N2 - Asthma is increasing dramatically among poor, inner-city children. Fourteen children with, and twelve without, asthma were interviewed and observed to examine how children with asthma understand their illness and how the asthma experience shapes their sense of place. Quantitative data showed no difference in objective preferences for particular places, but qualitative analysis showed important differences. We identified eight place-related themes, and on seven there were clear differences between children with and without asthma-- offering freedom, being aesthetically pleasing, being comfortable, nature of social contact, being isolating, being familiar and being safe. Children experienced asthma as an interruption in daily life that influences time spent outside, being active and being with friends. Children with asthma are more sensitive to places that are 'dirty' or contain asthma triggers, are less likely to explore new or people-free places and emphasize family interactions, while children without asthma emphasize friendships and are sensitive to neighborhood violence

N2 - **BACKGROUND:** Schools have the unique potential to provide numerous opportunities for promoting physical activity. This article describes findings from a statewide survey of opportunities for physical activity in West Virginia (WV) schools. The purpose was to provide baseline data for two of the WV Healthy People 2010 objectives related to schools and youth to identify priorities for action. **METHOD:** Survey questions were adapted from the 2000 School Health Policies and Programs Study (SHPPS), conducted by CDC. Random stratified sampling across school level and size resulted in a final sample of 296 elementary schools, 146 middle and junior high schools, and 124 high schools (total = 566). The overall response rate was 73%. **RESULTS:** Eleven percent of elementary, 2% of middle or junior high, and 31% of senior high schools met the SHPP's criterion of providing daily physical education. Ninety-four percent of elementary schools reported offering daily recess. Overall, 42.3% of schools provided student and community access to indoor facilities outside of normal school hours, while 80.7% of schools provided access to outdoor facilities beyond normal school hours. **CONCLUSIONS:** Survey results are being used to target increased physical education in elementary schools and increased opportunities beyond physical education at all school levels

N2 - BACKGROUND: Each year, hundreds of children unintentionally kill or injure other children while playing with firearms in the United States. Although the numbers of these deaths and injuries are distressing, few prevention programs have been developed to prevent gun play among children. OBJECTIVE: This study compared the efficacy of 2 programs designed to prevent gun play among young children. DESIGN: A posttest-only, control group design with 2 treatment groups was used. Children were randomly assigned to 1 of 2 treatment groups or a control group. For all children who did not exhibit the skills after training, 1 in situ (ie, real-life situation) training session was conducted. SETTING: Participant recruitment, training sessions, and assessments were all conducted in the children's after-school program facility. PARTICIPANTS: Forty-five children, 6 or 7 years of age, were recruited for participation. INTERVENTIONS: The efficacy of the Eddie Eagle GunSafe Program, developed by the National Rifle Association, and a behavioral skills training program that emphasized the use of instruction, modeling, rehearsal, and feedback was evaluated. MAIN OUTCOME MEASURES: The criterion firearm safety behaviors included both motor and verbal responses, which were assessed in a naturalistic setting and then assigned a numerical value based on a scale of 0 to 3. RESULTS: Both programs were effective for teaching children to verbalize the safety skills message (don't touch the gun, get away, and tell an adult). However, children who received behavioral skills training were significantly more likely to demonstrate the desired safety skills in role-playing assessments and in situ assessments than were children who received Eddie Eagle program training. In addition, in situ training was found to be effective for teaching the desired safety skills for both groups of children. CONCLUSIONS: Injury prevention programs using education-based learning materials are less effective for teaching children the desired safety skills, compared with programs incorporating active learning approaches (eg, modeling, rehearsal, and feedback). The efficacy of both types of injury prevention programs for teaching the desired skills could be significantly enhanced with the use of in situ training. This program, when implemented with 6- and 7-year-old children, was effective in teaching the desired safety skills

N2 - The purpose of this study was to develop a stair-climbing test to measure energy cost (EC) and mechanical efficiency (ME) in children with cerebral palsy (CP) to evaluate ambulation-related motor function and its changes after intervention or maturation. Five normally developed (ND) and 10 children with CP were tested. The gross ME (MEg) was calculated from the work done (W) and the total energy cost (oxygen consumption) measured while repeatedly ascending and descending four steps for approximately 5 min without subtracting the resting metabolic rate. The MEg was significantly lower in CP than ND (3% versus 20%, $P < 0.001$). The test was repeated in the 10 children with CP after a 4-month therapy recess. The MEg values correlated with the initial tests, with a small, significant increase of 2%. When calculating net ME (ME_n) from W and the energy cost above resting, the correlation of ME_n values before and after therapy was inferior to that using MEg values. Similarly, individual ME values obtained by estimating energy cost from the increase in heart rate (HR) during stair-climbing also correlated poorly, with large variability. These results show that MEg may be used to evaluate changes in motor function resulting from age-related development or therapy. MEg is as good or superior to ME_n; the extra time required to obtain resting energy cost and heart rate values is not necessary when measurements are desired within the same individual

N2 - OBJECTIVES: We examined the impact of relatively "green" or natural settings on attention-deficit/hyperactivity disorder (ADHD) symptoms across diverse subpopulations of children. METHODS: Parents nationwide rated the aftereffects of 49 common after-school and weekend activities on children's symptoms. Aftereffects were compared for activities conducted in green outdoor settings versus those conducted in both built outdoor and indoor settings. RESULTS: In this national, nonprobability sample, green outdoor activities reduced symptoms significantly more than did activities conducted in other settings, even when activities were matched across settings. Findings were consistent across age, gender, and income groups; community types; geographic regions; and diagnoses. CONCLUSIONS: Green outdoor settings appear to reduce ADHD symptoms in children across a wide range of individual, residential, and case characteristics

N2 - The match between ticks and pediatricians in Italy is usually a seasonal event related to the spring and summer trips and to the increasing of outdoor activity that sun and warm weather allow, both for children and ticks. So cared parents reach emergencies asking for tick removal but more often after the tick has yet been removed by empirical manoeuvres and after the killing and the destruction of the "enemy". We have scheduled, in the years 2002-2003, the 167 children that reached our unit for a tick bite; they were 92 males (mean age four years) and 75 females (mean age five years). Two of them had only a questionable tick bite but one had erythema on the lateral side of the left ankle, fever of obscure origin and weakness with generalised malaise. She was six years old and she lived with a dog on which, in more instances, ticks were found, but she never noticed ticks on her body. The dog had positive levels of anti rickettsial and anti borrelia antibodies but no evidence of concomitant illness. In this girl we found high titers of anti borrelia antibodies that WB testing confirmed to be anti *B. burgdorferi*. We diagnosed Lyme disease and treated the girl with amoxicillin (50 mg/kg/day) for three weeks achieving the complete relief of symptomatology till today. Three children with concomitant tick bite had positive levels of anti *Rickettsia conorii* antibodies with increasing levels at a twenty days control; two (aged four and five years) of them had a full symptomatology (tache noire, satellite lymphadenopathy, fever, and maculopapular erythema) for Mediterranean spotted fever; the latter (three years old) had an atypical form with the complete absence of maculopapular erythema. The therapy was clarithromycin (15 mg/kg/day) for three weeks. In Campania, in the years 2002/2003 on 167 children with tick bite that reached our unit, we found only four pathological correlable events; so are our ticks not infected? But we don't know how many children were tick bitten and if there were other children with Lyme disease or Rickettsial disease because of the lack of a pediatric reference centre for "tick bite diseases" and the incomplete and late diffusion of knowledge on these diseases. Other Italian regions and such as Trentino Alto Adige, Veneto, and Friuli Venezia Giulia had a remarkable officially notified number of cases of Lyme disease and in Sicilia, Sardegna and Lazio there were numerous officially notified Rickettsial diseases. So we hope that Campania may be an happy island but we also think that a more effective cooperation between pediatricians and veterinarians and the creation of regional reference centres for tick bite diseases may arise a surveillance net to prevent the diffusion of these world wide emerging diseases and so that parents can achieve an univoque and useful information, the only way to defeat the fear of ignorance. N2 - A correlation of respiratory diseases to traffic related air pollution and noise was observed in an interview study. Since in that study the exposure was subjectively assessed, in the present field study nitrogen dioxide as indicator for vehicle exhausts and the mean night-time noise level were measured outside the children's windows in representative locations. Based on these measurements each child was placed in one of the following categories: low, medium or high traffic immission (ambient emissions). The physician contacts due to bronchitis of 68 children were assessed retrospectively from the files of the participating paediatricians. Saliva samples were collected from all children and the cortisol concentration was estimated. Children under high noise exposure (L(night, 8h) = 54-70dB(A)) had in comparison to all other children significantly increased morning saliva cortisol concentrations, indicating an activation of the hypothalamus-pituitary-adrenal (HPA) axis. Analysing a subgroup of children without high noise exposure showed, that children with frequent physician contacts due to bronchitis did not have increased morning saliva cortisol. However, multiple regression analysis with stepwise exclusion of variables showed that bronchitis was correlated more closely to morning saliva cortisol than to traffic immissions. On the other hand, the rate of physician contacts due to bronchitis increased in a dose dependent manner and significantly with increasing traffic immissions. From these results it can be concluded that high exposure to traffic noise, especially at nighttime, activates the HPA axis and this leads in the long term to an aggravation of bronchitis in children. This seems to be more important than the effect of exhaust fumes on bronchitis symptoms. The results of the present study should be subjected to further investigation using specially designed studies

N2 - Indoor allergens represent an important precipitating factor for both asthma and atopic eczema dermatitis syndromes (AEDS). There is also accumulating evidence that sensitization to those allergens is associated with the onset of atopic disorders. Patients with AEDS present aeroallergen-specific T-cell responses associated with worsening of symptoms when exposed to specific aeroallergens. Furthermore, application of indoor allergens to the skin of patient with AEDS induces a local eczematous response in one-third of these patients. Exposure to high concentrations of mite allergens in early infancy have been demonstrated to be a risk factor for developing atopic dermatitis during the first 3 years of life. Moreover, a clear dose-response relationship has been documented between mite exposure and disease activity. Primary prevention of AEDS by avoiding indoor allergen exposure has been proved to be effective only when allergenic foods have also been avoided. Mite allergen avoidance in infants with AEDS and food allergy may however, prevent mite sensitization and the onset of asthma. Indoor allergen avoidance has been demonstrated to be effective in the majority of studies performed in patients with established AEDS. Negative results may be explained either by individual susceptibility variation, by long duration of disease with the consequent irreversible pathological changes in the target tissue or by exposure to allergens outside the house. Education of the patients and public consciousness of the problems are crucial for the efficacy of indoor allergen avoidance in allergic diseases. N2 - The objective of this study was to assess the risk of infection with *Giardia intestinalis* in children living in an area with artificial groundwater recharge and potable water reuse in Mexico City. Eligible wells and surrounding homesteads were defined by using a geographic information system. Five wells were tested for *G. intestinalis* cysts per 400 liters of water. A total of 750 eligible households were visited during two cross-sectional surveys. Stool samples were provided by 986 children in the rainy season study and 928 children during the dry season survey for parasitologic tests. Their guardians provided information on water, sanitation, hygiene, and socioeconomic variables. The prevalence rates of *G. intestinalis* infection were 9.4% in the rainy season and 4.4% in the dry season. Higher rates of infection were observed in older individuals (9.5% and 10.6%) and girls had a lower risk of infection than boys (odds ratio [OR] =0.55, 95% confidence interval [CI] = 0.34, 0.88 in the rainy season and OR = 0.47, 95% CI = 0.25, 0.90 in the dry season). During the wet season survey, a health risk was detected among those storing water in unprotected receptacles (OR = 4.00, 4.69, and 5.34 for those using uncovered jars, cisterns or tanks, and buckets, respectively), and bathing outside the dwelling, i.e., using a tap (OR = 1.93, 95% CI = 1.10, 3.39). A health risk was also detected among children from households with unsafe food hygiene practices (OR =2.41, 95% CI =1.10, 5.30) and those with no hand-washing habits (OR = 2.27, 95% CI = 1.00, 5.20). Groundwater reserves are at risk of fecal pollution, as indicated by the presence of *G. intestinalis* cysts. However, the endemic pattern of intestinal infection reflects low standards of personal hygiene and unsafe drinking water storage and food-related practices at household level. Prevention activities must address health education and environmental protection policies

N2 - **PURPOSE:** Recently, considerable attention has been directed toward computed tomography radiation doses (estimated 1 to 4 cGy) received by pediatric patients, because of the potential for increasing a pediatric patient's risk for developing a secondary malignancy. However, minimal attention has been given to the radiation exposure outside the treatment field resulting from the use of portal films to visualize surrounding anatomy. The objective of this study was to quantify the radiation dose from portal imaging delivered within and outside the radiation treatment field during a course of radiation therapy. **METHODS AND MATERIALS:** A retrospective review was conducted of the port film dose for 56 consecutive pediatric patients who underwent definitive radiation therapy between January 2001 and January 2002. Treatment locations were classified as brain, 27 patients; abdomen, 11 patients; extremities, 9 patients; pelvis, 6 patients; and thorax, 3 patients. Using the dose per monitor unit and total number of port films taken, the total port film dose for each patient was calculated. In addition, port film dose was quantified for 5 pediatric patients undergoing intensity modulated radiation therapy. **RESULTS:** The mean total port dose varied from a maximum of 46 cGy for brain to a minimum of 17 cGy for thorax. The mean total port dose as a percentage of prescribed dose was less than 1.25% for all locations in this study; however, most of the port dose is a result of the open-field dose from the double-

exposure technique. CONCLUSIONS: Care should be exercised while exposing port films of pediatric patients to minimize both the number of films and corresponding radiation exposure without compromising the quality of treatment delivery. Specifically, the number of monitor units used to image regions outside the treatment field should be kept to a minimum, because such exposure could lead to an increased risk of development of secondary neoplasms

N2 - PURPOSE: To establish the safety and possible efficacy of excimer laser photorefractive keratectomy (PRK) for treatment of pediatric anisometropia. DESIGN: Interventional case series METHODS: This is a prospective, noncomparative interventional case series at an individual university practice of photorefractive

keratectomy in 11 children aged 2 and 11 years with anisometropic amblyopia who were unable or unwilling to use contact lens, glasses, and occlusion therapy to treat the amblyopia. The eye with the higher refractive error was treated with PRK using a standard adult nomogram. The refractive treatment goal was to decrease the anisometropia to 3 diopters or less. Main outcome measures were cycloplegic refraction, refractive correction, degree of corneal haze, uncorrected and best spectacle-corrected visual acuity, and stereopsis over 12 months. RESULTS: All patients tolerated the procedure well. The mean refractive target reduction was -10.10 ± 1.39 diopters for myopia and $+4.75 \pm 0.50$ diopters for hyperopia. The mean achieved refractive error reduction at 12 months for myopia was -10.56 ± 3.00 diopters and for hyperopia was $+4.08 \pm 0.8$ diopters. Corneal haze at 12 months was minimal. Uncorrected visual acuity improved by 2 or more lines in 6 (75%) of the eight children able to perform psychophysical acuity tests. Best spectacle-corrected visual acuity improved by 2 lines in 3 (38%) of patients. Stereopsis improved in 3 (33%) of nine patients. CONCLUSIONS: Pediatric PRK can be safely performed for anisometropia. The refractive error response in children appears to be similar to that of adults with comparable refractive errors. Visual acuity and stereopsis improved despite several children being outside the standard age of visual plasticity. Photorefractive keratectomy may play a role in the management of anisometropia in selected pediatric patients

N2 - OBJECTIVES: Hispanic children who live along the United States-Mexico border historically have had among the highest hepatitis A rates in the United States, but risk factors have not been well characterized. The objective of this study was to examine risk factors associated with acute hepatitis A virus (HAV) infection in Hispanic children who live along the United States-Mexico border in San Diego County, California.

METHODS: In this case-control study, hepatitis A cases among Hispanic children who were younger than 18 years reported from June 1998 through August 2000 were matched by age group and exposure period to Hispanic children who were susceptible to HAV infection. Participants and their families were interviewed about demographic information and potential sources of HAV infection, including attending child care, food and waterborne exposures, cross-border and other international travel, and travel-related activities. RESULTS:

Participants included 132 children with hepatitis A and 354 control subjects. The median age of study participants was 7 years (range: 1-17). Sixty-seven percent of case-patients traveled outside the United States during the incubation period, compared with 25% of the children without hepatitis A (odds ratio [OR]: 6.3; 95% confidence interval [CI]: 4.0-9.7); all children, except 1, had traveled to Mexico. In multivariate analysis, hepatitis A was associated with having eaten food from a taco stand or street food vendor (adjusted OR: 17.0; 95% CI: 4.1-71.1) and having eaten salad/lettuce (adjusted OR: 5.2; 95% CI: 1.3-20.1) during travel.

CONCLUSIONS: Hepatitis A among Hispanic children who live in an urban area of the United States-Mexico border is associated with cross-border travel to Mexico and food-borne exposures during travel. Travelers to areas where hepatitis A is endemic should receive hepatitis A vaccine before travel

N2 - OBJECTIVE: To investigate the sources of lead in the environment in children with elevated blood, with the help of a Field Portable X-Ray Fluorescence Analyzer. METHODS: One hundred and seven school children were chosen for this study on a random basis, from Mangalore and Karnataka. Their blood lead was analyzed. Of the cases analyzed, 10 students whose blood lead level was more than 40 microg/dl were investigated using a field portable X-Ray Fluorescence Analyzer. This is the first time such a device has been available for this purpose in India. RESULTS: The 'likely' source of lead exposure could be determined in eight cases which was from the immediate environment of the children like 'lead-based' paint on surfaces in the house, on playground and other exterior equipment; lead storage batteries, contaminated dust and soil and other lead-containing substances. CONCLUSION: The use of an X-Ray Fluorescence Analyser appeared to be useful in determining the source of lead

N2 - Preventing habitual smoking by young people forms an important goal of health promotion in schools. In achieving this target, information is needed about the age at which smoking becomes a temptation for young people as well as knowledge about the attitudes that are associated with smoking. At two elementary schools and at one grammar school in a community of a former coalmining area, 985 German pupils aged 11-18 years were interviewed with the Youth Self Report (YSR) together with a questionnaire concerning their smoking habits. The rate of smoking among the pupils rose from the age group 11-15 years to the age group 16-18 years (in this age access to cigarettes is no longer restricted by law) from 12% to 63%; between the sexes there is no difference in smoking habits. According to the scales of the YSR in both types of school, smokers scored significantly higher on scales of "antisocial" and „aggressive behaviour". On the other hand non-smokers scored significantly higher on the scale "social problems". The significantly higher rate of smokers in both elementary schools compared with the corresponding rate in the grammar school will be interpreted by two interrelated explanations: the influence of lower social class as well as the lack of the deferred gratification pattern as an ingredient of the culture in elementary schools. The difference between smoking and non-smoking juveniles according to the scales of the YSR can be explained by the association of smoking behaviour with the juvenile culture of deviant groups on the one hand and by the attitudes of the non-smokers, who are more reluctant in joining peer groups. The results support a strategy for effectively preventing habitual smoking habits of juveniles in schools by combining youth activities inside and outside the schools

N2 - A numerical method is presented to estimate the concentration of occupant-generated CO(2) for the (time-varying) occupancy typically found in nonforced ventilated elementary school classrooms. Here, the governing mass balance was solved numerically and compared to experimental measurements in order to estimate the respiration and (time-varying) infiltration rates. For the cases studied, we estimate an average CO(2) generation rate per child as 404 mg/min(-1). This is similar to estimates found in the literature for the age and activity level of elementary students, the classroom occupants. The average estimated infiltration rates were found to be larger than those measured from the decay of the tracer gas SF(6) under closed-door static conditions. The in-use infiltration rates were increased by additional air exchange due to people entering and leaving the room. In addition, we show that the difference (or error) between the instantaneous concentration of CO(2) and the time-averaged value recorded by a data-logging CO(2) monitor varies depending on the infiltration rate and sampling time. Therefore, the time interval selected for averaging may increase the overall error of the apparent CO(2) concentration. We conclude that the methods used to measure air exchange rates in naturally ventilated rooms underestimate the actual ventilation rate of a room under "in-use" conditions. However, even with the addition of uncontrolled outdoor air, the concentration of CO(2) in the classrooms studied was higher than recommended to meet air quality objectives

N2 - Patients aged over 12 years with neurofibromatosis type 2 are considered candidates for an auditory brainstem implant (ABI). This study extends the indication criteria of ABI to subjects with profound hearing loss due to damaged cochleas and/or cochlear nerves (CNs) following head injuries. In our department, over the period from April 1997 to November 2002, 32 patients, 23 adults and 9 children, were fitted with ABIs. Their ages ranged from 14 months to 70 years. These patients were suffering from a variety of tumor (13 subjects) and nontumor CN or cochlear diseases (19 subjects). Six patients, 5 adults and 1 child, had profound hearing loss following head injury. Their mean age was 25 years (range: 16-48 years). Five were male and 1 female. The retrosigmoid approach was used in all 6 patients. The electrode array was inserted into the lateral recess of the fourth ventricle and correct electrode positioning was monitored with the aid of electrically evoked auditory brainstem responses and neural response telemetry. Correct implantation was achieved in all patients. No complications were observed due to implantation surgery or related to ABI activation and stimulation of the cochlear nuclei. At activation, an average of 9.8 electrodes (range 5-13) were switched on without side effects. One to 6 electrodes were activated in the following sessions after time periods ranging from 2 to 16 months. All patients achieved auditory-alone-mode closed-set word recognition scores ranging from 40 to 100%; 3 had auditory-alone-mode open-set sentence recognition scores of 60-100%; 2 of these even had speech-tracking performance scores of 38 and 43 words, respectively, showing an ability to engage in normal conversation and converse over the phone. The present study demonstrates that the ABI is a useful rehabilitation instrument in subjects with damaged cochleas and/or CN avulsion following head injury who are unamenable or poorly responsive to auditory rehabilitation using cochlear implants. N2 - This 5-year study demonstrated a statistically significant correlation between morbidity among children attending day-care centres and various weather parameters. The study was undertaken in south-central Sweden, where sharp seasonal contrasts in climatic and weather conditions occur. Illness-associated absence (IAA) decreased significantly when the weather was bright, sunny and warm, determined using average monthly weather parameters analysed over 60 months. This may be because good weather encourages outdoor activities which, in turn, reduce the risk of spreading respiratory tract infections as outdoor play areas are larger, body contact is less frequent, and any bacteria and viruses present will be readily dispersed. In multiple regression analysis, outdoor temperature was the most prominent parameter linked with IAA. This may reflect the behaviour of the staff with regard to various weather conditions. It is therefore to be recommended that children attending day-care centres should be allowed and encouraged to play outdoors when conditions allow

N2 - **OBJECTIVE:** A recent case series study found that only 4.7% of 402 playgrounds in which arm fractures occurred in Victorian schools complied with the recommended 20 cm depth of tanbark. Tanbark depths at fall sites varied between 0-27 cm and the mean was 11.1 (5.0) cm. The purposes of the present study were to (1) measure impact attenuation properties of shallow and compacted depths of tanbark; (2) validate laboratory measurements with in situ data; (3) compare impact attenuation properties of compacted tanbark with an Australian manufactured rubber based surface material; and (4) study the impact performance of rubber and tanbark hybrid surfacing. **METHODS:** A standard test headform was dropped on tanbark and rubber surfaces in a laboratory setting to measure peak impact deceleration and head injury criterion (HIC) values. Variations in surface depth ranged from 2 cm-20 cm (tanbark) and 2 cm-9 cm (rubber). Drop height ranged from 0.5 m-2.5 m. **RESULTS:** Peak deceleration and HIC increased with increasing drop height and decreasing surface depth. Laboratory measurements at depths less than 8 cm overestimated peak deceleration and HIC values compared with in situ playground measurements. Impact attenuation of a 9 cm thick bilaminar rubber material was comparable to that of an 18 cm depth of compacted tanbark. Rubber-tanbark hybrid surfaces showed improved impact attenuation over individual surfaces. **CONCLUSIONS:** Compacted tanbark of depth less than 8 cm is ineffective in attenuating playground falls, resulting in excessive impact deceleration and HIC values. Shallow and compacted tanbark found in many Victorian school playgrounds poses a high risk for severe head injury. This calls for stricter enforcement of playground surface depth compliance

N2 - **OBJECTIVE:** To assess compliance with current standards of playgrounds where children have sustained a fall-related arm fracture. **DESIGN, SETTING AND PARTICIPANTS:** Between October 2000 and December 2002, a consecutive prospective series of 402 children aged under 13 years who fell from playground equipment and sustained an arm fracture was identified by emergency department staff in five Victorian hospitals. Trained field testers measured playground equipment height, surface type and depth, and surface impact attenuation factors to determine compliance with safety standards. **MAIN OUTCOME MEASURES:** Playground compliance with current Australian safety standards. **RESULTS:** Ninety-eight percent of playgrounds had a recommended type of surface material. The mean surface depth was 11.1 cm (SD, 5.0 cm) and the mean equipment height was 2.04 m (SD, 0.43 m). Although over 85% of playgrounds complied with recommended maximum equipment height and surface impact attenuation characteristics, only 4.7% complied with recommended surface depth. **CONCLUSION:** Playgrounds where children have sustained an arm fracture generally comply with all important safety recommendations except surface depth. Playground fall-related arm fracture requires specific countermeasures for prevention, distinct from head injury prevention guidelines

N2 - Exposure to particulate matter (PM) air pollution has been shown to exacerbate children's asthma, but the exposure sources and temporal characteristics are still under study. Children's exposure to PM is likely to involve both combustion-related ambient PM and PM related to a child's activity in various indoor and outdoor microenvironments. Among 19 children with asthma, 9-17 years of age, we examined the relationship of temporal changes in percent predicted forced expiratory volume in 1 sec (FEV1) to personal continuous PM exposure and to 24-hr average gravimetric PM mass measured at home and central sites. Subjects were followed for 2 weeks during either the fall of 1999 or the spring of 2000, in a southern California region affected by transported air pollution. FEV1 was measured by subjects in the morning, afternoon, and evening. Exposure measurements included continuous PM using a passive nephelometer carried by subjects; indoor, outdoor home, and central-site 24-hr gravimetric PM2.5 (PM of aerodynamic diameter < 2.5 microm) and PM10; and central-site hourly PM10, nitrogen dioxide, and ozone. Data were analyzed with linear mixed models controlling for within-subject autocorrelation, FEV1 maneuver time, and exposure period. We found inverse associations of FEV1 with increasing PM exposure during the 24 hr before the FEV1 maneuver and with increasing multiday PM averages. Deficits in percent predicted FEV1 (95% confidence interval) for given PM interquartile ranges measured during the preceding 24-hr were as follows: 128 microg/m3 1-hr maximum personal PM, -6.0% (-10.5 to -1.4); 30 microg/m3 24-hr average personal PM, -5.9% (-10.8 to -1.0); 6.7 microg/m3 indoor home PM2.5, -1.6% (-2.8 to -0.4); 16 microg/m3 indoor home PM10, -2.1% (-3.7 to -0.4);

7.1 microg/m³ outdoor home PM_{2.5}, -1.1% (-2.4 to 0.1); and 7.5 microg/m³ central-site PM_{2.5}, -0.7% (-1.9 to 0.4). Stronger associations were found for multiday moving averages of PM for both personal and stationary-site PM. Stronger associations with personal PM were found in boys allergic to indoor allergens. FEV₁ was weakly associated with NO₂ but not with O₃. Results suggest mixed respiratory effects of PM in asthmatic children from both ambient background exposures and personal exposures in various microenvironments

N2 - **OBJECTIVES:** To explore the association between early computer experience (both accessibility and frequency of use) and cognitive and psychomotor development among young children. **METHODS:** The participants were 122 preschool children enrolled in a rural county Head Start program in the United States during 2001-2002. The following tests were administered to the children: the Bender Visual Motor Gestalt Test; the Boehm Test of Basic Concepts, Third Edition Preschool; the Test of Gross Motor Development, Second Edition; and a short form of the Wechsler Preschool and Primary Scales of Intelligence-Revised. Information pertaining to family characteristics and children's early computer experience was collected from parents. Both bivariate and multivariate analyses were used to assess the association between early computer experience and cognitive and motor development. **RESULTS:** Of the participating children, 53% had a computer at home. Among families who had a computer, 83% had children's software on the computer. According to parents' reports, 29% of these children played on the home computer on a daily basis, and an additional 44% of the children played on the computer at least weekly. Of those families who did not have a home computer, 49%

reported that their children had access to a computer somewhere outside home. Among these children, 10% had daily access to the computer and 33% had weekly access. The presence of a computer in the home was significantly associated with the family's income and the educational attainment of the parents. There was no gender difference in computer accessibility and frequency use among the participating children. Children who had access to a computer performed better on measures of school readiness and cognitive development, controlling for children's developmental stage and family socioeconomic status. The data in the current study did not suggest a relationship between computer experience and visual motor or gross motor skills among the participating children. **CONCLUSION:** The findings in the present study suggest that early computer exposure before or during the preschool years is associated with development of preschool concepts and cognition among young children. However, frequency of use did not reveal such a relationship; neither did the ownership of other child electronic or video games in the household

N2 - OBJECTIVES: This study aims to contribute to a scientific understanding of intuition, a process by which information normally outside the range of conscious awareness is perceived by the body's psychophysiological systems. The first objective, presented in two empirical reports (Part 1 and Part 2), was to replicate and extend the results of previous experiments demonstrating that the body can respond to an emotionally arousing stimulus seconds before it is actually experienced. The second objective, to be presented in a forthcoming publication (Part 3), is to develop a theory that explains how the body receives and processes information involved in intuitive perception. **DESIGN:** The study used a counterbalanced crossover design, in which 30 calm and 15 emotionally arousing pictures were presented to 26 participants under two experimental conditions: a baseline condition of "normal" psychophysiologic function and a condition of physiological coherence. Primary measures included: skin conductance; the electroencephalogram (EEG), from which cortical event-related potentials (ERP) and heartbeatevoked potentials (HBEP) were derived; and the electrocardiogram (ECG), from which cardiac decelerations/ accelerations were derived. These measures were used to investigate where and when in the brain and body intuitive information is processed. **RESULTS:** The main findings presented here are: (1) surprisingly, both the heart and brain appear to receive and respond to intuitive information; (2) even more surprisingly, there is compelling evidence that the heart appears to receive intuitive information before the brain; (3) there were significant differences in prestimulus ERPs for calm versus emotional stimuli; (4) the frontal cortex, temporal, occipital, and parietal areas appear to be involved in the processing of prestimulus information; (5) there were significant differences in prestimulus calm/emotional HBEPs, primarily in the coherent mode; (6) there were significant gender differences in the processing of prestimulus information. Especially noteworthy is the apparent interaction between the HBEPs and ERPs in the females, which suggests that the heart modulates the ERP and that females are more attuned to intuitive information from the heart. **CONCLUSIONS:** Overall, our data suggest that the heart and brain, together, are involved in receiving, processing, and decoding intuitive information. On the basis of these results and those of other research, it would thus appear that intuitive perception is a system-wide process in which both the heart and brain (and possibly other bodily systems) play a critical role. To account for the study's results, Part 3 will develop a theory based on holographic principles explaining how intuitive perception accesses a field of energy into which information about "future" events is spectrally enfolded

N2 - PURPOSE OF REVIEW: It is becoming increasingly clear that physical activity in children plays a critical role in growth and development, therapy for certain chronic diseases and disabilities, and in the pediatric origins of a variety of bone, metabolic, and cardiovascular diseases. New mechanistic insights have created the opportunity for a phase shift in understanding of the links between exercise and health in the context of the growing child. RECENT FINDINGS: Exercise even in healthy children profoundly alters stress, immune, and inflammatory mediators including peripheral blood mononuclear cells and circulating pro- and anti-inflammatory cytokines (like interleukin-6). Moreover, exercise even in healthy adults stimulates the production of reactive oxygen species (ROS) and mediators that attenuate them. Oxidative stress, in turn, alters growth and stress mediators. Both ROS and stress/inflammatory factors interact with powerful growth mediators like growth hormone and insulinlike growth factor-I. These findings suggest specific ways in which the balance between pro- and anti-inflammatory, catabolic, and anabolic factors associated with exercise can influence health and growth in children. SUMMARY: To address the current epidemic of physical inactivity and obesity in children and to optimize the therapeutic effects of exercise in children with disease and disability will require real changes in environments (eg, schools and playgrounds); innovative approaches to rehabilitation of children with chronic disease and disability; and enlightened training of child health professionals. Identifying novel exercise mechanisms involving stress, inflammation, and growth factors will help guide these efforts.

N2 - This study investigated the use of computer-based intervention for enhancing communication functions of children with autism. The software program was developed based on daily life activities in the areas of play, food, and hygiene. The following variables were investigated: delayed echolalia, immediate echolalia, irrelevant speech, relevant speech, and communicative initiations. Multiple-baseline design across settings was used to examine the effects of the exposure of five children with autism to activities in a structured and controlled simulated environment on the communication manifested in their natural environment. Results indicated that after exposure to the simulations, all children produced fewer sentences with delayed and irrelevant speech. Most of the children engaged in fewer sentences involving immediate echolalia and increased the number of communication intentions and the amount of relevant speech they produced. Results indicated that after practicing in a controlled and structured setting that provided the children with opportunities to interact in play, food, and hygiene activities, the children were able to transfer their knowledge to the natural classroom environment. Implications and future research directions are discussed

N2 - A program of childhood lead poisoning prevention was conducted in six cities of Silesia, the most industrialized region of Poland. We analyzed records of 11,877 children aged 24-84 months, tested between 1993 and 1998, to assess children's exposure to lead and associations of blood lead levels (BLL) with season of sampling, questionnaire data, and environmental levels of lead. Air lead concentrations and lead fallout, as measured in the ambient air monitoring system, were below current Polish air quality standards and gradually decreased. The geometric mean (GM) BLL was 6.3 microg/dL (range from 0.6 to 48 microg/dL), and >13% of children had BLL \geq 10 microg/dL. Mean BLL declined from 6.8 microg/dL in 1993-1994 to almost 5.5 microg/dL in 1998. GM BLL in spring and summer ('nonheating' season) months were 10% higher than BLL in children tested in fall and winter ('heating' season), although air lead concentrations were lower in nonheating and higher in the heating season. For both the heating and nonheating seasons, there was a significant increase in the mean BLL with increasing air lead concentrations. Poor housing (odds ratio (OR): 1.82; 95% CI: 1.4, 2.3), two or more siblings in the family (OR: 3.12; 95% CI: 2.6, 3.7), lack of recreational trips outside the region (OR: 1.66; 95% CI: 1.47, 1.89), and the time child spent outdoors were associated with elevated BLL. Variables found to affect BLL in the Silesian children should be used to propose criteria to improve identification of children at risk and to focus prevention activities more effectively

N2 - Physical activity causes acute physiological and long-term adaptive responses in the body. It is a protective factor for coronary heart disease (CHD) in adults. It has been assumed that children younger than 8 years of age may be in general active enough and there would be hardly any relationships between physical activity and CHD risk factors in early childhood. One hundred and fifty-five children (age 4-7 years) participated in this physical activity study during three consecutive years. Physical activity was examined twice a year with a special-purpose physical activity diary. CHD risk factors were measured during annual health care visits in the Specific Turku Coronary Risk-Factor Intervention Project (STRIP). We found that physical activity was related to CHD risk factors in early childhood. Among the girls, low-activity playing was related to a higher BMI. At the mean age of 6 years, high-activity playing was negatively related to serum total cholesterol ($r=-0.32^*$) and positively to the high-density lipoprotein (HDL)/total cholesterol ratio ($r=0.37^{**}$). The negative relationship between high-activity playing and triglycerides was highest ($r=-0.32^*$) at the mean age of six. Among 4-year-old boys, playing outdoors correlated positively with serum HDL cholesterol concentration ($r=0.29^*$) and the HDL/total ratio ($r=0.35^{**}$). At the age of 5 years, physically active playing correlated positively with systolic blood pressure ($r=0.25^*$). Playing outdoors and high-activity playing already have important health-maintaining effects in 4-7-year-old children. These positive effects differ between genders. (* $P<0.05$ ** $P<0.01$)

N2 - This paper summarizes a series of analyses of clustered, sequential activity/location data collected by Harvard University for 160 children aged 7-12 years in Southern California (Geyh et al., 2000). The main purpose of the paper is to understand intra- and inter-variability in the time spent by the sample in the outdoor location, the location exhibiting the most variability of the ones evaluated. The data were analyzed using distribution-free hypothesis-testing (K-S tests of the distributions), generalized linear modeling techniques, and random-sampling schemes that produced "cohorts" whose descriptive statistical characteristics were evaluated against the original dataset. Most importantly, our analyses indicate that subdividing the population into appropriate cohorts better replicates parameters of the original data, including the interclass correlation coefficient (ICC), which is a relative measure of the intra- and inter-individual variability inherent in the original data. While the findings of our analyses are consistent with previous assessments of "time budget" and physical activity data, they are constrained by the rather homogeneous sample available to us. Owing to a general lack of longitudinal human activity/location data available for other age/gender cohorts, we are unable to generalize our findings to other population subgroups

N2 - PURPOSE: To study the incidence of open globe injuries and the outcome in children, and to study the risk factors for post-traumatic endophthalmitis. METHODS: Paediatric patient population. Retrospective analysis of 72 consecutive cases of open globe injury over 3 years (January 1998 to December 2000).

RESULTS: The cause of trauma was sports related (n = 18), home-made bow and arrow (n = 16), household kitchen injuries (n = 10), cracker injuries (n = 7) and other miscellaneous outdoor activities (n = 16). In 5 children the cause could not be ascertained. Visual acuity of $\geq 3/60$ in the injured eye at the last follow-up examination was recorded in 37 of 70 patients (52.86%) whose visual acuity could be tested. The final visual acuity was significantly poorer in eyes where primary repair was delayed beyond 24 hours of injury ($P < 0.05$). Post-traumatic endophthalmitis developed in 39 of 72 (54.16%) eyes. Bow and arrow and household injuries ($P < 0.5$) and eyes in which primary repair was delayed beyond 24 hours of injury ($P < 0.01$) had a higher risk of endophthalmitis in univariate analysis. In multivariate analysis delayed repair was the only significant risk factor for the occurrence of endophthalmitis ($P = 0.014$). CONCLUSION: Delayed repair, bow and arrow injuries and household injuries were associated with significantly higher risk of endophthalmitis. The incidence of endophthalmitis can be reduced by early referral of trauma cases and parental supervision

N2 - **BACKGROUND AND PURPOSE:** Mobility of children with cerebral palsy (CP) has generally been examined in terms of capability (what a child can do) in a controlled environment, rather than performance (what a child does do) in everyday settings. The purpose of this study was to compare gross motor capability and performance across environmental settings in children with CP. **SUBJECTS:** The subjects were 307 children with CP, aged 6 to 12 years, who were randomly selected across Ontario, Canada. **METHODS:** Children were grouped by capability (the highest of 3 items achieved on the Gross Motor Function Measure). Performance was measured via a parent-completed questionnaire on usual mobility methods in the home, at school, and in the outdoors or community. **RESULTS:** There were statistically significant differences in performance across settings for children in all capability groups. Children who were capable of crawling performed crawling more at home than at school or in the outdoors or community. Children who were capable of walking with support performed walking with support more at school than in the outdoors or community. Children who were capable of walking alone performed walking alone more at home than at school or in the outdoors or community, and more at school than in the outdoors or community. **DISCUSSION AND CONCLUSION:** The results provide evidence that children with CP with similar capability demonstrate differences in performance across settings. The results suggest that physical therapists should examine performance in the settings that are important to the child's daily life

N2 - **BACKGROUND:** Pre-natal and post-natal periods are times when many women actively seek health information from multiple sources, including the Internet. However, little is known about how pregnant women and mothers of young children seek and process online pediatric health information. **OBJECTIVE:** To explore why and where mothers of young children look for online health information and how they determine if the information they receive is trustworthy. **METHODS:** Focus groups were conducted in a Southeastern US city to provide an in-depth exploration of web-related behaviors and beliefs among mothers who work inside and outside of the home. Data from the focus groups were coded using deductive and inductive coding schemes and content was analyzed for the existence of themes. **RESULTS:** Twenty mothers of young children participated in four focus groups. Most participants sought information on the Internet during pregnancy and nearly all sought online information after their child was born, primarily to diagnose or treat pediatric conditions and to seek advice on parenting and development. Participants mainly used commercial information websites for health information and many expressed disdain for commercial product websites. Many also expressed concerns about the reliability of health information on the web and described strategies for determining how much they trust each website. **CONCLUSIONS:** Women appear to be high information seekers during pregnancy and the first few years following delivery, and this period represents an important window of time for providing online health information. Participants suggested that online information sources and motives for providing online information should be clear in order to increase perceptions of trust. Participants expressed preference for online clinical health information that is presented by clinical professionals, and online parenting advice that is presented from other parents

N2 - OBJECTIVES: The authors measured and recorded the physical (outdoor playing) and mental (home study) activity behavior and blood pressure amongst school going children and observed their association with the blood pressure levels. METHOD: It was a cross sectional school-based study from 12 primary schools; selected by stratified random sampling. Participants included 2250 children aged 10 years and above.

Explanatory variables were age, sex, outdoor playing (hours/ day) and home-study (hours/ day). Outcome variables were mean and standard deviation (SD) of systolic and diastolic blood pressures in various activity groups. Statistical tools used were proportions, correlation co-efficient (r), coefficient of determination (r²) and Regression analysis. RESULTS: 47.8% boys and 2.5 % girls were engaged in outdoor playing for more than two hours. No trend was observed for systolic blood pressure (SBP) in both the sexes in various activity groups of outdoor playing. Both mean diagnostic blood pressure (DBP) and mean BMI showed decreasing trend in boys. Mean BMI had an inverse relationship with outdoor playing in girls. Correlation of age and weight with both SBP and DBP was highly significant in both the sexes and in all the age groups except that of the 15-year age. Both SBP and DBP were not associated with home study in all sex and age groups except the age group of 10 and 12 years. Both SBP and DBP were significantly associated with the outdoor playing taking the whole sample as one group, but not in different sex or age groups; except that the SBP was significantly correlated with outdoor playing in 10 to 13 years age groups in boys. CONCLUSION: Boys spent twice the time in outdoor playing than girls. They were spending more time on outdoor playing than on home study. Conversely girls spent more time in home study. A weak negative correlation was observed between outdoor playing and blood pressures. Less time spent in physical activities by the girls may have contributed to their higher BMI.

