only on the estimated beta coefficients. Differences from the previously published model include a different covariate and a different model specification. We used educational attainment, as opposed to the previously used GDP, based on out-of-sample cross validation analyses. We used spatiotemporal smoothing ( $h(r_{g,t})$ ), as opposed to the previously used region and geography random slopes to better capture the effect of time and incorporate more data in estimating the mean function in data-sparse regions. The ST-GPR method has been described in detail elsewhere.<sup>1</sup>

## Smoking prevalence data preparation

### Data extraction

We extracted primary data from individual-level microdata and survey report tabulations. We extracted data on current tobacco use reported as any combination of frequency of use (daily, occasional, and current, which includes both daily and occasional smokers) and of type of tobacco used (all tobacco including smoked and smokeless, all tobacco excluding cigarettes, smoked tobacco, cigarettes only, manufactured cigarettes, hand-rolled cigarettes, smoked tobacco excluding cigarettes, and smokeless tobacco), resulting in 24 possible combinations for frequency and type.

For microdata, we extracted relevant demographic information, including age, sex, location, and year, as well as survey metadata, including survey weights, primary sampling units, and strata. This information allowed us to tabulate individual-level data in the standard GBD five-year age-sex groups and produce accurate estimates of uncertainty. For survey report tabulations, we extracted data at the most granular age-sex group provided.

### Crosswalking

Our gold-standard smoking prevalence indicator is daily use of smoked tobacco products. All other data points were adjusted to be consistent with this definition. Table S3 shows the number of data points extracted for each indicator. Some sources contained information on more than one frequency-type combination indicator and these sources were used to develop the adjustment coefficient to transform that alternative frequency-type combinations to the gold-standard frequency-type combination of daily use of smoked tobacco. The adjustment coefficient was the beta value derived from the following model:

$$p_{\text{daily-smoked},k} = \beta p_{i,k} + \epsilon_k$$

where  $p_{\text{daily-smoked},k}$  is the prevalence of daily smoking reported in survey  $k$  and  $p_{i,k}$  is the prevalence of an alternative frequency-type combination  $i$  also reported in survey  $k$ . Models with adjusted R-squared values  $> 0.8$  were used in order of their R-squared value. Adjusting for frequency and type simultaneously improved upon the previously published method<sup>7</sup> by taking into account correlation between frequency and type. Five alternative frequency-type combinations had adjusted R-squared values  $> 0.8$ . For other alternative frequencies and types we used the previously published step-wise crosswalk, adjusting for frequency and type independently. Sources only reporting data on occasional use ( $n=202$  data points, 0.2%) were dropped because there was no sufficiently accurate crosswalk available. The estimated regression coefficients used for adjustment and the number of data points using that adjustment are reported in Table S4. Crosswalking models were fit using Stata 13.

We propagated uncertainty at the survey ( $k$ ) level from the crosswalk using the following equation:

$$PE_k = \sigma_\epsilon^2 + X_k^2 \text{var}(\hat{\beta})$$

where  $PE_k$  is the crosswalk prediction error that is added to the sampling variance of the data point,  $\sigma_\epsilon^2$  is the variance of the error,  $X_k^2$  is the squared value of the data being adjusted, and  $\text{var}(\hat{\beta})$  is the variance of the adjustment coefficient.

### Smoking prevalence modeling

We used ST-GPR to model smoking prevalence given the abundance of age and sex-specific data. Full details on the ST-GPR method have been previously published.<sup>1</sup> Briefly, the mean function input to GPR is a complete time series of estimates generated from a mixed effects hierarchical linear model plus weighted residuals smoothed across time, space, and age. The linear model formula, fit separately by sex using restricted maximum likelihood in R, is:

$$\text{logit}(p_{g,a,t}) = \beta_0 + \beta_1 \text{CPC}_{g,t} + \sum_{k=2}^{16} \beta_k I_{A[a]} + \alpha_s + \alpha_r + \alpha_g + \epsilon_{g,a,t}$$

where  $\text{CPC}_{c,t}$  is the tobacco consumption covariate, by geography  $g$  and time  $t$ , described above,  $I_{A[a]}$  is a dummy variable indicating specific age group  $A$  that the prevalence point  $p_{g,a,t}$  captures, and  $\alpha_s$ ,  $\alpha_r$ , and  $\alpha_g$  are super region, region, and geography random intercepts, respectively. Random effects were used in model fitting but were not used in prediction.

We used out-of-sample cross validation for hyperparameter selection for the space (zeta), age (omega), and time (lambda) weights used in spatiotemporal smoothing along with the scale used in Gaussian process regression (details on the effects of different parameters have been previously published). We used a space weight of 0.95 in data-dense countries (at least five years covered in a geography-age-sex group) and space weight of 0.7 in data-sparse countries. The other parameters were consistent across data-density levels: age weight = 1, time weight = 1, and scale = 10.