They need behavior change communication for involvement in physical activities

N2 - BACKGROUND: Among many published studies of specific IgE response or atopy, only a few showed positive marginal effects for 6 potentially functional single nucleotide polymorphisms (SNPs; C-590T in the IL4 gene, C-1055T and Arg130Gln in the IL13 gene, and Ile50Val, Ser478Pro, and Gln551Arg in the IL4RA gene). SNPs were commonly considered individually, and therefore the true effect could be masked by other genes or environmental factors. **OBJECTIVE:** We tested the relationship between these 6 SNPs and sensitization to food, mite, cat, and outdoor allergens in unrelated German children drawn from the Multicenter Atopy Study. Gene-gene and gene-environment interactions were also evaluated. **METHODS:** Multiple logistic regression models were used for the analyses of 4 sensitization outcomes. **RESULTS:** The variant C-1055T was significantly associated with increased risk of sensitization to food and outdoor allergens, with odds ratios of 3.49 (95% CI, 1.52-8.02) and 2.27 (95% CI, 1.04-4.94), respectively. The effects of the TT genotype on food sensitization appear to depend on variants in the IL4RA gene, in which marginally significant interaction terms were observed. Significant evidence supported an interaction between exposure to maternal smoking and variant Gln551Arg on risk of cat sensitization. In addition, we found that the effect of variant C-590T on sensitization to mite depended on Der p 1 allergen levels in carpet dust samples. **CONCLUSIONS:** These findings not only suggested that variants in the IL4, IL13, and IL4RA genes play an important role in controlling specific IgE response but also strengthened our understanding of gene-gene and gene-environment interaction on the development of specific sensitization in this study population

N2 - A 12-month, population-based, case-control study of *Campylobacter* infections was conducted at Foodborne Disease Active Surveillance Network surveillance areas during 1998-1999. Of 858 *Campylobacter* isolates tested for antimicrobial susceptibility to the fluoroquinolone ciprofloxacin, 94 (11%) were resistant. Travel outside of the United States was reported by 27 (42%) of 64 patients with fluoroquinolone-resistant *Campylobacter* infection and by 51 (9%) of 582 patients with fluoroquinolone-susceptible *Campylobacter* infection (odds ratio [OR], 7.6; 95% confidence interval [CI], 4.3-13.4). When patients with domestically acquired fluoroquinolone-resistant *Campylobacter* infection were compared with matched healthy control subjects in a multivariate analysis, those infected were 10 times more likely to have eaten chicken or turkey cooked at a commercial establishment (18 [55%] of 33 case patients vs. 7 [21%] of 33 controls; matched OR, 10.0; 95% CI, 1.3-78). Although travel outside of the United States was associated with fluoroquinolone-resistant *Campylobacter* infection, most infections among study participants were domestically acquired. This study provides additional evidence that poultry is an important source of domestically acquired fluoroquinolone-resistant *Campylobacter* infection. Control measures should include efforts to improve food handling in commercial establishments

N2 - To determine risk factors for sporadic Salmonella serotype Heidelberg diarrheal disease, we conducted a population-based case-control study in 5 Foodborne Diseases Active Surveillance Network (FoodNet) surveillance areas in 1996-1997. Forty-four case patients and 83 control subjects matched by age and telephone exchange were asked about exposures during the 5-day period before onset of illness in the case patient. Risk factors for infection were evaluated using conditional logistic regression analysis. Eating eggs prepared outside the home remained the only significant risk factor for illness (matched odds ratio [MOR], 6.0; 95% confidence interval [CI], 1.2-29.6). The population-attributable fraction of S. Heidelberg infections associated with eating eggs prepared outside the home was 37%. Eliminating the risk associated with out-of-home egg consumption could substantially reduce the incidence of S. Heidelberg infections. Control measures to prevent S. Heidelberg infection should include advising consumers to avoid eating undercooked eggs and educating food handlers about proper egg handling and cooking

N2 - The case for the universal application of 'safer surfacing' in playgrounds is assessed in terms of absolute risk, cost-benefit, and qualitative factors, and found to be open to question on each front. In parallel, it is noted that members of the child welfare and play communities are increasingly of the view that playgrounds are losing their appeal for children, which in turn has its own health, safety and developmental consequences. In part, this loss of attractiveness may have linkages with the recent concern over play safety and the imposition of measures such as 'safer surfacing'. It is proposed that the drive for play safety, which has existed for some 20 years, should be succeeded by a more holistic approach which, rather than considering play safety in isolation, acknowledges the importance of all attributes of play including child safety both on and off playgrounds, potential beneficial aspects of childhood risk exposure, adventure, and play value

N2 - OBJECTIVE: This study aimed to identify self report questionnaire measures of parent attributes and behaviors that have relevance for understanding injury risk among children 2-5 years of age, and test a new Parent Supervision Attributes Profile Questionnaire (PSAPQ) that was developed to measure aspects of protectiveness and parent supervision. **METHODS:** Naturalistic observations were conducted of parents' supervision of children on playgrounds, with questionnaires subsequently completed by the parent to measure parent education, family income, parent personality attributes, attributes relevant to parent supervision, and beliefs about parents' control over the child's health status. These measures were then related to children's risk taking and injury history. **RESULTS:** Visual supervision, auditory supervision, and physical proximity were highly intercorrelated, indicating that parents employed all types of behaviors in service of supervision, rather than relying predominantly on one type of supervisory behavior. Physical proximity was the only aspect of supervision behavior that served a protective function and related to children's risk taking behaviors: parents who remained close to their children had children who engaged in less risk taking. On questionnaires, parents who reported more conscientiousness, protectiveness, worry about safety, vigilance in supervision, confidence in their ability to keep their child safe, and belief in control over their child's health had children who showed less risk taking and/or experienced fewer injuries. The new PSAPQ measure was associated with specific aspects of supervision as well as children's risk taking and injury history. **CONCLUSIONS:** This study reveals several parent attributes and behaviors with relevance for child injury risk that can be measured via self report questionnaires, including the new PSAPQ

N2 - **BACKGROUND:** Keeping young children physically active is an important strategy to promote their health and well-being. To our knowledge, survey measures of physical activity in preschool-aged children are unavailable. Time spent playing outdoors is a potential surrogate measure of physical activity in preschoolers, but parental-report measures of outdoor playtime have not been evaluated. **OBJECTIVE:** To compare a direct measure of physical activity in preschool-aged children with 2 parental-report measures of children's outdoor playtime. **MAIN OUTCOME MEASURES:** Three days of recording with a 3-dimensional accelerometer were used to directly measure physical activity in 250 preschool-aged children. We calculated each child's average vector magnitude per minute while awake. Parental report of outdoor playtime was measured in 2 ways: (1) the score from a checklist used to record outdoor playtime over 3 days and (2) a recall of the usual minutes of daily outdoor playtime during the prior month. We calculated Spearman rank correlation coefficients among these 3 measures. **RESULTS:** The mean age of the children was 44 months, 87.7% were white, and 12.3% were black. Parents reported that their children spent a mean (+/-SD) of 146 (+/-113) minutes playing outdoors each day. Physical activity as measured by the accelerometer was significantly correlated to the time spent playing outdoors, as measured by the checklist ($r = 0.33$, $P < .001$) and recall ($r = 0.20$, $P = .003$). **CONCLUSION:** Parental-report measures of outdoor playtime were significantly correlated to a direct measure of physical activity in preschool-aged children, and are worthy of future evaluation as a survey measure

N2 - An ozone (O₃) exposure study was conducted in Nashville, TN, using passive O₃ samplers to measure six weekly outdoor, indoor, and personal O₃ exposure estimates for a group of 10- to 12-yr-old elementary school children. Thirty-six children from two Nashville area communities (Inglewood and Hendersonville) participated in the O₃ sampling program, and 99 children provided additional time-activity information by telephone interview. By design, this study coincided with the 1994 Nashville/Middle Tennessee Ozone Study conducted by the Southern Oxidants Study, which provided enhanced continuous ambient O₃ monitoring across the Nashville area. Passive sampling estimated weekly average outdoor O₃ concentrations from 0.011 to 0.030 ppm in the urban Inglewood community and from 0.015 to 0.042 ppm in suburban Hendersonville. The maximum 1- and 8-hr ambient concentrations encountered at the Hendersonville continuous monitor exceeded the levels of the 1- and 8-hr metrics for the O₃ National Ambient Air Quality Standard. Weekly average personal O₃ exposures ranged from 0.0013 to 0.0064 ppm (7-31% of outdoor levels). Personal O₃ exposures reflected the proportional amount of time spent in indoor and outdoor environments. Air-conditioned homes displayed very low indoor O₃ concentrations, and homes using open windows and fans for ventilation displayed much higher concentrations

N2 - OBJECTIVES: Celiac disease is caused by the interaction of multiple genes and environmental factors. Inheritance of the disease shows a complex pattern with a 10% sibling recurrence risk. The HLA-region is a major genetic risk locus in celiac disease, but genes outside this region are expected to contribute to the disease risk as well. The aim of this study was to identify the loci causing celiac disease in one large Dutch family with apparent dominant transmission of the disease. METHODS: The family comprised 17 patients in four generations, with possible transmission of the disease by both grandparents. Microsatellite markers evenly spread over all chromosomes were genotyped and linkage analysis was performed using both dominant and recessive disease models and a model-free analysis. RESULTS: Disease susceptibility in the family was linked to the HLA-region (lod score of 2.33) and all patients were HLA-DQ2. A dominantly inherited non-HLA locus with a maximum lod score of 2.61 was detected at 9p21-13, which was shared by 16 patients. Model-free analysis identified another possible non-HLA locus, at 6q25.3, which was shared by 14 patients (p = 0.01).

Neither of these regions was detected in a genomewide screen in Dutch affected sibpairs, but the 9p21 locus has been implicated in Scandinavian families. CONCLUSIONS: Two potential non-HLA loci for celiac disease were identified in this large Dutch family. Our results provide replication of the Scandinavian 9p21 locus, and suggest that this locus plays a role in celiac disease patients from different Caucasian populations

N2 - Little is known about the impact of intestinal transplantation on development of the infant brain. In this study we report four neurodevelopmental studies on children receiving either liver or intestinal/multivisceral transplants. Our preliminary investigation examined the pretransplant status of 27 infants, who were either liver or intestinal/multivisceral candidates, using the Bayley Scales of Infant Development. A second study examined 23 infants after liver or intestinal/multivisceral transplant. A third study included pre- and posttransplant evaluations on 5 multivisceral infant transplants. In the fourth study, 10 children were tested several years after intestinal/multivisceral transplantation. Some children are able to achieve a normal development. However, even several years posttransplant most children can still experience significant cognitive delays. Children

receiving a transplant during infancy may also suffer severe motor delays. Infants undergoing intestinal/multivisceral transplantation show significantly more cognitive delays than those undergoing single-organ liver transplantation. In addition, multivisceral transplanted infants are more likely to continue to be severely developmentally delayed at the time of hospital discharge. With improved survival rates for infant transplants, both cognitive and motor development must be evaluated to determine the need for early intervention. In addition, educating families on the importance of compliance with intervention services outside the hospital is essential to maximize long-term neurodevelopmental outcomes for these infants

N2 - **OBJECTIVE:** The objectives of our study were to assess biomechanics associated with feet-first free falls in 3-year-old children and to investigate the influence of impact surface type and fall height on key biomechanical measures associated with injury risk. **METHODS:** Repeatable feet-first free fall experiments were conducted in a laboratory mock-up environment using an instrumented Hybrid II 3-year-old test dummy. Impact surface type and fall height were varied to examine their influence on biomechanical measures. **RESULTS:** Feet-first falls from short distances (27 in.) (0.69 m) were found to have a low risk of contact-type

head injury, regardless of impact surface type. When comparing different types of impact surfaces in a 27 in. (0.69 m) fall, head acceleration associated with falls onto playground foam was significantly less than that associated with falls onto wood, linoleum or padded carpet. For falls onto playground foam, femoral compressive loads and bending moments were found to significantly increase as fall height increased.

CONCLUSIONS: Impact surface type and fall height were found to influence biomechanics associated with injury risk in feet-first free falls as assessed through experimental mock-ups using an instrumented child test dummy. Feet-first falls from short distances (27 in.) (0.69 m) were associated with a low risk of contact-type head injury as assessed using HIC, irrespective of impact surface type

N2 - OBJECTIVE: To provide reliable and comparable information on major injury (MIJ) (Injury Severity Score (ISS) > 15) by establishing a comprehensive and Utstein-style compliant registry of all occurrences in a defined geographical area. METHODS: Prospective, population-based, 12-month study targeting the 1,200,000 inhabitants of the Italian region Friuli Venezia Giulia (FVG). Deliberate self-harm was excluded. RESULTS: The total number of MIJ cases was 627, the resulting incidence 522 per million per year. Trauma was mostly blunt (98.4%). Young (15-44 years) adults (54.8%) and males (78.6%) were most affected. Leading mechanisms of injury were traffic accidents (81%) and falls (9.1%). Most events occurred in rural (80.9%) areas despite one third of the regional population living in major urban centres. Summer and weekends carried the highest frequency. The mean ISS (n = 455) was 30.0, median 25. On-scene vital parameters were often subnormal, e.g. 53.9%, GCS < 14. The Emergency Medical System was nearly always activated (98.4%). The time intervals were within standards although in part susceptible of improvement. The percentage of direct triage to the definitive hospital was 79.8%. Overall mortality was 45.6% or 238 per million per year. Most fatalities were found already dead (171/300) and no trimodal distribution was verified. Only 1.5% of the patients found alive died outside hospital. Mean GOS was 4.4 +/- 1 (S.D.), median 5. CONCLUSION: A considerable amount of information on MIJ in FVG has been gathered, of both local and general interest because it can help to assess the local trauma system and also, given the relative scarcity of prospective, population-based information on MIJ, contribute to scientific research

N2 - OBJECTIVE: To assess the impact of a 6 months nutrition education and physical activity intervention on primary school children through changes in adiposity and physical fitness. DESIGN: Longitudinal school-based controlled evaluation study. SUBJECTS: Children from 1st to 8th grade, 2141 in intervention and 945 in control schools. INTERVENTION: Nutrition education for children and parents, 'healthier' kiosks, 90 min of additional physical activity (PA) weekly, behavioral PA program and active recess. MEASUREMENTS: Adiposity indices (BMI, BMI Z-score, triceps skinfold thickness (TSF), waist circumference and physical fitness (20 m shuttle run test and lower back flexibility). RESULTS: Positive effect on adiposity indices (except TSF) was observed in boys ($P < 0.001$ for BMI Z), while both physical fitness parameters increased significantly in both boys ($P < 0.001$ for each test) and girls ($P < 0.0001$ for each test). A differential effect in BMI Z was observed according to baseline nutritional status. CONCLUSIONS: This intervention showed a robust effect on physical fitness in both genders and decreased adiposity only in boys

N2 - CCA-treated wood is widely used in the fabrication of outdoor decks and playground equipment. Because arsenic can be removed from the surface of CCA-treated wood both by physical contact and by leaching, it is important to determine whether children who play on such structures may ingest arsenic in quantities sufficient to be of public health concern. Based on a review of existing studies, it is estimated that arsenic doses in amounts of tens of micrograms per day may be incurred by children having realistic levels of exposure to CCA-treated decks and playground structures. The most important exposure pathway appears to be oral ingestion of arsenic that is first dislodged from the wood by direct hand contact, then transferred to the mouth by children's hand-to-mouth activity. The next most important pathway appears to be dermal absorption of arsenic, while ingestion of soil that has become contaminated by leaching from CCA-treated structures appears to be of lesser importance, except possibly in the case of children with pica. Considerable uncertainty, however, is associated with quantitative estimates of children's arsenic exposure from CCA-treated wood. Priorities for refining estimates of arsenic dose include detailed studies of the hand-to-mouth transfer of arsenic, studies of the dermal and gastrointestinal absorption of dislodgeable arsenic, and studies in which doses of arsenic to children playing in contact with CCA-treated wood are directly determined by measurement of arsenic in their urine, hair, and nails

N2 - Kidskin was a sun-protection intervention study involving 1776 children attending 33 primary schools in Perth, Western Australia. There were three study groups: a control group, a moderate intervention group and a high intervention group. In addition to receiving a specially designed curricular intervention (1995-1998), the moderate and high intervention groups received an environmental intervention aimed at creating SunSmart schools (1996-1998). The environmental intervention focused on encouraging implementation of 'No hat, no play' policies and reducing sun exposure at lunchtime. In 1995 and 1998, observational methods were used to measure children's lunchtime sun exposure (i.e. polysulfone film badges) and hat wearing (i.e. video-taping of children). The proportion of children wearing broad-brimmed hats or legionnaire caps increased in seven of the eight high intervention schools between 1995 and 1998. In three schools, however, the impact was very positive with almost all children wearing these hats in 1998. There was no improvement in wearing these types of hats in either the moderate intervention group or the control group. In terms of sun exposure, there were only small non-significant differences among the three groups in terms of lunchtime sun exposure. The Kidskin program had a positive effect on hat wearing in the playground, but did not change children's use of shade at lunchtime. In this study, disseminating policy guidelines to schools using a mail-only strategy was ineffective, even when combined with an awards program. More information on 'champions' who bring about change in schools is required

N2 - The relation among children's evening activities, behavioral characteristics, and activity of the hypothalamic-pituitary-adrenocortical axis was assessed in normally developing children ages 7 to 10 years. Salivary cortisol at bedtime was compared on evenings when children had structured activities outside of the home with unstructured evenings at home in relation to parental reports of children's behavioral characteristics. Participating in evening activities, particularly sport activities, was associated with small increases in bedtime cortisol levels in boys but not in girls. Differences in cortisol on activity versus no-activity nights were negatively related to children's social isolation. These results show that in studies with children, nights on which participants engage in sport activities should be avoided when collecting ambulatory measures of salivary cortisol concentrations

N2 - STUDY DESIGN: A prevalence survey of 101 randomly selected elementary schools in the Israel Central District. OBJECTIVES: To identify and describe risk factors for low back pain that exist in the elementary school environment. SUMMARY OF BACKGROUND DATA: Recent surveys report a high prevalence of low back pain in children and adolescents that increases with age, with a correlation between low back pain in adolescence and that experienced in adulthood. Environmental risk factors have been associated with the development of low back pain in children. Because of the significant amount of time children spend in their school environment, risk factors need to be identified in this environment. METHODS: A questionnaire, completed by school nurses, measured risk factors among 10,000 children in elementary schools in Israel. These included backpack and student weight, the availability of storage facilities, the appropriateness of chair and desk height to student height, seating arrangements during frontal lessons, and physical activity at recess. RESULTS: Between 30% and 54% of students carried >15% of their body weight. Nearly 15% of the first graders and 20% of sixth graders had inappropriate chairs. In 74% of the classes, students sat with their side facing the teacher and in 35% students sat with their backs. In 6% of schools, no physical activity is offered at recess. CONCLUSIONS: Shortcomings were found in all areas investigated. There is an urgent need for health promotion programs to increase awareness and reduce risks in the school environment

N2 - The aim of this study was to determine the prevalence of complementary and alternative medicine (CAM) use among children with cancer who had received or were receiving treatment at a large hospital in the UK, including the identification of the most commonly used therapies and parental motives for doing so. Using a cross-sectional survey design, questionnaires were sent to parents of paediatric patients diagnosed with cancer. Of the 49 respondents, 32.7% reported using some type of CAM. The most commonly used therapies included multivitamins, aromatherapy massage, diets and music as therapy. Most children had used more than one therapy. Many of the factors that motivated parents to use CAM were related to helping or supporting their child's medical treatment. The main benefits identified from using CAM included increased confidence, pain relief and relaxation. The longer the time since diagnosis the more children tended to use CAM. The reasons for parents not using CAM included the child doing well and therefore not seeing the need for CAM use; not being aware of CAM; CAM not being offered and lack of information available. Parents identified a need for more information to be available both at ward level and for information about CAM to be discussed by medical staff, particularly at the start of treatment. The results indicate that CAM is frequently used by children and young people with cancer and that their use plays a substantial role in helping children through their conventional cancer treatment

N2 - Internal and external noise surveys have been carried out around schools in London, UK, to provide information on typical levels and sources to which children are exposed while at school. Noise levels were measured outside 142 schools, in areas away from flight paths into major airports. Here 86% of the schools surveyed were exposed to noise from road traffic, the average external noise level outside a school being 57 dB L(Aeq). Detailed internal noise surveys have been carried out in 140 classrooms in 16 schools, together with classroom observations. It was found that noise levels inside classrooms depend upon the activities in which the children are engaged, with a difference of 20 dB L(Aeq) between the "quietest" and "noisiest" activities. The average background noise level in classrooms exceeds the level recommended in current standards. The number of children in the classroom was found to affect noise levels. External noise influenced internal noise levels only when children were engaged in the quietest classroom activities. The effects of the age of the school buildings and types of window upon internal noise were examined but results were inconclusive

N2 - In minority populations, those who do not maintain normal weight outnumber those who do; thus, overweight is often the community norm. Compared to many white populations, minority populations are transitioning from poverty, food scarcity, and jobs that require significant amounts of energy expenditure. This may mean food and activity habits of both black and Latino populations may have been developed during a more physically-active era. Caloric restriction and leisure-time physical activity are not routine in minority communities. In these communities, there are often few supermarkets that carry fresh produce, many fast food establishments and small grocery stores that sell high-fat, energy-dense foods, and high neighborhood crime rates that discourage outdoor activities and limit safe places for walking and bicycling, including school routes. Although specific dietary and activity behaviors related to weight control ultimately are undertaken by individuals, our current environment makes such individual choices difficult when it contains substantial barriers to establishing healthy lifestyles. Substantial environmental changes need to be made, especially in minority communities. [References: 31]

N2 - Studies in Caucasian populations have shown that a significant percentage of childhood extremity fractures occur at the playground. There are no comparable studies in Asian populations. Thus this study sets out to determine the pattern of playground related extremity fractures in Asian populations and to suggest modifications to prevent or reduce these injuries. This study involved a retrospective review of 390 patients with these fractures who visited our Department from May 1997 to December 1998. This accounted for 19.5% of all fractures seen in the same period. The largest age group affected were the five through 12-year-old patients with a male to female ratio of 2:1. Monkey bars or upper body devices were the most common cause (66%). The most common fracture was supracondylar fractures (43%). Further studies to determine the actual dimensions of playground equipment will be carried to ascertain with greater certainty the safety of these equipment in our playgrounds

N2 - The sources of lead exposure, soil, household dust, diet and ambient air near a former lead smeltery were studied. The blood lead level of small children was also determined. The aim of the study was to define, based primarily on blood lead measurements, whether children living in the contaminated area may be at risk. Within

500 m from the site of the smeltery, there were several areas where the Finnish limit value for soil Pb, i.e. 300 mg/kg, was exceeded. In the recently built areas, the surface soil has been replaced and soil remediation has taken place in schoolyards and the playgrounds of children's day-care centres. Lead content in household dust was clearly elevated in the contaminated areas. In approximately 20 years, after the smeltery was closed in 1984, the lead concentrations of the fruits and berries in local gardens have decreased to one-tenth. In some samples, the limit values are still exceeded. The lead concentration in ambient air is now 50 times lower than in the 1970s. The blood lead level of the children living in the area is slightly but statistically significantly higher than that of the children in the control areas. The critical blood lead level, i.e. 10 microg/100 ml, was not exceeded in any of the children examined. The average and maximum lead concentrations of 63 analysed blood samples were 2.2 and 5 microg/100 ml, respectively. In contrast, the average and maximum blood lead levels of school children in 1981 were 6.7 and 13.0 microg/100 ml, respectively. The risk reduction measures undertaken during the past 20 years are described

N2 - We studied 604 suspected snakebite cases seen at the peripheral snakebite treatment centre, Damak, Eastern Nepal from January to December 2000 using pre-designed proforma. Seventy-five per cent of the patients were in the age group 11-40 years. The common victims were farmers (44.2%) and housewives (31.7%). The bite was commonly encountered during farming (29.4%), working in the field (16.2%), walking (13.7%) and feeding cattle (9.2%). Sixty-five per cent were bitten during outdoor and agriculture related activities. Bite during sleep was recorded in 7%: 62% had sustained bite in lower limb. Forty-two per cent of the victims arrived at the treatment centre within 2 hours of being bitten. Fourteen patients arrived 7 hours after being bitten and six were dead on arrival. A common local practice (seen in 56.7%) was to eat chillies to confirm envenomation. Application of a tourniquet, often multiple, was the common (90%) first aid measure. Neurotoxicity was present in 11% (n=66) of the victims. Five had local features of envenomation. No case of coagulopathy was recorded. Reaction to anti-snake venom was noticed in 28.16% (n=20). Two patients died during treatment. Mortality among patients with features of neurotoxicity was 3%

N2 - Two Finnish cohorts, comprising 56 children with severe early-onset obesity (relative weight for height greater than or equal to +70% before age 10) and 252 morbidly obese adults (body mass index, ≥ 40 kg/m²), were screened for melanocortin-4 receptor (MC4R) mutations. We identified a pathogenic mutation (S127L) in one child, causing severe early-onset obesity. We describe the phenotype of this particular mutation for the first time. We also identified a novel (I226T) polymorphism in the coding and two new variations (-439delGC and 1059C>T) outside the coding region of the MC4R gene. Three previously described polymorphisms (V103I, T112M, and I125L) were identified. In vitro functional studies of variants T112M, S127L, and I226T supported a pathogenic role of the S127L mutation, because signaling properties of the receptor in response to the MC4R agonists alpha-MSH, beta-MSH, and gamma(1)-MSH were impaired. The S127L mutation did not affect receptor inhibition by the antagonist agouti-related protein. Localization of the three variant receptors was similar to that of wild type. In conclusion, a pathogenic MC4R mutation was found among subjects with severe early-onset obesity but not among morbidly obese adults. Impaired function of the S127L receptor was due to reduced activation, not a defect of protein transport to the cell membrane

N2 - Congenital hyperinsulinism (CHI) is related to two main histological pancreas anomalies: focal adenomatous hyperplasia and diffuse beta-cell hypersecretion. Pharmacological tests to measure acute insulin responses (AIR) to peripheral i.v. injections of glucose, calcium, and tolbutamide have been reported as potential means to distinguish between these histological forms. In patients with defects in ATP-sensitive potassium channels, tolbutamide will fail to induce insulin release in affected portions of the pancreas, whereas calcium gluconate will enhance insulin release through spontaneously active voltage-gated Ca(2+) channels. Consequently, in focal CHI patients, calcium should promote AIRs from the lesion, whereas tolbutamide should act to promote insulin secretion from the healthy region of the pancreas (outside the focal hyperplasia). We therefore studied AIRs to calcium and tolbutamide stimulation tests in 16 children with focal (n = 9) or diffuse (n = 7) CHI before pancreatic surgery. We found hypervariable AIRs to glucose and calcium stimulation in both focal and diffuse CHI patients. AIRs to tolbutamide stimulation were found modest in focal CHI patients, which might account for beta-cell quiescence in the healthy portion of the pancreas of these patients. We conclude that AIRs to calcium and tolbutamide stimulation tests are not sufficient to differentiate the focal from the diffuse CHI patients

N2 - **OBJECTIVE:** Approximately six million children with disabilities attend school in the United States. Cognitive and physical limitations may compromise their ability to handle environmental hazards and hence increase their risk for injury. The objective of this study was to describe the epidemiology of school related injury among children enrolled in 17 special education schools in one large, urban school district. **DESIGN:** Altogether 6769 schoolchildren with disabilities were followed up from 1994-98. Injury and population data were collected from pupil accident reports and existing school records. Associations were estimated through generalized estimating equations. **RESULTS:** A total of 697 injuries were reported for a rate of 4.7/100 students per year. Children with multiple disabilities had a 70% increased odds of injury compared with the developmentally disabled (odds ratio (OR) 1.7, 95% confidence interval (CI) 1.3 to 2.3). The physically disabled (OR 1.4, 95% CI 1.0 to 1.9) had a modest increased odds of injury. Cuts, bruises, and abrasions composed almost three fourths of all injuries; almost half of these injuries were to the face. Falls (34%) and insults by other students (31%) were the most common external causes. More than a fourth of injuries were sports related, and 21% occurred on the playground/athletic field. Injury patterns differed across disabilities. **CONCLUSIONS:** Although limited to one school district, the population studied is the largest cohort thus far of schoolchildren with disabilities. With this large study base, potentially high risk groups were identified and circumstances of injury described. This information is imperative for developing and improving school based injury prevention measures

N2 - **BACKGROUND:** Overexposure to ultraviolet radiation (UVR) in childhood is a major risk factor for skin cancer. Shady environments are recommended as one method of protection. **METHODS:** Environmental exposure to UVR and environmental protection were assessed by dosimeter measurements on 64 children aged 1-6 years at two geographically close and topographically similar pre-schools outside Stockholm. Outdoor play constructions of site 1 (34 children) were mainly exposed to the sun, and those of site 2 (30 children) were mainly shaded. Dosimetry was carried out during 11 work days in May-June 2002 under clear weather conditions. The reliability of dosimeters was tested with meteorologically modelled data from SMHI, and with stationary dosimeters exposed to free sky, and compared with other UV instruments. The differences between children's outdoor stays were adjusted for. **RESULTS:** The children's average daily exposures were approximately 200 J(CIE)/m(2) erythemally effective UVR. The average relative UVR exposure (% total available UVR 08:30-18:30) was 6.4% (7.0% at site 1, 5.7% at site 2). Fractions of available UVR during outdoor stay were 14.4% (both sites), 15.3% (site 1), and 13.3% (site 2). In terms of relative differences, 5-6-year-old children at site 2 were exposed to 41% less UVR, and 1-4-year-old children 6% less than those at site 1. **CONCLUSION:** The difference can be explained by the children's outdoor pre-school environments, and the behaviors linked to these environments. It is recommended to consider the attractiveness of shady environments in the design of children's pre-school playgrounds, particularly if these are extremely exposed to the sun

N2 - This paper summarizes numerous statistical analyses focused on the US Environmental Protection Agency's Consolidated Human Activity Database (CHAD), used by many exposure modelers as the basis for data on what people do and where they spend their time. In doing so, modelers tend to divide the total population being analyzed into "cohorts", to reduce extraneous interindividual variability by focusing on people with common characteristics. Age and gender are typically used as the primary cohort-defining attributes, but

more complex exposure models also use weather, day-of-the-week, and employment attributes for this purpose. We analyzed all of these attributes and others to determine if statistically significant differences exist among them to warrant their being used to define distinct cohort groups. We focused our attention mostly on the relationship between cohort attributes and the time spent outdoors, indoors, and in motor vehicles. Our results indicate that besides age and gender, other important attributes for defining cohorts are the physical activity level of individuals, weather factors such as daily maximum temperature in combination with months of the year, and combined weekday/weekend with employment status. Less important are precipitation and ethnic data. While statistically significant, the collective set of attributes does not explain a large amount of variance in outdoor, indoor, or in-vehicle locational decisions. Based on other research, parameters such as lifestyle and life stages that are absent from CHAD might have reduced the amount of unexplained variance. At this time, we recommend that exposure modelers use age and gender as "first-order" attributes to define cohorts followed by physical activity level, daily maximum temperature or other suitable weather parameters, and day type possibly beyond a simple weekday/weekend classification

N2 - The differential diagnosis of cutaneous B-cell infiltrates with follicular pattern of growth is one of the most vexing problems in dermatopathology. In this study we focused on histopathologic, immunophenotypic, and molecular differential diagnostic criteria between *Borrelia burgdorferi* (Bb)-associated lymphocytoma cutis (LC), primary cutaneous follicle center cell lymphoma (FCCL), and primary cutaneous marginal zone lymphoma (MZL) with reactive germinal centers (GCs). A total of 47 patients were included in the study, including 12 cases of LC (M:F = 2:1; mean age: 38.0; median: 31; range: 9-75), 29 cases of FCCL (M:F = 1.2:1; mean age: 57.5; median: 57; range: 24-97), and 6 cases of MZL (M:F = 1:1; mean age: 63.8; median: 67.5; range: 38-86). In all cases complete phenotypic data were available. In addition, the IgH gene rearrangement and the t(14;18) were analyzed using the polymerase chain reaction technique (PCR) in 41 (FCCL = 27, LC = 10, MZL = 4) and 18 cases (FCCL = 15, LC = 2, MZL = 1), respectively. Histology revealed in all cases of FCCL one or more atypical feature of the follicles including the lack of or a reduced mantle zone, lack of polarization, tendency to confluence, and absence of tingible body macrophages. In most cases of Bb-associated LC, the GCs were devoid of mantle zone, lacked polarization, and revealed tendency to confluence as well, but all cases showed the presence of several tingible body macrophages. In MZL, follicles showed typical features of reactive GCs. Immunohistology revealed a reduced proliferative activity of neoplastic follicles as detected by MIB-1 antibody in 23 of 29 cases of FCCL (79.3%), but only in 1 case of LC (8.3%). Proliferation of the GCs was normal in all cases of MZL. Positivity for CD10 and/or Bcl-6 was found in small clusters outside the follicles in 19 cases of FCCL (65.5%), and in 3 cases of LC (25%), but in no case of MZL. The intensity of CD10 staining on follicular cells on average was stronger in cases of FCCL, but overlapping features could be observed. Finally, staining for Bcl-2 protein was consistently negative on GC cells in cases of LC and MZL, and was positive on a variable proportion of the cells in 8 cases of FCCL (28.6%). Molecular analyses showed no evidence of the t(14;18) in all cases tested. Analysis of the IgH gene rearrangement revealed a monoclonal pattern in 1 of 10 cases of LC (10%), 14 of 27 cases of FCCL (51.9%), and 2 of 4 cases of MZL (50%) tested. In summary, Bb-associated LC and FCCL show sometimes overlapping histopathologic, immunohistochemical, and molecular features, whereas follicles in MZL show clear-cut aspects of reactive GCs. Absence of tingible body macrophages within follicles, reduced proliferation of the follicles as detected by immunohistology, presence of positivity for Bcl-2 protein within follicular cells, and monoclonality by PCR are the main criteria suggestive of malignancy. Diagnosis of cutaneous infiltrates of B lymphocytes with follicular growth pattern should be achieved by integration of clinical data with histopathologic, immunohistochemical, and molecular features of the lesions

N2 - **BACKGROUND:** We examined the relationship between overweight in preschool children and three environmental factors--the proximity of the children's residences to playgrounds and to fast food restaurants and the safety of the children's neighborhoods. We hypothesized that children who lived farther from playgrounds, closer to fast food restaurants, and in unsafe neighborhoods were more likely to be overweight. **METHODS:**

This was a cross-sectional study of 7,020 low-income children, 36 through 59 months of age living in Cincinnati, OH. Overweight was defined as a measured body mass index \geq 95th percentile. The distance between each child's residence and the nearest public playground and fast food restaurant was determined with geographic information systems. Neighborhood safety was defined by the number of police-reported crimes per 1,000 residents per year in each of 46 city neighborhoods. **RESULTS:** Overall, 9.2% of the children were overweight, 76% black, and 23% white. The mean (\pm SD) distances from a child's home to the nearest playground and fast food restaurant were 0.31 (\pm 0.22) and 0.70 (\pm 0.38) miles, respectively. There was no association between child overweight and proximity to playgrounds, proximity to fast food restaurants, or level of neighborhood crime. The association between child overweight and playground proximity did not differ by neighborhood crime level. **CONCLUSIONS:** Within a population of urban low-income preschoolers, overweight was not associated with proximity to playgrounds and fast food restaurants or with the level of neighborhood crime

N2 - This study was conducted to identify and evaluate the degree of appropriateness of children's playground standards and the level of compliance with the current safety specifications of the playgrounds in Elazig city in Turkey. This was accomplished by on-site observation and measurement in the total of 24 playgrounds present in this city centre. It was determined that 83.3% of the playgrounds were next to a street and in 60% of these playgrounds there were no fences or any barrier to keep children from running into the street. In 87.5% of playgrounds the surfacing was not in proper depth and good order. Separate playgrounds for different ages were provided in only 12.5% of the playgrounds. In 62.5% of the playgrounds children were supervised to make sure they were safe. There was unsafe equipment in 95.8% of the playgrounds. In 83.3% of the playgrounds there were sharp edges, pinch points, or playground debris that might injure a child. The findings of the present study indicate that nearly all of the playgrounds in Elazig city center do not meet the criteria for playground standards and are not in compliance with the current safety specifications and need improvement

N2 - Childhood overweight is a significant and growing health problem in the US and other parts of the world. Secular trend data in the US suggest that children have become substantially heavier over the last several decades and that their risk for a number of health problems is increasing as a result. Defining obesity in children has been difficult as assessing body fat is expensive and impractical. Body mass index (BMI), derived from weight and height, is used as a surrogate indicator in adults. In children, the consensus is to use BMI percentiles statistically derived from a reference population. There is evidence that the prenatal, early childhood, and adolescent periods are critical in the development of obesity but the mechanisms involved are yet to be elucidated. The recent rapid increase in childhood overweight and obesity is attributed to the modern obesogenic environment. Changes in dietary constituents including higher derivation of energy from nutritionally poor and energy dense foods, increased sweetened drink consumption, larger portion sizes, and more frequent intake of food outside the home have been associated with poorer diets and higher weights. Further, physical activity has reduced with decreases in school physical education classes and organized sports, fewer opportunities to expend energy for daily living activity due to more mechanization, lower frequency of walking and biking, and greater use of sedentary activities for leisure. Television watching remains the most common activity for children. There are significant health outcomes associated with childhood obesity, including the presence of cardiovascular risk factors, and greater prevalence of various medical problems including insulin resistance, type 2 diabetes mellitus, the metabolic syndrome, orthopedic problems, and pseudotumor cerebri. Of further concern is the increased risk for obesity in adulthood with its attendant co-morbidities. Interventions are imperative but not widely studied. The most effective interventions include comprehensive behavioral management, dietary modification, and exercise. Family-based interventions have been most successful at maintaining long-term weight loss. School-based interventions have the potential to significantly impact childhood overweight as large numbers of children can be reached. However, such programs require long-term follow-up and are expensive. Very low calorie diets, pharmacotherapy, and surgery remain experimental options for children. More recently, metformin has shown promise in promoting weight loss and improving insulin sensitivity among adolescents. Combining multiple approaches for treatment, addressing obesity-promoting sociocultural practices and policies, and focusing on prevention strategies will be necessary to address this epidemic. N2 - Protein losing enteropathy (PLE) is a gastrointestinal disorder that is associated with excessive loss of plasma protein into the gut resulting from abnormal mucosal permeability. The disease is usually caused by inflammation. The loss of protein in PLE is a nonselective process affecting albumin, globulin and transferrin. Abdominal scintigraphy with human serum albumin marked by Tc99m seems to be an easy and sensitive method for diagnosing PLE. An 4-year-old girl was presented to an outside Pediatric Department due to hypoproteinemia and recurrent pneumonia which had caused several prior hospitalizations. The laboratory tests revealed hypoproteinemia, hypoalbuminemia, low level of IgG, sideropenia, and a decreased level of T lymphocytes. The loss of protein into the gut was confirmed by fecal clearance of alfa-1 antitrypsin. Only nonspecific inflammation was detected by biopsy of the small intestine. These clinical and laboratory findings,

quickly decreasing IgG and albumin levels in spite of i.v. supplementation and the lack of proteinuria permitted PLE diagnosis. The abdominal scintigraphy was planned to assess and localise protein losing through GIT and for strategy of possible surgical treatment. Abdominal dynamic scintigraphy was performed immediately after the injection of 300 MBq Tc99m human albumin. 90 images were taken within 180 minutes. Delayed abdominal images were obtained 6 and 24 hours after the tracer injection. Anterior abdominal scintigraphy showed pathological activity of Tc99m-albumin in small bowel in the upper left segment of the abdomen in the 40th minute after injection. Extensive accumulation of albumin was seen in the 160th minute. Delayed images, after 3 and 6 hours, revealed translocation of the tracer into the lower right abdominal segment. The further passage and tracer concentration was detected in ascendant and transverse colon. Based on the laboratory tests and scintigraphic images the girl was suspected to have segmental lymphangiectasia of small intestine and was qualified for laparotomy and, possibly, for surgical resection of the pathologically changed bowel. However, diffuse pathological changes revealed in the guts during the operation, rendered the operation impossible. Tc99m-labelled human serum albumin scintigraphy may be considered the method-of-choice in the diagnosis of protein-losing enteropathy. However, in this test the assessment of the enteropathy dimension is difficult and surgical treatment should be planned with caution

N2 - Clinical material is presented from a multi-year treatment of a five-year-old girl with a variety of developmental interferences, making it necessary to consider whether standard technique would suffice. History includes the fact that she was adopted five days after birth and told as early as possible about her adoption; she was placed in a restrictive brace from four months to twenty months because of congenital hip displasia. Sandy's ability to let in the outside world was limited by her intense denial, not looking, not taking in, and by her detachment. Her passivity--whether a defense (modeled on her experience of physical restraint) or an arrest--was a formidable obstacle to the development of active transference moments. I use this case as an opportunity to look at the role of developmental sequences in the context of the analytic process. While I consciously did not do anything different than I would with any child analytic patient, I intuitively stressed certain kinds of interventions

N2 - Children under the age of 18 account for almost half of the world's population, with most living in developing countries. Young people are especially sensitive to acute and chronic environmental conditions and 43% of environmental diseases occur in the 12% of the world's population under age 5. The main environmental threats to the health of children in developing countries are inadequate access to clean water for drinking and hygiene, exposure to air pollution: primarily indoors and secondarily outdoors, risk of accidents and wounds, and poisoning due to toxic products. Recent data suggest that the number and diversity of environmental risk factors affecting child health is increasing as a result of increasing malnutrition, pollution, and violence and consequently that the level of health and quality of life of future generations will decrease. Due to the complexity of the interactions between environmental factors and socio-economic determinants, the epidemiological transition model is poorly suited to analyzing and predicting the concurring risks of infectious disease and chronic disease (diabetes, cancer...). This article presents a number of recommendations for training health professional, developing environmental reference centers, implementing risk assessment, coordinating decentralized activities and policy, and involving parents and children in the decisional process with emphasis on divulgating study findings and developing interfaces between the various stakeholders. N2 - The JEV widely is used in Asian countries each year and is an important vaccine for travelers to the East from other parts of the world. JE virus is a zoonotic disease with natural reservoirs and cannot be eliminated. Although a declining incidence of JE has been observed in Asia because of reduced transmission by agricultural approaches and vaccination, the most important control measure now, and in the future, is vaccination of humans against JE. The inactivated vaccine, produced from infected mouse-brain-derived tissue, is the only commercially available vaccine. There are several concerns with the use of this vaccine. It is expensive, requires two or three doses to achieve protective efficacy, and, in practice, requires further booster doses to maintain immunity. The apparent increase in allergic reactions in the first part of the 1990s has set focus on the safety of the JEV. A cheap, live attenuated SA 14-14-2 vaccine is used almost exclusively in China and parts of Korea, but there have been no trials of SA 14-14-2 vaccine outside JE endemic countries. The vaccine seems to be highly efficient, and few adverse events have been observed; however, PHK cells are used for the production of this vaccine, and these cells are not approved by the WHO. A satisfactory cell substrate is needed. A committee under the WHO has proposed that for the live JEV, there should be validity of the assays for retrovirus when applied to PHK cell substrate and validity of the mouse assays for neurovirulence. Further information should be reviewed on the long-term follow-up of recipients of the vaccine. Several new types of vaccines have reached

the phase of clinical trials; however, studies remain to be completed. Until a new vaccine is available, the priority of surveillance of adverse events and the continuous reporting of such events to the users of the vaccines must be of importance. This fact is highlighted by the possibility of the varying frequency of adverse events with different batches over the years. The WHO offers information and recommendations for vaccines in the EPI and issues a series of updated papers on other vaccines that are of international public health importance (eg, JEV). The development of alternative efficient, safe, and appropriately priced JEVs is recommended, as is intensified surveillance of adverse events. Prospective vaccine studies of safety may be limited because of sample size and because rare adverse events may not be detected. Several new initiatives have been taken to improve surveillance of adverse events to vaccines within the past 10 years. In Japan, there is an increasing awareness of the importance of efforts taken to improve vaccine safety, and surveillance of adverse events and possibilities of compensation for vaccine-related injuries are in place. In Vietnam, a database to detect adverse events after vaccination has been established; the project involves active visits to data collectors at the vaccination sites. Comparative studies of adverse events, such as one recent study from Japan and the United States, are important for the evaluation of the reporting systems. The reporting rate for JEV adverse events from Japan was approximately one order of magnitude lower than that in the United States. Japan had strict predefined reporting criteria and time limits for observations. If time limits for the observation are too strict (eg, defining a possible neurologic reaction to occur within 1 week after vaccination), later reactions will not be included (eg, if ADEM is elicited by a vaccine, the symptoms cannot be expected to occur until weeks after the vaccination). The passive surveillance systems have limitations with an underreporting of adverse events, depending on clinical seriousness, temporal proximity to vaccination, awareness of healthcare workers, and tradition of reporting particular events. In developed countries, surveillance of adverse events is formalized, although not necessarily optimal. An increase in reporting would be expected when the reporting of adverse events is mandatory. Reports have been sent to VAERS, the Vaccine Safety Datalink Project, and the European Union Pharmacovigilance System. A Brighton collaboration has been implemented to enhance comparability of vaccine safety data. Public health authorities in specific countries, such as the CDC in the United States and the National Advisory Committee in Canada, regularly have published information on the JE situation in Asia and the preventive measures to be taken, including information on the vaccines and adverse reactions. The conventional recommendation is that travelers should be vaccinated if they will spend more than 1 month in a JE endemic area or in areas with epidemic transmission with even shorter periods. Although the risk for JE for short-term travelers is considered small (1 case per 1 million travelers per year), sporadic cases, including deaths, have been reported among tourists traveling to endemic areas. Risk for travelers in rural districts in the season of risk is considerably higher (range, 1 case per 5000 travelers to 1 case per 20,000 travelers per week). Doctors who advise travelers should be updated on the latest JE occurrences in Asia. Updates on the JE situation can be found on bulletins at <http://www.promedmail.org> or are available from the WHO or CDC. The allergic reactions primarily described after vaccination with the inactivated mouse-brain-derived JEV have been observed in several countries during the 1900s. Allergic reactions, including the mucocutaneous and neurologic reactions reported after JE vaccination, may vary in frequency, and these reactions should be evaluated meticulously yearly. This step enables recommendations, including information on possible side effects, to be given in an optimal way. [References: 76]

N2 - Sun exposure in childhood is 1 of the risk factors for developing skin cancer, yet little is known about levels of exposure at this age. This is particularly important in countries with high levels of ultraviolet radiation (UVR) such as Australia. Among 49 children 3 to 5 years of age attending child care centers, UVR exposure was studied under 4 conditions in a repeated measures design; sunny days, cloudy days, teacher's instruction to stay in the shade, and a health professionals instruction to apply sunscreen. Three different data collection methods were employed: (a) completion of questionnaire or diary by parents and researcher, (b) polysulphone dosimeter readings, and (c) observational audits (video recording). Results of this study indicated that more than half the children had been sunburnt (pink or red) and more than a third had experienced painful sunburn (sore or tender) in the last summer. Most wore short sleeve shirts, short skirts or shorts and cap, that do not provide optimal levels of skin protection. However, sunscreen was applied to all exposed parts before the children went out to the playground. Over the period of 1 hr (9-10 a.m.) the average amount of time children spent in full sun was 22 min. On sunny days there was more variation across children in the amount of sun exposure received. While the potential amount of UVR exposure for young children during the hour they were outside on a sunny day was 1.45 MED (Minimum Erythema Dose), they received on average 0.35 MED, which is an insufficient amount to result in an erythema response on fair skin even without the use of sunscreen

 N2 - OBJECTIVES: To determine the influence of diagnostic adjuncts (dental brushing and drying) in dental caries diagnosis. To analyse the underestimation levels in epidemiological examinations when compared to traditional dental setting examinations. To evaluate the influence of including noncavitated (NC) carious lesions in the estimation of the disease. PARTICIPANTS: 51, 12-year-old children. INTERVENTIONS/METHODS: Four epidemiological exams performed in an outdoor setting and one performed in a traditional dental setting (visual-tactile method associated or not with diagnostic adjuncts). MAIN OUTCOME MEASURES: DMFS (Decayed, Missing and Filled Surfaces) index, according to the WHO criteria. RESULTS: When compared to exams carried out in a traditional dental setting, the epidemiological examinations showed no significant statistical differences for the DMFS score ($p>0.05$), presenting underestimation levels lower than 10% (except for the low prevalence caries group in the WHO exam). For the DMFS, previous dental brushing was more relevant than previous dental drying, although drying was the most important resource for NC diagnosis ($p<0.05$). CONCLUSION: The visual/tactile method, with or without diagnostic adjuncts, can diagnose cavitated lesions efficiently, but not NC lesions. However, for the low caries prevalence group, the implementation of dental brushing prior to an exam could be suggested

N2 - Viral pathogens are the most common causes of gastroenteritis in the community. To identify modes of transmission and opportunities for prevention, a case-control study was conducted and risk factors for gastroenteritis attributable to norovirus (NV), Sapporo-like virus (SLV), and rotavirus were studied. For NV gastroenteritis, having a household member with gastroenteritis, contact with a person with gastroenteritis outside the household, and poor food-handling hygiene were associated with illness (population attributable risk fractions [PAR] of 17%, 56%, and 47%, respectively). For SLV gastroenteritis, contact with a person with gastroenteritis outside the household was associated with a higher risk (PAR 60%). For rotavirus gastroenteritis, contact with a person with gastroenteritis outside the household and food-handling hygiene were associated with

a higher risk (PAR 86% and 46%, respectively). Transmission of these viral pathogens occurs primarily from person to person. However, for NV gastroenteritis, foodborne transmission seems to play an important role

N2 - **OBJECTIVES:** Wilderness Event Medicine (WEM), that is, the care of large groups of people participating in events in remote areas, is a rapidly growing subspecialty of wilderness medicine. Our goals are to report the injury rates from one wilderness event and to suggest ways to advance this emerging field.

METHODS: We describe a 1-day wilderness hike and compare the injury rates from this one event with rates from other urban and wilderness events. **RESULTS:** Of the total 350 hikers, 6 persons presented for medical evaluation (5 dehydration and 1 orthopedic), yielding a rate of 17 evaluations per 1000 person-days of exposure.

Only 1 person (or 2.9 per 1000) required medical assistance beyond oral rehydration. These rates are comparable to rates reported for urban events and other wilderness activities. **CONCLUSIONS:** According to very limited reports, the rates of injuries in wilderness events are similar to those for urban events. We recommend defining a wilderness event as an event with more than 200 participants and where the time from injury to care at a medical facility is likely to be greater than 1 hour. We also suggest the creation of a database of wilderness events, including standardized terms for the descriptions of activities, terrain, injuries, and medical response. Such a database could be used to help event planners anticipate and perhaps prevent injuries and to prepare effectively for those injuries that do occur

N2 - The relationship between interictal epileptiform activity and the epileptogenic zone is complex. Despite the fact that intraspikes propagation may occur, the peak of the spike is often used as indicator of the site of ictal onset. In this investigation, spatio-temporal segmentation was used to demonstrate this intraspikes propagation and to determine at which time point the voltage pattern corresponded best to the epileptogenic zone. Sixteen

patients with focal epilepsy were recorded with 125-channel EEG. Between one and five different map topographies were identified during the rising phase of the spike. A distributed source model (EPIFOCUS) was used to localize the source of each map, and the distance from the EPIFOCUS maximum to the anatomic lesion was calculated. In only 3 of 16 cases was the entire rising phase of the spike accounted for by one single map. In another five patients, several maps were obtained, although all were located within the epileptogenic lesion. In the remaining eight patients, however, parts of the rising phase had locations outside the epileptogenic lesion. On the average, 80% of the rising time had within lesion locations the most reliable time period being halfway between onset and peak. The results illustrate that intraspikes propagation has to be considered in source localizations, and they also illustrate the usefulness of spatio-temporal segmentation for visualizing this propagation

N2 - Interventions for prevention and treatment of childhood obesity typically target increases in physical activity and, more recently, reductions in physical inactivity (sedentary behaviour such as television viewing). However, the evidence base for such strategies is extremely limited. The main aim of the present review was to update the systematic review and critical appraisal of evidence in the light of the recent rapid expansion of

research in this area. Randomised controlled trials (RCT) that targeted activity or inactivity, that followed up children or adolescents for at least 1 year and that included an objective weight-related outcome measure were included. Trials were appraised using previously published criteria (Harbour & Miller, 2001), and literature search strategies described previously (Reilly et al. 2002) were updated to May 2002. A total of four new RCT, two new systematic reviews and one meta-analysis were identified. The evidence base has increased markedly since the completion of earlier reviews, although high-quality evidence is still lacking. The evidence on childhood obesity prevention is not encouraging, although promising targets for prevention are now clear, notably reduction in sedentary behaviour. There is stronger evidence that targeting activity and/or inactivity might be effective in paediatric obesity treatment, but doubts as to the generalisability of existing interventions, and the clinical relevance of the interventions is unclear. Further research in settings outside the USA is urgently needed, and two ongoing RCT in Scotland are summarised. [References: 48]

N2 - AIMS: The purpose of the study was to examine the correlation between illnesses, and in particular contagious illnesses, among daycare children and the amount of time spent outdoors, and whether through the intervention of increasing the amount of time spent outdoors it is possible to lower the incidence of illness.
METHODS: The study was conducted among eight daycare centres within the same county. A total of 326

children, 17 homeroom groups, were divided into two study groups. Each of the two study groups had a two-month period in which the percentage of time spent outdoors per day was almost double that of the other study group. RESULTS: The overall frequency of sick days was 4%. There was no significant effect of spending more time outdoors on the number of illness episodes, length of the episode, or cause of illness. CONCLUSION: Our negative findings are in accordance with the theory that illness among daycare children is largely a result of contact among children and the hygiene standards of the institution, and thus these are the factors that may need to be addressed to reduce the level of illness among daycare children

N2 - OBJECTIVE: To define the differences in emergency room usage patterns between patients with and without medical insurance coverage. METHODS: A retrospective analysis of the database of 34 642 consecutive patient visits to an urban hospital emergency room over a period of 509 days. Arrival times and admission rates were compared for insured and uninsured patients. RESULTS: A total of 46.8% of insured patients arrived at night or during the weekend versus 51.7% of the uninsured. Slightly more insured patients were admitted (18.6 versus 15.4%), both after their visit during the daytime (20.6 versus 17.1%) and outside daytime hours (16.3 versus 13.8%). The uninsured population was younger. CONCLUSION: Uninsured patients arrived more frequently during weekends and at night than insured patients. They were on average less likely to be admitted to the hospital. Demographic differences between both groups seemed to play an important role in the admission rate. Despite differences in emergency room usage patterns, it cannot be concluded that either group used the emergency room in excess of the other

N2 - All the FESUM centers in France, Belgium and Switzerland were invited to participate in this prospective audit, during 1 week in June 2002. In these FESUM centers, the patients are operated by senior hand surgeons or trainees graduated with a microsurgical and a hand surgery University degrees. All acute hand disorders, requiring surgery or not, were to be included. For every case, a standardized form was to be filled. This form included 22 fields concerning the specificities of the patient, the circumstances of the accident, the lesions and initial treatment up to exit of the patient out of the Hand Center. Out of the 43 French centers, 38 (90%) participated in this study, but only 30% in the other French speaking countries. A total of 2360 forms were completed and analyzed, representing a mean of 8 forms per day center (6-147). The population was predominantly active men with a mean age of 31. Manual workers represented 41%, scholars 33%. Most of them came to the Hand Center with a non-specialized vehicle (86%). Emergency medical transportation was required in 130 cases (5.8%). A majority of the patients were treated on an outdoor basis. A 1-day admission concerned 29% of the patients, and 4.6% have been admitted on an indoor basis during several days. Work accident represented 28% of all the cases, while the majority was daily living (62%) or sport (15%) accidents. Closed trauma represented 50% of the cases. Amongst open trauma (974 cases), 862 were simple skin lacerations, 156 skin loss, 140 extensor tendon lacerations, 70 flexor tendon lacerations. A preliminary wound exploration had been performed in a non-specialized center in 124 cases (12%). Complete amputation of some part was observed in 33 cases. In 32%, the initial severity of the lesion led to expect some degree of definitive consequences. Some kind of anesthesia was required in 43% of the cases (local in 41%, troncular in 19%, plexical in 28% and general in 9%). A surgical procedure was performed in 45% of the patients. Microsurgery was necessary in 15%, six of which were replantations. The period between presentation to the Hand Center and treatment was less than 1 day in 95% of the cases. Time of treatment was considered to be delayed in 113 cases (5%). Following this audit, it is considered that the FESUM centers make provision for the care of 120,000 cases per year, 54,000 of which needing a surgical procedure. This may be a small part of the total load of emergency hand surgery throughout the country (generally estimated over 1.4 million), but compares quite favorably with other European studies. We believe that improvement relies essentially on a better orientation of the patients whether they need a simple skill or specialist skill treatment. An information leaflet about orientation of hand trauma has been distributed to non-specialized emergency centers. Hand surgery training must be reevaluated inside the university system to avoid a dramatic lack of hand surgeons within a few years. A new audit will be presented next year

N2 - This article describes the theoretical background and methodology of ecological momentary assessment (EMA) and reports results from a pilot study using EMA techniques in 16 children and adolescents with affective disorders and 5 subjects who were healthy and at low risk to develop future affective disorders.

Multiple daily assessments of the subjects' mood, thoughts, and behaviors were performed in their natural environments using brief interviews on cellular phone calls by the study staff and by wrist actigraphy. The pilot results demonstrated that the EMA methodology is feasible in this population, as 17 of 21 subjects were able to complete the entire 8-week protocol. The potential usefulness of the EMA methodology is illustrated by specific case reports. Potential applications of the EMA methodology to the study of neurobehavioral systems and the pathophysiology of pediatric affective disorders are discussed

N2 - Body fatness and the components of energy expenditure in children aged 5-14 years were investigated. In a group of seventy-nine healthy children (thirty-nine female, forty male), mean age 10.0 (sd 2.8) years, comprising twenty-seven Maori, twenty-six Pacific Island and twenty-six European, total energy expenditure (TEE) was determined over 10 d using the doubly-labelled water method. Resting metabolic rate (RMR) was measured by indirect calorimetry and physical activity level (PAL) was calculated as TEE:RMR. Fat-free mass (FFM), and hence fat mass, was derived from the (18)O-dilution space using appropriate values for FFM hydration in children. Qualitative information on physical activity patterns was obtained by questionnaire. Maori and Pacific children had a higher BMI than European children ($P<0.003$), but % body fat was similar for the three ethnic groups. The % body fat increased with age for girls ($r\ 0.42$, $P=0.008$), but not for boys. Ethnicity was not a significant predictor of RMR adjusted for FFM and fat mass. TEE and PAL, adjusted for body weight and age, were higher in Maori than European children ($P<0.02$), with Pacific children having intermediate values. PAL was inversely correlated with % body fat in boys ($r\ -0.43$, $P=0.006$), but was not significantly associated in girls. The % body fat was not correlated with reported time spent inactive or outdoors. Ethnic-related differences in total and activity-related energy expenditure that might account for higher obesity rates in Maori and Pacific children were not seen. Low levels of physical activity were associated with increased body fat in boys but not in girls

N2 - Parathyroid hormone (PTH) immunoradiometric assays (IRMA) exhibit cross-reactivity between 1-84 PTH and long carboxyl-terminal-PTH (C-PTH) molecules. C-PTH antagonizes the biological actions of 1-84 PTH and circulates in excess in chronic renal failure (CRF), partially explaining why supra-physiological PTH levels are recommended to maintain bone turnover. Furthermore, the ratio 1-84 PTH/C-PTH may be related to bone turnover. This study characterizes the 1-84 PTH/C-PTH ratio in children with varying severity of CRF and levels of PTH. Two hundred and forty-one children with CRF, managed with the aim of preventing the development of hyperparathyroidism, had PTH measured by 'intact' IRMA and a new more specific Cyclase-Activating-PTH (CAP) IRMA. C-PTH levels were calculated by subtracting CAP-IRMA from 'intact' IRMA. Fifty-three controls with normal renal function were also recruited. Mean 'intact' IRMA correlated with CAP-IRMA ($r=0.98$), but was higher ($P<0.001$). The mean 1-84 PTH/C-PTH ratio was lower than controls in dialysis patients ($P=0.022$) and those with a glomerular filtration rate <30 ml/min per m^2 ($P=0.033$). This ratio was comparable to controls when the PTH level was normal, but was lower with PTH levels outside the normal range ($P<0.01$). These data suggest that CAP-IRMA gives a more accurate assessment of actual PTH levels than 'intact' IRMA in CRF. Maintenance of normal PTH levels throughout the course of CRF permits the

maintenance of a normal 1-84 PTH/C-PTH ratio, the clinical significance of which requires further investigation in children

N2 - Lead arsenate (PbHAsO4) was used as an insecticide in Washington fruit orchards from 1905 to 1947. We examined exposure potential for children living in an agricultural community with historic PbHAsO4 use. Soil and housedust samples were collected from 58 residences. Families were asked about land use history, age of home, and remodeling activities. Median concentrations of arsenic were higher in housedust than in soil (9.0 and 4.2 microg/g, respectively; P=0.05), as were lead concentrations (129 and 46 microg/g, respectively;

P=0.0001). Significant associations were observed between indoor and outdoor levels of each metal, indicating track-in as an important exposure pathway. Homes on or near land use for pear or apple production between 1905 and 1947 had significantly higher soil (P=0.005) and housedust (P=0.004) lead, and soil arsenic (P=0.04) than did the other homes. Homes more than 30 years old had significantly higher soil and housedust lead than did newer homes (P=0.01). Homes remodeled within the past two years had significantly higher soil (P=0.01) and housedust (P=0.04) lead. Child doses extrapolated from these data indicate that 36% of homes had soil or dust arsenic levels above the minimum risk level estimated by the Agency for Toxic Substances and Disease Registry. None of the measured lead levels exceeded current US Environmental Protection Agency guidelines. Public health education programs focused on residential hygiene would be of value in areas of historic

PbHAsO4 use

N2 - The purpose of this study is to assess patterns of lay health advisor (LHA) activity in an intervention to reduce lead exposure in Native American children exposed to mine waste. A total of 39 LHAs were recruited and trained to become LHAs from eight tribes in northeastern Oklahoma. LHAs completed activity tracking forms over a 2-year intervention period to document contacts made with community groups and individuals in their social networks. They engaged in an average of 5.4 activities per month, reaching an average of 39 persons. Close members of their social networks were reached in 40.4% of the contacts; persons outside of their networks were reached in 24% of the contacts. This study suggests that 1 to 3 contacts per week may be a reasonable expectation for LHA activity. Findings also suggest that LHA interventions are a promising approach for engaging Native American communities in addressing an environmental health problem

N2 - OBJECTIVE: To observe the distribution of copper in the subcellular structure for the understanding of primary pathogenesis of hepatolenticular degeneration (HLD). METHODS: Skin fibroblasts taken from HLD patients were cultured as an in vitro model of HLD, and the control cells taken from healthy volunteers were cultured in the same way. The distribution of copper inside and outside of lysosomes in fibroblasts was detected by quantitative electron probe X-ray microanalysis. The relationship between the subcellular location of copper and the genotype of the patients, and relationship between the distribution of copper and the course of the disease were analyzed. RESULTS: The content of Cu²⁺inside lysosomes of HLD cells (14.6+/-2.1 mmol/kg) and of heterozygote cells (11.6+/-0.6 mmol/kg) was higher than that of normal cells (4.5+/-1.2 mmol/kg) (P<0.01). The content of Cu²⁺outside lysosomes of HLD cells (17.5+/-4.2 mmol/kg) and of heterozygote cells (12.0+/-0.9 mmol/kg) was higher than that of normal cells (4.7+/-1.2 mmol/kg) (P<0.01). The distribution of copper in the subcellular structure was correlated with disease courses of HLD patients. With the progression of the disease, more copper was deposited in lysosomes (r=0.85, P<0.01). The content of copper in the diffused cytoplasmic compartment in HLD cells was correlated with that of sulfur (r=0.86, P<0.05), but not in heterozygote and normal cells. CONCLUSIONS: In the early stage of HLD, copper is accumulated outside lysosome, which is paralleled with increase of metallothionein-like proteins (copper and sulfur-binding proteins). With the development of the disease, more copper is deposited inside lysosome than outside lysosome. We conclude that the up-regulation expression of copper and sulfur-binding proteins and copper accumulation in lysosomes may play an important role in lowering the ATP7B gene mutation-induced toxic effects of free copper on the cell

N2 - The physical fitness of school children resident in an urban colonia and in a rural indigenous community in Oaxaca, southern Mexico, was compared. Two measures of performance-related fitness (standing long jump, 35-yard dash [32 m]) and four measures of health-related fitness (grip strength, sit and reach, timed sit-ups, distance run) were taken on 355 rural (175 boys, 184 girls) and 324 urban (163 boys, 161 girls) school children, 6-13 years of age. Urban children were significantly taller and heavier than rural children. Absolute grip strength did not consistently differ between rural and urban children, but when adjusted for age and body size, strength was greater in rural children. Explosive power (standing long jump) and abdominal strength and endurance (timed sit-ups) were better in urban than in rural children without and with adjustment for age and body size. Urban-rural differences in running speed (dash) and flexibility (sit and reach) varied by age group and sex. Younger rural children and older urban girls performed better in the distance run, whereas older rural and urban boys did not differ in endurance. The size advantage of urban children does not necessarily translate into better levels of performance- and health-related physical fitness. The observed differences may be related to activity habits associated with school physical education and lifestyle in the respective communities. Copyright 2003 Wiley-Liss, Inc

N2 - In order to investigate the distribution and causes of the spread of anthroponotic cutaneous leishmaniasis (ACL) in Kabul, Afghanistan, a cross-sectional study was conducted during 1997-98 amongst 75,787 residents in the 13 central districts of the city. Using data on active lesions and scars with their times of onset, migration patterns and age of subjects, 2 independent methods were used to estimate, retrospectively, the annual incidence of ACL in recent years. Results indicated a rapid increase in incidence from 1987, peaking in 1996 when an estimated 12% of the population had active disease. Active prevalence was lowest in infants (aged < 2 years), and while risk was gender-independent in children and adolescents, active prevalence in those aged > 20 years was significantly higher amongst females than males (odds ratio [OR] = 1.51, 95% CI 1.34-1.70). About 44% of lesions were located on the head, 38% on upper limbs, 16% on lower limbs and 2% elsewhere. The relative frequency of head lesions dropped with age ($P < 0.001$), and amongst adults was lowest amongst males ($P < 0.001$), possibly due to the protective effect of a beard. Within the study population, 32% reported that they had immigrated from outside Kabul, 34% that they had been born in Kabul but had since migrated to another district of the city, and 34% that they had been born in the district of their present residence. Active prevalence amongst those born in their current district of residence was positively associated with the percentage of immigrants in their district ($P = 0.027$), indicating that a 1% increase in the percentage of immigrants increased the odds of an active lesion by 12% (OR = 1.12, 95% CI 1.01-1.24), but there was no association with the percentage of migrants from other districts in Kabul ($P = 0.65$) or with war damage ($P = 0.33$). As active prevalence was not significantly greater in immigrants than local Kabulis, these results support the hypothesis that the epidemic in Kabul has been maintained by a steady influx of susceptible immigrants. It is important that the new opportunities for social development that now exist in Kabul are not hampered by this unpleasant and stigmatizing disease. As population movement is clearly a contributing factor to its transmission, this threat is very real

N2 - **BACKGROUND:** Wood smoke has been associated with respiratory symptoms. This study examined the prevalence of respiratory symptoms and health effects of wood smoke exposures (from home heating, curing meat, and tanning hides) among residents of Deline, Northwest Territories (NWT). **METHODS:** A survey was conducted of all residents. Relationships between wood smoke and respiratory symptoms were examined.

RESULTS: The response rate was 70.2% (n=402). 71% of people at least 18 years old were current smokers. Prevalence of symptoms was higher for women (odds ratios (ORs) 1.3-3.1). Women who smoked were more likely to be exposed to indoor smoke from curing and tanning. ORs for respiratory symptoms were higher for females, increased with age, and were strongly affected by smoking. Among those at least 18 years old, phlegm on winter mornings (6.5 (95% CI: 2.3-18.1)), dyspnoea (5.1 (95% CI: 1.9-13.2)), and watery or itchy eyes (3.6 (95% CI: 1.4-9.0)) were significantly related to self-reported outdoor wood smoke and smoke curing. Home heating was marginally associated with wheeze. No significant associations were found for males.

CONCLUSIONS: Women engaged in curing/tanning demonstrated increased prevalence of respiratory symptoms. The cultural importance of these activities precludes abandoning them. Smoking cessation, limiting wood smoke exposure times, and process modifications in curing and tanning could reduce risk of adverse health effects

N2 - **OBJECTIVES:** To characterise travelling immigrants and the international movements they undertake. To identify the risk journeys that this population makes and to assess the international preventive activities for them compared with those for autochthonous travellers. **DESIGN:** Retrospective, observational study. **SETTING:** Unit of International Health (UIH) Santa Coloma de Gramenet (Barcelona), in the Barcelones Nord i Maresme Health Area, Primary Care Division of the Catalan Institute of Health. **PARTICIPANTS:** Patients seen between June 1999 and June 2002 (n=1163) at the UIH. They were divided into two groups, depending on their origins: those born inside (autochthonous group; n=1019) or outside (immigrant group; n1=144) the European Union. **MAIN MEASUREMENTS:** Age, country of origin, length of residence in Spain, interval between consultation and journey, reason for journey, destination, duration of the journey, kind of journey, stay in rural or isolated area, exposure to malaria, vaccinations and anti-malaria chemoprophylaxis prescribed, and overall risk of journey. **RESULTS:** Immigrants spent more time abroad than autochthonous people (mean 43.5 days; 95% CI, 37.9-49.1; and 15.8 days, 95% CI, 14.9-16.7, respectively; $P<.0001$). Periods between the journey and the consultation at the UIH were generally similar in the two groups (mean of 26.8 days for immigrants and 30.41 days for autochthonous people; ns), although the immigrants consulted more often in periods of less than 15 and 7 days ($P<.005$). 31.9% of immigrants stayed in areas of high malaria transmission (95% CI, 24.4%-39.6%) vs 21.3% (95% CI, 18.8%-23.8%) of autochthonous people ($P=.04$). Overall, immigrants made more risk journeys than autochthonous people (54.8% vs 43.1%; $P<.01$). No significant differences between the two groups were found in terms of quality in the administration of the international vaccinations prescribed. Compliance with the guidelines for anti-malaria chemoprophylaxis was less in the immigrant group than in the autochthonous one (36% vs 84%; $P<.005$). **CONCLUSIONS:** The immigrant group in our environment needs to be thought of as a risk group for catching and importing tropical diseases during their international movements. They form a population for whom international preventive measures should be prioritized

N2 - The effect of different levels of preintentional and intentional communication development on musical interaction with children with severe and multiple disabilities has not been explored in the music therapy literature. Aside from stage of communication development, what are the particular influences of disability on musical interaction with children who have preintentional and early intentional communication? A qualitative research project explored these issues. Ten school-aged children with severe and multiple disabilities participated in the project. The most common medical diagnosis was cerebral palsy. Analysis of video recordings and other data confirmed that the children's level of communication development was reflected in individual music therapy. Specifically, children at different levels of communication development varied in their abilities to initiate, anticipate, and sustain participation in turn taking, and to maintain attention to and engagement in the interaction. Both turn taking and playing and singing together were found to be important forms of communication during music therapy. Communication problems related to disability included: difficulties in using objects as a focus of joint attention, difficulties in interpreting the interactive environment, being sufficiently motivated to communicate, severely limited means of interaction, attaining and maintaining an appropriate level of arousal, and lack of interest in interaction and the outside environment. Further study of how music therapy can be related to general issues in communication for individuals with severe and multiple disabilities is recommended

N2 - BACKGROUND: Although previous studies have discussed age-related changes in the presentation of early onset bipolar illness, the developmental progression of early symptoms remains unclear. The current study sought to trace parents' retrospective report of yearly occurrence of symptoms in a sample of children with and without a diagnosis of bipolar disorder in the community. METHODS: Parents retrospectively rated the

occurrence of 37 activated and withdrawn symptoms causing dysfunction for each year of their child's life (mean age 12.6 +/- 6.9). Children were divided into three groups based on parent report of diagnosis by a community clinician: bipolar (n=78); non-bipolar diagnosis (n=38); and well (no psychiatric diagnosis) (n=82). Principal components analysis was performed to understand the relationship among the symptom variables and their potential differences among the three groups as a function of age. RESULTS: Four symptom components were derived and these began to distinguish children with bipolar disorder from the other groups at different ages. Component II (irritability/dyscontrol), which included temper tantrums, poor frustration tolerance, impulsivity, increased aggression, decreased attention span, hyperactivity and irritability, began to distinguish bipolar children from the others the earliest (i.e., from ages 1 to 6). The other components (I, III, and IV) which included symptoms more typical of adult depression (I), mania (III), and psychosis (IV), distinguished the children with a bipolar diagnosis from the others much later (between ages 7 and 12). LIMITATIONS: The data were derived from retrospective reports by parents of their children's symptoms on a yearly symptom check list instrument which has not been previously utilized. Parents' ratings were not validated by an outside rater. Moreover, the children were diagnosed in the community and a formal diagnostic interview was not given. CONCLUSIONS: By parental report, the cluster of symptoms in the irritability/dyscontrol component may characterize the earliest precursors to an illness eventually associated with more classic manic and depressive components that are diagnosed and treated as bipolar disorder in the community. These retrospective survey data suggesting a longitudinal evolution of symptom clusters in childhood bipolar-like illness identify a number of areas for prospective research and validation

N2 - BACKGROUND: Injuries resulting from accidents in the home are among the most common causes of morbidity in children. Preventing these accidents by educating parents has proved to be the most successful way of reducing such accidents and protecting children. AIMS: To study the prevalence, demographic variables and risk factors of childhood injuries in Northern Israel and to determine risk groups for preventive activities.

METHODS: The study was prospective and conducted during the year 2000 in 36 urban (not including Arab clinics) and rural community clinics of Clalit Health Services in Northern Israel that provided health care for approximately 62,000 children (about 55% of all children residing in these communities). The survey included all children 0-18 years of age admitted to the clinics with home injuries during the study period. Data regarding clinical, demographic and socioeconomic variables was obtained from parents or guardians by a detailed questionnaire. Statistical analysis of the data was conducted using Chi-Square to compare the different groups and logistic regression for analysis of risk factors for injury. RESULTS: An overall number of 2,086 (prevalence of 3.2%) children were included in the study of whom 61.5% and 38.5% were non Jews and Jews, respectively, (prevalence of 4.2% and 2.2% respectively) and 66.5% of all the children were boys ($p < 0.01$). The most common injuries among both populations were falls, blows, burns, and cuts (43%, 23%, 15%, and 13% respectively). The injuries occurred at home, or close to the home (31%), at school or kindergarten (32%), or elsewhere (37%). Seventy eight percent and 49% of the injuries in the non-Jewish and Jewish populations, respectively, occurred at or around the home ($p < 0.001$). Logistic regression analysis revealed that falling was most prevalent outside the home in non-Jewish males older than 3 years. Burns were more prevalent at home in non-Jewish girls under the age of 3, and blows were prevalent in the Jewish population outside the home in children over the age of 3. CONCLUSIONS: This study provides data that could direct preventive measures in the community in order to decrease the prevalence of injury to children. In order to be effective and have significant impact, these preventive activities should concentrate on specific risk groups

 N2 - OBJECTIVES: To present the development of a novel multidisciplinary method to investigate physical risk factors for playground related arm fracture. RATIONALE: Previous playground injury research has been limited in its ability to determine risk factors for arm fractures, despite their common and costly occurrence. Biomechanical studies have focused exclusively on head injury. Few epidemiological studies have quantified surface impact attenuation and none have investigated specific injury outcomes such as arm fracture. DESIGN: An unmatched case-control study design was developed. An instrumented child dummy and rig were designed to simulate real playground falls in situ. Validated output from the dummy was used to quantify arm load. Other field measurements included equipment height, fall height, surface depth, headform deceleration, and head injury criterion. DISCUSSION: Validated methods of biomechanics and epidemiology were combined in a robust design. The principle strength of this method was the use of a multidisciplinary approach to identify and quantify risk and protective factors for arm fracture in falls from playground equipment. Application of this method will enable countermeasures for prevention of playground related arm fracture to be developed

N2 - INTRODUCTION: The goal of this study was to track any changes in injuries and injury hazards during the first 3.5 years of implementation of the North Carolina Child Care Commission's 1996 playground safety regulations. METHODS: All reports (n=5402) of medically attended injuries in regulated child care settings in North Carolina during the period 1 January 1997 through 30 June 2000 were reviewed and analyzed. A total of 294 playground safety inspections were conducted in November and December 1998 in randomly selected North Carolina child care centers, and the playground safety inspections were repeated in 76 child care centers in August 2000. Finally, in 1999 a 1992 child care center director self assessment of safety features in classrooms was sent to the directors of 291 of the 294 centers. RESULTS: The annual rate of reported, medically attended injuries occurring in regulated child care facilities in North Carolina declined by 22% from 1997 to 1999. The playground safety inspections in the year 2000 revealed that, for nine of 10 playground concerns and 12 of 18 playground safety hazards, average ratings were equal to or better than those of 1998. Finally, the director surveys revealed no dramatic changes in classroom safety hazards since 1992.

DISCUSSION: This study represents the first time that the authors are aware of that a significant decline in state-wide child care injury rates has been associated with improved regulation of playground safety in the US

N2 - OBJECTIVE: The purpose of this study was to determine the frequency of use of play equipment in public schools and parks in Brisbane, Australia, and to estimate an annual rate of injury per use of equipment, overall and for particular types of equipment. METHODS: Injury data on all children injured from playground equipment and seeking medical attention at the emergency department of either of the two children's hospitals in the City of Brisbane were obtained for the years 1996 and 1997. Children were observed at play on five different pieces of play equipment in a random sample of 16 parks and 16 schools in the City of Brisbane. Children injured in the 16 parks and schools were counted, and rates of injury and use were calculated. RESULTS: The ranked order for equipment use in the 16 schools was climbing equipment (3762 uses), horizontal ladders (2309 uses), and slides (856 uses). Each horizontal ladder was used 2.6 times more often than each piece of climbing equipment. Each horizontal ladder was used 7.8 times more than each piece of climbing equipment in the sample of public parks. Slides were used 4.6 times more than climbing equipment in parks and 1.2 times more in public schools. The annual injury rate for the 16 schools and 16 parks under observation was 0.59/100 000 and 0.26/100 000 uses of equipment, respectively. CONCLUSIONS: This study shows that annual number of injuries per standardized number of uses could be used to determine the relative risk of particular pieces of playground equipment. The low overall rate of injuries/100 000 uses of equipment in this study suggests that the benefit of further reduction of injury in this community may be marginal and outweigh the economic costs in addition to reducing challenging play opportunities

N2 - OBJECTIVE: To evaluate the influence of average family income in a geographic area on the effectiveness of helmet legislation on observed helmet use by children (5-14 years). **METHODS:** The study was conducted in East York, a health district of Metropolitan Toronto, in collaboration with the East York Health Unit. In 1996, the total population was 107 822, 11 340 of which were children 5 to 14 years. Census data were used to group the 21 census tracts in East York into 7 geographically distinct areas. The boundaries of these areas are natural barriers to travel, such as expressways, ravines, railway tracks, and hydroelectric power lines. The areas were also ranked according to average family income (based on Statistics Canada data). For analytical purposes, areas were defined as low-, mid-, and high-income areas. Census data profiles of the areas have been previously described. For each consecutive year from 1990 to 1997 inclusive, direct observations of children riding bicycles in East York during the months of April through October were made. In 1995, observations were completed before the introduction of the law on October 1, 1995. Only children who were between 5 and 14 years of age and riding a 2-wheeled bicycle were included in the study. In total, 111 sites across all 7 areas were selected for observation. Observational sites included school yards of all elementary and middle schools (kindergarten to grade 8) and all parks in East York. In addition, 5 major intersections and 5 residential streets from each area were randomly selected. Observers were trained and used a standardized data collection form. A pilot study showed that the data collected by observers were reliable and valid. Observers remained at each site for 1 hour and collected data on helmet use and sex. Ethical approval for the study was obtained from the Hospital for Sick Children Research Ethics Board, the East York Board of Education, and the Metropolitan Separate School Board. The proportion of children who were wearing a bicycle helmet was estimated by year (1990-1997, inclusive), sex (male, female), location (school, park, major intersection, residential street), and income area (low, mid, high). For estimating the effect of legislation on helmet use, data from the year immediately after legislation (1996) were compared with data from the year preceding legislation (1995). The relative risk (RR) of helmet use (after vs before legislation) was calculated along with a 95% confidence interval (CI). Logistic regression analysis was used to adjust for potential confounding variables (sex and location). **RESULTS:** During the 8-year study period, 9768 observations were made (range: 914-1879 observations per year). The proportion of child cyclists who wore a bicycle helmet increased steadily during the first 4 years of the study period, from 4% in 1990 (34 of 914), to 16% in 1991 (303 of 1879), to 25% in 1992 (383 of 1563), and to 45% in 1993 (438 of 984). During 1994 (460 of 1083) and 1995 (568 of 1227), helmet use remained relatively stable at approximately 44%. Helmet use rose markedly in 1996 (the first year after helmet legislation was introduced) to 68% (818 of 1202) and remained stable at 66% (609 of 916) in 1997. Throughout the study period, girls were consistently more likely to wear helmets than were boys. In total, 47% (1420 of 3047) of girls wore helmets, compared with 33% (2193 of 6721) of boys (RR: 1.43; 95% CI: 1.36-1.50). In addition, children who were riding to school were more likely to use helmets, compared with children who were riding on residential streets, major intersections, and parks. Overall, 48% (1497 of 3129) of children who were riding to school wore bicycle helmets, compared with 32% (2116 of 6639) of children who were riding at other locations (RR: 1.50; 95% CI: 1.43-1.58). Children in the high-income areas were consistently more likely to wear helmets, compared with children in the mid- and low-income areas. Helmet legislation was associated with a significant increase in helmet use by children in East York. In 1995, 46% (568 of 1227) of children wore bicycle helmets, compared with 68% (818 of 1202) of children in 1996 (RR: 1.47; 95% CI: 1.37-1.58). The effect of legislation, however, varied by income area. In low-income areas, helmet use increased by 28% after legislation, from 33% (213 of 646) in 1995 to 61% (442 of 721) in 1996 (RR: 1.86; 95% CI: 1.64-2.11). In mid-income areas, helmet use increased by 29% after legislation, from 50% (150 of 300) in 1995 to 79% (185 of 234) in 1996 (RR: 1.58; 95% CI: 1.39-1.80). In high-income areas, helmet use increased by only 4%, from 73% (205 of 281) in 1995 to 77% (191 of 247) in 1996 (RR: 1.06; 95% CI: 0.96-1.17). This finding of a significant increase in helmet use after legislation in low- and mid-income areas but not in high-income areas remained even after logistic regression analysis adjusted for sex and location. **CONCLUSIONS:** This study showed that bicycle helmet use by children increased significantly after helmet legislation. In this urban area with socioeconomic diversity and in the context of prelegislation promotion and educational activities, the legislative effect was most powerful among children who resided in low-income areas

N2 - Children and their parents in residences are often protected by insecticides from nuisance and disease-bearing mosquitoes. The annual worldwide consumption of the four major types of residential insecticide products--aerosols, mosquito coils, liquid vaporizers, and vaporizing mats--is in the billions of units. Mosquito coils are burned indoors and outdoors in East Asia and to a limited extent in other parts of the world, including the United States. Coils consist of an insecticide/repellent, organic fillers capable of burning with smoldering, binder, and additives such as synergists, dyes, and fungicide. The number of coil users in China is in the millions. In Indonesia alone, an estimated seven billion coils are purchased annually. Coils containing pyrethroid insecticides, particularly d-allethrin, may contain octachlorodipropyl ether (S-2, S-421) as a synergist or active ingredient. Use of those coils likely exposes children and adults to some level of bis(chloromethyl)ether (BCME). BCME is formed from formaldehyde and hydrogen chloride, combustion products formed from the slow smoldering (about 8 hr/coil) of the mosquito coils. Because BCME is an extremely potent lung carcinogen, the nature and extent of prolonged exposures that recur in homes during the

mosquito season in tropical regions must be evaluated with respect to health. In a small analytical study, coils purchased in Indonesia and in the United States contained highly variable amounts of S-2. Some coils that contained S-2 were not labeled, making it impossible for consumers to make an informed decision about coil contents. Mosquito coils containing S-2 are unregistered, and their use is illegal in the United States. Indoor air monitoring under conditions that represent conditions of use in tropical settings and epidemiology to assess health impacts of coil use are essential to permit responsible regulatory decisions regarding continuing S-2 use

N2 - OBJECTIVE: To evaluate the effects of active infant orthopedic treatment on dental arch relationships and determine the effect on maxillary growth in children born with unilateral complete cleft lip and palate (UCCLP).

DESIGN: The GOSLON Yardstick was used to assess dental models taken on patients treated with and without active infant orthopedics. PATIENTS: Two groups of nonsyndromic Caucasian children born with UCCLP (total n = 40), all treated by the same surgeon and ranging from 5 to 10 years of age, were evaluated.

INTERVENTIONS: One group had a Latham dentomaxillary alignment (DMA) appliance inserted at 5 to 6 weeks of age, after which a lip-nasal adhesion was performed at an average age of 3.5 months. This was followed by more definitive nasolabial repair at the average age of 5.9 months. Those patients treated without preoperative orthopedics underwent a lip-nasal adhesion at average age 1.5 months followed by nasolabial repair at average age 5.1 months. MAIN OUTCOME MEASURES: Randomized assessments using the GOSLON Yardstick were done independently at two separate times by three different examiners. Differences in GOSLON scores between the active orthopedic group and nonorthopedic group were evaluated by both categorical and continuous statistical analyses. RESULTS: The mean GOSLON score was 3.30 for the orthopedic group and 3.21 for the nonorthopedic group. There was no significant group difference in the modal scores of the two groups. CONCLUSIONS: This study showed that active infant orthopedics does not affect the dental arch relationships in preadolescent children with repaired UCCLP, compared with a similar group treated without orthopedic intervention at this center

N2 - OBJECTIVE: To describe physical activity (PA) and inactivity levels and patterns in Chinese school children (aged 6-18 y). DESIGN: PA and inactivity were assessed in a youth cohort enrolled in the China Health and Nutrition Survey (CHNS) in 1997. SUBJECTS: A total of 1423 males (11.5+/-3.2 y) and 1252 females (11.5+/-3.3 y). MEASUREMENTS: PA and inactivity were assessed by self-reported usual activity (questionnaire). Children under 10 y were assisted by parents. RESULTS: Approximately 84% of Chinese youth actively commute to school for a median of 100-150 min/week. A total of 72% engage in in-school moderate/vigorous (MOD/VIG) PA for a median of 90-110 min/week. Relatively few children (approximately 8%) participate in any MOD/VIG PA outside of school. A total of 72% engage in study-related activities outside of school for a median of 420 min/week. Only 8% of Chinese school children, regardless of gender, watch television > or =2 h/day; less than 1% watch > or =4 h/day. Chores related to housework are not a part of life for Chinese school children; fewer than 20% performed these tasks. CONCLUSION: Chinese youth are unique compared to those in other developing countries because they do not perform household chores. Instead, they are under pressure to achieve scholastically. Participation in MOD/VIG PA outside of school is almost nonexistent. Current television watching habits are relatively low compared to developed countries and walking/biking is a common form of commuting. The descriptive analysis herein represents the foundation upon which future longitudinal studies of PA in this population will be based

N2 - **BACKGROUND:** The increasing incidence of obesity in children may be attributed in part to increased sedentary behavior, such as watching television, which leads to less energy expended in physical activity. We have theorized that by middle school, many children lack the physical skills or self-confidence to participate in competitive physical activities. Thus, we hypothesized that if we provided a summer and after-school program featuring noncompetitive, outdoor activities such as gardening and adventure education, we would observe increased physical activity relative to habitual physical activities at home. **METHODS:** To test this hypothesis, 2 experiments were conducted. In the first, 4 children aged 12 years were evaluated while they participated in a summer recreation program for 2 hours and again while they watched a videotape. They wore a uniaxial accelerometer to assess physical movement, and we used a bicarbonate labeled with ¹³C tracer technique to assess energy expenditure. In a second experiment, we evaluated 8 children (aged 10-12 years) twice using uniaxial accelerometry only, once while they attended the after-school program for 2 hours and then during a similar period at home. **RESULTS:** The first study showed that the estimated energy expenditure (kilocalories.kilograms⁻¹. hours⁻¹) was 60% increased during the program (mean +/- SD) (2.6 +/- 0.5) compared with watching a videotape (1.6 +/- 0.3) (P =.02). Physical movement (accelerations per minute) also was significantly increased (3959 +/- 896 vs 513 +/- 182) (P =.004). In the second experiment, movement was 95% increased during the program (4578 +/- 1004) compared with the behavior at home (2345 +/- 746) (P =.005).