We minimized out-of-sample root mean squared error (RMSE) in parameter selection, and also assessed the full model fit using RMSE. The in-sample RMSE of the final model was 0.05 and the out-of-sample RMSE was 0.08. The in-sample coverage of the final model was 99.4% and the out-of-sample coverage was 99.8%.

## Smoking Impact Ratio calculation

We calculated SIR for each geography, year, age group, and sex included in attributable burden analysis using the following formula:

$$SIR = \frac{C_{LC} - N_{LC}}{S_{LC}^* - N_{LC}^*} \times \frac{N_{LC}^*}{N_{LC}}$$

where  $C_{LC}$  is the lung cancer mortality rate specific to the age-sex-geography-year of interest,  $N_{LC}$  is the age- sex- geography- year-specific lung cancer mortality rate of never-smokers in the population of interest,  $S_{LC}^*$  is the lung cancer mortality rate in a reference population of smokers,  $N_{LC}^*$  is the lung cancer mortality rate in a reference population of never-smokers. Additional details on SIR calculation can be found elsewhere.<sup>8</sup>

## Estimating attributable burden

### Assessment of risk-outcome pairs

We included outcomes based on the strength of available evidence supporting a causal relationship. Table S6 reports the strength of evidence for included outcomes and the exposure metric (5-year lagged prevalence or SIR) used for each outcome. Table S7 reports the sources used in evaluating strength of included outcomes.

### Relative risk

Table S8 reports relative risk estimates and uncertainty for the 38 outcomes included in analysis, by age and sex where applicable. Sources used in generating relative risk estimates are cited in the GBD 2015 Data Input Sources Tool (<http://ghdx.healthdata.org/gbd-2015/data-input-sources>).

### Population Attributable Fraction (PAF) calculation

We calculated population attributable fractions (PAFs) based on exposure estimates, relative risk estimates, and the theoretical minimum risk exposure level (TMREL), using the following formula for a dichotomous exposure:

$$PAF_{oasgt} = \frac{\sum_{x=0}^1 RR_{oasg}(x)P_{asgt}(x) - RR_{oasg}(TMREL_{as})}{\sum_{x=0}^1 RR_{oasg}(x)P_{asgt}(x)}$$

where  $PAF_{oasgt}$  is the population attributable fraction for outcome  $o$ , age group  $a$ , sex  $s$ , geography  $g$ , and year  $t$ .  $RR_{oasg}(x)$  is the relative risk as a function of exposure level  $x$  for outcome  $o$ , age group  $a$ , sex  $s$ , and geography  $g$ ;  $P_{asgt}(x)$  is the proportion of the population with exposure level  $x$  for age group  $a$ , sex  $s$ , geography  $g$ , and year  $t$ ;  $TMREL_{as}$  is the TMREL for age group  $a$ , and sex  $s$ . The TMREL for smoking is zero, meaning nobody in the population smokes. Additional details on PAF calculation are published elsewhere.<sup>1</sup>

### Attributable burden calculation

We calculated smoking attributable burden using the following formula for DALYs:

$$AB_{asgt} = \sum_{o=1}^{38} DALY_{oasgt} * PAF_{oasgt}$$

and deaths:

$$AB_{asgt} = \sum_{o=1}^{38} deaths_{oasgt} * PAF_{oasgt}$$

where  $AB_{asgt}$  is the total smoking attributable burden (as either DALYs or deaths) for a given age group  $a$ , sex  $s$ , geography  $g$ , time  $t$ , calculated from the sum of  $deaths * PAF$  for outcomes  $o$  one through 38. Further details on calculation of attributable burden are published elsewhere.<sup>1</sup>

### Decomposition

For the decomposition analysis, we used the methods developed by Das Gupta to decompose changes in total percent change in DALYs from 2005-2015 by SDI level due to changes in population structure (population ageing and population growth), risk-deleted DALY rate, which is the background DALY rate observed if smoking levels were at their TMREL, and risk exposure. Details on the decomposition methodology and implementation have been reported elsewhere.<sup>1</sup>

### Supplemental results

Figure S2 shows age-specific smoking prevalence for men and women ages 20-24. Figure S4 shows cohort plots by super region.

**Footnotes**

- 1 Evidence on the relationship between smoking and lower respiratory infections comes 10 case-control or cross-sectional studies
- 2 The evidence on causal relationship of alcohol and smoking with nasopharynx cancer was from the studies evaluating oral cavity and pharyngeal cancers as outcome
- 3 Liver cancer included liver cancer due to alcohol use, hepatitis B, hepatitis C, and other causes
- 4 The evidence on causal relationship of smoking and bladder cancer was based on the studies evaluating the lower urinary tract as outcome
- 5 Asbestosis, coal workers pneumoconiosis, other pneumoconiosis, silicosis were included as outcomes for smoking as they were included in the other chronic respiratory diseases category