CONCLUSION: These results show that an organized, noncompetitive, leisure-time program can increase physical activity in children

N2 - The presence of flies is one of the earliest risk factors for trachoma and it has been suggested that flies could act as vectors for transmission of chlamydiae. A national trachoma survey was conducted in 1997 in Burkina Faso to (i) study the relationship between trachoma occurrence, flies, dirty faces and some environmental factors, and (ii) investigate the role of flies in the presence of trachoma. The country was stratified into eight groups of provinces and a random sample of 30 clusters was selected in each group. All children aged < 10 years were examined for the diagnosis of active trachoma (trachomatous inflammation which was follicular and/or intense) and the dirtiness of the face and the presence of flies on the face were recorded. The children's carers were questioned about the number of baths given and daily face-washing. Household heads were asked about ownership of cattle and small ruminants. The presence of latrines, a stable, and garbage collection inside the yard was noted. Among 16,514 children examined, 27.0% had active trachoma and 3.3% intense inflammatory trachoma. Flies were present on 11.2% of children's faces and 82.4% and 19.7% of these children had active and intense inflammatory trachoma, respectively. Among the 30.2% of children with dirty faces, 70.2% had active and 10.2% intense inflammatory trachoma. In multivariate analysis, at least one daily bath showed a protective effect on both active and intense inflammatory trachoma. Face-washing twice daily was found to be significantly protective for active trachoma in some regions. A strong association was demonstrated between the presence of flies and dirty faces (odds ratio = 334, 95% confidence interval 202-546). The presence of flies on children's faces, dirty faces and trachoma appeared to be strongly associated. Although the presence of flies may be a marker of socio-economic status and is probably linked with other trachoma risk factors, our data indicated that interventions targeting fly control should be an important issue in controlling trachoma

N2 - Malaria transmission from humans to mosquitoes was assessed in two neighbouring villages in a rural area near Yaounde, Cameroon during high and low transmission seasons during 1998-2000, using several indices previously evaluated in different areas endemic for malaria but never directly compared. These indices were estimated from human parasitological data and mosquito infection rates and, for each individual, thick blood films were prepared at the same time as experimental infection of laboratory-bred mosquitoes. Among the 685 volunteers examined, the prevalence of Plasmodium falciparum gametocyte carriers was 16%, and 8% of individuals were able to infect mosquitoes. The percentage of mosquitoes that became infected by feeding on the infectious individuals was 21%. Children aged < 10 years contributed to about 75% of the infectious reservoir, although they constituted only 35% of the total population. Differences were found between the transmission seasons and the villages, and varied according to the index examined. Although there were more infectious individuals in one of the two villages, they were less infectious than those in the other village during the high transmission season. Comparative analysis of the transmission indices suggests the existence of functioning transmission-blocking immunity in one of the villages, which until now has been only hypothetically considered to play a role in malaria transmission in a natural setting. The epidemiological value

of all the indices used and their accuracy in estimating the human infectious reservoir and its natural or induced variations are discussed

N2 - Disposal of used tires has been a major problem in solid waste management. New uses will have to be found to consume recycled tire products. One such proposed use is as ground cover in playgrounds. However, concern has been expressed regarding exposure of children to hazardous chemicals and the environmental impact of such chemicals. We designed a comprehensive hazard assessment to evaluate and address potential human health and environmental concerns associated with the use of tire crumb in playgrounds. Human health concerns were addressed using conventional hazard analyses, mutagenicity assays, and aquatic toxicity tests of extracted tire crumb. Hazard to children appears to be minimal. Toxicity to all aquatic organisms (bacteria, invertebrates, fish, and green algae) was observed; however, this activity disappeared with aging of the tire

crumb for three months in place in the playground. We conclude that the use of tire crumb in playgrounds results in minimal hazard to children and the receiving environment

N2 - The aim was to highlight the role of childcare products as causes for mild brain injury (concussion) in small children (0-4 years of age) and to determine the most dangerous products. By childcare products this report means the following items: child and baby furniture, nursing tables, baby walkers, toys, baby carriages, sport equipment for children, playground equipment and security equipment for children. The data were derived from the EHLASS (European Home and Leisure Accident Surveillance System) for 1998 and 1999 and covered a restricted population of Sweden (approximately 5 per cent). According to this register 182 mild brain injuries (concussions) were recorded following a fall, an accident or a blow to the head among children (0-4 years of age) during 1998 and 158 for 1999. Of those injuries, childcare products were the cause of the accident in 84 (46 per cent) and 76 (48 per cent) cases respectively for 1998 and 1999. The number of children admitted for hospital care was 68 (57/84) and 74 (56/76) per cent respectively. The home was the most common place of the accident and play and leisure activity were the most common activities. More than 50 per cent of these accidents took place during daytime. The product type that caused most accidents was nursery furniture and, in this

category, the baby walker was the most dangerous. The product type that caused the second most frequent accidents was playground equipment

N2 - **PURPOSE:** With the aim of improving the measurement of child health and disability in survey research, this paper reviews the coverage of chronic health conditions and the domains of disability and related environmental factors as they are laid out in the ICD-10 and ICF, respectively, in national surveys of school-aged children conducted in Canada since 1980. Recommendations are made for future survey use and construction. **METHODS:** Two reviewers independently examined each of the surveys. Coverage of chronic health conditions, the domains of disability, and environmental factors in survey questions was identified by mapping question content onto ICD-10 and ICF codes. The reviewers then compared their findings and came to a final consensus. **RESULTS:** Surveys vary in the range and depth of coverage of the ICD-10 and ICF chapters. Disability surveys and health surveys for persons aged 12 and over contain the most comprehensive lists of chronic conditions. Coverage of impairments is limited. Coverage of activity limitations and participation restrictions is most limited in the domains of personal care and domestic life. Environmental factors not covered include natural environmental changes, attitudes, and policies. **CONCLUSIONS:** Development of a comprehensive standard list of chronic health conditions based on the ICD-10 and development of standard survey measures of the domains of disability and environmental factors based on the ICF for use in surveys of

school-aged children would facilitate an understanding of children's health and disability in the context of the current international health framework provided by the World Health Organization. [References: 62]

N2 - Systematic observations of 231 children (infancy to 5 years) and the 231 adults accompanying them were made in 29 supermarkets in Edmonton, Alberta, Canada. The objective of the study was to describe the influence of two indices of adult supervision in supermarkets on children's activities in shopping carts. Adult supervision was measured by whether the adult ever lost sight of the child and whether the adult was 10 feet or more from the child at any time during a shopping trip. 23% of the children stood on the ends or sides of carts; 49% climbed or tried to climb out of carts. Adults lost sight of a child, whether in or outside the cart, a mean of 3.3 times and were 10 feet away 2.7 times during an average shopping trip. Logistic regression showed that a child rather than an adult pushing a shopping cart through the store was the strongest factor related to standing on ends or sides of carts. Pushing by a child was more likely to occur when adult monitoring was low and when children were older. Climbing out was predicted by the number of times an adult was > or = 10 feet away, older children, and a child being in the cart basket as opposed to outside the cart or in the child safety seat

N2 - OBJECTIVE: A substantial proportion of homes and automobiles serve as settings for environmental tobacco smoke (ETS) exposure, and many public settings that children frequent are still not smoke-free. Tobacco control efforts are attempting to increase smoking bans. The objective of this study was to describe the knowledge, attitudes, and practices of smokers and nonsmokers regarding smoking bans and child ETS exposure in multiple public and private settings and to report changes from 2000-2001. METHODS: Cross-sectional data from the annual Social Climate Survey of Tobacco Control were analyzed for changes in knowledge, attitudes, and practices regarding tobacco. These data were collected via automated, random-digit-dialing telephone surveys that were conducted in the summers of 2000 and 2001. The samples were weighted by race and gender to be representative of the US population. RESULTS: Response rates for eligible adults actually contacted were 1501 (75%) of 1876 in 2000 and 3002 (84%) of 3566 in 2001. The majority of adults, both smokers and nonsmokers, support smoking bans in a wide variety of places. The percentage of all respondents reporting the presence of smoking bans in several public and private places increased from 2000-2001: the

household (69%-74%), in the presence of children (84%-88%), convenience stores (68%-74%), fast-food restaurants (52%-58%), and non-fast-food restaurants (25%-28%). Support for smoking bans also increased in shopping malls (71%-75%), fast-food restaurants (77%-80%), and indoor sporting events (78%-80%). There were no significant changes in support for smoking bans in convenience stores, restaurants, or outdoor parks. Adults' knowledge of the harm caused by tobacco was unchanged, with the vast majority of adults recognizing the dangers of exposure to ETS from parental smoking (95%) and exposure to ETS in cars (77%).

CONCLUSIONS: Small improvements in adult attitudes and practices regarding children's ETS exposure occurred from 2000-2001. However, a significant number of adults in the United States still report ignorance of the harmful effects of child ETS exposure, and there was no improvement in reported knowledge in this 1-year period. In contrast, a growing majority of smokers and nonsmokers favor restrictions on smoking in public settings, suggesting that states and communities have public support for broad public smoking restriction policies. There are significant roles that pediatricians can play in preventing children's ETS exposure, through both patient and family education and by moving smoking restriction policies forward on their community's agenda

N2 - The purpose of this study was to examine the weekday patterns of moderate-to-vigorous physical activity (MVPA) in school children and adolescents and determine if there are periods of the day that are representative of their typical MVPA. The sample comprised 84 subjects (boys, n = 30; girls, n = 54), age 8-15 years old. Daily totals for the physical activity variables were calculated by summing the values from 13 hr of physical activity (PA) measurements (9:00-22:00), with 60-min time blocks comprising each day. The MVPA data values were categorized in four daily periods: morning (9:00-11:59), noon (12:00-14:59), late afternoon (15:00-17.59), and evening (18:00-21.59). Our data show that boys participated significantly more in MVPA than girls. Despite no clear patterns or differences among sex being found, girls showed higher percent of time engaged in MVPA during the morning and early afternoon periods (sum of two periods 51.0%), while boys' percent of time engaged in MVPA is higher at late afternoon and evening periods (sum of two periods 53.8%). The principal components analyses showed four distinct components that accounted for 67% of the variance, as follows: school hours (component 1); lunchtime and outside-school activities (component 2); morning time before school period (component 4); and period before bedtime (component 3) appear as distinct periods of the day. In conclusion, the present study shows that boys engaged more in MVPA than girls. Girls tend to be more active during school periods, while boys are more active after school. N2 - In this article we present results from a 2-year comprehensive exposure assessment study that examined the particulate matter (PM) exposures and health effects in 108 individuals with and without chronic obstructive pulmonary disease (COPD), coronary heart disease (CHD), and asthma. The average personal exposures to PM with aerodynamic diameters < 2.5 microm (PM2.5) were similar to the average outdoor PM2.5 concentrations but significantly higher than the average indoor concentrations. Personal PM2.5 exposures in our study groups were lower than those reported in other panel studies of susceptible populations. Indoor and outdoor PM2.5, PM10 (PM with aerodynamic diameters < 10 microm), and the ratio of PM2.5 to PM10 were significantly higher during the heating season. The increase in outdoor PM10 in winter was primarily due to an increase in the PM2.5 fraction. A similar seasonal variation was found for personal PM2.5. The high-risk subjects in our study engaged in an equal amount of dust-generating activities compared with the healthy elderly subjects. The children in the study experienced the highest indoor PM2.5 and PM10 concentrations. Personal PM2.5 exposures varied by study group, with elderly healthy and CHD subjects having the lowest exposures and asthmatic children having the highest exposures. Within study groups, the PM2.5 exposure varied depending on residence because of different particle infiltration efficiencies. Although we found a wide range of longitudinal correlations between central-site and personal PM2.5 measurements, the longitudinal r is closely related to the particle infiltration efficiency. PM2.5 exposures among the COPD and CHD subjects can be predicted with relatively good power with a microenvironmental model composed of three microenvironments. The prediction power is the lowest for the asthmatic children

N2 - PURPOSE: The authors examine differences in reports of residual disability and unmet need by type of long-term care arrangement (assistive technology or personal care). DESIGN AND METHODS: This study compares three specific dimensions of residual difficulty (pain, fatigue, and time intensity) and reports of unmet need across care arrangements. Samples from the U. S. 1994-1995 National Health Interview Survey Phase 2 Disability Supplements include adults with limitations in bathing, transferring, walking, and getting outside. RESULTS: Even when differences in underlying disability are accounted for, assistive technology (AT) confers no additional benefit in the three dimensions of residual difficulty analyzed here. AT users equally or more often report that tasks are tiring, time consuming, or painful, even when they use assistance. Though this would appear to indicate unmet needs for care, fewer AT users report a desire for hands-on personal care. IMPLICATIONS: Though disability alleviation by technology is no better on specific dimensions of difficulty, technology users report less unmet need for personal care. Designing appropriate and cost-effective home care for adults with disabilities requires a better understanding of the ways in which technology users may differ from others and the circumstances under which technology can be most effective

N2 - BACKGROUND: Based on the technologies of applied behavior analysis and person-centered planning, positive behavior support is a process for designing and implementing proactive behavioral interventions with the goal of positive lifestyle changes. PARTICIPANTS: The two adolescents who received the intensive, longitudinal, multicomponent intervention had experienced escalating behavior challenges over several years after brain injury in early childhood. MAIN OUTCOME MEASURES: Quantitative data included episodes of aggression and property destruction. Qualitative data included intensity of supports, family involvement, peer relationships, medication regime, vocational status, educational status, community access, and self-help skills. RESEARCH DESIGN: A long-term, natural-environment, case-study method was used. RESULTS: The targeted challenging behaviors were reduced to zero. In addition, the participants' domains of activity increased and self-management improved even as supports were systematically withdrawn. CONCLUSIONS: These results illustrate the potential for successfully treating extreme chronic behavior disorders after childhood brain injury

N2 - This study conducted a quantitative ethnographic analysis of the influence of demographic factors and early experience (childhood exposure to dogs) on Taiwanese dog-keeping practices and behavior. A telephone survey of a randomly selected sample of 2001 Taiwan residents determined their dog ownership histories, current patterns of dog ownership and disposal, and other dog-related activities. The results suggest that low rates of neutering, easy availability of low- or no-cost puppies, a tendency to allow owned dogs free access to the outdoors, unrealistic expectations of dog ownership, canine behavioral problems, and religious and cultural taboos against euthanasia and shelter relinquishment have contributed to the recent increase in the numbers of free-roaming dogs in Taiwan. Logistic regression analyses determined that a relatively small number of demographic and experiential variables predicted dog ownership and disposal patterns. The most important of these was childhood experience of living with household dogs. In light of these findings, future efforts to reduce the stray dog problem should focus on enforcing registration fees, particularly for unsterilized animals; low-cost neutering schemes; and educational programs designed to promote neutering, improve knowledge of canine behavior and behavior problems, and develop more realistic expectations and attitudes toward dog ownership. Marked Taiwanese resistance to canine euthanasia and shelter relinquishment suggests a need for alternative methods of managing the existing free-roaming dog population

N2 - Exposure to human immunodeficiency virus (HIV) can occur in a number of situations unique to, or more common among, children and adolescents. Guidelines for postexposure prophylaxis (PEP) for occupational and nonoccupational (eg, sexual, needle-sharing) exposures to HIV have been published by the US Public Health Service, but they do not directly address nonoccupational HIV exposures unique to children (such as accidental exposure to human milk from a woman infected with HIV or a puncture wound from a discarded needle on a playground), and they do not provide antiretroviral drug information relevant to PEP in children. This clinical report reviews issues of potential exposure of children and adolescents to HIV and gives recommendations for PEP in those situations. The risk of HIV transmission from nonoccupational, nonperinatal exposure is generally low. Transmission risk is modified by factors related to the source and extent of exposure. Determination of the HIV infection status of the exposure source may not be possible, and data on transmission risk by exposure type may not exist. Except in the setting of perinatal transmission, no studies have demonstrated the safety and efficacy of postexposure use of antiretroviral drugs for the prevention of HIV transmission in nonoccupational settings. Antiretroviral therapy used for PEP is associated with significant toxicity. The decision to initiate prophylaxis needs to be made in consultation with the patient, the family, and a clinician with experience in treatment of persons with HIV infection. If instituted, therapy should be started as soon as possible after an exposure—no later than 72 hours—and continued for 28 days. Many clinicians would use 3 drugs for PEP regimens, although 2 drugs may be considered in certain circumstances. Instruction for avoiding secondary transmission should be given. Careful follow-up is needed for psychologic support, encouragement of medication adherence, toxicity monitoring, and serial HIV antibody testing. [References: 122]

N2 - BACKGROUND: A reduction in cause-specific mortality may be the most important public health measure of the efficacy of a new vaccine. However, in developing countries, assignment of causes of deaths occurring outside hospitals can be assessed often only through the questioning of relatives about the signs and symptoms leading to death ('post-mortem questionnaire'). Causes assigned in this way have poor sensitivity and specificity. We illustrate the effects of this misclassification on the power of a large trial of a pneumococcal polysaccharide/protein conjugate vaccine with a mortality endpoint. METHODS: Required sample sizes to achieve a study with specified power were calculated for all-cause and acute lower respiratory tract infection (ALRI) mortality for different levels of sensitivity and specificity of post-mortem questionnaires. Data from active community-based surveillance and post-mortem questionnaires collected 1989-1993 from the study area were used in the calculations. FINDINGS: The mortality rate among children aged 6-29 months from all causes was 34.2 per 1000 child-years; 19% of deaths were attributable to ALRI. Assuming that pneumococci would be responsible for 50% of ALRI deaths and that the vaccine would cover 70% of disease serotypes and would be 90% effective against these serotypes, the expected efficacy of the vaccine would be 6.0% ($19\% \times 50\% \times 70\% \times 90\%$) against all causes combined and 31.5% ($50\% \times 70\% \times 90\%$) against deaths from ALRI. If, as suggested by various reports, the sensitivity and specificity of assigning a death to ALRI by post-mortem questionnaire are about 40% and 90% respectively, then the observed vaccine efficacy against ALRI (as classified using the post-mortem questionnaire) would fall to 20%, and the power to detect this would be reduced by approximately 40%. Furthermore, low sensitivity of diagnosis would lead to a falsely low estimate of the burden of ALRI mortality in the population and the trial might have greater power to detect a reduction in mortality from all causes combined than that estimated at the outset. CONCLUSIONS: Low sensitivity and specificity of diagnosis by post-mortem questionnaire may mean that the power of a trial to detect a reduction in all-cause mortality is similar to that to detect a reduction in ALRI mortality. Since the latter is more susceptible to bias from misclassification of cause of death, all-cause mortality may be the most suitable endpoint. Similar considerations apply to trials of interventions against other diseases for which a cause-specific endpoint is subject to substantial misclassification

N2 - Approximately 25% of polymorphonuclear leukocytes (PMNL) circulate in heterotypic complexes with one or more activated platelets. These platelet-neutrophil complexes (PNC) require platelet CD62P expression

for their formation and represent activated subpopulations of both cell types. In this study, we have investigated the presence, time course, and mechanisms of PNC formation in 32 cases of severe pediatric meningococcal disease (MD) requiring intensive care. There were marked early increases in PMNL CD11b/CD18 expression and activation, and reduced CD62L expression compared with intensive care unit control cases. Minimal platelet expression of the active form of alphaIIb beta3 (GpIIb/IIIa) was seen. PNC were reduced on presentation and fell to very low levels after 24 h. Immunostaining of skin biopsies demonstrated that PNC appear outside the circulation in MD. In vitro studies of anticoagulated whole blood inoculated with *Neisseria meningitidis* supported these clinical findings with marked increases in PMNL CD11b/CD18 expression and activation but no detectable changes in platelet-activated alphaIIb beta3 or CD62P expression. In vitro PMNL activation with *N. meningitidis* (or other agonists) potentiated the formation of PNC in response to platelet activation with adenosine diphosphate. Therefore, in severe MD, PMNL activation is likely to promote PNC formation, and we suggest that the reduced levels of PNC seen in established MD reflect rapid loss of PNC from the circulation rather than reduced formation

N2 - **BACKGROUND:** Childhood injuries cause significant mortality and morbidity in Singapore. With injury surveillance, patterns of repeated injury can be identified and injury prevention strategies devised. **METHODS:** We conducted a retrospective study of all children aged 12 and below seen for trauma in an Emergency Department over one year. Data captured in the real-time computer system was studied with regards to patient profile, mechanism of injury and patient disposition. Clinical summaries were extracted with follow-up telephone interviews done. **RESULTS:** Two thousand five hundred and seventeen children aged 12 and below were seen for accidental trauma in 1999, accounting for 37.1% of the total attendance for that age. Mean age was 7.7 years with males making up 62.7%. Home injuries (56.4%) were the most common, followed by road-related (14.4%), sports (8.2%) and playground injuries (7.4%). 48.5% sustained head and face injuries. Pre-school children (age <5) were more likely to sustain home injuries ($p < 0.0001$), a higher proportion of head injuries ($p < 0.0001$), foreign bodies, burns and poisoning compared to school-going children (age 6-12), who were more likely to sustain injuries in road accidents, sports, at playgrounds or schools, with more limb, trunk and multi-trauma. We highlight drownings, falls from height, rollover falls from beds, slamming door injuries, the low use of child car restraints, bicycle injuries and playground falls as areas of concern. **CONCLUSION:** Several injury prevention strategies have been suggested and it is hoped these may contribute to addressing preventable childhood injuries in Singapore. We also advocate the establishment of a national childhood injury surveillance database

N2 - In the summer of 1997, we measured the aggregate exposures of nine preschool children, aged 2-5 years, to a suite of organic pesticides and other persistent organic pollutants that are commonly found in the home and school environment. The children attended either of two child day care centers in the Raleigh-Durham-Chapel Hill area of North Carolina and were in day care at least 25 h/week. Over a 48-h period, we sampled indoor and outdoor air, play area soil and floor dust, as well as duplicate diets, hand surface wipes, and urine for each child at day care and at home. Our target analytes were several polycyclic aromatic hydrocarbons (PAH), organochlorine pesticides, and polychlorinated biphenyls (PCB); two organophosphate pesticides (chlorpyrifos and diazinon), the lawn herbicide 2,4-dichlorophenoxyacetic acid (2,4-D), three phenols (pentachlorophenol (PCP), nonyl phenols, and bisphenol-A), 3,5,6-trichloro-2-pyridinol (TCP), and two phthalate esters (benzylbutyl and dibutyl phthalate). In urine, our target analytes were hydroxy-PAH, TCP, 2,4-D, and PCP. To allow estimation of each child's aggregate exposures over the 48-h sampling period, we also used time-activity diaries, which were filled out by each child's teacher at day care and the parent or other primary caregiver at home. In addition, we collected detailed household information that related to potential sources of exposure, such as pesticide use or smoking habits, through questionnaires and field observation. We found that the indoor exposures were greater than those outdoors, that exposures at day care and at home were of similar magnitudes, and that diet contributed greatly to the exposures. The children's potential aggregate doses, calculated from our data, were generally well below established reference doses (RfDs) for those compounds for which RfDs are available

N2 - **BACKGROUND:** Short-distance falls, such as from a bed, are often falsely reported scenarios in child abuse. In attempting to differentiate between abusive and nonabusive injury, knowledge of factors that affect injury risk in falls could prove useful. **OBJECTIVES:** To assess the biomechanics associated with simulated short-distance falls in children (one fall scenario, without attempting to maximize injury potential) and to investigate the effect of impact surface type on injury risk. **METHODS:** Repeatable fall experiments from bed height (0.68 m) onto different surfaces were conducted using an instrumented side-lying Hybrid II 3-year-old test dummy. Biomechanical measures assessed in falls included head acceleration, pelvis acceleration, femur loading, and head injury criteria. **RESULTS:** Fall dynamics resulted in the pelvis or legs making first contact. Biomechanical measures assessed in simulated bed falls were below known head injury criteria and lower extremity injury thresholds. The impact surface type had a significant effect on head injury risk and lower extremity loading. Playground foam proved to have the lowest associated injury risk of all the tested surfaces. **CONCLUSIONS:** The biomechanics of a child falling from a short distance, such as from a bed, were investigated using an experimental laboratory mock-up and an instrumented test dummy. Despite the impact surface having an effect on injury risk, rolling from a 0.68-m (27-in) horizontal surface from a side-lying posture presented low risk of contact-type head injury and leg injury on all tested impact surfaces

N2 - OBJECTIVE: To outline the severity and long-term sequelae of eye injuries in soccer. DESIGN: Prospective observational study of 163 patients who sustained soccer-related ocular injuries between April 1, 1992, and March 31, 2000 (8 years). METHODS: Patients were observed at a sports ophthalmology unit located in the largest university hospital of the northern region of the country and central to all major soccer fields in town. The data were recorded using the United States Eye Injury Registry report forms for initial and follow-up observation. MAIN OUTCOME MEASURES: (1) Self-reported history surrounding the ocular trauma, initial visual acuity, diagnosis, and operations and (2) final visual acuity, late diagnosis, and additional operations. RESULTS: Injuries occurred predominantly in young men (mean +/- SD age, 23.2 +/- 8.8 years) practicing indoor soccer (50.9%) or outdoor soccer (47.2%), and most resulted from a kicked ball (79.1%) near the goal post (60.1%). Angle recession and peripheral vitreoretinal lesions were more likely to occur in the superotemporal quadrant (54.7%; 95% confidence interval, 44.2%-65.0%; and 57.6%; 95% confidence interval, 48.4%-66.4%; respectively). Vitreoretinal lesions were present in 42.2% (95% confidence interval, 33.1% - 51.8%) of patients with "normal" visual acuity (> or =20/40) and in 50.0% (95% confidence interval, 38.1% - 61.8%) of patients without hyphema. No significant association was found between severity of injury and age, sex, type of soccer, level of athletic expertise, or player position. CONCLUSIONS: Severe ocular lesions can occur in soccer players without symptoms and at all skill levels. The development of laboratory models will be essential to explain the tendency for lesions to be in the superotemporal quadrant. The data support the need for protective eyewear designed specifically for soccer

N2 - **PROBLEM:** The common view is that clumsy children experience unintentional injury more frequently. Empirical evidence supporting this position is mixed. **METHOD:** One hundred 6- and 8-year-olds completed a battery of nine tasks designed to assess motor ability. Mothers completed a lifetime injury history measure about their children and families completed a 2-week injury diary assessing frequency and severity of daily injuries. **RESULTS:** Internal reliability for the motor ability battery was good. Correlations between motor ability measures and injury risk were nonsignificant and near zero. **DISCUSSION:** Motor ability does not appear to be directly related to injury risk. Possible explanations include: (a) coordinated and clumsy children engage in hazardous activities with differing frequency; or (b) other individual difference factors may interact with motor ability to explain children's injury risk. **IMPACT ON INDUSTRY:** Children's motor abilities do not appear to be directly linked to rate of unintentional injury, but instead may influence risk for injury in conjunction with other factors. Results could have implications to the engineering of children's toys and playground equipment and to the design of appropriate supervision strategies for children engaging in potentially dangerous activities

N2 - In early summer 2001, an outbreak of atypical rash occurred among children from 24 junior schools who attended an outdoor games event. The event comprised a series of five water games including a water slide, and within 24 hours of attending the event 151/593 (26%) children developed a papulopustular rash. The rash had a characteristic distribution, predominantly over the lower trunk and buttocks, with some involvement of the arms and legs. Pseudomonas aeruginosa was isolated from a water butt used to draw water for the games, and from the tank of a fire engine that supplied the water. Similar outbreaks, due to Pseudomonas folliculitis, have been previously described and in immunocompromised people this can be associated with serious illness. We recommend that superchlorinated water be used for water play events and that care be taken to avoid abrasive surfaces

N2 - There is a great need for developing and validating measures of child neglect that can be applied to survey samples outside of a child welfare context. A prospective assessment of child neglect would afford a better estimation of the etiology of various types of child neglect and would greatly inform the development of primary prevention strategies related to child maltreatment. This article offers guidance on the tasks involved with constructing new measures of neglect for prospective survey research. Methodological issues pertaining to child neglect measurement are discussed, and a framework is offered for developing neglect measures for survey research. A discussion is also offered on how this framework is being applied in an ongoing longitudinal study of low-income families with young children. The intended result of this exercise is to encourage the development of new child neglect measures for survey research with both high-risk and general populations.

N2 - Raising poultry at home is common in many periurban communities in low-income countries. Studies demonstrate that free-range domestic poultry increase children's risk of infection with diarrhea-causing organisms such as *Campylobacter jejuni*. Corralling might reduce risk, but research on the socioeconomic acceptability of corralling is lacking. To explore this issue, we studied local knowledge and practices related to poultry-raising in a Peruvian shantytown. Our objectives were to understand: (1). motives for raising domestic poultry; (2). economic and cultural factors that affect the feasibility of corralling; and (3). local perceptions about the relationship between domestic poultry and disease. During 1999-2000, we met with community health volunteers and conducted ethnographic and structured interviews with residents about poultry-raising practices. We then enrolled 12 families in a 2-month trial of corral use during which field workers made biweekly surveillance visits to each family. Most participants reported that they raise birds because home-grown poultry and eggs taste better and are more nutritious and because they enjoy living around animals. Some want to teach

their children about raising animals. To prevent theft, many residents shut their birds in provisional enclosures at night, but most stated that birds are healthier, happier, and produce better meat and eggs when let loose by day. Many view bird feces in the house and yard as dirty, but few see a connection to illness. Residents consider chicks and ducklings more innocuous than adult birds and are more likely to allow them inside the house and permit children to play with them. After extensive orientation and technical assistance, participants were willing to corral birds more often. But due to perceived disadvantages, many kept birds penned only intermittently. Additional food and water costs were a significant obstacle for some. Adequate space, bird care and corral hygiene would also need to be addressed to make this intervention viable. Developing a secure, acceptable and affordable corral remains a challenge in this population

N2 - Evoked play narratives have been demonstrated to provide a novel window towards internal emotion regulation and mental representations. The present study evaluates covariations between emotion themes and mother-child interaction, as well as child behavior problems. An exploratory study in non-referred children in the 3-6 age span utilizing the MacArthur-method was conducted by taking emotional, conflictive and moral themes as indices of emotion-regulatory processes. Emotion themes were linked to external measures of dyadic Emotional Availability, interparental relationship quality, and behavior problems employing the 4/18 version of the Child Behavior Checklist. Mental representations were aggregated using the Person Representation Coding System. Of a principal components analysis with subsequent varimax-rotation for narrative content codes resulted four emotion theme composites: social conflicting, a prosocial aggregate, an antisocial aggregate, and a composite conflict solving/-understanding. The 4-factor solution displayed meaningful correlation patterns with the mental representations of self and parents, as well as with most of the external measures. Although subsequent studies ought to be methodologically improved both in design and sample size, the results of the present investigation give rise to the assumption that future efforts of validating emotion-regulatory processes with more established outside measures are likely to be successful

N2 - The solar ultraviolet radiation (UVR) exposure of 30 children and adolescents in three age groups (4-6 years, 7-9 years and 13-14 years) was measured for 1 week in late summer (February-March) in Durban, South Africa, using UVR-sensitive polysulfone film badges (PSFB) attached to the lapel region of the body. The mean

and median values for all ages over the study period were 2.0 and 1.2 standard erythemal dose (SED) units, respectively, where 1 SED = 100 J x m(-2). Individual PSFB doses were analyzed as a function of age, gender and behavior. No significant statistical differences were found between different age groups; however, there was a statistical difference between males and females, with males generally receiving higher PSFB doses. Subjects completed UVR exposure journals documenting their time outdoors, shade versus sun conditions, nature of their activities, clothing worn and their use of sunscreen for each day of the study. Activity patterns were noted as the most important factor influencing individual UVR dose. Ambient erythemal UVR was measured by a Yankee Environmental Systems UVB pyranometer, and a relationship between ambient UVR and individual UVR dose was derived. On average, subjects received a dose of 4.6% of the total daily erythemal UVR. Based on this factor, the potential dose of an individual over a full annual cycle was estimated. Accordingly, there were 139 days during the year when an individual with skin type I (light skin) would be likely to experience minimal erythema and 97 and 32 days for individuals with skin types II and III, respectively

N2 - This study determined the incidence of violence-related injuries in an urban school district, and compared characteristics of unintentional and intentional school injuries. A sample of student Accident Report Forms completed for a school district in 1997 were reviewed for demographic characteristics of the student and injury characteristics. Injuries were categorized as unintentional, intentional, or of unknown intent. Annual incidence rates of injury per 100 students were calculated by intention, grade, and gender. Comparisons between unintentional and intentional injuries were made using odds ratios and 95% confidence intervals. Of 11,674 annualized injuries, 77.2% were unintentional, 16.8% were intentional, and 6.0% were of unknown intent. The overall annualized injury rate was 1.74 injuries per 100 students/year. The unintentional injury rate was almost five times the intentional injury rate of 0.29 injuries per 100 students/year. High school students had both the highest unintentional and intentional injury rates. Males in all grade levels had the highest rates of injury. Most injuries occurred during school hours. Intentional injuries were almost three times more likely to be associated with unstructured play or after school playground hours; were less likely to be witnessed events; and were more likely to occur on the surrounding school grounds than unintentional injuries. Unintentional injuries represent a greater risk to school children than do intentional injuries. A potential area to focus interventions for intentional injuries are modifications of the school environment and surrounding grounds to improve supervision and monitoring

N2 - The Atlantic and Pacific coasts are the boundaries of Lyme disease with the Northeastern and Midwestern regions of the United States continuing to report the majority of cases. New reported cases of Lyme disease doubled from 1991 to 2001 according to statistics published by the Centers for Disease Control and Prevention. Within that population are more children between the ages of 5 and 9. The younger the child, the more difficult it is to diagnose Lyme disease. Children under the age of 19 are at high risk for Lyme disease because of the amount of time spent in outdoor activities during the late spring and summer. These months correlate with the tick breeding cycle and the peak time for outdoor recreational activities. Lyme disease can pose serious health risks in late stage illness. A Lyme disease case study on a school-age child provides comprehensive assessment data, interventions, and educational information for parents. A template of an individualized healthcare plan using standardized language is a guide for school nurses. The value of school nurses as guardians of the public's health is addressed

N2 - BACKGROUND: Deficits in joint attention are considered by many researchers to be an early predictor of childhood autism (e.g., Osterling & Dawson, 1994) and are considered to be pivotal to deficits in language, play, and social development in this population (Mundy, 1995). Although many researchers have noted the importance of joint attention deficits in the development of children with autism (e.g., Mundy, Sigman, & Kasari, 1994) and have called for intervention strategies (e.g., Mundy & Crowson, 1997), few studies have attempted to target joint attention. In this study, joint attention behaviors were taught to children with autism using a behavior modification procedure. **METHODS:** A multiple-baseline design was implemented to evaluate intervention effects. The following target behaviors were included in the intervention: 1) Responding to showing, pointing, and gaze shifting of adult; 2) Coordinated gaze shifting (i.e., coordinated joint attention); and 3) Pointing (with the purpose of sharing, not requesting). Generalization to setting and parent, follow-up sessions, and social validation measures were also analyzed. **RESULTS:** Joint attention behaviors were effectively trained and targeted behaviors generalized to other settings. In addition, positive changes were noted by naive observers using social validation measures. **CONCLUSIONS:** Integrating joint attention training into existing interventions may be important for children with autism. In addition, training parents in these techniques may help to maintain joint attention skills outside of the treatment setting

N2 - In an interdisciplinary approach the exposure to lead and cadmium of the population living in the vicinity of a Bulgarian non-ferrous metallurgical plant was studied to determine the routes of exposure. Two exposed villages situated 4 and 6 km SW and W, respectively,--in the plume of the plant's emissions--and a village for comparison situated 14 km SE of the plant were selected for the study. The blood of children aged 3-13 years from the exposed villages (n = 111) and the village for comparison (n = 18) was analyzed for lead (PbB) and cadmium (CdB) as well as for free erythrocyte protoporphyrin (FEP) and haematological parameters. A personal questionnaire concerning nutrition habits and life-style was filled in by interviewers of the children's parents. The cadmium levels in blood were within the variation range stated for Bulgaria. The exposed children had a mean CdB of 0.38 +/- 0.18 microgram/l (range 0.10-0.90 microgram/l) and the comparison group 0.31 +/- 0.35 microgram/l (0.06-1.42 micrograms/l). The mean PbB value measured in the exposed children was 240 +/- 96 micrograms/l (77-631 micrograms/l), while the mean value of PbB for the reference group was 149 +/- 57 micrograms/l (63-285 micrograms/l). Individual PbB levels > 150 and > 200 micrograms/l were found in 85% and 62%, respectively, of the exposed children and FEP > 80 micrograms/dl erythrocytes was detected in 21%. There was a concentration-response and a concentration-effect relationship (r = 0.51, D > 0.001) between PbB and FEP. According to the questionnaire only 10.3% of the interviewed families in the two exposed villages buy all food from the market, the others produce a significant part of their food themselves. The PbB levels of children who consume certain foods of local production (cabbage, cereals, poultry, and beef) were significantly higher compared to the PbB values of children whose families purchase these foods from the market. No significant relationship between lead in children's blood and the use of tin and ceramic utensils, drinking and irrigation water, hygiene habits, family tobacco smoking habits, playgrounds and traffic intensity were revealed. There was a significantly higher incidence of prematurely born babies in the exposed population. The proven relationship between lead intake via the food chain and existing significant health risks is the basis for risk communication. Measures aimed at healthier nutrition and life-style intend to contribute to decreasing the risk of the population living in the smelter region

N2 - Paternal mutation of ATP-sensitive K(+) (K(ATP)) channel genes and loss of heterozygosity (LOH) of the 11p15 region including the maternal alleles of ABCC8, IGF2, and CDKN1C characterize the focal form of persistent hyperinsulinemic hypoglycemia of infancy (FoPHHI). We aimed to understand the actual nature of FoPHHI in comparison with insulinoma. In FoPHHI, the lesion consists in clusters of beta-cells surrounded by non-beta-cells. Compared with adjacent islets, proinsulin mRNA is similar and proinsulin production higher ($P < \text{or} = 0.02$), indicating regulation at a translational level, with slightly lower insulin stock and lower ABCC8 peptide labeling ($P < 0.05$). Insulinomas, composed of beta-cell nests or cords, have similar proinsulin mRNA compared with adjacent islets, highly variable proinsulin production, lower insulin stock ($P < \text{or} = 0.02$), and higher ABCC8 peptide labeling ($P < 0.05$). Proinsulin mRNA is lower than in FoPHHI ($P < 0.001$). Islets adjacent to FoPHHI appear to be resting, in contrast to those adjacent to insulinomas, evidencing intrapancreatic regulation of islet beta-cell activity. IGF2 peptide is present inside and outside both lesions, but IGF2 mRNA is restricted to the lesions. The 11p15 LOH and absence of CDKN1C peptide staining are demonstrated in all FoPHHI but also in three of eight insulinomas. Despite some molecular similarities, FoPHHI is thus fundamentally different from insulinoma

N2 - OBJECTIVE: To determine in complete unilateral cleft lip and palate (UCLP) subjects the characteristics (location, shape) of the cleft-side lateral incisor. The presence of a supernumerary tooth at the cleft side and the prevalence of hypodontia outside the cleft area were evaluated. A comparison was made of the shape of the cleft side lateral incisor to its contralateral incisor. SETTING: Hospital for Rehabilitation of Craniofacial Anomalies (HRCA), Sao Paulo, Brazil. PATIENTS: Orthopantomograms of 203 subjects with UCLP and without syndromes were chronologically selected from the HRCA data bank, within an age range of 5 to 10 years.

Outcome Measure: Orthopantomograms were analyzed by the same observer according to established criteria.

RESULTS: There were no statistically significant differences between sexes for any of the criteria studied. The cleft-side lateral incisor was present in 50.2%, and it was more commonly located at the distal side (76.5%). The congenital absence of the cleft-side lateral incisor was observed in 49.8% of the sample, and its antimere was congenitally missing in 10.9%, this difference being statistically significant. The most commonly missing tooth outside the cleft area was the maxillary second premolar. CONCLUSIONS: The high prevalence of hypodontia of the permanent lateral incisor in the cleft side showed that the cleft could play an important role in this absence. There were different patterns for the presence of the cleft-side lateral incisor

N2 - Radiotherapy plays an important role in the management of children with cancer. The aim is to achieve local tumour control while minimizing long-term effects. In the treatment of tumours of the central nervous system (CNS) the most important long-term effects are neuropsychological. Elsewhere orthopaedic long-term effects may compromise function or be cosmetically harmful. Proton therapy has the potential for homogeneous irradiation of the target volume while reducing the magnitude and/or extent of the low dose area outside the target volume. This may be clinically relevant for long-term effects in children. Proton radiotherapy has an established role in the treatment of children with chordomas and chondrosarcomas of the base of skull. Planning studies have demonstrated the potential for improving the therapeutic ratio for radiotherapy for tumours of the central nervous system by achieving a uniform dose within the target volume while minimizing the severity of neuropsychological sequelae. Clinical experience of proton radiotherapy for children remains limited with potential areas for clinical research

N2 - One of the most challenging aspects of therapy for school-age children who stutter is generalizing the skills learned in the therapy room to other settings such as the classroom, lunchroom, playground, or home. An additional challenge is seen in maintaining gains over the long term. This article reviews common roadblocks to generalization and maintenance, including the goals of therapy, the nature of the treatment strategies that require generalization, the scheduling and implementation of generalization activities within the overall therapy process, and the child's understanding of the treatment goals. Specific strategies for overcoming these roadblocks include: desensitizing children to both stuttering and treatment strategies designed to improve fluency, using hierarchies as a way of structuring treatment and moving children toward success in their daily activities, integrating the child's real world and clinical settings, and using structured practice activities to help children solidify all of the lessons they learn in treatment. This article highlights the importance of taking a broad-based

view of stuttering to help children improve their overall communication across a variety of settings and over time

N2 - Attention deficit hyperactivity disorder (ADHD) constitutes one of the most common childhood syndromes and its negative outcomes on all the child's functional domains have been consistently reported in the literature. As a result, their early identification is becoming a topic of increasing concern among the researchers from the field. However, given that many of the behaviors of interest are normative behaviors during this period, diagnosis in preschool years is controversial. Specifically, from a developmental perspective, although it is well known that high levels of motor activity, poor self control, and lack of attention are typical during these years, both expression and intensity of these behaviors are markedly higher on the group of ADHD preschool children. Consequently, their negative interference with daily living, produce significant maladjustments in the child's natural settings. All these ideas justify the need of considering and studying the most appropriate assessment techniques to reliably identify the deficits of ADHD in preschool children. On the basis of these statements, this paper offers a theoretical overview of the most recent developments regarding ADHD assessment and intervention techniques directed to the prevention of cognitive deficits as well as the achievement of a better school and social adjustment of ADHD preschool children. N2 - Superfund sites that are contaminated with lead and undergoing remedial action generate lead-enriched dust that can be released into the air. Activities that can emit lead-enriched dust include demolition of lead smelter buildings, stacks, and baghouses; on-site traffic of heavy construction vehicles; and excavation of soil. Typically, air monitoring stations are placed around the perimeter of a site of an ongoing remediation to monitor air lead concentrations that might result from site emissions. The National Ambient Air Quality (NAAQ) standard, established in 1978 to be a quarterly average of 1.5 microg/m³, is often used as a trigger level for corrective action to reduce emissions. This study explored modeling approaches for assessing potential risks to children from air lead emissions from the RSR Superfund site in West Dallas, TX, during demolition and removal of a smelter facility. The EPA Integrated Exposure Uptake Biokinetic (IEUBK) model and the International Commission of Radiologic Protection (ICRP) lead model were used to simulate blood lead concentrations in children, based on monitored air lead concentrations. Although air lead concentrations at monitoring stations located in the downwind community intermittently exceeded the NAAQ standard, both models indicated that exposures to children in the community areas did not pose a significant long-term or acute risk. Long-term risk was defined as greater than 5% probability of a child having a long-term blood lead concentration that exceeded 10 microg/dl, which is the CDC and the EPA blood lead concern level. Short-term

or acute risk was defined as greater than 5% probability of a child having a blood lead concentration on any given day that exceeded 20 microg/dl, which is the CDC trigger level for medical evaluation (this is not intended to imply that 20 microg/dl is a threshold for health effects in children exposed acutely to airborne lead). The estimated potential long-term and short-term exposures at the downwind West Dallas community did not result in more than 5% of children exceeding the target blood lead levels. The models were also used to estimate air lead levels for short-term and long-term exposures that would not exceed specified levels of risk (risk-based concentrations, RBCs). RBCs were derived for various daily exposure durations (3 or 8 h/day) and frequencies (1-7 days/week). RBCs based on the ICRP model ranged from 0.3 (7 days/week, 8 h/day) to 4.4 microg/m³ (1 day/week, 3 h/day) for long-term exposures and were lower than those based on the IEUBK model. For short-term exposures, the RBCs ranged from 3.5 to 29.0 microg/m³. Recontamination of remediated residential yards from deposition of air lead emitted during remedial activities at the RSR Superfund site was also examined. The predicted increase in soil concentration due to lead deposition at the monitoring station, which represented the community at large, was 3.0 mg/kg. This potential increase in soil lead concentration was insignificant, less than 1% increase, when compared to the clean-up level of 500 mg/kg developed for residential yards at the site

N2 - The 21 square mile Bunker Hill Superfund Site in northern Idaho includes several thousand acres of contaminated hillsides and floodplain, a 365-acre abandoned lead/zinc smelter and is home to more than 7000 people in 5 residential communities. Childhood lead poisoning was epidemic in the 1970s with >75% of children exceeding 40 microg/dl blood lead. Health response activities have been ongoing for three decades. In 1991, a blood lead goal of 95% of children with levels less than 10 microg/dl was adopted. The cleanup strategy, based on biokinetic pathways models, was to reduce house dust lead exposure through elimination of soil-borne sources. An interim health intervention program, that included monitoring blood lead and exposures levels, was instituted to reduce exposures through parental education during the cleanup. In 1989 and 2001, 56% and 3% of children, respectively, exceeded the blood lead criteria. More than 4000 paired blood lead/environmental exposure observations were collected during this period. Several analyses of these data were accomplished. Slope factors derived for the relationship between blood lead, soil and dust concentrations are age-dependent and similar to literature reported values. Repeat measures analysis assessing year to year changes found that the remediation effort (without intervention) had approximately a 7.5 microg/dl effect in reducing a 2-year-old child's mean blood lead level over the course of the last ten years. Those receiving intervention had an additional 2-15 microg/dl decrease. Structural equations models indicate that from 40 to 50% of the blood lead absorbed from soils and dusts is through house dust with approximately 30% directly from community-wide soils and 30% from the home yard and immediate neighborhood. Both mean blood lead levels and percent of children to exceed 10 microg/dl have paralleled soil/dust lead intake rates estimated from the pathways model. Application of the IEUBK model for lead indicates that recommended USEPA default parameters overestimate mean blood lead levels, although the magnitude of over-prediction is diminished in recent years. Application of the site-specific model, using the soil and dust partitions suggested in the pathways model and an effective bioavailability of 18%, accurately predicts mean blood lead levels and percent of children to exceed 10 microg/dl throughout the 11-year cleanup period. This reduced response rate application of the IEUBK is consistent with the analysis used to originally develop the cleanup criteria and indicates the blood lead goal will be achieved

N2 - Trail, British Columbia has been the site of an active lead-zinc smelter for approximately 95 years. Since 1989, the community has been monitoring blood lead levels in children, studying exposure pathways and conducting comprehensive education and case management programs. From 1989 through 1996, mean blood lead levels of pre-school children declined at an average rate of 0.6 microg/dl per year. From 1996 to 1999, mean blood lead levels fell at an average rate of 1.8 microg/dl per year, from 11.5 in 1996 to 5.9 in 1999. The recent rapid decline appears to be mainly attributable to the start-up of a new lead smelter using modern flash-smelting technology in May of 1997. In 1998, the annual arithmetic mean air lead level in Trail was 0.28 microg/m³, compared with 1.1 microg/m³ in 1996. Reductions of approximately 50% were observed in lead loadings and concentrations in outdoor dustfall, street dust and indoor dustfall after smelter emissions were reduced. Slight reductions (statistically insignificant) have been observed in carpet dust and soil lead concentrations. During the summer of 2001, the smelting and refining operations at Trail were shut down completely for 3 months. During this period, average air lead levels in Trail dropped to 0.03 microg/m³. The average blood lead level in Trail pre-school children at the end of the shutdown was 4.7 microg/dl. These results challenge prevailing theories about the relative importance of various environmental lead sources. For example, the US EPA Integrated Biokinetic Uptake Model for Lead (IEUBK), with its emphasis on soil concentrations, would not have predicted the dramatic decline in children's blood lead levels seen in Trail following the reductions in air lead levels. The Trail experience suggests that increased attention should be paid to the importance of active sources of highly bioavailable and mobile lead bearing dusts

N2 - Convulsive disorders are common in the pediatric age group, and measurement of serum concentration of an antiepileptic drug (AED) is frequently ordered for epileptic patients in the emergency department (ED). The objective of this study was to develop a better understanding of the indications for, and consequences of, monitoring AED serum concentrations in the pediatric ED. Charts of 116 patients who visited the ED and were tested for blood levels of AED were retrospectively reviewed. Main outcome measures were number and percentage of levels outside the therapeutic range, discontinuation of an AED or introduction of a new one, dosage modifications, and admission to hospital. Two pediatricians and a pediatric neurologist aware only of patients' age, weight, diagnosis, history, clinical presentation, and drug details reviewed each case and on the basis of predetermined criteria decided whether measurement of AED was indicated. Mean age (+/- SD) of the study population was 7 +/- 5 years (range, 2 months-17 years). Forty-two patients (36%) were on monotherapy, and 74 (64%) were on polytherapy. Sixty-eight patients (59%) presented with increased seizure frequency, 7 (6%) with status epilepticus, and 13 (11%) with suspected AED toxicity. The remainder of the children presented with problems unrelated to epilepsy. No significant difference was found between patients with AED levels within the therapeutic range and those with levels outside it in the proportion of children needing dosage change, change in medication, or hospital admission ($P = 0.5, 0.8, \text{ and } 0.8$, respectively). None of the patients presenting with status epilepticus and only 15% of those with increased seizure activity had subtherapeutic levels. Review of the cases suggested that measuring serum AED level was not indicated in 57 (49.1%) patients. In the pediatric ED, abnormal AED levels do not correlate with clinical management. Before ordering tests, physicians should consider whether their results would alter patient treatment

N2 - BACKGROUND: Melanocytic nevi have been identified as the most important risk factor for cutaneous melanoma. Sun exposure, sunburns, and light pigmentation have been found to be associated with their development in childhood. To the authors' knowledge, nevus proneness of parents and the exact type of ultraviolet (UV) exposure have not yet been investigated in this context. The authors' objective was to determine independent risk factors and their impact for nevus development in childhood. **METHODS:** The current study was conducted by two university departments of dermatology in 49 public nursery schools in Stuttgart, Germany and in 38 public nursery schools in Bochum, Germany. The cross-sectional study included 1,812 children aged 2-7 years and their parents. Total body nevus counts in children, assessment of pigmentary features, and nevus counts on the arms of parents were performed. Parents underwent a standardized interview concerning national origin and lifestyle features, as well as habits and magnitude of sun exposure of children. Analysis was performed by multivariate linear regression analysis and by multiple logistic regression analysis. **RESULTS:** The number of nevi was found to steadily increase with age from a median of 3 at age 2 years to 19 at age 7 years ($P < 0.0001$). High numbers of nevi in children were associated with the number of weeks on sunny holidays, outdoor activities at home, skin type, facial freckling, ethnicity of parents, and the number of nevi on the arms of parents. Previously experienced sunburns failed significance ($P = 0.0620$).

CONCLUSIONS: The authors found a strong association between nevus development in children and the number of parental moles, which most likely points to an inherited factor. Moderate sun exposure such as outdoor activities during a German summer without sunburns seemed to be sufficient for induction of melanocytic nevi. The authors believe that these findings will have direct impact on concepts for preventive strategies. Copyright 2003 American Cancer Society. DOI 10.1002/cncr.11114

N2 - **OBJECTIVES:** To delineate the clinicopathological features of fatal childhood electrocutions and to identify specific risk factors. **METHODS:** Coronial files in Adelaide (Australia) were searched from 1967 to 2001 and Medical Examiners' files in San Diego (USA) were searched from 1988 to 2001, for cases of deaths of children and adolescents younger than 16 years attributed to electrocution. **RESULTS:** Sixteen cases were identified aged between 10 months and 15 years (mean 8.0 years) with a male : female ratio of 5 : 3. Deaths were due to accidents occurring while playing with or near faulty electrical equipment at home or at school (n = 8), electrical equipment while in the bath (n = 2), damaged outdoor electrical equipment (n = 1), overhead wires (n = 1), and a high voltage electricity substation (n = 1). In addition, one death was due to suicide involving an electrical appliance placed in a bath, and two other deaths occurred in older children who were moving equipment under overhead wires. No homicides were identified. **CONCLUSIONS:** Childhood deaths due to electrocution are rare and are more likely to occur when children are playing around electrical wires or equipment, and often result from either faulty apparatus, or a lack of understanding of the potential dangers involved. The majority of deaths (11/16; 69%) occur in the home environment. In contrast to adult electrical deaths, high-voltage electrocutions, suicides and workplace deaths are uncommon. Strategies for eliminating childhood electrocution should concentrate on ensuring safe domestic environments with properly maintained electrical devices

N2 - Global positioning system (GPS) technology is used widely for business and leisure activities and offers promise for human time-location studies to evaluate potential exposure to environmental contaminants. In this article we describe the development of a novel GPS instrument suitable for tracking the movements of young children. Eleven children in the Seattle area (2-8 years old) wore custom-designed data-logging GPS units integrated into clothing. Location data were transferred into geographic information systems software for map overlay, visualization, and tabular analysis. Data were grouped into five location categories (in vehicle, inside house, inside school, inside business, and outside) to determine time spent and percentage reception in each location. Additional experiments focused on spatial resolution, reception efficiency in typical environments, and sources of signal interference. Significant signal interference occurred only inside concrete/steel-frame buildings and inside a power substation. The GPS instruments provided adequate spatial resolution (typically about 2-3 m

outdoors and 4-5 m indoors) to locate subjects within distinct microenvironments and distinguish a variety of human activities. Reception experiments showed that location could be tracked outside, proximal to buildings, and inside some buildings. Specific location information could identify movement in a single room inside a home, on a playground, or along a fence line. The instrument, worn in a vest or in bib overalls, was accepted by children and parents. Durability of the wiring was improved early in the study to correct breakage problems. The use of GPS technology offers a new level of accuracy for direct quantification of time-location activity patterns in exposure assessment studies

N2 - Population-based surveillance and a case-control study were conducted in Abancay, Peru, to estimate the burden of disease and to determine risk factors for sporadic lymphocutaneous sporotrichosis (LS). Laboratory records from local hospitals were reviewed for the years of 1997 and 1998, and prospective surveillance was conducted for the period of September 1998 through September 1999. A case-control study was conducted with 2 matched control subjects per case patient. The mean annual incidence was 98 cases per 100,000 persons. Children had an incidence 3 times higher than that for adults and were more likely to have LS lesions on the face and neck. Identified risk factors included owning a cat, playing in crop fields, having a dirt floor in the house, working mainly outdoors, and having a ceiling made of raw wood or conditions associated with a lower socioeconomic status. Decreased environmental exposure, such as wearing protective clothing during construction activities for adults or limiting contact with cats and soil for children, and improvements in living spaces may decrease the incidence of LS

N2 - **BACKGROUND AND AIM OF THE STUDY:** Chronic infection with *Pseudomonas aeruginosa* (PA) is associated with accelerated worsening of lung disease in patients with cystic fibrosis (CF). Fears of PA are widespread among parents of CF children, and many parents take precautions at home to prevent acquisition of the bacterium from the environment. The present study was undertaken to describe the type and intensity of these activities. **METHODS:** Parents of 21 CF children (7 without prior PA infection, 10 with intermittent and 4 with chronic PA infection) were investigated using semistructured interviews. These were analyzed descriptively and with respect to predominant themes. Additionally, a German personality test was used to evaluate the influence of psychological factors. **RESULTS:** The clinical impression of widespread parental anxieties of PA infection was confirmed. Misunderstandings concerning PA infections were related to a simplistic concept of the underlying biological mechanisms. Some parents which we classified as 'bacterium-focussed' thought that each contact with PA would lead to bacterial infection. These parents used a large variety of measures, which concerned both domiciliary and outdoor surroundings and activities. At the other end of the spectrum were parents which we classified as 'child-focussed' who mostly supported (and relied on) the child's defense mechanism instead of hygienic measures. **CONCLUSIONS:** Recommendations by physicians on how to prevent PA acquisition from the environment should take into account possible non-intended side effects, since some parents will exaggerate daily precautions to the detriment of the child's (and the parent's) quality of life

N2 - The work aimed to determine the leisure time activities in teenagers on weekdays, weekends, during winter and summer holidays. Vast majority of teenagers spend their leisure time resting in a passive way, i.e. watching TV or playing computer games irrespectively of the season. As a result of this, the number of kids with posture defects increase. On weekdays the country teenagers spend much more time doing outdoor sports and games than town children. They also more often help their parents and less frequently travel away from their homes than children living in towns

N2 - Concern has been raised about the amount of time provided for students to consume school lunch. This study analyzed the amount of time used by elementary students to consume school lunch vs sack lunch. Data collectors used stop watches to collect wait time, opportunity time to eat and consumption time for elementary students consuming school lunch, sack lunch, and sack lunch with a separate milk purchase. Students consuming school lunch had a significantly longer wait time than those consuming sack lunch or sack lunch with milk ($P < .0001$). In contrast, students consuming sack lunch and sack lunch with milk had significantly longer opportunity times to eat ($P < .0001$) and consumption times ($P < .001$). There was also a significant decrease in opportunity time to eat and consumption time as grade level increased, particularly in boys ($P < .05$). Older boys appeared more anxious to finish eating so they could go out to recess

N2 - UNLABELLED: Penicillin resistant *Streptococcus pneumoniae* poses an increasing problem in paediatrics, particularly in less developed countries. Outside of South Africa, little is known about *S. pneumoniae* susceptibilities in Sub-Saharan Africa. The objective of this study was to determine the prevalence of pneumococcal colonization and antimicrobial susceptibility among children in urban Ghana. **METHODS:** Nasopharyngeal pneumococcal colonization was examined in 311 children attending a polyclinic for sick children and an immunization clinic in Kumasi, Ghana. Isolates were tested for antibiotic susceptibility to penicillin, tetracycline, erythromycin, chloramphenicol, cefuroxime, cefotaxime, ceftriaxone, and trimethoprim-sulfamethoxazole. **RESULTS:** Over half (51.4%) of subjects were colonized with *S. pneumoniae* and 17% of isolates were resistant to penicillin, all demonstrating intermediate resistance. *S. pneumoniae* strains were also frequently resistant to trimethoprim-sulfamethoxazole and tetracycline, less so to chloramphenicol and cefuroxime and were almost uniformly sensitive to cefotaxime, ceftriaxone and erythromycin. **CONCLUSIONS:** Our study shows a high rate of pneumococcal nasopharyngeal colonization and a concerning level of penicillin resistance although at a less alarming rate than seen in some other countries. Multiple antimicrobial resistance was also noted especially among drugs readily available and commonly used. These data impact treatment choices in pneumococcal disease. Vaccine may play an important role in disease limitation. An effort to curtail the misuse of antibiotics, by prescription and otherwise, may prevent further increases in resistance rates

N2 - A hospital based case-control study was performed to determine causes of unintentional injuries among children aged 1-4 years at home. Data were obtained by interviewing parents and guardians of 242 children at Lerdsin Hospital in Bangkok, from August to October 1999. The results showed that falls were the most common type of injuries (54.6%). The age of 2 years comprised the major group (28.9%). The study subjects were injured within the home (60.7%). Sunday and Saturday were the most frequent days of injuries (18.2% and 16.5% respectively). The proportion of cases involving playing with others was 71.1%. Most of the injuries occurred in the period 16.00-19.00 hours (32.2%). Head and neck were the main injured area (45.5%). The multivariate model showed that children who had previous injuries were 19.22 times more likely to be injured again than those who had not previously been injured. Children with vigorous physical activities also had a higher risk (OR = 19.73, 95% CI 6.11-63.74). Outdoor working mothers were at higher risk than houseworking mothers (OR = 4.14, 95% CI 1.57-10.93) of having children affected. Children who spent most of the daytime at their relatives' houses had a higher risk than those who stayed at their home (OR = 3.48, 95% CI 1.02-11.81), while, 37.9% of children injured at their relatives' houses and 50.8% of all injured children were without supervision

N2 - Recently, new long-acting formulations of racemic methylphenidate (MPH: Ritalin LA, Metadate CD and Concerta) and amphetamine (AMP: Adderall XR) were developed and are now approved by the Food and Drug Administration (FDA). In addition, dexmethylphenidate (Focalin), the pharmacologically active d-threo enantiomer of MPH, also was approved by the FDA. In the initial phases of development, prototypes of these five new formulations were evaluated using the University of California, Irvine (UCI) Laboratory School Protocol (LSP), in which surrogate measures of efficacy are collected in highly controlled settings rather than clinical measures of effectiveness in the less-controlled, natural environments of home or school. The LSP studies were followed by large effectiveness and safety studies required for gaining FDA approval. These initial efficacy and side effect studies in the LSP provided missing information about the basic pharmacokinetic (PK) and pharmacodynamic (PD) properties of MPH and AMP and produced some new discoveries (i.e., acute tolerance) that were used to help design the final products. The final once-a-day formulations used different drug delivery systems to achieve long-acting efficacy (Ritalin LA, Metadate CD, Concerta, Adderall XR). All four drug delivery systems were based on two processes: first, a bolus delivery (BD) process to achieve rapid onset of efficacy (mg), and second, a controlled delivery (CD) process to achieve rates of delivery (mg/hr) or a delayed bolus (mg) to maintain efficacy. A theoretical approach was used to compare and contrast the new once-a-day formulations of MPH by selecting total daily doses (mg/d) that would equate drug delivery by the first process (mg of the initial bolus) and the second process (mg/hr over specified time period). In addition to efficacy, applications of the LSP to measure common side effects related to eating and sleeping were described and discussed

N2 - Strategies to promote lifelong physical activity among children are needed to stem the adverse health consequences of inactivity. However, the health effects in growing children of long-term exposure to a polluted atmosphere are of deep concern. The atmosphere of south Mexico City (SMC) is characterized by a complex mixture of air pollutants, including ozone, particulate matter, and aldehydes. Radiological evidence suggests that small-airway disease could be present in clinically healthy, tobacco unexposed SMC children. The aim of this study was to assess, by means of a self-reported questionnaire, the physical education class times, daily outdoor after-school exposure time, and tobacco exposure in students attending public elementary and middle schools in SMC. Additionally, the time each student spent viewing television was assessed, and the authors measured each student's weight and height to determine body mass index (BMI, weight in kg divided by height in m²). The survey included 1,159 students in grades 7-9. The authors identified 2 critical periods of outdoor exposure in SMC children that coincided with significant concentrations of both ozone and particulate matter with diameters less than 10 micrometers (PM₁₀): during school time after 11:00 A.M. and in the after-school outdoor activity period, usually extending from 1:00 P.M. to 6:00 P.M. Thirty-two percent of elementary and 61% of middle school students have physical education classes after 11:00 A.M. Students in SMC spend an average of 19.6 hr/wk outdoors in the after-school period, during which time they are engaged in light to moderate physical activities. Half of the students are exposed to tobacco smoke at home, and 7% of middle school students smoke. On the basis of BMI, 60% of students were classified as undernourished, overweight, or obese. No correlations were found between BMI and time spent viewing TV, time outdoors (on weekdays and weekends), or exposure to environmental tobacco smoke. Children and adolescents in SMC are participating in physical activities that enhance multiple components of health-related fitness. However, their activities occur outdoors, where they are exposed to high concentrations of air pollutants throughout the year. The authors believe that SMC children and adolescents must be educated, through both the school and health systems, regarding ways to obtain the necessary exercise while protecting themselves from the high concentrations of pollutants. Individuals should instruct and encourage young people to be involved in lifetime fitness activities and to eat balanced diets, if the goal is to control health-care costs, reduce disease incidence, and improve the overall quality of life of the Mexico City population

N2 - OBJECTIVE: To assess the impact of livestock keeping on the human biting rate (HBR) of anopheline mosquitoes and malaria transmission around Ziway in the middle course of the Ethiopian Rift Valley. **DESIGN:** As a passive experiment, man landing captures were done in homesteads with mixed dwelling, separate cattle shed and without livestock; and as an active experiment, captures were in experimental tukuls (huts) of cattle, goats, and without livestock. Parasite and spleen rates of children were compared among those residents under variable living conditions mentioned for passive experiment. **SUBJECTS:** For entomological study, human-baits were used for man-landing captures of mosquitoes. Study subjects for parasitological and clinical studies were children below 10 years old. **MAIN OUTCOME MEASURES:** Human-biting rate (HBR) of anopheline mosquitoes; and the parasite and spleen rates of the study subjects in different living conditions. **RESULTS:** In the passive experiment, the mean HBR of *Anopheles arabiensis* in mixed dwelling, separate cattle shed and without livestock was 8.45, 4.64 and 5.97, respectively. Similarly, the HBR of *An. pharoensis* was 2.88, 1.79 and 1.61, respectively. In the active experiment, the mean HBR of *An. arabiensis* in tukuls with cattle, goats, and without livestock was 3.50, 3.38 and 1.43 respectively; while that of *An. pharoensis* was 0.37, 0.70 and 0.55 respectively. Parasitologically, mean parasite rates of 26.67%, 15.05% and 23.85% were, respectively, recorded from children living under the above conditions stated for passive experiment. Similarly, the mean spleen rates of 50.0%, 26.9%, and 47.37% were recorded, respectively. **CONCLUSION:** These observations in the present study indicate that the presence of cattle in homesteads tends to increase the man biting rate of *An. arabiensis*, although differences in the mean HBR of vector mosquitoes were not statistically significant for all groups. In contrast, cattle keeping in separate cattle sheds outside of the human dwellings tends to reduce the man biting rate of *An. arabiensis* and malaria transmission in the study area

N2 - Research suggests that impairments in executive functions play a role in the cognitive deficit in autism. Possible autism-specific impairments include an inability to engage in goal-directed behaviors and adjust behaviors given environmental demands. What has been described as executive functions is based largely on observations of performance in the laboratory rather than in natural settings. An ecological method first described by Barker and Wright and adapted by Scott was used to assess the patterns of goal-directed behaviors of eight children with autism and eight chronological and mental age comparable children with Down syndrome. Quantitative and qualitative features of naturalistic behaviors were collected, and coded using previously described categories of children's behavior. Results indicated that children with autism exhibited shorter and less overlapping goal-directed behaviors. These data suggest a cognitive difference rather than developmental delay, and lend support for impaired executive functions in autism. Practical implications for educators and caregivers are discussed

N2 - **BACKGROUND:** Although asthma is the most common pulmonary condition in pediatrics, the incidence of exercise-induced asthma (EIA) in school children is not well documented and few studies have been devoted to the condition. There are considerable variations in morbidity and mortality between countries. This study was designed to evaluate the prevalence of EIA in children in the 6th grade (11-14 year-olds) in one French department (Haute-Vienne) and to identify undiagnosed cases. **METHODS:** The representative sample was obtained over a period of 28 days (February 2(nd) to April 10(th) 1998) by cluster sampling method, stratified by size of the schools. The number of subjects planned was 891. The selected children filled in a questionnaire on their asthma history and were subjected to an outdoor exercise test (6 minute run). Respiratory function was measured with a peak flow-meter. **RESULTS:** Seven hundred and eighty two school children were included in this survey. Participation rate was 87.8%. The prevalence of asthma from the questionnaire was 10.7% (CI 95%: 8.7 - 12.8). After exercise, 68 school children presented exercise-induced bronchospasm: the prevalence of the EIA was 8.7% (CI 95%: 6.9 - 10.5). Among these 68 school children, 27 were known asthmatics and 41 were not. With the 10 treated asthmatics, the overall prevalence of EIA was therefore estimated at 9.9% (CI 95%: 8.2 - 11.7). **CONCLUSION:** The prevalence of asthma and EIA was close to that found in other studies using a similar methodology. EIA remains under-diagnosed since 41 undeclared asthmatic school children were identified in our population. Nurses'information is necessary to initiate the use of systematically testing

respiratory function (with a peak flow meter) at least once a year. Efficient management of the asthmatic child requires cooperation between the various professionals dealing with school children

N2 - OBJECTIVES: Cumulative trauma disorder is a major health problem for adults. Despite a growing understanding of adult cumulative trauma disorder, however, little is known about the risks for younger populations. This investigation examined issues related to child/adolescent computer product use and upper body physical discomfort. **METHODS:** A convenience sample of 212 students, grades 1-12, was interviewed at their homes by a college-age sibling or relative. One of the child's parents was also interviewed. A 22-item questionnaire was used for data-gathering. Questionnaire items included frequency and duration of use, type of computer products/games and input devices used, presence of physical discomfort, and parental concerns related to the child's computer use. **RESULTS:** Many students experienced physical discomfort attributed to computer use, such as wrist pain (30%) and back pain (15%). Specific computer activities-such as using a joystick or playing noneducational games-were significantly predictive of physical discomfort using logistic multiple regression. Many parents reported difficulty getting their children off the computer (46%) and that their children spent less time outdoors (35%). **CONCLUSIONS:** Computer product use within this cohort was associated with self-reported physical discomfort. Results suggest a need for more extensive study, including multiyear longitudinal surveys

N2 - This study analyzed the database of Canadian Accident Injury Reporting and Evaluation (CAIRE) for the injuries reported from January 1986 to March 1996 in seven provinces at children's or general hospitals in Canada. In order to describe the characteristics of injuries, we compared the different categories of injuries by sex and by age groups, identified patterns of injuries, and detected the products causing injury to Canadian people. The results showed that there were 130,489 injury cases in Canada during the 10 years from 1986 to 1996. The 10-19 year age group had 57,582 cases, representing 44.13% of total injuries, and making it the group with the highest occurrence of injuries. The male injury rate (69.75%) was significantly higher than the female rate (30.25%) ($P = 0.0001$). Six areas were identified as priorities for intervention: 1) injuries occurring on playgrounds among children and youth; 2) sports and playground apparatus injuries and injuries sustained in transit among young people; 3) the top five causes of injuries; 4) diagnosis and treatment of injuries; 5) consumer products and safety; and 6) nature and physical sites of injuries. Further work is needed in: evaluating injury causes, comparing the results with reports from other countries and the necessary approaches and prevention measures to reduce and control injury occurrences to improve the quality of consumer products, and to protect the health of the population in Canada

N2 - Children with developmental coordination disorder/dyspraxia (DCD) are at high risk of reading and writing delay. The difficulties with motor skills are heterogeneous and many children have features of poor cerebellar function, reflected in problems with posture, balance and fast accurate control of movement. This study confirmed a high level of parental reporting of reading and writing delay in a clinical group of 23 children with DCD, defined on the basis of both clinical examination and standardized testing of motor function. Direct measurement of reading delay, identified still further children in the group. Those children with reading delay had associated findings typical of phonological awareness difficulties. The children also underwent a standardized test of neurological function and although they all had difficulties with cerebellar function, no distinctive pattern emerged for those whose presentation was complicated by delayed reading and writing. Both the children with DCD and 136 typically developing children, completed the pilot parental questionnaire on gross motor skills. The three skills of catching a ball, jumping on a moving playground roundabout and handwriting, distinguished the children with DCD. This study therefore confirms that children with DCD should be assessed for difficulties in phonological awareness. Additionally, children aged between 7 and 12 years are on the whole, highly competent in a range of gross motor skills and further study might determine whether a simple parental questionnaire might detect children who would benefit from further assessment. The study also suggests that all the children with DCD have cerebellar dysfunction and further work with a larger group might determine particular patterns associated with reading delay

N2 - Aspects of Toxocara spp. epidemiology and paratenic infestation of children are described. Human toxocariasis is caused by infestation of zoonotic roundworms of dogs and cats. Soil sampling shows widespread contamination of the environment, particularly parks and playgrounds, with the eggs of Toxocara spp. Toxocara seroprevalence values in children vary between 3.5% in the West Poland and 19% in the South-East Poland. Children more frequently have clinical symptoms of the disease because of the closer contact with contaminated soil in sand-boxes and relatively frequent geophagia. A 3 years old girl with covert toxocariasis is described. As this case illustrates, this disease can be present without its classic visceral, ocular or neurological manifestations. On admission to the hospital the results of blood tests were as follows: white blood cells count, $43 \times 10^3 / \text{mm}^3$ (norm $< 13 \times 10^3$) and hyper eosinophilia, 81%. The girl was treated with albendazole 15 mg/kg for five days, after one year the treatment was repeated. The patient was followed with blood samples throughout a period of one and half year. During that time results of serological tests for Toxocara canis were strongly positive. The lowest blood count was $20.0 \times 10^3 / \text{mm}^3$ and eosinophilia, 19%. Possible association between high eosinophilia in toxocariasis and development of allergic and cardiovascular diseases is discussed

N2 - The current conditions in Belgium are paradoxical. Indeed, adequate measures are now in place to allow sports activities in a favorable environment: increase in leisure time, widespread availability of indoor and outdoor facilities. However, there has been a significant increase in obesity among young people as well as a gradual erosion in physical fitness of young Belgians. Therefore, physical activity is mandated, not only as a general personal health issue, but also as a public health issue. It should be encouraged, taking into account psychological and physiological growth parameters of teenagers

N2 - This study compares two North American time-activity data bases: the National Human Activity Pattern Survey (NHAPS) of 9386 interviewees in 1992-1994 in the continental USA with the Canadian Human Activity Pattern Survey (CHAPS) of 2381 interviewees in 1996-1997 in four major Canadian cities. Identical surveys and methodology were used to collect this data: random sample telephone selection within the identified telephone exchanges, computer-assisted telephone interviews, overselection of children and weekends in the 24-h recall diary and the same interviewers. Very similar response rates were obtained: 63% (NHAPS) and 64.5% (CHAPS). Results of comparisons by age within major activity and location groups suggest activity and location patterns are very similar (most differences being less than 1% or 14 min in a 24-h day) with the exception of seasonal differences. Canadians spend less time outdoors in winter and less time indoors in summer than their U.S. counterparts. When exposure assessments use time of year or outdoor/indoor exposure gradients, these differences may result in significant differences in exposure assessments. Otherwise, the 24-h time activity patterns of North Americans are remarkably similar and use of the combined data set for some exposure assessments may be feasible

N2 - OBJECTIVES: To evaluate the pharmacodynamic effects of an experimental (EXP) delivery of methylphenidate (MPH) in children with attention-deficit/hyperactivity disorder and to investigate the situational nature of effects in laboratory classroom and playground settings. METHOD: A "sipping" study methodology was used to deliver a bolus followed by small but increasing MPH doses as the EXP regimen. A randomized, double-blind crossover design was used to compare the EXP regimen to a thrice-daily (TID) regimen and a placebo (PLA) regimen. Measures of efficacy were obtained from a Motionlogger actigraph to quantify activity and from the Swanson, Kotkin, Agler, M-Flynn, and Pelham (SKAMP) rating scale to quantify two domains of behavior (attention and deportment). RESULTS: Compared with PLA, both EXP and TID delivery of MPH produced large, significant reductions in activity and inappropriate behavior in the classroom, but the two MPH regimens did not differ in onset or duration of effects across the day. The MPH effects were situationally dependent and were smaller for the playground than for the classroom settings. CONCLUSIONS: The findings of this "proof of concept" study support the efficacy of a continuous, ascending delivery of MPH. The situational effects of MPH provide support for the theory of selective effects of stimulants, dependent on the demands of the environment

N2 - **PROBLEM:** Two problems were addressed in this study. First, are daily injury diaries an effective means to gather information about children's unintentional injuries? Second, what are the circumstances of children's injuries as recorded through the diary method? **METHOD:** Two studies were conducted with a total of 172 children to describe the ecology of children's daily unintentional injuries. Families completed a daily diary for 14 days, describing the circumstances surrounding the injuries children experienced each day. **RESULTS:** Descriptive data is provided on the locations, causes, and types of injuries children incurred, as well as who was present when they were injured. Daily injury rate was modestly related to the number of major injuries children had incurred in their lifetimes. **DISCUSSION:** The diary methodology was an effective means to study the ecology of children's daily injuries. Children's injuries occur in a wide range of circumstances that can be quantified through diary techniques. **IMPACT ON INDUSTRY:** Data obtained from daily injury diaries may be useful in a variety of areas, including study of the etiology of childhood injury, design of interventions to prevent injury, and engineering of toys and playground equipment for children

N2 - One current theory of attention-deficit/hyperactivity disorder (ADHD) proposes that a primary deficit in behavioral inhibition gives rise to secondary deficits in 4 executive functions and motor control. To date, empirical support for this model is based primarily on laboratory-based cognitive methods. This study assessed behavioral inhibition and executive functioning in children with ADHD in 2 real-life contexts: videogames (motor-skill target game, cognitively demanding adventure game) and an outing at the zoo (route tasks). Participants were a community sample of 57 boys diagnosed with ADHD (20 inattentive, 37 combined type) and 57 normally developing control boys, matched individually for age and nonverbal IQ. Operationally defined measures of behavioral inhibition and specific executive functions were derived from these activities and assessed under contrasting conditions of low or high working memory and distractor loads. There were no group differences in basic motor skills on the target game, nor in terms of the ability to inhibit a prepotent or ongoing response in the adventure videogame. However, boys with ADHD exhibited more self-talk, more effortful response preparation, and completed fewer challenges in the latter videogame. Also, they manifested inhibition deficits in terms of interference control during the route task at the zoo and took longer to complete the tasks. Typically, these differences were greatest under conditions of high working memory and distractor loads. Findings from this study suggest that cognitive difficulties in ADHD may be context dependent and that ADHD is associated with deficits in some but not all aspects of behavioral inhibition

N2 - Exercise-induced bronchospasm (EIB) is widely used in epidemiological studies to investigate the prevalence of asthma. We aimed to determine seasonal variations in the prevalence of EIB in Ghanaian school children from urban-rich (UR), urban-poor (UP), and rural (R) schools. We have previously reported the prevalence of EIB in 9-16-year-old children to be 3.1% in the dry season, with UR children having a significantly higher prevalence of both EIB and atopy compared to UP or R children. In the current study, the prevalence of EIB was assessed in the same 1,095 children in the wet season (5 months following the initial study) using the same methodology. Exercise provocation consisted of free running outdoors for 6 min. In the wet season, 17/1,095 children [mean 1.55%, 95% confidence interval (CI): 0.91-2.47] had a positive response to exercise, compared to our previous report of 34 children (mean 3.1%, 95% CI: 2.15-4.32) with EIB in the dry season (dry vs. wet season, difference 1.55, 95% CI: 0.41-2.69). The proportion of children with a positive response to exercise in the UR school fell from 4.2% (25/599) to 1.3% (8/599) (difference 2.9, 95% CI: 1.2-4.5). In the wet season, there was no difference in the prevalence of EIB among the UR, UP, and R children. Only five of 1,095 subjects (mean 0.5%, 95% CI: 0.15-1.07) demonstrated EIB in both seasons. In conclusion, although exercise challenge remains a useful tool for determining asthma prevalence in epidemiological studies, seasonal variations in the pattern of responses may occur and the results should be interpreted with caution

N2 - Several studies among adult populations showed that an array of outdoor and indoor sources of particles emissions contributed to personal exposures to atmospheric particles, with tobacco smoke playing a prominent role (J. Expo. Anal. Environ. Epidemiol. 6 (1996) 57, Environ. Int. 24 (1998) 405, Arch. Environ. Health 54 (1999) 95). The Vesta study was carried out to assess the role of exposure to traffic emissions in the development of childhood asthma. In this paper, we present data on 68 children aged 8-14 years, living in the metropolitan areas of Paris (n = 30), Grenoble (n = 15) and Toulouse (n = 23), France, who continuously carried, over 48 h, a rucksack that contained an active PM_{2.5} sampler. Data about home indoor sources were collected by questionnaires. In parallel, daily concentrations of PM₁₀ in ambient air were monitored by local air quality networks. The contribution of indoor and outdoor factors to personal exposures was assessed using multiple linear regression models. Average personal exposure across all children was 23.7 microg/m³ (S.D. = 19.0 microg/m³), with local means ranging from 18.2 to 29.4 microg/m³. The final model explains 36% of the total between-subjects variance, with environmental tobacco smoke contributing for more than a third to this variability; presence of pets at home, proximity of the home to urban traffic emissions, and concomitant PM₁₀ ambient air concentrations were the other main determinants of personal exposure

N2 - OBJECTIVES: To determine risk factors for acquiring Burkholderia cepacia complex among patients with cystic fibrosis (CF). STUDY DESIGN: A case-control study was conducted with active surveillance for B cepacia complex colonization/infection among patients at 21 CF centers from April 1986 to March 1989 (study period). A case-patient was defined as any CF patient with B cepacia complex colonization for the first time during the study period. Control patients were patients with CF not B cepacia complex colonized during the study period. For each patient, a questionnaire was completed semiannually. RESULTS: In multivariate analyses, hospitalization for pulmonary exacerbations, living with a B cepacia complex-positive person, attending a CF summer camp, and direct contact with a B cepacia complex-colonized CF person outside of camp and home were associated with B cepacia complex acquisition. Receiving antimicrobial aerosol therapy or cleaning and drying a home-used nebulizer between uses were associated with a decrease in B cepacia complex acquisition. CONCLUSIONS: Numerous factors inside and outside the health care setting are associated with person-to-person transmission of B cepacia complex among patients with CF. Prevention programs should reduce direct or indirect contact between noncolonized and B cepacia complex-colonized/infected patients with CF

N2 - The objective was to evaluate the effects of therapeutic dietary supplements and drugs on cognitive function in subjects with Down syndrome. The study design was a systematic review of randomized controlled trials of dietary supplements and/or drugs reporting any assessment of cognitive function in subjects with Down syndrome. Eleven trials were identified with 373 randomized participants. None of the trials reported cognitive enhancing effect in subjects with Down syndrome. Meta-analysis was not conducted due to the heterogeneous nature of the population, interventions and outcome measures used. Overall, the quality of the trials was poor with few subjects and generally inadequate allocation concealment of the treatments given. This comprehensive systematic review provides no positive evidence that any combination of drugs, vitamins and minerals enhance either cognitive function or psychomotor development in people with Down syndrome. However, because of the small number of subjects involved and the overall unsatisfactory quality of the trials, an effect cannot be excluded at this point. At present there is no justification for the use of such regimes outside the context of large well designed trials. Parents of children with Down syndrome should be actively discouraged from giving these 'miracle drugs' to their children. [References: 36]

N2 - This report is the second part of a study on the nutrition of urban schoolchildren in the city of Manila; the first part was on nutritional status. The primary purpose of the study was to gather data that will assist authorities in planning and implementing nutrition education programs focused on the growing problem of obesity and overweight in children. The study included 1,208 children 8 to 10 years of age, who were randomly selected from all public and private schools in the city of Manila. Data on the children's dietary and physical activity patterns, together with information on nutrition-related knowledge, attitudes, and preferences of the children and their parents, were gathered by interviews and self-administered questionnaires. There were distinct differences in dietary and physical activity patterns between the two groups of children. Children from private schools, who are generally of higher socioeconomic status than those from public schools, tended to consume more total food, more animal foods, fats, and oils, and more beverages, resulting in higher intakes of calories, protein, iron, and vitamin A than public schoolchildren. Moreover, children from private schools were apparently less physically active, were more likely to be driven to school instead of walking, and were more likely to prefer television and computer games over outdoor games. These differences agree with an earlier report on the nutritional status of the children as determined by anthropometry, which showed a higher proportion of overnutrition and a lower proportion of undernutrition among private schoolchildren than among

public schoolchildren. Although the emphasis in public schools should be on prevention and control of undernutrition in children, private schools should begin to look at the emerging problem of overnutrition and the role of physical activity programs in the health of children. The information on the knowledge, attitudes, and preferences of the children and their parents showed that parents or guardians, teachers, and television influence the nutritional practices of schoolchildren. These groups should therefore be the major targets for nutrition education programs meant to improve the nutrition and health of schoolchildren

N2 - Maxima of hourly data from outdoor monitors may capture adverse effects of outdoor particulate matter (PM) exposures in asthmatic children better than do 24-hr PM averages, which form the basis of current regulations in the United States. Also, asthmatic children on anti-inflammatory medications may be protected against the proinflammatory effects of air pollutants and aeroallergens. We examined strengths of pollutant associations with asthma symptoms between subgroups of asthmatic children who were on versus not on regularly scheduled anti-inflammatory medications, and tested associations for different particle averaging times. This is a daily panel study of 22 asthmatic children (9-19 years of age) followed March through April 1996 (1,248 person-days). They lived in nonsmoking households in a semirural area of Southern California within the air inversion mixing zone (range, 1,200-2,100 feet) with transported air pollution from urban areas of Southern California. The dependent variable derived from diary ordinal scores is episodes of asthma symptoms that interfered with daily activities. Minimum to 90th-percentile levels of exposures at the outdoor monitoring site were 12-63 microg/m³ for 1-hr PM < 10 microm in aerodynamic diameter (PM(10)); 8-46 microg/m³ for 8-hr PM(10); 7-32 microg/m³ for 24-hr PM(10); 45-88 ppb for 1-hr O₃; 6-26 ppb for 8-hr NO₂; 70-4,714 particles/m³ for 12-hr daytime fungi; and 12-744 particles/m³ for 24-hr pollen. Data were analyzed with generalized estimating equations controlling for autocorrelation. There was no confounding by weather, day of week, or linear time trend. Associations were notably stronger in 12 asthmatic children who were not taking anti-inflammatory medications versus 10 subjects who were. Odds ratios (95% confidence intervals) for asthma episodes in relation to lag 0 minimum to 90th-percentile pollutant changes were, respectively, 1-hr maximum PM(10), 1.92 (1.22-3.02) versus 0.96 (0.25-3.69); 8-hr maximum PM(10), 1.68 (0.91-3.09) versus 0.75 (0.18-3.04); 24-hr average PM(10), 1.35 (0.82-2.22) versus 0.80 (0.24-2.69); 1-hr maximum O₃, 1.28 (0.75-2.17) versus 0.76 (0.24-2.44); 8-hr maximum NO₂, 1.91 (1.07-3.39) versus 1.08 (0.30-3.93); 12-hr fungi, 1.89 (1.24-2.89) versus 0.90 (0.35-2.30); 24-hr pollen, 1.90 (0.99-3.67) versus 0.85 (0.18-3.91). Pollutant associations were stronger during respiratory infections in subjects not on anti-inflammatory medications. Although lag 0 1-hr maximum PM(10) showed the strongest association, the most robust associations were for lag 0 and 3-day moving averages (lags 0-2) of 8-hr maximum and 24-hr mean PM(10) in sensitivity analyses testing for thresholds. Most pollutant effects were largely driven by concentrations in the upper quintile. The divergence of exposure-response relationships by anti-inflammatory medication use is consistent with experimental data on inflammatory mechanisms of airborne pollutants and allergens

N2 - A four-year-old boy received 30 sessions of radiotherapy, at a rate of one session daily for five days every week, under anesthesia with midazolam and propofol in spontaneous ventilation. Monitoring was by pulse oximetry and capnography; no adverse events were recorded. The presence of an anesthesiologist during diagnostic and therapeutic procedures outside the operating room is essential, given that lack of cooperation can make the procedure difficult or impossible to perform. Radiotherapy under anesthesia is a special case because it is scheduled daily, and care must be taken to interfere as little as possible with a child's meals or other activities

N2 - **BACKGROUND:** In early life, the innate immune system can recognize both viable and nonviable parts of microorganisms. Immune activation may direct the immune response, thus conferring tolerance to allergens such as animal dander or tree and grass pollen. **METHODS:** Parents of children who were 6 to 13 years of age and were living in rural areas of Germany, Austria, or Switzerland where there were both farming and nonfarming households completed a standardized questionnaire on asthma and hay fever. Blood samples were obtained from the children and tested for atopic sensitization; peripheral-blood leukocytes were also harvested from the samples for testing. The levels of endotoxin in the bedding used by these children were examined in relation to clinical findings and to the cytokine-production profiles of peripheral-blood leukocytes that had been stimulated with lipopolysaccharide and staphylococcal enterotoxin B. Complete data were available for 812 children. **RESULTS:** Endotoxin levels in samples of dust from the child's mattress were inversely related to the occurrence of hay fever, atopic asthma, and atopic sensitization. Nonatopic wheeze was not significantly associated with the endotoxin level. Cytokine production by leukocytes (production of tumor necrosis factor alpha, interferon-gamma, interleukin-10, and interleukin-12) was inversely related to the endotoxin level in the bedding, indicating a marked down-regulation of immune responses in exposed children. **CONCLUSIONS:** A subject's environmental exposure to endotoxin may have a crucial role in the development of tolerance to ubiquitous allergens found in natural environments. N2 - **OBJECTIVE:** To implement a planned nutrition education program aiming to promote healthy eating and consumption of a variety of foods in a residential camp setting for Australian girls aged 9-15 years. **METHODS:** 1,600 girls attending a seven-day residential camp in Queensland (2000) participated in a program involving the provision of healthy, tasty foods based on the Australian Dietary Guidelines for Children and Adolescents and a nutrition education package for use at the camp restaurants each evening that included nutrition information together with individual 'passport booklets involving puzzles and questions with incentives for completion. Process and impact evaluations were conducted by surveying a sample of participants using questionnaires and focus groups. **RESULTS:** Of those surveyed, 77% felt they had learned something from the health promotion material; 94% said they had changed their eating habits to include more core food groups during the camp, with more than 40% stating they had increased vegetable consumption compared with their usual intake. However, approximately 60% of campers were apparently unaware of the incentives offered and less than 30% demonstrated completion of their passports. **CONCLUSIONS:** Barriers to the involvement of this target group in the health promotion activities need to be explored further. Involvement and training of key personnel is suggested to ensure consistent implementation and encouragement for all participants. Long-term behaviour changes outside the camp environment should also be assessed in any future programs. **Implications:** Using residential camp settings to target children is an innovative strategy for nutrition education. Integration of such strategies into longer time frame programs may benefit participants and improve effectiveness of nutrition education programs aimed at this group

N2 - **OBJECTIVES:** To explore the immediate pre-crash activities and the routine traffic exposure (street crossing and play) in a sample of urban children struck by automobiles. In particular, the traffic exposure of children who were struck while playing was compared with that of those struck while crossing streets. **DESIGN:** Cross sectional survey. **SETTING:** Urban pediatric emergency department. **PATIENTS:** A total of 139 children ages 4-15 years evaluated for acute injuries resulting from pedestrian-motor vehicle collisions during a 14 month period. **MAIN OUTCOME MEASURES:** Sites of outdoor play, daily time in outdoor play, weekly number of street crossings, pre-crash circumstance (play v walking). **RESULTS:** Altogether 39% of the children routinely used the street and 64% routinely used the sidewalks as play areas. The median number of street crossings per week per child was 27. There were no differences in exposures for the 29% who were hit while playing compared with the 71% who were hit while walking. Although 84% of the children walked to or from school at least one day per week, only 15% of the children were struck while on the school walking trip. The remainder were injured either while playing outdoors or while walking to other places. **CONCLUSIONS:** Urban children who are victims of pedestrian crashes have a high level of traffic exposure from a variety of circumstances related to their routine outdoor playing and street crossing activities. The distributions of traffic exposures were similar across the sample, indicating that the sample as a whole had high traffic exposure,

regardless of the children's activity preceding the crash. Future pedestrian injury programs should address the pervasive nature of children's exposure to traffic during their routine outdoor activities

N2 - BACKGROUND: House dust mite (HDM) allergen might induce and maintain atopic dermatitis (AD). Reduction of allergen load by applying encasings might improve the clinical symptoms of AD. OBJECTIVE: We sought to investigate, in a randomized, double-blind, placebo-controlled study, whether reducing HDM allergen levels by using mattress, duvet, and pillow encasings for 12 months will result in improvement in AD symptoms. METHODS: Patients with AD (8-50 years old and allergic to HDM), having a Leicester sign score (a dermatitis score) of at least 1% extent and a severity score of 6 points or greater, were randomly allocated to an active (n = 45) or a placebo allergen-avoidance group (n = 41). Avoidance measures consisted of applying HDM-impermeable encasings for mattresses, pillows, and duvets for the active treatment group and cotton encasings for the placebo group. Effect on allergen concentrations (Der p 1 and Der p 1 plus Der f 1), Leicester sign score extent and severity, visual analogue scale scores for itching and sleeplessness, intradermal test results, atopy patch test results, total serum IgE levels, anti-Der p 1-specific IgE levels, and total blood eosinophil counts were studied. RESULTS: The active encasings reduced the Der p 1 allergen concentration in the mattress after 12 months with a factor 2.1 (P = .007) and the Der p 1 plus Der f 1 allergen concentration with a factor of 2.5 (P = .005); no significant change in allergen concentrations in mattresses was seen in the placebo group. Although the decrease in allergen load was significant, no differences in treatment-induced changes were seen between the placebo and active groups. CONCLUSIONS: Use of HDM-impermeable encasings resulted in a significant decrease in Der p 1 and Der p 1 plus Der f 1 allergen concentrations. However, this reduction in allergen load did not result in significant changes in clinical parameters between the groups. Reduction of allergens in other environments (work, school, and outdoors) might be equally important in improving symptoms of AD

N2 - Environmental factors are usually considered as risk factors for increase of asthma prevalence. They may act isolately but are frequently associated. They act either directly by inducing asthma or more likely by increasing allergenic sensitization. Geographic situation is a well known risk factor. Important differences are noted between countries. The western lifestyle is evocated, including type of alimentation, small size of siblings, increased allergen exposure in houses. Intrauterine environment may play a role, particularly tobacco smoke during pregnancy and its respiratory effects on infant. Maternal allergenic exposure during pregnancy is an important factor because of maternofetal immunologic interactions. Outdoor pollution acts by enhancing bronchial responsiveness, allergenic sensitization and worsening respiratory diseases. Its effect is probably less important in infants and small children who are living indoor most of the time. Infections seems to have a complex action. Some virus, including respiratory syncytial virus, act to induce asthma or sensitization. Other type of infections (viral ou microbial) have a protector effect. Exposure to tobacco smoke, particularly maternal smoking, is identified in all studies, as one of the most important factors to be considered in childhood asthma. Exposure to allergen increases the risk of sensitization. Its direct responsibility to induce asthma is not established. Some of recent studies are suggesting the concept of a protective effect of early exposure. As far as preventive intervention is concerned, the recognition of these factors is important to limit the prevalence of childhood asthma. [References: 62]

N2 - INTRODUCTION: Adherence to highly active antiretroviral therapy is required to obtain an optimal long term virologic response rate of HIV-1-infected children. Plasma concentrations of protease inhibitors (PIs) outside the limits of the reference values indicate nonadherence to antiretroviral therapy in adults. We studied during a 2-year follow-up period routinely taken plasma protease inhibitor concentrations to assess adherence to antiretroviral therapy in HIV-1-infected children. **METHODS:** In 40 children (ages 3 months to 18 years) blood samples were taken at regular outpatient visits every 12 weeks after the start of highly active antiretroviral therapy and analyzed for plasma concentrations of indinavir or nelfinavir by high performance liquid chromatography and for plasma HIV-1 RNA load. The percentage of samples fulfilling the criteria for adherence was assessed for each child by three methods. For each sample a concentration ratio was calculated by dividing the concentration in that sample by the time-adjusted population value. According to Method 1 concentration ratios below or above concentration ratio limits (CORALs) of population data obtained in adults were highly indicative of nonadherence. Because many children have high PI levels, Method 2 evaluated plasma samples of PIs with only the lower CORAL. According to Method 3 only children with plasma samples below the limit of quantification (0.04 mg/l) were considered noncompliant. Differences in adherence rate between virologic responders and virologic nonresponders and between adherence rates and the two protease inhibitors were analyzed. The cumulative incidence of HIV-1 RNA levels >500 copies/ml in children was calculated. **RESULTS:** Thirty-one children started treatment with indinavir, and nine children started treatment with nelfinavir. The median adherence rates for indinavir as determined by methods 1, 2 and 3 were 54% [interquartile range (IQR), 25 to 69%], 67% (IQR 50 to 92%) and 80% (IQR 63 to 100%), respectively. For nelfinavir median adherence rates of 60% (IQR 39 to 75%), 100% (IQR 67 to 100%) and 100% (IQR 100 to 100%) were observed. Adherence rates calculated with Method 2 were significantly higher in virologic responders ($p = 0.04$). Adherence rates calculated with Methods 2 and 3 were significantly lower in children using indinavir compared with those using nelfinavir ($p = 0.02$ and $p = 0.02$, respectively). **CONCLUSION:** Calculation of adherence rates using the lower limit of CORALs of indinavir or nelfinavir in children may be a useful measurement for the assessment of nonadherence to antiretroviral therapy in children

N2 - Environmental suspended particulate matter and NO2 are possible factors causing chronic obstructive pulmonary diseases. These and other pollutants are monitored at the National Ambient Air Pollution Monitoring Stations and local monitoring stations. Environmental NO2 concentrations in large cities exceed the Japanese Environmental Quality Standards (JEQS); in particular, more than 30% of the Roadside Air Pollution Monitoring Stations (RAMS) do not achieve JEQS. To evaluate the exposure levels to environmental NO2 and its health effects, the data from the monitoring stations are useful. However, there are few reports on the

relationships between these data and the exposure level in daily life. In this study, environmental NO₂ concentrations in homes and its exposure levels were investigated by using passive samplers. Two areas along main roads in the south and north of metropolitan Tokyo were selected and about 150 junior high school students and their family members took part in the study. The investigation was conducted five times seasonally, 3 days each, from February 1998 to January 1999. The residence of each subject was plotted on a map, and the distance from the main road was entered on the same map. Environmental NO₂ was measured outside of the house and indoors, that is, living room, kitchen, bedroom, and student's room. The average NO₂ concentration of outdoors was within JEQS, and the highest value was 52.9 ppb. There was a tendency for outdoor NO₂ concentrations to decrease with distance from the roadside, but the NO₂ concentration differences between the roadside and the site far from the roadside were less than 10 ppb. The average outdoor NO₂ concentrations and the value obtained at RAMS are slightly correlated, but not significant. The stations' data showed about 10 ppb higher values than the average outdoor concentrations obtained at each house. NO₂ concentrations in living rooms based on the distance from the main road and NO₂ exposure levels in daily life of students and family members were also investigated. This study clearly showed that in wintertime we are highly exposed to NO₂ emitted from many types of heaters such as kerosene heater, and the family members' study suggested that the indoor NO₂ levels were similar to the personal exposure levels in all seasons

N2 - OBJECTIVES: To examine in detail the activation of the primary (SI) and secondary (SII) somatosensory cortex in CLN5, the Finnish variant of late infantile neuronal ceroid lipofuscinoses (NCL). METHODS: Somatary evoked magnetic fields were recorded with a 122-channel planar gradiometer in response to median nerve stimulation in 5 CLN5 patients (aged 8.8-16.7 years) and in 10 healthy age-matched controls. RESULTS: The first two responses from contralateral SI, N20m and P35m, were 6-20 times stronger in the patients than in the controls. The morphology of the subsequent deflections from SI was abnormal in the patients: a prominent N45m was detected, while the normally present P60m deflection was missing. In 4 patients the contra- and in two patients the ipsilateral SII responses were also enlarged. Furthermore, the SII activation was detected at shorter latency in patients than in controls. CONCLUSIONS: At SI, CLN5 is associated with a selective enhancement of the early cortical responses. We propose that the enlargement of N20m most likely reflects increased synchronous input from thalamus, whereas the altered morphology of the following responses may reflect defective interneuronal inhibition at the cortex. The enlargement of SII responses shows that the imbalance between excitation and inhibition in CLN5 extends outside the primary somatosensory areas

N2 - UNLABELLED: The aim of this case-control study was to identify and quantify risk factors of injuries in playgrounds, where children spend an increasing amount of time in developed countries. The study took place in Greater Athens during 1999. A continuous Emergency Departments Injury Surveillance System (EDISS) of hospitals that cover about 30% of the children's time at risk in Greater Athens identified 777 injuries in public and private playgrounds out of a total of 17 497 injuries. Public playgrounds differ from private ones, because the former generally have more equipment, usually of greater height, with less resilient surfaces, and supervision relies mainly on parents or guardians. Patterns of type of playground use were assessed in a sample of 294 children from the same study base who served as a control group in a hierarchical case-control design. The annual incidence of playground injuries in Greater Athens was about 7 in 1000 among boys and 4 in 1000 among girls, with a 2.2 times higher risk for an injury in public than in private playgrounds (95% confidence interval 1.61-3.07). Children in public vs private playgrounds had a statistically significant eight times higher odds for concussion and six times higher for open wounds, whereas the odds for long bone fractures were four and for other fractures two; swings, slides and seesaws were the types of equipment most frequently associated with injuries. It was further shown that supervision of children was suboptimal (< 60%) in both public and private playgrounds, and children in private playgrounds sustained an unduly high frequency of sprain/dislocation injuries (odds ratio 1.75) because they were encouraged to play bare-footed. CONCLUSION: Close to 50% of playground injuries could be prevented by structural and equipment changes, while further reduction could be accomplished through simple measures including closer supervision and encouraging children to wear proper shoes and use protective equipment whenever necessary

N2 - **BACKGROUND:** It is currently fashionable to consider atopic dermatitis (AD), like other inflammatory dermatoses, as immunologic in pathogenesis ("inside-outside" hypothesis). Accordingly, topical glucocorticoids and other immunosuppressive agents are mainstays of therapy, but the risk of toxicity from these agents is not insignificant, particularly in children. Alternatively, because stratum corneum (SC) permeability barrier function is also abnormal in AD, it has been hypothesized that the barrier abnormality could drive disease activity. Yet commonly used emollients and moisturizers do not correct the SC ceramide deficiency, the putative cause of the barrier abnormality. **OBJECTIVES:** We assessed the efficacy of a newly developed, ceramide-dominant, physiologic lipid-based emollient, when substituted for currently used moisturizers, in 24 children who were also receiving standard therapy for stubborn-to-recalcitrant AD. **METHODS:** All subjects continued prior therapy (eg, topical tacrolimus or corticosteroids), only substituting the barrier repair emollient for their prior moisturizer. Follow-up evaluations, which included severity scoring of atopic dermatitis (SCORAD) values and several biophysical measures of SC function, were performed every 3 weeks for 20 to 21 weeks. **RESULTS:** SCORAD values improved significantly in 22 of 24 patients by 3 weeks, with further progressive improvement in all patients between 6 and 20 or 21 weeks. Transepidermal water loss levels (TEWL), which were elevated over involved and uninvolved areas at entry, decreased in parallel with SCORAD scores and continued to decline even after SCORAD scores plateaued. Both SC integrity (cohesion) and hydration also improved slowly but significantly during therapy. Finally, the ultrastructure of the SC, treated with ceramide-dominant emollient,

revealed extracellular lamellar membranes, which were largely absent in baseline SC samples. CONCLUSION: These studies suggest that (1) a ceramide-dominant, barrier repair emollient represents a safe, useful adjunct to the treatment of childhood AD and (2) TEWL is at least as sensitive an indicator of fluctuations in AD disease activity as are SCORAD values. These studies support the outside-inside hypothesis as a component of pathogenesis in AD and other inflammatory dermatoses that are accompanied by a barrier abnormality

N2 - CONTEXT: Preadolescent friendships and early teenage dating relationships have implications for adolescent sexual initiation that may differ by race and gender. METHODS: Data on participants in the National Longitudinal Survey of Youth and their children are used to profile friendship and dating patterns among a

sample of youth born to relatively young mothers. Logistic regression analyses examine whether these patterns predict early sexual initiation, and whether there are differences associated with gender and race. **RESULTS:** As youth moved from late childhood to mid-adolescence, they shifted from having almost exclusively same-sex, same-grade friends to having more relationships with persons who are of the opposite sex and older. By ages 15-16, 34% had had sexual intercourse; the proportion was significantly higher among blacks (45%) than among others (31%). Most adolescents reported neither frequent dating nor a steady partner by ages 15-16, although the prevalence of such reports was related to friendship patterns in late childhood. Twelve percent of youth who initiated sex in early adolescence did so outside of a dating relationship. For most subgroups examined, the odds of initiating intercourse during early adolescence were associated with going steady, but not with frequency of dating. **CONCLUSIONS:** Prior social networking is an important element in predicting early sexual activity. Overall, youth whose mothers gave birth at young ages remain sexually inexperienced into middle adolescence, but certain subgroups are more likely than others to initiate early sexual activity

N2 - **BACKGROUND:** Alarming secular declines in physical activity (PA) have been observed among youth over the last decade. A better understanding of the predictors of these declines is crucial to identifying those

children most at risk and to developing interventions that target youth before the onset of decline. This report identifies 1- and 2-year predictors of decline in PA among fourth- and fifth-grade students from inner-city neighborhoods in Montreal, Canada. **METHODS:** Data for this study were collected in classroom questionnaires each May/June from 1993 to 1997. Analyses for this paper were completed in 2001. The cohort included active (at least one PA per day) children with baseline and 1-year (n =1873) or 2-year (n =509) follow-up data. **RESULTS:** In boys, 1-year predictors of decline to an inactive status identified in generalized estimating equations analysis included moderate (vs high) baseline PA (odds ratio [OR]=1.66, 95% confidence interval [CI]=0.91-3.05); low PA self-efficacy (OR=1.67, 95% CI=1.03-2.71); born outside Canada (OR=2.13; 95% CI=1.31-3.46); Asian origin (OR=1.81; 95% CI=1.03-3.16) and no participation in school teams (OR=1.81, 95% CI=0.93-3.55). In girls, these 1-year predictors included moderate PA (OR=1.91, 95% CI=1.10-3.32); low PA self-efficacy (OR=1.70, 95% CI=1.15-2.49); watching four or more TV programs per day (OR=1.40, 95% CI=0.97-2.02); mother unemployed (OR=1.54, 95% CI=1.07-2.23); and grade five (vs grade four) (OR=1.35, 95% CI=0.94-1.93). Two-year predictors in boys included moderate baseline PA (OR=2.52, 95% CI=0.84-7.50), and born outside Canada (OR=1.96, 95% CI=0.91-4.20). In girls, these 2-year predictors included moderate baseline PA (OR=2.75, 95% CI=1.01-7.49); no participation in school teams (OR=2.14, 95% CI=0.92-5.00); watching four or more TV programs per day (OR=1.93, 95% CI=0.99-3.74); and born outside Canada (OR=1.85, 95% CI=0.96-3.55). **CONCLUSIONS:** Reduced TV viewing among girls and increased participation in school sports teams in boys and girls may prevent declines in PA among pre-adolescents from inner-city neighborhoods

N2 - Only a small fraction of people with epilepsy in developing countries has access to medical facilities. Even with effective treatment, their psychosocial needs are often overlooked in the absence of obvious disability. In rural areas, community-based rehabilitation programmes assist in the integration of people with disabilities into employment and the community. However, the functional impairment associated with epilepsy is not well recognised in intervention programmes in developing countries. We report, for the first time, the social activities of children with epilepsy and their peers in rural India. We employed a cross-sectional design using a new age and sex-specific social activity questionnaire. Population screening in the context of a community-based rehabilitation programme identified 88 children with epilepsy and 250 randomly selected controls. A trained interviewer administered the questionnaire to mothers in Bengali. Girls' activities were principally domestic, whilst boys' were mostly outdoors and involved peers. All groups of children with epilepsy had significant social deficits, equally for boys and girls in the age range from 2 to 18 years ($p < 0.05$). Boys with epilepsy had limited peer group activities, and parents conferred fewer responsibilities to school age and adolescent children compared to controls. The nature and degree of deficits were beyond the constraints imposed by neurological impairment. Our findings in pre-schoolers were consistent with parental attitudes of overprotection found in previous research. We conclude that social integration needs active and early promotion among children with epilepsy. The assessment of remediable risk and protective factors in the family and community is an important practical area for research in community-based rehabilitation

N2 - An equation has been developed to reduce the error in predicting energy expenditure (EE) from heart rate (HR) monitoring, by correcting for climate-related HR increases. To evaluate the effects of such a correction in a "real life" situation, a group of 9- to 14-year-old obese boys [mean (SD) 36.6 (3.3)% body fat; n=14] was monitored for 6 days during the summertime. An activity interview was taken daily. During times of outdoor activities, measurements of HR were corrected for the influence of ambient temperature (T) using the aforementioned equation. Time spent outdoors was 196.7 (21.1) min/day at a T of 17-34 degrees C. Temperature correction reduced the time spent at HR>140 beats/min and >160 beats/min by 20-25% during outdoor activity. Estimated outdoor EE corrected for the influence of temperature was 2.46 (2.37) MJ; the uncorrected value was 2.68 (2.45) MJ. The respective values for the waking hours and over 24 h were 7.34 (2.77) MJ versus 7.55 (2.81) MJ and 10.83 (2.72) MJ versus 11.05 (2.77) MJ, respectively. The excessive HR measured in a warm summer climate could explain 8.8 (3.5)% of EE during outdoor activities, which resulted in a 2.9 (2.7)% overestimate of EE during daily waking hours and a 1.9 (1.8)% overestimate of the total 24-h EE. Thus, the influence of temperature on HR may, at least in part, explain the previously reported overestimate of EE calculated using the HR/oxygen consumption relationship versus that calculated using the doubly labelled water method. We recommend correcting HR for the influence of climate in studies using HR profiles to determine outdoor physical activity levels and/or EE during summertime. However, when total daily EE or waking hours EE is assessed, even in subjects who are engaging in long intervals of outdoor play, the temperature correction required is minimal

N2 - BACKGROUND: Individuals with low activity of a key metabolic enzyme, thiopurine methyl transferase (TPMT), are more susceptible to azathioprine-induced myelosuppression. Aim: To determine the pattern of use of TPMT activity estimation, with respect to azathioprine use, by medical practitioners in the UK. DESIGN: Retrospective analysis of assay use. METHODS: We analysed all test results (n=3291), and patient and practitioner details, from inception of TPMT assay in 1990 to the end of December 2000, held at the Purine Research Laboratory, Guy's Hospital, London. Patient details were anonymized. Repeat analyses and requests from outside the UK were excluded. RESULTS: The male:female ratio was approximately equal and the mean age was 46.6 (range 0.5-97) years. Thirteen different medical specialities requested assays; Dermatology and Gastroenterology were the most frequent users, together accounting for 86% of requests. The numbers of centres requesting the assay varied widely both within and between different specialities. Some 80% of individuals had normal TPMT activity, 9% enzymic activity above normal, and 10% low activity. Fifteen had no detectable enzymic activity: 0.45% (1:220) of the study population. DISCUSSION: This incidence of undetectable enzyme activity is significantly higher than the previously reported level of 1:300 derived from smaller studies, and makes the economics of screening more attractive

N2 - OBJECTIVE: To compare the distribution and observation of helmet use patterns among 4 common childhood leisure activities-bicycle riding, in-line skating, skateboarding, and scooter riding-in a setting with no helmet use legislation. DESIGN: A cross-sectional, unobtrusive, direct observation of children engaged in 1 of the 4 activities was conducted during an 8-week period. SETTING: Eight communities of at least 1000 persons each in a 2-county Central Texas area. MAIN OUTCOME MEASURES: Prevalence of activity, helmet use, and correct helmet use. RESULTS: Of 841 children observed, most rode bicycles (74.8%); only 4.2% rode skateboards. They included 127 children estimated to be younger than 6 years (15.1%) and 495 estimated to be aged between 6 and 12 years (58.9%). Most were male (67.3%) and observed in urban communities (61.7%). The locations of highest concentration of the 4 activities were minor streets for bicycle riding, playgrounds for in-line skating, and sidewalks for skateboarding and scooter riding. The rate of overall helmet use was 13.6% and did not vary significantly by activity: in-line skating, 18.2%; skateboarding, 14.3%; bicycle riding, 13.5%; and scooter riding, 11.5%. However, the observed correct helmet use prevalence of 72.6% differed significantly by activity. Most children riding scooters wore their helmets incorrectly. Helmet use was positively associated with helmet use by accompanying children and/or adults. CONCLUSIONS: While bicycle riding was the most popular activity observed, helmet use was most prevalent among in-line skaters and least prevalent among scooter riders, many of whom also wore them incorrectly. Observed helmet use was influenced mostly by adult and peer helmet use, indicating that public education and interventions should target children and their parents as well as scooter riders

N2 - Children's aggressive behavior and reading difficulties during early elementary school years are risk factors for adolescent problem behaviors such as delinquency, academic failure, and substance use. This study determined if a comprehensive intervention that was designed to address both of these risk factors could affect teacher, parent, and observer measures of internalizing and externalizing problems. European American (n = 116) and Hispanic (n = 168) children from 3 communities who were selected for aggressiveness or reading difficulties were randomly assigned to an intervention or no-intervention control condition. Intervention families received parent training, and their children received social behavior interventions and supplementary reading instruction over a 2-year period. At the end of intervention, playground observations showed that treated children displayed less negative social behavior than controls. At the end of a 1-year follow-up, treated children showed less teacher-rated internalizing and less parent-rated coercive and antisocial behavior than controls. The study's limitations and implications for prevention are discussed

N2 - Nitrogen oxides (NO(x)) are ubiquitous pollutants in outdoor and indoor air. However, epidemiologic studies that evaluate health effects associated with NO(x) commonly rely upon outdoor concentrations of NO(x), nitrogen dioxide (NO(2)), or residence characteristics as surrogates for personal exposure. In this study, personal exposures (48 h) and corresponding indoor and outdoor concentrations of nitric oxide (NO), NO(2), and NO(x) were measured (July-September) in 39 adults and 9 children from 23 households in Richmond, Virginia, using Ogawa passive NO(x) monitors. Demographic, time-activity patterns, and household data were collected by questionnaire and used to develop exposure prediction models. Adults had higher NO(2), NO, and NO(x) exposures (means: 16, 63, and 79 ppb, respectively) than children (13, 49, and 62 ppb). Measurements taken in bedrooms (18, 57, and 75 ppb) and living rooms (19, 65, and 84 ppb) surpassed measurements taken outdoors (15, 21, and 36 ppb). In indoor locations, NO(x) concentrations were influenced largely by NO, and consequently, personal exposure prediction models for NO(x) were reflective of models for NO. Statistical models that best predicted personal exposures included indoor measurements; outdoor measurements contributed relatively little to personal exposure. Close to 70% of the variation in personal NO(2) and NO(x) exposure was explained by two variable models (bedroom NO(2) and time spent in other indoor locations; bedroom NO(x) and time spent in kitchen). Given appropriate resources, measurement error in epidemiologic

studies can be reduced significantly with the use of personal exposure measurements or prediction models developed from indoor measurements and survey data

N2 - **OBJECTIVES:** The purpose of the study was to evaluate the magnitude of environmental lead contamination in the downtown area of Miami. **METHODS:** Lead inspections took place at 121 homes in Little Haiti and Liberty City and involved the collection of representative samples from floors, window wells, tap water, soil and air. Community health workers (CHWs) trained in interview and safety techniques went from door to door to enlist participation. On-site investigations were tailored to areas most utilized by children under the age of 6 years. The presence of lead-containing paint was also investigated in situ via X-ray fluorescence (XRF) analysis. **RESULTS:** Of the sampling areas, the window wells area had the most abundant occurrence of lead. On analysis, 24% of sites returned window well samples with lead levels above Department of Housing and Urban Development (HUD) guidelines. Of the soil samples, the playgrounds around the house had the highest concentration of lead. Soil sampling demonstrated that 27.5% of sites returned samples with lead levels (400 to 1600 ppm) in excess of HUD/Environmental Protection Agency (EPA) standards. Positive XRF readings in one or more components were returned by 18% of sites. **CONCLUSIONS:** More than half of the houses in these two neighborhoods exhibited unacceptably high levels of lead dust and soil in areas where

children live and play. Limitations of this study did not allow the assessment of how many children in this area are affected. A more comprehensive study including other areas of Miami-Dade County with older housing stock is recommended

N2 - The risk of pedestrian injury during childhood in industrialised countries is decreasing in a trend that is related to exposure to traffic. Examining the differences between age groups and their behaviour provides an insight into exposure to risks. Using data for the period 1968-1998, we compared the changes in pedestrian mortality and morbidity in pre-school children (aged 0-6) with those of school-age children (aged 7-12). Pedestrian mortality and morbidity decreased in children of all ages in the early 1970s. However, after the mid-1970s, both mortality and morbidity continued to decrease only in pre-schoolers. In school-age children, mortality continued to decrease but morbidity did not change. These age-related differences in mortality and morbidity indicate that over the past 30 y the environment for child pedestrians did not become safer. Instead, some of the decrease in children's injuries was probably achieved at the expense of their outdoor activities. Efforts to protect children from vehicular traffic should focus on changing the outdoor environment rather than on restricting children's activities

N2 - **BACKGROUND:** Parental supervision is an important factor related to childhood injuries. However, little research has been done on; what outdoor activities children believe they are allowed or their parents allow them to do; parents' ideas about the age children can do activities, and the age they would allow their children to do them. This study described children's independent outdoor activities after-school, comparing age groups (school year 5 and 3), boys with girls, and the less socio-economically well off with the better off. **METHODS:** A cross-sectional study using questionnaires completed by 476 children aged seven and nine years and 471 parents in nine primary schools in Newcastle-upon-Tyne, England. **RESULTS:** Children reported they were permitted many outdoor activities such as cycling (78.8%), playing (78.6%) and roller skating in the street (62.7%). Parents of older children, boys, and more socio-economically deprived children were more likely than their comparison groups to allow children to do outdoor activities independently e.g. 34% of 9-year-olds were allowed to cross a road without an adult compared with 8% of 7-year-olds. Mostly, parents of boys and socio-economically deprived children, perceived children can do outdoor activities slightly younger than parents of girls and the socio-economically better off. **CONCLUSION:** Children and parents value and support children's independent outdoor activity. Differences in children's and parents' understanding of what activities are permissible and in their judgements about the appropriate age for children's independent activities, may partly underline variations by sex, age and socio-economic status in injury patterns

N2 - OBJECT: Neurofibromatosis Type 2 (NF2) has typically resulted in deafness after surgical removal of bilateral vestibular schwannomas (VSs). Cochlear implants are generally ineffective for this kind of deafness because of the loss of continuity in the auditory nerve after tumor removal. The first auditory brainstem implant

(ABI) in such a patient was performed in 1979 at the House Ear Institute, and this individual continues to benefit from electrical stimulation of the cochlear nucleus complex. In 1992, an advanced multichannel ABI was developed and a series of patients with NF2 received this implant to study the safety and efficacy of the device. METHODS: At the time of first- or second-side VS removal, patients received an eight-electrode array applied to the surface of the cochlear nucleus within the confines of the lateral recess of the fourth ventricle. The device was activated approximately 6 weeks after implantation, and patients were tested every 3 months for the 1st year after the initial stimulation, and annually thereafter. The protocol included a comprehensive battery of psychophysical and speech perception tests. CONCLUSIONS: The multichannel ABI proved to be effective and safe in providing useful auditory sensations in most patients with NF2. The ABI improved patients' ability to communicate compared with the lipreading-only condition, it allowed the detection and recognition of many environmental sounds, and in some cases it provided significant ability to understand speech by using just the sound from the ABI (with no lipreading cues). Its performance in most patients has continued to improve for up to 8 years after implantation

N2 - PURPOSE: To assess whether parents and children report the same information regarding children's near vision activities when given similar questionnaires. METHODS: Data from questionnaires administered to 406 children and their parents were analyzed to evaluate the agreement between parent and child reports. The questionnaires were completed during the 1994 testing of the Orinda Longitudinal Study of Myopia. Each child and parent was asked to categorize how often the child reads for pleasure. In addition, each subject was asked to estimate how many hours per week were spent in each of five visual activities. The weighted kappa statistic, paired t-tests, and polytomous logistic regression were used for analyses. RESULTS: A weighted kappa = 0.42 (moderate agreement) was found in the comparison of child-reported vs. parent-reported classification of reading. Agreement between parent- and child-reported number of hours spent doing homework (0.21), reading for pleasure (0.31), watching television (0.31), playing video games (0.31), and engaging in sports/outdoor activities (0.26) was fair for each activity. CONCLUSIONS: Although the results indicate fair to moderate levels of agreement, better methods of reporting near-work activities are needed for future myopia research

N2 - The objective of this study was to compare urban and suburban preschool and school age activities. A prospective survey using a convenience sample was conducted at one urban and one suburban primary care pediatric office. Questionnaires were completed for 66 urban preschool children, 70 suburban preschool children, 57 urban school age children and 61 suburban school age children during the school year. Also, questionnaires were completed for 63 suburban school age children during the summer. The suburban preschool children spent more time outdoors, were read to more frequently, visited the library more frequently and more often attended summer camp. The suburban school age children spent more time outdoors, more frequently participated in a community sport league and more often attended summer camp. The urban school age children watched more television or videos. During the summer, suburban school age children spent more time outdoors, while during the school year, suburban school age children used the library more frequently. Important differences exist between the activities of urban and suburban children in two practices in the New York metropolitan area. Pediatricians caring for urban children may have an important opportunity to promote participation in sports and educational activities

N2 - **BACKGROUND:** Melanoma, the most fatal form of skin cancer, is rising at a rate faster than that of all preventable cancers except lung cancer in the United States. Childhood exposure to ultraviolet (UV) light increases the risk for skin cancer as an adult; thus starting positive sun protection habits early may be key to reducing incidence. **METHODS:** We evaluated the US Environmental Protection Agency's SunWise School Program, a national, environmental education program for sun safety of children in primary and secondary schools (kindergarten through eighth grade). The program was evaluated with surveys administered to participating students. An identical 18-question, self-administered survey was completed by students (median age, 10 years) in the classroom before and immediately after the SunWise educational program. **RESULTS:** Surveys were completed by students in 40 schools before (pretests; n = 1894) and after the program was presented (post-tests; n = 1815). Significant improvement was noted for the 3 knowledge variables: appropriate type of sunscreen to be used for outdoor play, highest UV Index number, and need for hats and shirts outside. Intentions to play in the shade increased from 73% to 78% (P <.001), with more modest changes in intentions to use sunscreen. Attitudes regarding healthiness of a tan also decreased significantly. **CONCLUSIONS:** Brief, standardized sun protection education can be efficiently interwoven into school health education and result in improvements in knowledge and positive intentions for sun protection

N2 - **OBJECTIVE:** To assess quality of life after continent ileal reservoir diversion in children and adolescents. **MATERIAL AND METHODS:** Nine boys and 9 girls (10.8-18 years old at surgery) were operated with a Kock reservoir and followed for 5-12 years. They participated in an interview using a questionnaire based on the Swedish self-esteem inventory, "I think I am". The questionnaire consisted of 76 questions that covered medical, physical, psychological, social, body image and sexual aspects. **RESULTS:** Six of 18 patients had some difficulties on catheterization. Five complained of pain or bleeding during evacuation. Two patients had slight urinary leakage between evacuations and 6 had mucus secretion. Ten patients had diarrhea with different frequencies. Physical activities were not hampered by the operation in any patient. Instead, activities such as full day outside home, friend at home overnight, using all types of clothes, and participation in camps were increased in 8, 6, 5 and 5 patients, respectively. All patients but 2 had an excellent relation with friends and family members. More than half of patients had excellent positive self-esteem and body image and the rest had

very good self-esteem. However, some patients were concerned about how they looked and felt that life was unfair to them. CONCLUSIONS: The patients were satisfied with their operation. They were physically active and declared a positive perspective regarding self-esteem and body image. The medical problems related to the operation did not have any negative influence on the self-esteem or body image. The choice of the operation can only be determined on the basis of an attentive dialogue between surgeon, child and parents

N2 - An entomological and serological survey was performed in three localities of the Department of Concepcion, Province of Corrientes, Argentina in 1998 and 1999, to identify triatomines species involved in domestic and wild transmission of Chagas disease. Triatomines were collected by man/hour capture in 32 houses randomly selected and 44 nearby outdoor ecotopes. Trypanosoma cruzi infection in triatomines was assessed by direct microscopic observation (400x) of feces and polymerase chain reaction. Serological techniques used for people were Indirect Hemagglutination Test and Indirect Fluorescent Test. Triatomines were collected in 28.1% of the houses and 31.8% of the wild biotopes. Triatoma infestans (Klug 1834) was exclusively found indoors and T. cruzi infected 60% of them. Triatoma sordida (Stal 1859) was mainly found in extradomestic ecotopes where trypanosome infection rate reached 12.7%. Serological study of 98 local people showed that 29.6% were seroreactive; most of their houses were closed to wild biotopes colonized by T. sordida. Results indicate that there is an active T. infestans mediated transmission of Chagas disease in this zone that yields important human prevalence and that the populations of T. sordida in wild biotopes not only sustain the wild T. cruzi cycle but also represent an actual risk for people living in the area

N2 - AIMS: To examine sun protection among New Zealand children (ten years and under) at beaches and playgrounds. METHODS: In the summers of 1998, 1999 and 2000, observations were made of 753 children at selected beaches and playgrounds in Dunedin and Hawkes Bay to determine the extent of sun protection. Parents/carers were also interviewed about sun protection. RESULTS: Across most body sites, levels of protection were high. Clothing and SPF15+ sunscreen were used most often, while the use of shade was relatively low. About four in every ten parents/caregivers were aware of the UV index or burn-time. Level of sun protection among children at beaches was best predicted by parent/carer's own level of protection, the child's perceived susceptibility to burning, and being a preschooler. CONCLUSIONS: Observed levels of sun protection among the children were high and most likely reflected an increased awareness among parents and carers of the social acceptability of protective behaviours. Nevertheless, opportunities to seek shade were limited, and the provision of shade at beaches and playgrounds represents an important next step in a community wide approach to sun protection

N2 - An exposure study of children (aged 10-12 years) living in Santiago, Chile, was conducted. Personal, indoor and outdoor fine and inhalable particulate matter (< 2.5 µm in diameter, PM2.5 and < 10 microm in diameter, PM10, respectively), and nitrogen dioxide (NO2) were measured during pilot (N = 8) and main (N = 20) studies, which were conducted during the winters of 1998 and 1999, respectively. For the main study, personal, indoor and outdoor 24-h samples were collected for five consecutive days. Similar mean personal, indoor and outdoor PM2.5 concentrations (69.5, 68.5 and 68.1 microg/m³, respectively) were found. However, for coarse particles (calculated as the difference between measured PM10 and PM2.5, PM2.5-10), indoor and outdoor levels (35.4 and 47.4 microg/m³) were lower than their corresponding personal exposures (76.3 microg/m³). Indoor and outdoor NO2 concentrations were comparable (35.8 and 36.9 ppb) and higher than personal exposures (25.9 ppb). Very low ambient indoor and personal O3 levels were found, which were mostly below the method's limit of detection (LOD). Outdoor particles contributed significantly to indoor concentrations, with effective penetration efficiencies of 0.61 and 0.30 for PM2.5 and PM2.5-10, respectively. Personal exposures were strongly associated with indoor and outdoor concentrations for PM2.5, but weakly associated for PM2.5-10. For NO2, weak associations were obtained for indoor-outdoor and personal-outdoor relationships. This is probably a result of the presence of gas cooking stoves in all the homes. Median I/O, P/I and P/O ratios for PM2.5 were close to unity, and for NO2 they ranged between 0.64 and 0.95. These ratios were probably due to high ambient PM2.5 and NO2 levels in Santiago, which diminished the relative contribution of indoor sources and subjects' activities to indoor and personal PM2.5 and NO2 levels

N2 - Recognizing that most poor families are single-parent families, the federal welfare reform law of 1996 emphasized the responsibility of both parents to support their children. In addition to strengthening the child support enforcement system, the law included several provisions designed to decrease childbearing outside of marriage and to promote two-parent families. This article focuses on the important role that fathers play in children's lives and how public policies have affected childbearing and father involvement. Key observations are: Compared with children living with both biological parents, children in father-absent families often have fewer economic and socioemotional resources from their parents, and do not fare as well on many outcome measures. Efforts to reduce the rising number of father-absent families by focusing on preventing unwanted pregnancy among unmarried women, especially teen girls, have met with some success; those programs seeking to alter adolescents' life opportunities in addition to providing education or family planning services appear to hold the most promise. Efforts to encourage greater father involvement by focusing almost exclusively on increasing absent parents' child support payments reap only minimal benefits for poor children because their absent parents often have few resources and little incentive to make support payments. To date, efforts to increase the emotional involvement of unmarried fathers with their children have produced disappointing results, but new research suggests that such programs can make a difference when targeting fathers at the time of a child's birth. Many children spend some time living away from their fathers, deprived of the financial and emotional resources they can provide. Because of the importance of fathers to child well-being, the authors conclude that new directions in research and public policies are needed to encourage greater father involvement across the wide diversity of family arrangements in society today. N2 - UNLABELLED: Underdiagnosis of asthma is frequent in children and may be improved by the development of school-based health programs. MATERIAL AND METHODS: We developed an educational program in 11-year-old schoolchildren who participated in a screening test for exercise-induced asthma (EIA). All children were given an asthma questionnaire before and after two educational sessions. RESULTS: Mean score for asthma knowledge quiz increased from 63 to 85% ($p < 0.001$). Thirty-six children (3.7%) were initially considered as asthmatic and showed better responses than non-asthmatic children. Peak expiratory flow (PEF) was measured before and after an outside running exercise. A fall in PEF of at least 15% was considered an abnormal result. Seventy-eight children (8%) had a decrease in PEF, including 65 children initially not recognized as asthmatic. For these latter, a medical evaluation was recommended to parents. Only 28 of these children gave informations on follow-up: 19 had lung function tests, two received a treatment without preliminary function test, and seven had neither lung function test nor treatment. Among the children who realized lung function tests, five had criteria for airway obstruction at baseline, and ten had significant bronchial hyperreactivity. CONCLUSIONS: However, a new screening test revealed that only a small minority of children initially not recognized as asthmatic but having decreased their PEF, were consequently considered as asthmatic by their practitioner, even in case of positive lung function test

N2 - Various factors have been associated with a predisposition to the development of clinical American visceral leishmaniasis (AVL). However, little information is available about the factors that predispose to asymptomatic infection. To identify the risk factors associated with asymptomatic infection, a study was carried out between July 1997 and June 1998 on children aged 0-5 years in the districts of Vila Nova and Bom Viver in the municipality of Raposa in the island of Sao Luis, State of Maranhao, Brazil. A questionnaire containing socioeconomic, demographic and epidemiological data was used. The delayed-type hypersensitivity (DTH) test was carried out on 639 children in the first phase, and on 572 in the second, 7 months after the first survey, using *Leishmania amazonensis* antigen. Infection was determined by enzyme-linked immunosorbent assay (ELISA) in 638 children during the first phase, and in 572 during the second. Six outcome measures were used: initial prevalence, final prevalence and incidence, each determined by DTH and ELISA. The incidence of infection was 10.8% when determined by DTH and 28.5% when determined by ELISA. After adjustment for confounding variables using Cox regression, infection by *L. chagasi* was associated with child's age ($>$ or $=$ 2 years), location of the dwellings (Vila Nova) and reporting of relatives with AVL. Bathing outside the house and playing outdoors between 18:00 and 20:00 were identified as risk factors in some analyses but not in others. Presence of intra- and peridomestic *Lutzomyia* sandflies and animals such as dogs or chickens in the house or in the neighbourhood appeared as risk factors in some analyses but in others they unexpectedly seemed to protect from infection. Malnutrition was not found to be associated with infection

N2 - BACKGROUND: During liver transplantation, an oversized graft or active bleeding in the hepatic area can make performance of the suprahepatic caval anastomosis extremely difficult or even impossible. In other instances, a brief as possible warm ischemia is desired to provide a marginal graft with maximum chances of good functioning. METHODS: In order to manage those conditions, a suture technique was devised that allows the construction of a substantial part of the suprahepatic caval anastomosis keeping the graft outside the abdomen of the recipient. RESULTS: Over a 12-month period, the technique was applied in 7 out of 148 transplants (5%). The 7 cases presented one or more of the following conditions: significant oversize mismatch (n = 6), active bleeding in the hepatic area (n = 1), and marginal graft (n = 4). Warm ischemia time averaged 27 minutes, a value not significantly different from the mean warm ischemia time of 25 minutes recorded in the easier transplants in which the conventional technique was used (P = 0.2467). CONCLUSIONS: This extracorporeal suture technique allows construction of the suprahepatic caval anastomosis in critical situations arising during liver transplantation and avoidance of the prolonged warm ischemia that could be expected in such cases

N2 - The role of the occupational therapist working in the school system is to facilitate a student's task performance or ability to do purposeful and meaningful activities so that the student benefits from the educational experience. To fulfill this role, occupational therapists need assessments that address functional performance issues in the classroom and provide information for effective programming and consultation. The School Version of the Assessment of Motor and Process Skills (School AMPS) is an observational evaluation of functional skills in the classroom. Common classroom activities are observed to assess a child's school motor and school process skills. This study examined the validity of the School AMPS by comparing it to the Peabody Developmental Motor Scale-Fine Motor (PDMS-FM), a common assessment used in local area school districts in Edmonton, Alberta. Results show a higher correlation of the PDMS-FM with the motor scale of the School AMPS than with the process scale of the School AMPS, which was expected. The School AMPS appears to be a promising instrument for measuring the constructs of school motor and school process skills within a naturalistic setting

N2 - STUDY OBJECTIVES: To determine whether actigraph placement affects sleep estimation in children. DESIGN: Descriptive study. SETTING: Naturalistic setting. PARTICIPANTS: Twenty children aged 7-12 years from primary schools. INTERVENTIONS: N/A. MEASUREMENTS: Motor activity was measured from the waist and non-dominant wrist with actigraphs for three consecutive days during a school week. RESULTS: The minute-by-minute agreement of sleep-wake states between the two measurement sites was 92.5%. Wrist- and waist-recorded sleep parameters correlated well and the mean values did not differ. CONCLUSIONS: Although the placement of the actigraph slightly affected the measured activity parameters, its influence on 3-night mean sleep estimates in children was not statistically significant

N2 - AIM: To make a survey of children's health and psychosocial needs after the 1992-1995 war in Sarajevo, Bosnia and Herzegovina. METHODS: Representative samples of school-age children (n=310) from 6 public schools in the Sarajevo Canton, their parents (n=280), and teachers (n=156) were surveyed by means of self-administered questionnaires and standardized psychometric scale (Ryan-Wengers Schoolagers Coping Strategies Inventory). The survey was conducted in October-November 1999, approximately four years after the war. RESULTS: At the time of survey, well-being of children in Sarajevo was still heavily impacted by many various unhealthy life conditions and psychosocial stressors. Many school-age children lived in unhealthy and dangerous environment, including overcrowded living conditions (40%), unsafe playgrounds (68%), and no access to sports fields (52%). Most felt unsafe on streets (74%), many (73%) coped with one or more school problems, and even 84% were ill at least once during the past 12 months. General poverty was the prime stressor (common variance explained: 23.5%), followed by school- and health-related risks (common variance explained: 17.0%). At the third place were family-associated risk factors impacting children's health and development, such as overcrowded living conditions and lack of social support within their own family (common variance explained: 10.5%). Parents and teachers also lived and worked in stressful life conditions and were concerned for both their children's and their own well-being. Despite all that, most children tended to use healthy strategies in coping with stressful events in their everyday lives. CONCLUSION: The reinforcement of children with positive (healthy) coping skills and strengthening of their social support networks seems to be the most important intervention strategy to help the war-traumatized children in Bosnia and Herzegovina

N2 - The purpose of this action study was to apply an ecological program for teaching motor skills to individuals with disabilities in naturalistic settings. The program was developed based on an ecological survey. Participants were 22 individuals with disabilities, ages 7 to 26 years in the Fall of 1998 and 18 individuals with disabilities, ages 7 to 24 in the Winter of 1999. In each semester, a participant received one or two 50-min, training session(s) per week for 10 weeks. The number of steps in a motor-activity task performed correctly by a participant was measured in the first and last sessions in each semester. The magnitude of increase in the motor performance by participants and answers to questions in a short survey by participants' parents were used to describe the group performance. Analysis showed group performance of targeted motor skills could be improved using this ecological program in this local learning lab for special physical education

N2 - CONTEXT: Although blunt, nonpenetrating chest blows causing sudden cardiac death (commotio cordis) are often associated with competitive sports, dangers implicit in such blows can extend into many other life activities. OBJECTIVE: To describe the comprehensive spectrum of commotio cordis events. DESIGN AND SETTING: Analysis of confirmed cases from the general community assembled in the US Commotio Cordis Registry occurring up to September 1, 2001. MAIN OUTCOME MEASURE: Commotio cordis event. RESULTS: Of 128 confirmed cases, 122 (95%) were in males and the mean (SD) age was 13.6 (8.2) years (median, 14 years; range, 3 months to 45 years); only 28 (22%) cases were aged 18 years or older. Commotio cordis events occurred most commonly during organized sporting events (79 [62%]), such as baseball, but 49 (38%) occurred as part of daily routine and recreational activities. Fatal blows were inflicted with a wide range of velocities but often occurred inadvertently and under circumstances not usually associated with risk for sudden death in informal settings near the home or playground. Twenty-two (28%) participants were wearing commercially available chest barriers, including 7 in whom the projectile made direct contact with protective padding (baseball catchers and lacrosse/hockey goalies), and 2 in whom the projectile was a baseball specifically designed to reduce risk. Only 21 (16%) individuals survived their event, with particularly prompt cardiopulmonary resuscitation/defibrillation (most commonly reversing ventricular fibrillation) the only identifiable factor associated with a favorable outcome. CONCLUSIONS: The expanded spectrum of commotio cordis illustrates the potential dangers implicit in striking the chest, regardless of the intent or force of the blow. These findings also suggest that the safety of young athletes will be enhanced by developing more effective preventive strategies (such as chest wall barriers) to achieve protection from ventricular fibrillation following precordial blows

N2 - OBJECTIVE: To investigate how daily variations in ambient air pollution, especially in particles, during the cold of winter affect repeated measurements of baseline lung function and exercise induced bronchial responsiveness among primary school children with chronic respiratory symptoms. METHODS: During alternate school weeks (maximum five) from February to April 1994, 33 children took part in exercise challenge tests (n=141 tests). The exercise challenges were conducted outdoors in a school yard in the centre of Kuopio, Finland. Spirometric lung functions were measured indoors before the exercise, and 3 and 10 minutes after. Daily mean concentrations of PM(10), black smoke (BS), NO(2), CO, SO(2), and particle size and numbers were monitored at a nearby fixed monitoring site. RESULTS: Daily variations in ambient air pollution were not associated with enhanced bronchial responsiveness. However, increased concentrations of BS, PM(10), particle numbers, NO(2), and CO were consistently associated with an impairment of baseline lung functions. The reductions in forced vital capacity (FVC) and forced expiratory volume in 1 second (FEV(1)) were 0.5% and 0.6%, respectively, for each 10 microg/m(3) increase in BS (lag 2). CONCLUSION: Particles derived from combustion affect baseline lung function rather than bronchial responsiveness among children with chronic respiratory symptoms

N2 - BACKGROUND: Little is known about the effect of exposure to air pollution during exercise or time spent outdoors on the development of asthma. We investigated the relation between newly-diagnosed asthma and team sports in a cohort of children exposed to different concentrations and mixtures of air pollutants.

METHODS: 3535 children with no history of asthma were recruited from schools in 12 communities in southern California and were followed up for up to 5 years. 265 children reported a new diagnosis of asthma during follow-up. We assessed risk of asthma in children playing team sports at study entry in six communities with high daytime ozone concentrations, six with lower concentrations, and in communities with high or low concentrations of nitrogen dioxide, particulate matter, and inorganic-acid vapour. FINDINGS: In communities with high ozone concentrations, the relative risk of developing asthma in children playing three or more sports was 3.3 (95% CI 1.9-5.8), compared with children playing no sports. Sports had no effect in areas of low ozone concentration (0.8, 0.4-1.6). Time spent outside was associated with a higher incidence of asthma in areas of high ozone (1.4, 1.0-2.1), but not in areas of low ozone. Exposure to pollutants other than ozone did not alter the effect of team sports. INTERPRETATION: Incidence of new diagnoses of asthma is associated with heavy exercise in communities with high concentrations of ozone, thus, air pollution and outdoor exercise could contribute to the development of asthma in children

N2 - **OBJECTIVE:** The purpose of this study was to explore the effects of a powered mobility riding toy on the participation behaviors of young children with complex developmental delays. **METHOD:** A single-subject withdrawal design was used to study the effects of powered mobility on child-initiated movement occurrences, initiation of contact with others, and affect. The participants were two young children with complex developmental delays, including spastic quadriplegia. The intervention consisted of having the children use a powered mobility riding toy in their school settings during gym class and outdoor recess. **RESULTS:** Primary findings were that use of the powered mobility riding toy (a) increased the number of self-initiated movement occurrences; (b) appeared to have some effect on initiation of contacts with adults and, for one child, negative adult initiations and positive peer initiations; and (c) did not have a clear impact on the amount of positive affect. **CONCLUSION:** For some young children with severe motor impairments and developmental delay, use of a powered mobility device may increase self-initiated movement occurrences during free play

N2 - **BACKGROUND:** People with degenerative retinal diseases such as retinitis pigmentosa, may have adequate day vision but suffer from poor night vision. We have tested newly developed night vision goggles (NVG) to help these patients overcome their night blindness, thereby promoting more opportunities for normal activities at night or in the dark. **METHODS:** A total of 42 subjects with night blindness due to retinitis pigmentosa, choroideremia, cone rod dystrophy, or Bardet Biedl syndrome were recruited and clinically examined (visual acuity, visual field, and contrast sensitivity). Using an experienced mobility trainer, we tested binocular NVG on the subjects in two locations: a dark room and a 1 to 2 h outside course at night that provided different levels of difficulties (i.e., obstacles, brightness, and contrast). The assessment of which patients benefited from the NVG was predominantly based on the subjective evaluation of the mobility trainer, followed by their graded responses on two questionnaires. **RESULTS:** Based on the evaluation of the mobility trainer, 23 (61%) of the 42 subjects experienced improved mobility and orientation with the NVG outdoors, and 19 (39%) subjects did not. The ophthalmic data demonstrated that a visual acuity better than 20/100 and a visual field > 5 degrees (Goldmann perimetry III4) is necessary to benefit from NVG usage. In addition, subjective responses on increased mobility and independence were positively correlated with successful NVG testing.

CONCLUSIONS: Night vision goggles have the ability to improve poor night vision in subjects with visual acuity > 20/100 and a visual field > or = 5 degrees (Goldmann: III4). In so doing, NVG can help overcome the obstacles experienced by many people suffering from night blindness. NVG, therefore, have the potential to greatly improve quality of life

N2 - BACKGROUND: Data are lacking on primary care interventions to reduce children's television viewing. Low-income African-American children watch greater amounts of television than their peers.

DESIGN/METHODS: A randomized controlled pilot and feasibility trial was conducted. Twenty-eight families

with 7- to 12-year-old African-American children receiving primary care at an urban community clinic serving a low-income population were randomized to receive counseling alone or counseling plus a behavioral intervention that included an electronic television time manager. The main outcome was hours of children's television, videotape, and video game use. Parents/guardians and children completed baseline and 4-week follow-up self-report surveys. Additional outcomes included overall household television use, time spent in organized physical activity and playing outside, and meals eaten by the child while watching television.

RESULTS: Both intervention groups reported similar decreases in children's television, videotape, and video game use (mean changes of -13.7, SD=26.1 and -14.1, SD=16.8 hours per week). The behavioral intervention group reported significantly greater increases in organized physical activity (changes of +2.5, SD=5.9 and -3.6, SD=4.7 hours per week; $p=0.004$) and nearly significant greater increases in playing outside (changes of 1.0, SD=5.9 and -4.7, SD=9.4 hours per week; $p<0.06$). Changes in overall household television use and meals eaten while watching television also appeared to favor the behavioral intervention, with small to medium effect sizes, but differences were not statistically significant. **CONCLUSIONS:** This small pilot and feasibility study evaluated two promising primary care-based interventions to reduce television, videotape, and video game use among low-income African-American children. The effects on physical activity suggest that the behavioral intervention may be more effective

N2 - Soil examinations made in 5 regions of Poland in the 1990s comprised 1184 samples taken from urban areas and 590 samples from suburban and rural areas. *Toxocara* spp. eggs were found more often in urban areas (14% positive samples) than in suburban and rural once (12% positive samples). The average ratio of positive samples was: in the streets and roads--19.3% (0.36 eggs/100g of soil), near houses (backyards, gardens)--18.6% (1.11 eggs/100g), in sandpits--13.0% (0.23/100g), in parks and public gardens--10.5% (0.46 eggs/100g), on playgrounds and playing fields 9,4% (0,06 eggs/100g) and on the beaches--3.4% (0.03 eggs/100g). In children habitual play areas the prevalence of *T. cati* eggs was higher than *T. canis* eggs

N2 - BACKGROUND: In spite of its importance for lumbar radicular syndroms only a few reports about lumbar lateral recess stenosis exist in literature. Most important clinical symptom is radicular pain, which may be exercise-dependent. Confirmation of diagnosis and differentiation from disc herniation requires imaging like CT, MRI or post-myelo-CT. Surgical treatment options include selective decompression techniques like foraminotomy, medial facetectomy and undercutting as well as hemilaminectomy, laminotomy and wide laminectomy or fusion. METHOD: We treated 35 patients with selective decompression techniques. RESULTS: In the follow-up 5 up to 18 months after surgery 25 patients for themselves described the results as good or excellent. Therefore, individually tailored selective microsurgical decompression is an appropriate and successful treatment strategy for lumbar lateral recess stenosis, if conservative treatment fails

N2 - The aim of this study was to know the experience of the institutionalized child and was guided by the theoretical referential of the "Symbolic Interactionism" and by the methodological referential of the "Grounded Theory". The data had been collected in two stages: the first one understood group activities and second stage consisted of personal interviews. The results had shown that the institutionalization occurred for abandonment and reject of the parents or for legal decision as a measure of child protection, having as context the poverty of

its family. The child's experience is conflicting in relation to being institutionalized, because while he/she perceives the necessity of material gain, they miss their family, their home, their friends, and simply life outside

N2 - This is the third in this series of articles examining nutrition and the life cycle. The first considered current thinking regarding nutrition in pregnancy (Vol 9(17): 1133-8), and the second discussed nourishing the infant, particularly in relation to weaning (Vol 9(21): 2205-16). This article considers nutrition and the older child. The school years are characterized by increasing independence from parents and exposure to values from outside the home. After being neglected for some years, childhood nutrition is again giving cause for concern. Some children are not eating enough, or not the right nutrients at the right time, while others are becoming overweight, with possible severe long-term effects on their health. Many of these problems are not related to poverty, but rather to changes in lifestyle. Some older children, however, are undernourishing themselves in an attempt to obtain a particular body shape. The last two articles in this series will review nutrition in adulthood and in older years. [References: 30]

N2 - To understand the transmission dynamics of malaria in three different ecotypes, namely watershed (forest), seepage (Nanak Matta Dam) and plain (non-forest, non-dam) areas of Nainital and Udham Singh Nagar districts of Uttaranchal, entomological and parasitological investigations were carried out from July 1996 to June 1997. In the three ecotypes, average per man hour densities of adult vector species in human dwellings and cattlesheds recorded were high for *Anopheles culicifacies* from April to September and October to March for *An. fluviatilis*. Prevalence of both *An. culicifacies* and *An. fluviatilis* was higher in the forest area as compared to other two areas. Observations on gonotrophic condition revealed endophilic tendency of both vector species. Higher number of both vector species were found in outdoor than indoor during night human bait collections. Out of 864 specimens of *An. fluviatilis* dissected, one showed natural infection of sporozoites in salivary glands in the month of November from the forest area only. Sibling species study of *An. fluviatilis* revealed the presence of species S for the first time in the forest area. Parasitological investigations also depicted high incidence of malaria in the forest area as compared to other two areas. Overall results from the study indicated active malaria transmission in the forest area

N2 - The aim of the study was the evaluation of the influence of 4-month concomitant tiagabine (TGB) and valproic acid (VPA) or carbamazepine (CBZ) therapy on renal function of epileptic children and teenagers. Initial parameter values, indicated on renal disfunction, were compared with these obtained after VPA and TGB or CBZ and TGB therapy and with values in healthy children and teenagers. Investigation group was composed of 22 children and teenagers with drug-resistant focal epilepsy. We observed that in the time of concomitant VPA and TGB therapy increased the NAG/g creatinine activity index. In spite the fact of statistical significance of these changes, they were not outside the normal range. beta 2-microglobulin concentrations in urine of epileptic children treated with VPA in monotherapy before concomitant therapy with TGB were higher than in control group. That difference was statistically significant. Addition of TGB to the therapy normalized this parameter. During concomitant VPA and TGB or CBZ and TGB therapy we didn't observe statistically significant changes of parameters indicating on glomerular disfunction. In the VPA therapy before concomitant treatment with tiagabine the disfunction of tubules and glomerules was observed. On the other side in the concomitant VPA and TGB therapy the disfunction of tubules and glomerules didn't occurred. We can conclude that concomitant therapy VPA or CBZ with tiagabine don't affect the renal function in clinical significant manner. Therapy with VPA could leads to minimal disfunction of tubules what is represented by increasing of beta 2-microglobulin level in urine

N2 - OBJECTIVE: To identify factors associated with increased or decreased risk of infection for Lyme disease in Chester County, Pennsylvania. METHODS: The authors designed an unmatched case-control study involving 294 incident cases reported to the Chester County Health Department in 1998 and 449 controls selected by random digit dialing. All case and control participants were interviewed by telephone. RESULTS: Age is a risk factor for Lyme disease for groups aged 10-19 years old and 50 years or older. Sex was not a risk factor.

Incidence of Lyme disease in a rural setting was three times the incidence in an urban setting. Increased risk also was associated with living in single family homes, homes with yards or attached land, woods on the land, signs of tick hosts seen on the land, and homes within 100 feet of woodland. Gardening for more than four hours per week was also a risk factor, but most other outdoor activities were not. Twice as many participants took protective measures against tick bites before outdoor employment than those who merely ventured into the yard or land associated with the home. Only checking for ticks during outdoor activity and the use of repellents prior to outdoor activities outside the yard were unequivocally associated with a reduced risk of Lyme disease.

CONCLUSIONS: It is important to increase public awareness about the risk of acquiring Lyme disease from ticks in the immediate environment of the home

N2 - OBJECTIVE: To determine the prevalence, trends, and severity of injuries attributable to playground falls relative to other common unintentional mechanisms that resulted in an emergency department (ED) visit in the United States. DESIGN AND SETTING: Data from the emergency subset of the National Hospital Ambulatory Medical Care Survey collected from 1992 to 1997 for children <20 years. METHODS: Injury rates and 95% confidence intervals (CIs) were estimated and injury severity scores were computed. RESULTS: There were 920551 (95% CI: 540803 to 1300299) ED visits over the 6-year study period by children and adolescents that were attributable to falls from playground equipment. The annual incidence of visits for playground injuries did not significantly decrease over the course of the study (187000 to 98000, $P = .053$). Injury visits for playground falls were twice as prevalent as pedestrian mechanisms, but they were less prevalent than visits for motor vehicle-- and bicycle-related injuries. A larger proportion of playground falls resulted in "moderate-to-severe" injury than did bicycle or motor vehicle injuries. Children aged 5 to 9 years had the highest number of playground falls ($P = .0014$). Playground falls were most likely to occur at school compared to home, public, and other locations ($P = .0016$). CONCLUSIONS: Playground injury emergency visits have not significantly declined and remain a common unintentional mechanism of injury. Injury visits for playground falls were proportionally more severe than injury visits attributable to other common unintentional mechanisms. Interventions targeting schools and 5- to 9-year-old children may have the greatest impact in reducing emergency visits for playground injuries

N2 - The relationship among morphologically different forms of smiling and laughter was examined. The participants were 19 Brazilian preschool children. Each child was observed a total of 60 min. in three 10-min. sessions on the playground and three 10-min. sessions in the classroom. Analysis suggests that the various forms of smiling do not simply express different intensities of a single emotion. A two-dimensional structure was indicated by factorial analysis. The first dimension, which could be called playfulness-mock aggression, consisted of a broad smile and laughter. The second dimension, which could be called friendliness-appeasement, consisted of a closed and upper smile. The pattern of correlation found between expressive behaviors and both teacher's and peers' evaluations gives further support to the interpretation that smiling is an heterogeneous category

N2 - The study on development regularities and psychopathological structure of anxiety phobic disorders has been conducted in 92 patients, aged 5-15 years. The structure of anxiety-phobic complex is represented. A level of anxiety affect development (primary or secondary, presence and direction of affect cognitive component) and negative effectiveness were emerged in the children as common obligate anxiety-phobic characteristics, which contributed to complex structure stability. Three anxiety-phobic disorder types--situation-dependent, personality-dependent and vital--were distinguished. The first one is characterized by the combination of secondary anxiety with cognitive vector expression, the vector being outside directed, and emotionally unstable negative effectiveness variant (particular sensitivity to negative situations with disability for negative emotion control). The second type is distinguished by secondary anxiety manifestations, the anxiety vector being directed towards the self-ego. In these cases, personality component--rigid variant of negative effectiveness (higher sensitivity to negative events, along with disability for negative emotion modulation) dominates. The third type is defined by the combination of primary anxiety (with vital disturbance, diffusion, psychic activity disorganization in the absence of cognitive component) with rigid variant of negative effectiveness. The types of manifesting anxiety-phobic disorders described correspond to reactive (situation-dependent type), endoreactive (personality-dependent type) and autochthonous (vital type) variants of the disease course

N2 - For malaria vector control in Madagascar, 10 WP (lambda-cyhalothrin 10% wettable powder) was compared with DDT 75% WP for house-spraying, from November 1997 to September 1998. This study was implemented at the fringe of the malaria epidemic zone, in villages on western slopes of the central highlands, outside the area covered for the past five years by routine DDT house-spraying (OPID). Four types of treatment were compared in different areas: 1) DDT 2 g ai/m² and 2) lambda-cyhalothrin 30 mg ai/m² in previously unsprayed villages, 3) no intervention (control); 4) yearly DDT spraying (OPID fifth cycle). To investigate the malariological impact of spraying, cross-sectional surveys of the village populations were performed in each study area at intervals of two months, before and after spraying. In the newly sprayed areas, from December to June, malaria indices decreased by 62% in the ICON area and 44% in the DDT area, whereas in the unsprayed village malaria increased by 32% during the same season. There was a similar decrease in the number of gametocyte carriers in the newly sprayed areas. Active malaria case detection among febrile individuals was performed fortnightly in each village outside the OPID area. Results showed decreased malaria incidence from February (two months post-spraying) in the sprayed villages, despite the rainy season, whereas in the unsprayed area the decline occurred only after the main transmission season. This study demonstrated that, parasitologically as well as entomologically, house-spraying with residual insecticide (DDT or ICON) was an effective method for controlling malaria on the western fringes of the Madagascar highlands epidemic zone. Both products were effective, but ICON had slightly better impact than DDT, i.e. more reduction of malaria indices and of vector longevity, less irritancy of mosquitoes. For best results in this area of transition between stable and unstable malaria, we recommend earlier annual spraying (as soon as November) and extension of the OPID barrier towards western and northern slopes of the Plateau

N2 - Twenty children with autism, ages 3 to 6 years, were randomly assigned to massage therapy and reading attention control groups. Parents in the massage therapy group were trained by a massage therapist to massage their children for 15 minutes prior to bedtime every night for 1 month and the parents of the attention control group read Dr. Seuss stories to their children on the same time schedule. Conners Teacher and Parent scales, classroom and playground observations, and sleep diaries were used to assess the effects of therapy on various behaviors, including hyperactivity, stereotypical and off-task behavior, and sleep problems. Results suggested that the children in the massage group exhibited less stereotypic behavior and showed more on-task and social relatedness behavior during play observations at school, and they experienced fewer sleep problems at home

N2 - The National Human Exposure Assessment Survey (NHEXAS)/Minnesota Children's Pesticide Exposure Study (MNCPEs) was a population-based study designed to characterize children's exposure to residential pesticides and to evaluate the contribution of residential and children's activities to children's exposure. Families of 168 children were surveyed for residential use of pesticides and children's activities. From these homes, families of 102 children between the ages of 3 and 13 years participated in a week-long intensive exposure study. Of the 102 children, 19 children were videotaped for four consecutive hours in their normal daily activities. The survey responses indicated that the youngest children were more likely to exhibit behaviors that would foster exposure to environmental contaminants. Comparison of questionnaire responses indicated that the videotaped subsample was representative of the exposure study population. The microactivities of the videotaped children that might contribute to their exposure via ingestion or dermal routes were quantified. Hand-to-mouth and object-to-mouth activities were observed most frequently among the youngest children. The youngest children were also most likely to be barefoot both indoors and outside. Gender differences were found in mouthing behavior and the proportion of observed time spent outdoors

N2 - A population exposure model for particulate matter (PM), called the Stochastic Human Exposure and Dose Simulation (SHEDS-PM) model, has been developed and applied in a case study of daily PM(2.5) exposures for the population living in Philadelphia, PA. SHEDS-PM is a probabilistic model that estimates the population distribution of total PM exposures by randomly sampling from various input distributions. A mass balance equation is used to calculate indoor PM concentrations for the residential microenvironment from ambient outdoor PM concentrations and physical factor data (e.g., air exchange, penetration, deposition), as well as emission strengths for indoor PM sources (e.g., smoking, cooking). PM concentrations in nonresidential microenvironments are calculated using equations developed from regression analysis of available indoor and

outdoor measurement data for vehicles, offices, schools, stores, and restaurants/bars. Additional model inputs include demographic data for the population being modeled and human activity pattern data from EPA's Consolidated Human Activity Database (CHAD). Model outputs include distributions of daily total PM exposures in various microenvironments (indoors, in vehicles, outdoors), and the contribution from PM of ambient origin to daily total PM exposures in these microenvironments. SHEDS-PM has been applied to the population of Philadelphia using spatially and temporally interpolated ambient PM(2.5) measurements from 1992-1993 and 1990 US Census data for each census tract in Philadelphia. The resulting distributions showed substantial variability in daily total PM(2.5) exposures for the population of Philadelphia (median=20 microg/m³; 90th percentile=59 microg/m³). Variability in human activities, and the presence of indoor-residential sources in particular, contributed to the observed variability in total PM(2.5) exposures. The uncertainty in the estimated population distribution for total PM(2.5) exposures was highest at the upper end of the distribution and revealed the importance of including estimates of input uncertainty in population exposure models. The distributions of daily microenvironmental PM(2.5) exposures (exposures due to time spent in various microenvironments) indicated that indoor-residential PM(2.5) exposures (median=13 microg/m³) had the greatest influence on total PM(2.5) exposures compared to the other microenvironments. The distribution of daily exposures to PM(2.5) of ambient origin was less variable across the population than the distribution of daily total PM(2.5) exposures (median=7 microg/m³; 90th percentile=18 microg/m³) and similar to the distribution of ambient outdoor PM(2.5) concentrations. This result suggests that human activity patterns did not have as strong an influence on ambient PM(2.5) exposures as was observed for exposure to other PM(2.5) sources. For most of the simulated population, exposure to PM(2.5) of ambient origin contributed a significant percent of the daily total PM(2.5) exposures (median=37.5%), especially for the segment of the population without exposure to environmental tobacco smoke in the residence (median=46.4%). Development of the SHEDS-PM model using the Philadelphia PM(2.5) case study also provided useful insights into the limitations of currently available data for use in population exposure models. In addition, data needs for improving inputs to the SHEDS-PM model, reducing uncertainty and further refinement of the model structure, were identified

N2 - The concentrations of a suite of persistent organic chemicals were measured in multiple media in 10 child day care centers located in central North Carolina. Five centers served mainly children from low-income families, as defined by the federal Women, Infants, and Children (WIC) assistance program, and five served mainly children from middle-income families. The targeted chemicals were chosen because of their probable carcinogenicity, acute or chronic toxicity, or hypothesized potential for endocrine system disruption. Targeted compounds included polycyclic aromatic hydrocarbons (PAHs), pentachloro- and nonyl-phenol, bisphenol-A, dibutyl and butylbenzyl phthalate, polychlorinated biphenyls (PCBs), organochlorine pesticides, the organophosphate pesticides diazinon and chlorpyrifos, and the herbicide 2,4-dichlorophenoxyacetic acid (2,4D). Sampled media were indoor and outdoor air, food and beverages, indoor dust, and outdoor play area soil.

Concentrations of the targeted compounds were determined using a combination of extraction and analysis methods, depending on the media. Analysis was predominantly by gas chromatography/mass spectrometry (GC/MS) or gas chromatography with electron capture detection (GC/ECD). Concentrations of the targeted pollutants were low and well below the levels generally considered to be of concern as possible health hazards. Potential exposures to the target compounds were estimated from the concentrations in the various media, the children's daily time-activity schedules at day care, and the best currently available estimates of the inhalation rates (8.3 m³/day) and soil ingestion rates (100 mg/day) of children ages 3-5. The potential exposures for the target compounds differed depending on the compound class and the sampled media. Potential exposures through dietary ingestion were greater than those through inhalation, which were greater than those through nondietary ingestion, for the total of all PAHs, the phenols, the organophosphate pesticides, and the organochlorine pesticides. Potential exposures through dietary ingestion were greater than those through nondietary ingestion, which were greater than those through inhalation, for those PAHs that are probable human carcinogens (B2 PAH), the phthalate esters, and 2,4D. For the PCBs, exposures through inhalation were greater than those through nondietary ingestion, and exposures through dietary ingestion were smallest. Differences in targeted compound levels between the centers that serve mainly low-income clients and those that serve mainly middle-income clients were small and depended on the compound class and the medium

 N2 - The ultraviolet (UV) doses of American young adults were never measured, but are needed for assessing UV-related health risks. These doses were calculated using a novel approach. The National Human Activity Pattern Survey recorded the daily minute-by-minute activities of about 2000 young adults (0-19 years) over the course of 2 years to assess their exposure to environmental pollutants. From that survey, only the outdoor daylight data of northern and southern girls and boys were extracted and stratified by season and age to find the time American children (0-5 and 6-12 years) and adolescents (13-19 years) spend outside. They spend about 10% of the day outdoors, but only get about 30% of the available terrestrial UV radiation (on a horizontal plane). American children have about the same percent personal ambients as adults (3.1%), 2.8% for girls and 3.4% for boys. Adolescents have the lowest personal ambients (2.6%), 2.1% for girls and 3.1% for boys. To get their UV doses, their percent ambients are multiplied by the total available terrestrial UV. Excluding vacation, the erythemally weighted UV doses for American children are 25 kJ/m²/year, 23 for girls and 28 for boys. Adolescents get the lowest UV exposure of any group, 21 kJ/m²/year, 18 for girls and 24 for boys. Young adult northern girls get 18 kJ/m²/year and boys get 21 kJ/m²/year, whereas southern girls get 24 kJ/m²/year and boys get 31 kJ/m²/year. The youngest children (0-5 years) get slightly higher summer doses. Thus, we can now assess the UV-related health risks for American children and adolescents

N2 - The characteristics of vivax malaria epidemics along the demilitarized zone (DMZ) in the Republic of Korea has been established by the early surveillance data. To further characterize the epidemic, data of civilian patients microscopically diagnosed with malaria from 1995 through 2000 were analyzed in Yonchon-gun (county). Malaria incidence was greater in male civilians > 30 years of age ($p < 0.05$). The annual parasite index was significantly higher in those living in the administrative areas (Myeon) traversed by DMZ than those living in Myeons not traversed by DMZ ($p < 0.05$). Analysis according to the distance (4 to 14 km) from DMZ showed that people living in villages close to DMZ had higher annual parasite indices than those living in villages remote from DMZ (p for trend < 0.05). Civilians living in Myeons with plains and located in northwestern part of the county had higher annual parasite indices than those living in hilly Myeons located in southeastern part of the county (p for trend < 0.05). These findings suggest that the contraction of vivax malaria is related with night-time outdoor activities, and that the distance from DMZ is a risk factor. In this area, the flying distance of infected vector mosquitos can explain the annually repeating occurrence of civilian cases

N2 - This study assessed links between free-time activities in middle childhood (hobbies, sports, toys and games, outdoor play, reading, television viewing, and hanging out) and school grades, conduct, and depression symptoms both concurrently and 2 years later, in early adolescence. It also explored two mechanisms that might underlie activity-adjustment links: whether the social contexts of children's activities mediate these links, child effects explain these connections, or both. Participants were 198 children (M = 10.9 years, SD = .54 years) in Year 1, and their parents. In home interviews in Years 1 and 3 of the study, mothers rated children's conduct problems, children reported on their depression symptoms, and information was collected on school grades from report cards. In seven evening phone interviews, children reported on the time they spent in free-time activities during the day of the call and their companions in each activity. Links were found between the nature of children's free-time activities and their adjustment. The social contexts of free-time activities explained activity-adjustment links to a limited degree; with respect to child effects, evidence also suggested that better adjusted children became more involved in adaptive activities over time

 N2 - Neurons must respond to a bewildering array of external and internal stimuli and must distinguish among them to generate an appropriate response or change in metabolic or electrical activity. Furthermore, the response of a cell to a given stimulus must depend on what else is happening inside and outside the cell at the time of arrival of that stimulus. The process of signal transduction is what gives the cell and organism the flexibility and "knowledge base" to carry out these functions. Conversely, aberrations of signal transduction underlie an increasing array of developmental, genetic, and acquired diseases and conditions of the nervous system. Pharmacological modulation of signal transduction pathways and their effectors holds great promise for the remediation of these neurologic disorders

N2 - This thesis describes the different aspects of otitis media (OM) in the population of Greenland viewed in a historical and modern clinical perspective. Chapter 1 outlines the addressed problems and aims while chapters 2 and 3 deal with historical studies and an evaluation of the present knowledge based on the literature. Physical anthropological studies, using skeletal samples of adult Eskimo crania from before and after the colonization of Greenland in 1721 and information about modern living Eskimos (Inuit), have shown that OM sequelae of the temporal bones were significantly less common in pre-colonization Eskimos and that the mean area size of the pneumatized cell system in the temporal bone was significantly larger in pre-colonization Eskimos. These findings indicated an increase in OM after the colonization most likely caused by the social, cultural, habitary, and dietary changes due to increased contact with the outside world. Historical reports after the colonization confirm a high prevalence of OM especially in children. Modern epidemiological studies from the 1960's to 1980's in the Arctic region of Alaska, Canada, and Greenland along with reports from visiting consultant otologists in Greenland almost uniformly mention prevalent OM problems in children as well as in adults. The aim was therefore to further describe the epidemiological pattern of the different OM disease entities (acute OM (AOM), chronic OM (COM), COM with suppuration (CSOM), secretory OM (SOM), and cholesteatoma) and investigate the potentially associated risk factors in especially Greenlandic children because these diseases are primarily established and problematical in childhood. Chapter 4 describes the definitions used in the thesis and chapter 5 describes the studies included. Section 5.1 describes a study of cholesteatoma in Greenlanders. The study revealed an almost similar incidence of hospital treated children with cholesteatoma (6.6 per 100,000) as seen in comparable studies from other parts of the world. Furthermore, childhood cholesteatomas were the most aggressive. The frequency of residuals or recurrences after otosurgical treatment was high with a trend for better results when using the extensive canal wall-down procedure. It could be concluded that these patients urgently need close follow-up for at least five years postoperatively, if not lifelong. Section 5.2 describes a hearing screening survey of 167 school children using school registration charts. A high prevalence of hearing loss (HL) was found. A total of 43% of the children had hearing thresholds exceeding 20 dB at one or more frequencies between 250-8000 Hz in one or both ears, and 19% had the same type of HL in the frequencies 500-2000 Hz. HL was significantly associated with episodes of OM. These findings were in accordance with reports from Alaska and Canada. It is therefore concluded that a hearing screening programme of school children is important and that OM seems to have an impact on hearing in school children in Greenland. In section 5.3 an epidemiological survey is described concerning the prevalence of the different OM disease entities. The survey was carried out in Nuuk and Sisimiut and involved 740 children aged 3, 4, 5, and 8 years. A total of 591 children participated and selection bias was not found when controlling for age, sex, and episodes of AOM. The survey revealed that 52% of children in Nuuk and 54% in Sisimiut had some kind of pathological affection of their middle ear. COM and CSOM were found in 9%, but more prevalent among children in Sisimiut (12%) than in Nuuk (7%). Middle ear effusion (MEE) diagnosed by tympanometry was found in 23% in Nuuk and 28% in Sisimiut while simple tubal dysfunction (STD) was found in 13% and 8%, respectively. MEE and STD were associated with young age. Sequelae of OM was apparent in 11% in both towns. When comparing the results with a 10-year-older, almost similar survey of 142 children, it was evident that the OM situation had not changed in the period between the studies. The survey underlines the need for increased focus on the different OM entities in Greenlandic children. Section 5.4 deals with microbiological aspects. The nasopharyngeal microflora and ear discharge microflora of potential pathogens were evaluated in 54 children with AOM and in 201 control children without AOM. Very high carriage rates expressed qualitatively and semiquantitatively of potentially pathogenic bacteria were found in the nasopharynx of children with AOM (98%) but also in that of

the control children (91%) and even in children denoted as being very healthy (94%). However, the same bacterial species were cultured from the nasopharynx and ear discharge as in comparable studies world-wide. Only *S. pneumoniae* was carried significantly more often in the nasopharynx of AOM children compared with age matched control children. Chlamydiae, *M. pneumoniae*, adenovirus, respiratory syncytial virus, parainfluenza- type 1, 2, and 3 virus, and influenza- type A and B virus were not major pathogens. In contrast, entero- and rhinoviruses were detected significantly more frequent in nasopharyngeal specimens from AOM children (59%) compared with age matched controls (33%) and also in 29% of the examined ear discharge specimens. It is therefore concluded that the potentially pathogenic bacterial load is early and massive. This alone or in interplay with entero- and rhinovirus infection and occasionally with other viruses may play an important role in the high prevalence of OM among children in Greenland. Section 5.5 deals with an examination of potential risk factors for AOM, recurrent AOM (rAOM), and COM in the same 591 children as studied in section 5.3. Early age at first AOM episode was associated with rAOM episodes (> or = 5 episodes since birth). Thus, the relative risk of developing rAOM was eight times higher if the first episode of AOM occurred before 7 months of age than after 24 months of age. Furthermore, compared with studies elsewhere in the world, a high proportion (40%) of the children in this survey had their first AOM episode during their first year of life and 41% of these children developed rAOM. It was also found that children had an increased risk of AOM, rAOM, or COM when both parents were born in Greenland, when parents also have had OM, when living in very crowded households, and when having experienced a long period of exclusive breast feeding, or when recalling of breast feeding was not possible. Gender, type, and size of housing, insulation standard of housing, daycare, exposure to passive cigarette smoking, and dietary habits were not associated with AOM, rAOM, or COM in the surveyed children. It is concluded that early onset of AOM occurs frequently in Greenlandic children and that a high proportion of these children develop rAOM. The study confirms that AOM is a highly multifactorial disease determined by a number of genetic and environmental factors. Finally, section 5.6 is a hypothesis generating study attempting to explain the high prevalence of early episodes of AOM in community-based children in Nuuk. The hypothesis is based on a possible association between findings of mannose-binding lectin genotypes, early Epstein-Barr virus infections and episodes of AOM, rAOM, or nasopharyngeal colonization with potentially pathogenic bacteria. However, the study does not support any of this hypothesis. In chapter 6, future studies are suggested and chapter 7 presents concluding remarks.

N2 - AIMS/HYPOTHESIS: Differences in seasonality of birth patterns between the general population and the group who develop Type I (insulin-dependent) diabetes mellitus indicate that environmental factors operating around the antenatal and perinatal period could be important. We investigated whether the same unusual patterns in seasonality of birth observed in children with Type I diabetes in Great Britain could also be found in other European populations. METHODS: Population-based incidence cohorts of children diagnosed with Type I diabetes under 15 years of age from 1989 onwards were analysed. Previously reported data sets from Great Britain were also included together with data on children diagnosed over an additional 5 year period (1988-1992). To assess the role of seasonality in diabetes, we used the method of Walter and Elwood to examine monthly birth figures for each country or region. RESULTS: Outside of Great Britain, no seasonality of birth was seen for any single or combination of European countries. Significant sinusoidal patterns were observed in Scotland, Yorkshire and Leicester, although the peak for Leicester appeared around autumn rather than spring. There was little evidence that sex or age at diagnosis played a part in differences in seasonal patterns, either overall or for any individual country. CONCLUSIONS/INTERPRETATION: We found no uniform seasonal pattern of birth in childhood diabetes patients across European populations, either overall or according to sex and age. This study provides no consistent evidence that environmental factors, which vary from season to season, have any influence on the fetal or neonatal life to determine the onset of Type I diabetes. However, a study of seasonality that takes into account possible changes both over time and over geographical areas could provide more insights

N2 - UNLABELLED: Haemangiomas are the commonest tumours of infancy. They can become even more serious if followed by consumption coagulopathy and even life-threatening in cases of Kasabach-Merritt syndrome, with thrombocytopenia and haemorrhage. Data exist concerning systemic coagulation abnormalities in children with haemangiomas but to our knowledge there are no data on local consumption coagulopathy in haemangioma per se. We examined blood coagulation and fibrinolysis parameters in blood withdrawn from haemangioma blood vessels and blood withdrawn from the systemic vein in 14 children with cutaneous haemangiomas (3M, 11F; age range 3 mo to 10y). Compared with controls, significant decreases in fibrinogen levels, FVII activity, antithrombin and plasmin inhibitor levels and increases in international normalized ratio (INR) and D-dimer levels were observed in the blood samples withdrawn directly from haemangioma blood vessels. Fibrinogen and antithrombin levels in samples withdrawn from systemic veins were reduced in relation to control values whilst INR values increased, but within normal ranges. D-dimer levels were increased in peripheral blood. The fibrinogen level was significantly lower and the INR and D-dimer levels were significantly higher in blood samples from haemangiomas compared to systemic blood. Clinical signs of systemic disseminated intravascular coagulation were not observed. CONCLUSIONS: Our results suggest a strong local activation and local consumption coagulopathy in haemangioma, along with less conspicuous but observable systemic changes in coagulation and fibrinolysis parameters, although without signs of consumptive coagulopathy. These systemic changes could be a reflection of intra-lesion coagulation activation although there is no evidence to suggest truly systemic disseminated intravascular coagulation

N2 - Deaths from lightning injuries are infrequent--0.2-0.8 per million per year. The victims are mostly young, active people who are struck during various outdoor activities in the summer months. From November 1975 to October 1998; 22 lightning burns were treated in Ankara Numune Teaching and Research Hospital. The mean age of the patients was 32.9 (12-65) years, the female/male ratio 9/13 and the mean duration of hospital stay 15.4 (1-62) days. The commonest clinical symptoms were confusion, amnesia (5 patients), neurological dysfunction (2 patients), cystitis (4 patients), and cardiac arrhythmias (1 patient). There were no deaths. Sixteen surgical procedures were carried out on 14 patients; this was significantly fewer than from any other cause of burns. The commonest long-term complication was chronic pain. Because complications are frequently seen in lightning injuries, our results revealed that patients should be hospitalised and treated as soon as possible after the accident with fluid resuscitation, cardiac resuscitation, tetanus prophylaxis and antibiotics where necessary

N2 - OBJECTIVE: To assess if a school based intervention was effective in reducing risk factors for obesity. DESIGN: Group randomised controlled trial. SETTING: 10 primary schools in Leeds. PARTICIPANTS: 634 children aged 7-11 years. INTERVENTION: Teacher training, modification of school meals, and the development of school action plans targeting the curriculum, physical education, tuck shops, and playground activities. MAIN OUTCOME MEASURES: Body mass index, diet, physical activity, and psychological state. RESULTS: Vegetable consumption by 24 hour recall was higher in children in the intervention group than the control group (weighted mean difference 0.3 portions/day, 95% confidence interval 0.2 to 0.4), representing a difference equivalent to 50% of baseline consumption. Fruit consumption was lower in obese children in the intervention group (-1.0, -1.8 to -0.2) than those in the control group. The three day diary showed higher consumption of high sugar foods (0.8, 0.1 to 1.6)) among overweight children in the intervention group than the control group. Sedentary behaviour was higher in overweight children in the intervention group (0.3, 0.0 to 0.7). Global self worth was higher in obese children in the intervention group (0.3, 0.3 to 0.6). There was no difference in body mass index, other psychological measures, or dieting behaviour between the groups. Focus groups indicated higher levels of self reported behaviour change, understanding, and knowledge among children who had received the intervention. CONCLUSION: Although it was successful in producing changes at school level, the programme had little effect on children's behaviour other than a modest increase in consumption of vegetables

N2 - PURPOSE: Previous studies among young pitchers have focused on the frequency and description of elbow injuries. The purpose of this study was to evaluate the frequency of elbow and shoulder complaints in young pitchers and to identify the associations between pitch types, pitch volume, and other risk factors for these conditions. METHODS: A prospective cohort study of 298 youth pitchers was conducted over two seasons. Each participant was contacted via telephone after each game pitched to identify arm complaints. Generalized estimating equations were used to assess associations between arm complaints and independent variables. RESULTS: The frequency of elbow pain was 26%; that of shoulder pain, 32%. Risk factors for elbow pain were increased age, increased weight, decreased height, lifting weights during the season, playing baseball outside the league, decreased self-satisfaction, arm fatigue during the game pitched, and throwing fewer than 300 or more than 600 pitches during the season. Risk factors for shoulder pain included decreased satisfaction, arm fatigue during the game pitched, throwing more than 75 pitches in a game, and throwing fewer than 300 pitches during the season. CONCLUSION: Arm complaints are common, with nearly half of the subjects reporting pain. The factors associated with elbow and shoulder pain were different, suggesting differing etiologies. Developmental factors may be important in both. To lower the risk of pain at both locations, young pitchers probably should not throw more than 75 pitches in a game. Other recommendations are to remove pitchers from a game if they demonstrate arm fatigue and limit pitching in nonleague games

 N2 - Hepatitis is common in the Stann Creek District of southern Belize. To determine the etiologies, incidence, and potential risk factors for acute jaundice, we conducted active surveillance for cases. Cases of jaundice diagnosed by a physician within the previous 6 weeks were enrolled. Evaluation included a questionnaire and laboratory tests for hepatitis A, B, C, D, and E, a blood film for malaria, and a serologic test for syphilis. Etiologies of jaundice among 62 evaluable patients included acute hepatitis A, 6 (9.7%), acute hepatitis B, 49 (79.0%), hepatitis non-A-E, 2 (3.2%), and malaria, 5 (8.1%). There were no cases of acute hepatitis E. One patient each with antibody to hepatitis C and D were detected. The annualized incidence of

hepatitis A was 0.26 per 1,000. All cases of hepatitis A were in children 4-16 years of age. The annualized incidence of hepatitis B, 2.17 per 1,000, was highest in adults aged 15-44 years (4.4 per 1,000) and was higher in men (36 cases; 3.09 per 1,000) than women (13 cases; 1.19 per 1,000). Four (31%) of the women with hepatitis B were pregnant. The annualized incidence was significantly higher in Mestizo (6.18 per 1000) and Maya (6.79 per 1,000) than Garifuna (0.38 per 1,000) or Creole (0.36 per 1,000). Persons with hepatitis B were significantly more likely to be born outside of Belize (82%), had been in Belize < 5 years (73%), and lived and worked in rural areas (96%) than was the general population. Of those > or = 14 years of age with hepatitis B, only 36% were married. Few persons admitted to transfusions, tattoos, IV drug use, multiple sexual partners, visiting prostitutes, or sexually transmitted diseases. Only 1 of 49 had a reactive test for syphilis. Six patients were hospitalized (including 3 with acute hepatitis B and one with hepatitis A), and none to our knowledge died. Acute hepatitis B is the most common cause of viral hepatitis in the Stann Creek District, but the modes of transmission remain obscure. Infants, women attending prenatal clinics, and new workers are potential targets for immunization with hepatitis B vaccine

N2 - In this review I examine the role of play and assessment in the lives of young children. These two seemingly opposing constructs are first defined. Next, I address a particularly important form of assessment, "high stakes" assessment, and argue that if it must be used, we should use a variety of assessment methods. One such method that I discuss in great detail is the use of direct observations of children's play. Examples of reliable and valid inferences about children's social cognitive functioning made with this family of methods are

provided. Two specific observational instruments (one for observing play in the classroom and one for observing play in the playground) are presented. Recommendations for their use by practitioners are made.

N2 - BACKGROUND: School playgrounds during break times provide potential opportunities for children to be active during the school day. However, there is limited research on how active children really are during these breaks. METHODS: The CAST (Children's Activity Scanning Tool) instrument was developed, validated, and used to assess the percentages of children engaged in moderate to vigorous physical activity (MVPA) and vigorous physical activity (VPA-a subset of MVPA) in 18 primary schools (children ages 5-12) in rural Australia. Related environmental factors were also measured. RESULTS: For a school of median size (200 students), 51.4% of boys and 41.6% of girls were engaged in MVPA while 14.7% of boys and 9.4% of girls were engaged in VPA. Levels of engagement in MVPA and VPA were significantly higher during lunch periods than during recess. MVPA and VPA engagement in smaller schools was significantly higher than in larger schools. CONCLUSIONS: With growing concern about children's physical activity (PA), school playgrounds offer an opportunity to increase children's MVPA engagement especially among girls. Consideration may be

given to the lengthening of recess periods in order to increase PA levels. More research is needed to investigate factors affecting PA levels in larger schools. Copyright 2001 American Health Foundation and Academic Press

N2 - A case of pretending a homicide to conceal a child suicide is reported in which characteristic findings of the postmortem examination and conclusions from the analysis of forensic autopsy series provided substantial support for the police investigation. In the late night hours of a spring day the police authorities were informed that a 10-year-old girl had been found dead on a playground near its parents' house. As injuries of the neck were recognized by the police officers a homicide investigation was initiated. The post mortem examination showed a furrow symmetrically slanting from the front to the nape of the neck, discrete punctate haemorrhages of the skin of the face and numerous 'tram-line' bruises of the back, buttocks and extremities. These findings indicated as cause and manner of death suicidal hanging following corporal punishment. Confronted with these conclusions the mother immediately made a corresponding confession

N2 - **OBJECTIVES:** The aim of the study was to assess the intake (by various routes of exposure) of polycyclic aromatic hydrocarbons (PAH) by children living in a Czech city, and its effect on excretion of 1-hydroxypyrene (1-OHP) in summer and winter periods. **METHODS:** Four groups of children (3-6 years old) were chosen: (1) two groups from a kindergarten situated in the city center with a higher traffic density ("polluted" area); (2) two groups from a kindergarten situated in a green zone of the same city ("non-polluted" area). Food consumption was recorded in all children and PAH intake from foodstuffs was estimated. Ambient air samples were collected from the playground and inside the kindergartens. Soil samples were collected too. Morning and evening urine samples were collected during sampling days. **RESULTS:** In both seasons, the mean outdoor total PAH concentration (sum of 12 individual PAH) in the "polluted" area was approximately three-times higher than that in the "non-polluted" area. Indoor concentration in the "polluted" area was more than six-times higher than that in the "non-polluted" area in summer, and almost three-times higher in winter. The same trend was observed for pyrene and for the sum of carcinogenic PAH. The contribution to the total pyrene absorbed dose from food consumption was much more important than that from inhalation and from ingestion of soil dust. Significantly higher urinary concentrations of 1-OHP (evening samples) were found in children from the "polluted" kindergarten in both seasons. The number of significant relationships between 1-OHP and pyrene absorbed dose was weak. **CONCLUSIONS:** Food seems to be the main source of total pyrene and total PAH intake in small children, even under relatively higher air PAH exposure in the city. Estimated pyrene ingestion from soil had a negligible contribution to the total pyrene absorbed dose. Urinary 1-OHP seems to be an uncertain (non-sensitive) marker of the environmental inhalation exposure to pyrene (PAH) if the pollution of air by pyrene (PAH) is not excessive and the pyrene (PAH) dose by this route is much less than by ingestion. Usefulness of the urinary 1-OHP as an indicator of overall environmental exposure to PAH needs further investigation

N2 - OBJECTIVE: The purpose of this study was to analyze causes of injury hospitalization/death by individual year of age and by specific causes of injury and to examine how well aggregate age groups represented individual year-of-age rates. METHODS: Hospital discharge data and death certificate data for California residents age 0 to 19 years with a principal external cause of injury code (E-code) of E800 to E869, E880 to E929, or E950 to E999, calendar year 1997, were analyzed. Annual rates of injury hospitalization/death by year of age were calculated using combined hospital discharges and deaths as the numerator for major causes and important subcategories. For comparison, rates of injury hospitalization/death were calculated for

conventional vital statistics age groups: <1 year, 1 to 4 years; 5 to 9 years, 10 to 14 years, and 15 to 19 years. RESULTS: In 1997 in California, 35 277 children and adolescents 0 to 19 years were hospitalized and 1934 died as a result of injury, a ratio of 17 hospitalizations to 1 death. The distribution was bimodal with rates highest among 18-year-olds (732/100 000) and 1-year-olds (495/100 000). Except for children who were 5 to 9 years of age, the group rates for all injuries were not reflective of the individual year-of-age rates. In specific categories of injuries, variation in rates by year of age were masked by age group rates for unintentional poisoning among 1- to 4-year-olds, self-inflicted poisoning for 10- to 19-year-olds, falls from playground equipment among 5- to 9-year-olds, falls from furniture among 1- to 4-year-olds, and motor vehicle occupant injury rates among 10- to 19-year-olds. The peak rate of falls from playground equipment among 6-year-olds (34/100 000) was more than twice the rate for 9-year-olds (15/1000,000). Motor vehicle occupant injury rates doubled between 10 and 14 years of age and quadrupled between 14 and 18 years of age. CONCLUSIONS: Analyses using conventional age groups did not identify the age of highest risk for many causes of childhood injury. Changes in the rates often transected the traditional age groups and were not apparent with conventional age group analysis. These data can inform on the age at which to begin a specific injury intervention and on how to allocate resources. These data allow pediatricians and other health professionals to be anticipatory in providing injury prevention counseling. The greatest impact can be achieved by making the counseling topic most age appropriate in anticipation of the high-risk period

N2 - **BACKGROUND:** Latex causes anaphylaxis in specific contexts among children. We present 2 cases that show that severe reactions may occur in everyday circumstances with latex as a contaminant. **OBJECTIVE:** Because 2 cases of severe reactions to latex suggested similar circumstances of exposure, we investigated the immediate environment in which episodes occurred. **METHODS:** A 5-year-old girl presented to our casualty department with anaphylaxis after playing in a ball pit filled with approximately 10-cm diameter plastic balls in an American-style fast-food outlet. Two months later, a 9-year-old boy had severe anaphylaxis followed by an asthma attack with loss of consciousness while playing in the playpen of a different outlet belonging to the same company. Latex sensitization was confirmed in both cases by means of skin prick testing, latex glove skin prick testing, and 1-glove finger testing. Immunoblotting of elutions from a ball, the natural rubber latex foam pit lining, and its polyvinyl chloride sheet were performed. **RESULTS:** In the girl's immunoblot high levels of IgE specific to Hev b 4, Hev b 7, and Hev b 2 were found. The boy's immunoblot showed positivity to Hev b 7. The polyvinyl chloride ball sample showed a high concentration of specific Hevea species allergen similar to that of the foam layer sample. **CONCLUSION:** Severe anaphylaxis can result from contact with latex proteins as a contaminant, rather than as a component, of play area ball pits and therefore outside the reported settings. Emergency health care workers should be aware of this kind of risk. A latex-reduced environment might prevent potentially severe reactions in young customers of fast-food outlets

N2 - OBJECTIVE: Injuries resulting from falls from playground equipment are a public health concern in New Zealand. Like many other countries, New Zealand has a safety standard aimed at reducing the incidence and severity of these injuries by limiting the height from which children can fall from playground equipment and requiring the provision of impact-absorbing surfaces beneath equipment from which falls are possible. The purpose of this study was to examine progress towards achieving compliance with these requirements in Dunedin school playgrounds. **METHODS:** Sixty-two schools were audited over the summer of 1997/98 and information recorded on equipment type, maximum fall height, surface type, and depth of loose-fill surface materials. Comparisons were made with audits conducted in 1989 and 1981. **RESULTS:** Substantial increases in the amount of playground equipment and in the provision of impact-absorbing surfaces were observed. A small increase in compliance with the requirement that the maximum fall height of equipment not exceed 2.5 metres was also observed. **CONCLUSIONS:** Any gains in safety achieved through increased compliance with the height and surface requirements of the New Zealand Standard have been counteracted by the substantial increase in the amount of equipment available in playgrounds. **IMPLICATIONS:** A more drastic measure is needed to achieve a meaningful reduction in the incidence of injury following falls from playground equipment

N2 - This paper presents a probabilistic, multimedia, multipathway exposure model and assessment for chlorpyrifos developed as part of the National Human Exposure Assessment Survey (NHEXAS). The model was constructed using available information prior to completion of the NHEXAS study. It simulates the distribution of daily aggregate and pathway-specific chlorpyrifos absorbed dose in the general population of the State of Arizona (AZ) and in children aged 3-12 years residing in Minneapolis-St. Paul, Minnesota (MSP). Pathways included were inhalation of indoor and outdoor air, dietary ingestion, non-dietary ingestion of dust and soil, and dermal contact with dust and soil. Probability distributions for model input parameters were derived from the available literature, and input values were chosen to represent chlorpyrifos concentrations and demographics in AZ and MSP to the extent possible. When the NHEXAS AZ and MSP data become available, they can be compared to the distributions derived in this and other prototype modeling assessments to test the adequacy of this pre-NHEXAS model assessment. Although pathway-specific absorbed dose estimates differed between AZ and MSP due to differences in model inputs between simulated adults and children, the aggregate model results and general findings for simulated AZ and MSP populations were similar. The major route of chlorpyrifos intake was food ingestion, followed by indoor air inhalation. Two-stage Monte Carlo simulation was used to derive estimates of both inter-individual variability and uncertainty in the estimated distributions. The variability in the model results reflects the difference in activity patterns, exposure factors, and concentrations contacted by individuals during their daily activities. Based on the coefficient of variation, indoor air inhalation and dust ingestion were most variable relative to the mean, primarily because of variability in concentrations due to use or no-use of pesticides. Uncertainty analyses indicated a factor of 10-30 for uncertainty of model predictions of 10th, 50th, and 90th percentiles. The greatest source of uncertainty in the model stems from the definition of no household pesticide use as no use in the past year. Because chlorpyrifos persists in the residential environment for longer than a year, the modeled estimates are likely to be low. More information on pesticide usage and environmental concentrations measured at different post-application times is needed to refine and evaluate this and other pesticide exposure models

N2 - The purpose of this study was to evaluate the adaptations of a playground, and subsequently staff development, on the participation of a 3-year-old boy with congenital blindness. A single-subject design with three conditions (baseline, adaptations of the playground, and staff development) was used. The playground adaptation involved adding musical stations in strategic locations on the playground and connecting them with a "path" that provided auditory feedback. The staff training involved the music therapist providing individualized instruction to the staff who supervised the child. The child's participation was measured in terms of social interaction with peers or adults, play and engagement with materials, movement on the playground, and stereotypic behaviors. The playground adaptation resulted in no changes in the child's social interactions with peers or adults, increases in engagement, no change in movement on the playground, and a decrease in stereotypic responses. Staff training resulted in increased but variable interactions with adults and peers, in additional increases in engagement, less movement, and similar levels of stereotypic behavior. The findings suggest that musical adaptations of physical environments may be helpful but not sufficient for promoting desired outcomes

N2 - **OBJECTIVES:** Manual methods of measuring duration of cortical silent periods (CSP) evoked by transcranial magnetic stimulation (TMS) depend upon subjective visual estimation of onset and offset. Because of this, the measurements are susceptible to poor rater reliability. We describe a graphical method to measure silent periods with greater precision. The statistical process underlying this new method is simple and particularly suited to signal detection in serially dependent data. **METHODS:** TMS-evoked silent periods were recorded in 13 healthy subjects. Two investigators subjectively measured silent period duration on each subject to estimate rater reliability. Using the graphical method, the mean and 99.76% variation limits of pre-stimulus electromyogram (EMG) activity were computed. Each averaged trial was displayed and CSP onset and offset detected when post-stimulus EMG activity moved outside the 99.76% limits. **RESULTS:** Maximum variation in silent period duration was 21.8 ms between the two investigators' subjective measurements. Silent period duration measured with the graphical method closely approximated measurements obtained using the manual method. It was possible to automate the procedure. **CONCLUSIONS:** This graphical method allowed precise measurement of CSP duration, independent of subjective estimations of onset or offset points. Further studies are necessary to determine if this method can provide a framework for other physiologic measures

N2 - **BACKGROUND:** Substantial differences exist in how and where physical education (PE) is conducted in elementary schools throughout the United States. Few effectiveness studies of large-scale interventions to improve PE have been reported. **DESIGN:** Multicenter randomized trial. **SETTING/ PARTICIPANTS:** The Child and Adolescent Trial for Cardiovascular Health (CATCH) was implemented in PE classes in 96 schools (56 intervention, 40 control) in four study centers: California, Louisiana, Minnesota, and Texas.

INTERVENTION: The 2.5-year PE intervention consisted of professional development sessions, curricula, and follow-up consultations. **MAIN OUTCOME MEASURES:** Intervention effects on student physical activity and lesson context in PE were examined by teacher type (PE specialists and classroom teachers) and lesson location (indoors and outdoors). **RESULTS:** Differential effects by teacher type and lesson location were evidenced for both physical activity and lesson context. Observations of 2016 lessons showed that intervention schools provided more moderate-to-vigorous physical activity ($p=0.002$) and vigorous physical activity ($p=0.02$) than controls. Classroom teachers improved physical activity relatively more than PE specialists, but PE specialists still provided longer lessons and more physical activity. Classroom teachers increased lesson length ($p=0.02$) and time for physical fitness ($p=0.03$). **CONCLUSIONS:** The intervention improved PE of both specialists' and classroom teachers' lessons. States and districts should ensure that the most qualified staff teaches PE. Interventions need to be tailored to meet local needs and conditions, including teacher type and location of lessons

N2 - This study investigated the relations between various measures of social understanding and social interaction competence in verbally able children with autism. Measures of social understanding included measures of verbalizable knowledge (false belief understanding, affective perspective taking), as well as measures of more intuitive forms of social responsiveness (empathy, concern to distress, and initiating joint attention). Two measures of social interaction competence were employed: level of engagement with peers on the playground, and prosocial behavior in a structured laboratory task. For children with autism, initiating joint attention and empathy were strongly related to both measures of social interaction competence. No understanding-behavior links were identified for a language-age matched comparison sample of developmentally delayed children. Several accounts of these understanding-behavior links are considered, including the possibility that for children with autism, more impaired forms of understanding are more closely linked to behavior because they serve as limits on competence

N2 - Dhaka, Bangladesh, has one of the highest air lead levels in the world. In February 2000, we evaluated children at five primary schools in Dhaka to determine blood lead (BPb) levels, sources of environmental exposure, and potential risk factors for lead poisoning. Selected schools represented a range of geographic and socioeconomic strata. A total of 779 students 4-12 years of age participated. The mean BPb level was 15.0 microg/dL (range 4.2-63.1 microg/dL). Most students (87.4%) had BPb levels above the Centers for Disease Control and Prevention's level of concern (10 microg/dL). Elevated BPb levels correlated with soil eating [odds ratio (OR) = 3.31; 95% confidence interval (CI), 1.30-8.39], low parental education (OR = 2.72; 95% CI, 1.97-3.75), living close to major roads (OR = 2.30; 95% CI, 1.23-4.29), and increasing age (OR = 1.11; 95% CI, 1.06-1.16). BPb levels measured were similar to those in other countries that use leaded gasoline. No other potential sources of lead exposure were consistently identified. Combustion of leaded gasoline is the main source of lead exposure in Dhaka, resulting in ubiquitous contamination of the environment. The increase in BPb levels with age, a finding contrary to observations in the United States and Australia, may be related to increased outdoor activities. The Bangladeshi government recently announced a plan to eliminate leaded gasoline. Baseline BPb surveys are critical to develop and evaluate intervention policies. Strategies to reduce BPb levels need to address variations in socioeconomic status, construction type and location of housing, and levels of hygiene

N2 - The UV doses of Americans were never measured, but are needed for assessing the risks of UV-related health effects. We calculated these doses using a novel approach. The Environmental Protection Agency's (EPA) National Human Activity Pattern Survey (NHAPS) recorded the activity profiles of 9386 Americans over 24 months to assess their exposure to environmental pollutants, one of which is UV radiation. NHAPS used randomized telephone interviews to get their previous day's minute-by-minute activities. From NHAPS we extracted only the outdoor-daylight data of the northern and southern indoor workers (95%), stratifying by season, sex and age (0-21, 22-40, 41-59 and 60+ years) to find the average time Americans spend outdoors. Knowing the total daylight time and that while outdoors Americans are exposed to about 30% of the available solar UV (on a horizontal plane), we calculated their percent ambients. The average American's percent ambients are 2.6 and 2.5% for northern and southern females, respectively, and 3.5 and 3.6% for northern and southern males, respectively. Men over 40 years of age have the highest ambients (4%). From their ambients we calculated their annual doses using seasonal averages of UV measurements taken daily for over 2 years by EPA Brewer spectrophotometers located in four quadrants of the United States: Atlanta, GA; Boston, MA; Bozeman, MT and Riverside, CA. The average erythemal UV doses of Americans are about 25,000 J/m²/year, 22,000 for females and 28,000 for males, or 33,000 J/m²/year including a conservative continental U.S. vacation (7800 J/m²). Thus, we can now assess the risks of UV-related health effects for Americans

N2 - BACKGROUND/AIMS: Primary schoolchildren in their everyday school life are exposed to solar ultraviolet radiation. This may be through time spent outdoors whilst having meal breaks, physical education classes and other class orientated outdoor activities. METHODS: This research investigates the UV exposure of primary schoolchildren and the effect real-time UV irradiances data and an associated software package, UVGUIDE, have on UV exposure. This software utilises scientifically collected data, such as facial distribution of UV, as well as accessing real-time on-line UV irradiances data to estimate the UV distribution to the head region. The students can also enter other parameters such as hat usage and hat type to show the effect of using such a UV protective device on their facial UV distribution. CONCLUSIONS: The results from this study found that the average 3-day erythemal UV exposure in late summer and early autumn to the left shoulder was 33% higher for the students not having access to the on-line UV data and software package

N2 - A number of disorders of the respiratory tract and some even outside the respiratory tract can cause cough. A systematic approach towards a patient of chronic cough consisting of detailed history, physical examination of upper as well as lower respiratory tract, complete blood counts, tuberculin test, chest X-ray, and peak flow rate testing will give the diagnosis in majority of children. Pulmonary tuberculosis and asthma are the two commonest conditions diagnosed. If the initial work up is inconclusive, further laboratory testing and imaging studies should be considered. Thus, radiolabelled milk scan, barium swallow and 24-hour pH monitoring would diagnose gastroesophageal reflux. Spirometry, methacholine/exercise challenge test or a therapeutic trial may be required for confirming bronchial asthma. Flexible bronchoscopy is useful for evaluation for suspected aspiration syndromes and any anatomical or dynamic problem of the airway (e.g. tracheomalacia). Spiral and high resolution computed tomography (HRCT) along with magnetic resonance imaging are the modern day imaging techniques used for studying mediastinal masses, airway obstruction and even lung parenchyma (HRCT). Sputum examination for type of cells and bacteria can be useful, especially if pseudomonas or acid-fast bacilli are identified. Pseudomonas suggests cystic fibrosis (an uncommon disease in India) which can be confirmed by sweat chloride test and gene mutation studies

N2 - OBJECTIVE: Head injury (HI) in sport is common and can have serious consequences. This study examines the epidemiology of sport/recreational (SR)-related HI presenting to the emergency department (ED). DESIGN: Retrospective review of medical records. SETTING: Five EDs in the Capital Health Region (Edmonton) located in the province of Alberta, Canada. PATIENTS: All persons in a 1-year period reporting to the EDs with an HI. HI was defined as IC9-CM coded skull fracture, loss of consciousness, or concussion. MAIN OUTCOME MEASURES: Hospitalization, utilization of diagnostic testing, and discharge destination. RESULTS: In total, 10,877 (3%) of 288,948 ED encounters were for sports and recreational injuries; 358 (3%) were for HI. Males (71%) were more frequently injured; patients < 20 years old were involved in 66% of all HI cases. The highest proportion of HI occurred during ice hockey (21%), cycling (13%), and playground-related activities (8%). 9% of HI were hospitalized (versus 4% admission rate for other SR injuries: $p < 0.01$). CONCLUSIONS: These results demonstrate the utility of an ED-based injury registry and indicate that patients with HI presenting to the ED from SR activities are common. These injuries appear to be more severe than other types of SR injuries treated in the ED

N2 - PURPOSE: To examine the prevalence of myopia in rural and urban schoolchildren in Xiamen, China, and to assess the impact of environmental factors on rates of myopia. METHODS: Second-grade children attending either a city (n=119) or rural (n=91) school in Xiamen, China, were examined using cycloplegic autorefraction and biometry. Detailed questions on socioeconomic status, near-work activity, reading and writing habits, and family histories of myopia were asked in a face-to-face interview using a standard questionnaire. RESULTS: The prevalence of myopia was 19.3% (95% confidence interval [CI], 12.3, 29) in the city and 6.6% (95% CI, 2.4, 14.3) in the countryside. The average hours per day children spent reading and writing outside of school was 2.2 hours in the city compared with 1.6 hours in the countryside (P<.0001). In both schools, the odds ratio for total reading and writing, adjusted for parental history of myopia, was 2.2 (95% CI, 1.1, 4). CONCLUSION: These data suggest the prevalence of myopia is higher in the city than in the countryside. One possible explanation for these different rates could be that schoolchildren in the city spend more time reading and writing outside of school compared with children in the countryside. Myopic children in both the city and the countryside spent more time reading and writing compared with nonmyopic children. This increased near-work activity may contribute to the prevalence of myopia

N2 - Based on recent studies of the photoreceptor-specific ABC transporter gene ABCR (ABCA4) in Stargardt disease (STGD1) and other retinal dystrophies, we and others have developed a model in which the severity of retinal disease correlates inversely with residual ABCR activity. This model predicts that patients with late-onset STGDI may retain partial ABCR activity attributable to mild missense alleles. To test this hypothesis, we used late-onset STGDI patients (onset: > or =35 years) to provide an in vivo functional analysis of various combinations of mutant alleles. We sequenced directly the entire coding region of ABCR and detected mutations in 33/50 (66%) disease chromosomes, but surprisingly, 11/33 (33%) were truncating alleles.

Importantly, all 22 missense mutations were located outside the known functional domains of ABCR (ATP-binding or transmembrane), whereas in our general cohort of STGDI subjects, alterations occurred with equal frequency across the entire protein. We suggest that these missense mutations in regions of unknown function are milder alleles and more susceptible to modifier effects. Thus, we have corroborated a prediction from the model of ABCR pathogenicity that (1) one mutant ABCR allele is always missense in late-onset STGDI patients, and (2) the age-of-onset is correlated with the amount of ABCR activity of this allele. In addition, we report three new pseudodominant families that now comprise eight of 178 outbred STGDI families and suggest a carrier frequency of STGDI-associated ABCR mutations of about 4.5% (approximately 1/22)

N2 - INTRODUCTION: The incidence of melanoma has increased in the past 10 years more rapidly than any other cancer. Exposure to intense solar radiation in youth significantly increases the lifetime risk of developing melanoma. We postulate that teenagers have little awareness of melanoma prevention or detection principles.

The purpose of this study was to assess the knowledge of teenagers about melanoma and to identify which age groups are most receptive to altering their sun exposure behaviors. METHODS: Two hundred and ten examinations testing general knowledge of sun exposure and melanoma were completed and returned by junior high and high school students ages 12 to 18 in Dallas and Houston, Texas. All students completing and returning the examination were provided with the correct answers to the test and a detailed explanation of each of the test items as part of an educational exercise. A second questionnaire was then administered to determine the effect of the educational exercise on future sun exposure practices. Students were divided into two age groups (12 to 15 and ≥ 16 years old) for comparison of scores on the knowledge examination and responses to behavioral items. Comparison of response rates between age groups was performed using chi(2) analysis.

RESULTS: The return rate was 100%, with 109 students age 12-15 years, and 101 students ≥ 16 years.

Seventy-six percent of all respondents sunbathed outdoors, and 18% had used a tanning bed in the past 6 months. Thirty-three percent of students admitted to at least three blistering sunburns in the past. The average score on the knowledge assessment examination was 65% correct for students ≥ 16 years old and 54%

correct for those 12-15 years old. Students 12 to 15 years old were significantly more likely to indicate they planned to change future behaviors regarding performance of skin self-examinations and limiting sun exposure as compared to the older students. **CONCLUSION:** A significant number of teenagers have already enhanced their risk for future melanoma by suffering severe sunburns. Students younger than 16 years of age were significantly more likely to indicate they planned to change future behaviors after receiving information about melanoma. The data from this pilot study support education aimed at younger age groups to most effectively achieve risk reduction and prevent future melanomas. Copyright 2001 Academic Press

N2 - The authors investigated airborne fungal exposure of Taiwanese children at homes and schools-locations where they spent the majority of their time. Pairs of asthmatic and healthy children, matched by age, gender, classes (schools), and residence, participated in the study. Airborne fungal concentrations at homes and schools, and time-activity data of the study subjects were collected. In winter, the indoor geometric mean concentration was 9,672.1 colony-forming units per cubic meter and 4,380.9 colony-forming units per cubic meter in summer. The indoor/outdoor concentration ratio was similar in all homes for both seasons. Fungal concentrations in

southern Taiwan were high during both winter and summer. Personal fungal exposure was not statistically different between asthmatic and nonasthmatic children, after adjustment of time-activity patterns. Higher symptom scores were shown for children in homes with higher fungal exposures

N2 - INTRODUCTION: In Sweden, several ambulance helicopter programs have been used during the past 3 decades. This article describes one of these programs. SETTING: The catchment area of the helicopter system under study was a typical rural setting with a population density of less than 5 people per square kilometer. METHODS: We describe in detail, with special reference to medical aspects, the activities of an helicopter ambulance program in 1997. RESULTS: A total of 288 missions, including 328 patients (204 men), were analyzed. Trauma cases (29%) and patients with cardiovascular (24%) and neurologic problems (13%) dominated the missions. One-sixth of the cases occurred at night. The median response time was 12 minutes,

and the median on-scene time was 28 minutes. The medical interventions performed included intubations; central venous catheter, arterial needle, and duodenal tube insertions; and medication administered intravenously, orally, and intrabronchially. CONCLUSION: We detected a higher rate of trauma cases than in previously published investigations, probably related to the outdoor activities of the area. We believe that the rapid institution of thrombolytic treatment in suspected acute myocardial infarction and a more rapid and flexible transport of trauma cases in a rural area are important. We estimate that, in most cases, the helicopter service could provide a quicker transport than a ground ambulance; however, for short distance transports, ground ambulance is faster than helicopter ambulance

N2 - PURPOSE: Myasthenia gravis can cause variable strabismus with disabling diplopia and/or poor cosmesis. A retrospective study of a group of patients with myasthenia gravis or 'myasthenia gravis like'

syndromes was made. **METHODS:** The study group consisted of patients who had undergone botulinum toxin treatment and/or surgery for disabling diplopia, poor cosmesis or both. Surgical treatment was by conventional techniques including recess/resect, posterior fixation, superior oblique tenotomy and adjustable sutures.

RESULTS: There were 9 patients in the study group (8 female, 1 male). Age at surgery ranged from 21 to 59 years (mean 46 years). Six were symptom-free following treatment. Two, although symptomatically improved, had occasional diplopia. One patient failed treatment and required an occlusive contact lens. **CONCLUSIONS:** The ocular manifestations of myasthenia gravis or 'myasthenia gravis like' syndromes may respond to surgery and/or botulinum toxin injection. Active intervention should be considered when deviations become stable. To our knowledge this is the first report of the use of botulinum toxin in such patients

N2 - **BACKGROUND:** Although limited environmental exploration in autism is an obvious behavioral feature and may be a manifestation of "restricted interests" as described in DSM-IV criteria, there have been no behavioral or neurobiological studies of this important aspect of the disorder. Given consistent reports of cerebellar abnormality in autism, combined with animal research showing a relationship between exploration and the cerebellum, this study aimed to test the possible link between cerebellar abnormality and exploration in

autism. **METHODS:** The relationship between visuospatial exploration, stereotyped motor movements, and magnetic resonance imaging measures of the cerebellar vermis, whole brain volume, and frontal lobes in 14 autistic and 14 normal children was investigated. Children were exposed to a large room with several exploration containers and instructed to play. Exploration behavior was videotaped and scored for percentage of time engaged in exploration, number of containers explored, as well as stereotyped movements. **RESULTS:** Children with autism spent significantly less time in active exploration and explored fewer containers overall than normal children. Measures of decreased exploration were significantly correlated with the magnitude of cerebellar hypoplasia of vermal lobules VI-VII in the autistic children, but no relationship to vermis size was found with normal control children. Further, measures of rates of stereotyped behavior were significantly negatively correlated with area measures of cerebellar vermis lobules VI-VII and positively correlated with frontal lobe volume in the autism sample. **CONCLUSIONS:** Reduced environmental exploration and repetitive behavior may have particularly important developmental consequences for children with autism because it may lead them to miss learning opportunities that fall outside their scope of interest. Our findings represent the first documented link between the restricted range of interests and stereotyped behaviors pathognomonic of autism and particular neuroanatomic sites

N2 - PURPOSE: To discuss the incidence and to characterize the clinical features of ocular trauma associated with bungee cord injuries. DESIGN: Retrospective case series. PARTICIPANTS: The authors identified 67 subjects (60 males) treated at Wills Eye Hospital for ocular trauma resulting from bungee cords between September 1, 1994, and September 1, 1999. METHODS: The authors reviewed subjects' records from Wills Eye Hospital, records from outside physicians involved in the subjects' care, and conducted telephone interviews when additional information was needed. MAIN OUTCOME MEASURES: Each chart was reviewed for demographic information, mechanism of injury, presenting visual acuity, anterior segment, posterior segment and periocular injuries, medical and surgical intervention, final visual acuity, and length of follow-up. RESULTS: Mean visual acuity on presentation was 20/150. The most common anterior, posterior, and periocular injuries were hyphema (42/67, 63%), commotio retinae (30/55, 55%), and eyelid edema/ecchymosis (40/67, 60%), respectively. Seven subjects (10%) sustained open globe injuries, three (4%) of whom required enucleation. Eighteen subjects (27%) required medical treatment, and 4 subjects (6%) required surgical treatment for increased intraocular pressure. A total of 21 subjects (31%) required some form of surgical intervention. Mean final visual acuity was 20/60, with an average follow-up of 34 weeks. CONCLUSIONS: This series, the largest to date, demonstrates a wide spectrum of serious ocular injuries related to bungee cord use. Medical and surgical treatments are commonly necessary to manage these injuries. We advocate a modification in the design of these cords and appropriate printed warnings directed to the users of bungee cords regarding the potential for severe ocular trauma. [References: 7]

 N2 - ISSUES AND PURPOSE: To describe patient demographics, injury characteristics, and circumstances of playground injuries in children admitted to Pennsylvania trauma centers and to identify injury prevention strategies. DESIGN AND METHODS: Retrospective, descriptive study of 234 children ages 1 to 18 years sustaining playground-related injuries and whose hospital data were entered into the Pennsylvania Trauma Outcome Study. RESULTS: Most of the injuries occurred between April and September (77%), and noon to 6 P.M. (69%). Falls from playground equipment constituted the highest proportion of incidents (73%). Of 421 injuries (M = 1.8/patient), most were upper extremity (n = 117) and head (n = 110) injuries. PRACTICE IMPLICATIONS: Nurses can advocate for playground safety by teaching children to play safely and recommending age-appropriate equipment and protective surfacing. [References: 23]

N2 - OBJECTIVE: To evaluate the Latrobe Valley Better Health Injury Prevention Program, a regional community based intervention in south east Victoria, Australia. **METHOD:** The evaluation design was quasiexperimental including pre-intervention and post-intervention observations in a predominately town dwelling population of approximately 76,000. There was no comparison community. Process measures included key informant interviews. Impact evaluation utilised self reported changes in injury risk and protective factors, gathered by a random household telephone survey. Outcome evaluation was based on five years of emergency department injury surveillance data for the Latrobe Valley. **RESULTS:** The program built strategic partnerships, increasing the emphasis on local safety. Activities were implemented in the targeted areas of home, sport, and playground injuries. Some 47,000 educational contacts were made with the community and at least 6,000 resource items distributed. There were significant increases in home safety knowledge. Some changes in the areas of playground and sport safety were achieved after partnership development with relevant agencies. Poisson regression models showed significant decreases in the presentation rate for all home injury and for the more severe home injuries. **CONCLUSION:** This study clearly demonstrates the difficulty of conducting robust evaluation in the absence of readily available and reliable data and adequate budgets. The Latrobe Valley Better Health Program activities contributed to structural, environmental, and organisational changes that have the potential to reduce injury. The extent of this contribution beyond that made by the statewide injury prevention strategy is not able to be determined

N2 - OBJECTIVES: To evaluate whether surface characteristics (absorption level (g-max), material) and the height of play equipment are related to the occurrence and severity of injuries from falls. SETTING AND METHODS: During the summers of 1991 and 1995, conformity of play equipment to Canadian standards was assessed in a random sample (n = 102) of Montreal public playgrounds. Surface absorption (g-max) was tested using a Max Hic instrument and the height of equipment was measured. Concurrently, all injuries presenting at the emergency department of Montreal's two children's hospitals were recorded and parents were interviewed. Inspected equipment was implicated in 185 injuries. The g-max measurements (1995 only) were available for 110 of these playground accidents. RESULTS: One third of falls (35 %) occurred on a surface exceeding 200 g and the risk of injury was three times greater than for g level lower than 150 (95% confidence interval (CI) 1.45 to 6.35). On surfaces having absorption levels between 150 g and 200 g, injuries were 1.8 times more likely (95% CI 0.91 to 3.57). Injuries were 2.56 times more likely to occur on equipment higher than 2 m compared with equipment lower than 1.5 m. Analysis of risk factors by severity of injury failed to show any positive relationships between the g-max or height and severity, whereas surface material was a good predictor of severity. CONCLUSIONS: This study confirms the relationships between risk of injury, surface resilience, and height of equipment, as well as between type of material and severity of injury. Our data suggest that acceptable limits for surface resilience be set at less than 200 g, and perhaps even less than 150 g, and not exceed 2 m for equipment height. These findings reinforce the importance of installing recommended materials, such as sand, beneath play equipment

N2 - Industrial growth has created the potential for environmental problems in Mexico, since attention to environmental controls and urban planning has lagged behind the pace of industrialization. The aim of this cross-sectional study was to assess lead exposure in children aged 6-9 yr attending 3 primary schools and living in the vicinity of the largest smelter complex in Mexico. One of the schools is located 650 m distant from a smelter complex that includes a lead smelter (close school); the second is located 1750 m away from the complex and at the side of a heavy traffic road (intermediate school) in Torreon, Coahuila. The third school is located in Comez Palacio, Durango, 8100 m away from the smelter complex and distant from heavy vehicular traffic or industrial areas (remote school). Lead was measured in air, soil, dust, and well water. Lead in blood (PbB) was determined in 394 children attending the above mentioned schools. Determinations were performed by atomic absorption spectrometry. Diet, socioeconomic status, hygienic habits, and other variables were assessed by questionnaire. Median (range) PbB values were 7.8 microg/dl (3.54-29.61) in the remote school, 21.8 microg/dl (8.37-52.08) in the intermediate school and 27.6 microg/dl (7.37-58.53) in children attending the close school. The percentage of children with PbB > 15 microg/dl was 6.80%, 84.9%, and 92.1% respectively. In this order, the geometric means (range) of Pb concentrations in air were 2.5 microg/m³ (1.1-7.5), 5.8 microg/m³ (4.3-8.5), and 6.1 microg/m³ (1.6-14.9). The Pb concentrations in dust from playgrounds areas in the intermediate and close school settings ranged from 1,457 to 4,162.5 mg/kg. Pb concentrations in drinking water were less than 5 microg/L. Soil and dust ingestion and inhalation appear to be the main routes of exposure. Our results indicate that environmental contamination has resulted in an increased body burden of Pb, suggesting that children living in the vicinity of the smelter complex are at high risk for adverse effects of lead

N2 - OBJECTIVES: To analyse ongoing education within primary care teams from managers' perspective.

DESIGN: Cross-sectional descriptive study. SETTING: The Mother-Infant Health Programme of Andalusia in primary care. INTERVENTION: The views of health centre professionals were obtained through 8 groups. The type of health district and the number of years in operation were used as criteria for division. The views of the area managers were collected through a self-filled questionnaire from all the managers in the autonomous community. MEASUREMENTS AND MAIN RESULTS: Professionals believed it necessary to keep up to date and train in new technology. They thought that training activities should focus on questions such as evaluation of programmes, focus of risk, counselling and communication, and certain techniques such as IUD insertion. Both managers and professionals coincided in recognising the effect of training on the development of mother-child services. There was consensus among professionals in affirming that training increases the quality of care delivered. Access to training was the main incentive element used by most area managers and one of those most highly valued by professionals. The professionals affirmed that in recent years there had been obstacles to their education by attending scientific events outside their areas. Many professionals stated that the economic

assistance of the pharmaceutical industry for courses caused inequalities between doctors and nurses in access to training. Professionals were very critical of training combined with specialist training. CONCLUSIONS: Professionals think they have sufficient training for mother-child health care. It is generally recognised that family doctors are better trained for working on health programmes than other professionals at the centres. Ongoing training was rated very highly by both professionals and directors, as it was seen as a motivating element and thought to be an activity almost solely carried out at health centres

N2 - The study of water contact patterns in rural Brazil presents unique challenges due to widely dispersed settlement patterns, the ubiquity of water contact sites, and the privatization of water resources. This study addresses these challenges by comparing the two most widely used methods of assessing water contact behaviour: direct observation and survey. The results of a 7-day direct observation of water contact were compared with water contact surveys administered 1 week after and then 1 year after the direct observation study. The direct observation study recorded a water contact rate higher than reported by other investigators (3.2 contacts per person per day); however, 75% of these contacts were for females and consisted mainly of domestic activities occurring around the household. A comparison of the frequency of water contact activities between the direct observation and the two surveys revealed several important points. First, no significant differences were found between methods for routine water contact activities (e.g. bathing), indicating that participants were able to accurately self-report some types of water contact activities. Second, significant differences were found in the recording of water contact activities that took place outside the observation area, indicating that direct observation may under-report water contact activities in areas where contact sites are dispersed widely. Third, significant differences between the direct observation and the survey method were more common for males than for females, indicating that the combination of widespread water contact sites and gender-specific division of labour may result in under-reporting of male contacts by direct observation methods. In short, despite the limitations in the recording of duration and body exposure, the survey method may more accurately record the frequency of water contact activities than direct observation methods in areas of widely dispersed water contact sites. Hence, surveys may be more suitable for the unique challenges of water contact in rural areas of Brazil

N2 - **STUDY OBJECTIVE:** To analyze the epidemiology of wilderness mortalities in a localized area with diverse terrain. **METHODS:** We conducted a retrospective review of the Pima County (Arizona) Sheriff's Office (PCSO) search and rescue logs and case reports, hospital records, and autopsy reports for all wilderness deaths from 1980 to 1992. The study group comprised all victims of injury or illness in Pima County wilderness who died during a 13-year period in a location remote enough so that standard ground-based emergency medical services units could not extract the body. **RESULTS:** One hundred fatalities occurred during the 13-year study period. There were 59 unintentional traumas, 18 suicides, 9 homicides, 12 medically related deaths, and 2 deaths of unknown causes. Toxicology tests performed on body fluids yielded positive findings for alcohol in a total of 50 (50%) cases and positive findings for drugs of abuse in 12 (12%) cases. It was estimated that alcohol was "a very probable" or "a probable" causative factor in 23 (40%) of the 59 unintentional trauma deaths, and in 1 (8.3%) of the 12 medically related deaths. Fifty-five (55%) deaths were witnessed events, with 45 (80%) of these victims reported as dying immediately or before arrival of search and rescue personnel. Ten (10%) victims received resuscitation in the field, and according to a review of hospital charts and autopsy reports, only 2 victims had a potentially survivable injury or illness. **CONCLUSION:** Many wilderness mortalities are related to incidents involving alcohol. Once the accident or injury has occurred, the majority of deaths are immediate, or at least before the arrival of medical personnel. Higher levels of medical care would not have improved the outcomes of those who did survive long enough to receive medical care. Therefore, primary efforts to reduce mortalities in the wilderness should be directed toward prevention, especially diminishing alcohol use in wilderness areas

N2 - AIM: To assess the prevalence of injuries in elementary schools and determine specific risk groups of school-age children. METHODS: According to the 1991 census, there were 6,398 children between 7 and 14 years of age in the study area of the former Koprivnica district. During the 1992-1997 period, 354 children were injured in school. The registration of injured children was performed via structured questionnaires filled out at the emergency clinic and outpatient surgical clinic of the General Hospital in Koprivnica. The mechanism of accident and activities preceding it were categorized according to the Nordic Medico-Statistical Committee classification. Chi-square test was used to determine groups of school children at specific risk and a classification tree was made on the basis of minimum entropy values for age, sex, activity, and mechanism of injury. RESULTS: The highest injury rate of was recorded in 12-year-olds (21.7%). Upper extremities were most common site of injury (52.8%), whereas the most common type of injury was contusion (45.2%). The rate of head injuries was 3.2 times higher in younger (aged 7-10) children, whereas the rate of sports injuries was 3.5-fold higher in older (aged 11-14) children ($p=0.001$). Entropy classification revealed younger school-age children to be at the highest risk of contusion due to a blow from a ball, an object, or contact during sports activities. CONCLUSION: In Koprivnica County, most school-related injuries occurred during sport activities (42%) and play during recess (55%), with specific differences in age and sex

N2 - CONTEXT: The relationship between exposure to aggression in the media and children's aggressive behavior is well documented. However, few potential solutions have been evaluated. OBJECTIVE: To assess the effects of reducing television, videotape, and video game use on aggressive behavior and perceptions of a mean and scary world. DESIGN: Randomized, controlled, school-based trial. SETTING: Two sociodemographically and scholastically matched public elementary schools in San Jose, Calif. PARTICIPANTS: Third- and fourth-grade students (mean age, 8.9 years) and their parents or guardians. INTERVENTION: Children in one elementary school received an 18-lesson, 6-month classroom curriculum to reduce television, videotape, and video game use. MAIN OUTCOME MEASURES: In September (preintervention) and April (postintervention) of a single school year, children rated their peers' aggressive behavior and reported their perceptions of the world as a mean and scary place. A 60% random sample of children were observed for physical and verbal aggression on the playground. Parents were interviewed by telephone and reported aggressive and delinquent behaviors on the child behavior checklist. The primary outcome measure was peer ratings of aggressive behavior. RESULTS: Compared with controls, children in the intervention group had statistically significant decreases in peer ratings of aggression (adjusted mean difference, -2.4%; 95% confidence interval [CI], -4.6 to -0.2; $P = .03$) and observed verbal aggression (adjusted mean difference, -0.10 act per minute per child; 95% CI, -0.18 to -0.03; $P = .01$). Differences in observed physical aggression, parent reports of aggressive behavior, and perceptions of a mean and scary world were not statistically significant but favored the intervention group. CONCLUSIONS: An intervention to reduce television, videotape, and video game use decreases aggressive behavior in elementary schoolchildren. These findings support the causal influences of these media on aggression and the potential benefits of reducing children's media use

N2 - The long-distance travellers could be important to any cost-benefit assessment of policies to increase or improve local resources. This study examines the out-of-area hospital admission pattern for patients with Ambulatory Care Sensitive (ACS) conditions, also known as preventable conditions. The availability of local resources play a significant role for hospitalization for these conditions. Despite a growing literature investigating hospital choice, little is known about the effects of resource availabilities in local areas and patient characteristics prompting people to seek care at a longer distance from home for these conditions. Based on hospital discharge data for New York residents (children) admitted to hospitals in New York, Pennsylvania, New Jersey or Connecticut in 1994, the study uses logistic regression to predict travel out of the local area for ACS admission. The actual distance between residence and hospital is a highly skewed and problematic

measure, but the crossing of county boundaries is a related and very useful dichotomous measure of distant hospitalization. The study finds a strong association of types of insurance and availability of primary care with episodes of hospitalization for children outside the area of residence, after controlling for severity of illness and several other patient and county characteristics. N2 - **BACKGROUND:** A new conceptual framework is needed to evaluate health-based interventions based on the premise that like the environment, workplaces are complex ecologies. The proposed Work Environment Impact Assessment (WEIA) is analogous to Environmental Impact Assessment (EIA), a concept and method developed 30 years ago in the environmental policy arena to evaluate potential consequences of human activity for the natural environment. WEIA entails identifying and evaluating both intended and unintended consequences, or outcomes, associated with a particular intervention. Because the workplace is a complex ecology, changes in one aspect may lead to changes in other aspects. WEIA calls for a systematic and comprehensive approach to the total work environment. **METHODS:** To illustrate the utility of WEIA we use

this approach to evaluate an intervention to reduce the public's exposure to the pesticide Alar, which had been used on apples until it was withdrawn from the market in 1989. RESULTS: While this intervention did indeed reduce the public's exposure to Alar, it also led to other unintended consequences, namely new ergonomic hazards for apple pickers, increased stress levels in the orchards for both pickers and growers, as well as new worker, and perhaps public, exposure to potent neurotoxins. CONCLUSIONS: The goal of using WEIA is not to engage in a risk-risk debate that stalls worthwhile interventions. Rather, we propose that by conducting a Work Environment Impact Assessment, all possible positive and negative "ripple" effects stemming from an intervention can be considered, so that the intervention can be designed to achieve maximum benefit. N2 - **OBJECTIVE:** To assess the skills of community health volunteers in diagnosing active trachoma and distributing azithromycin in the Northern Region of Ghana. **METHODS:** Six community health volunteers from Daboya were trained to diagnose trachoma and to treat the disease using azithromycin. They were also informed of the drug's possible side-effects. Under supervision, each volunteer then examined, and if necessary treated, 15 households. The dose of azithromycin was determined by weight; height was also measured. Tablets were given in preference to suspension when possible. **RESULTS:** The volunteers' diagnostic sensitivity for active trachoma was 63%; their specificity was 96%. At the household level, their "decision to treat" was correct in 83% of households. In 344 treatment episodes, volunteers planned a dose of azithromycin outside the range 15-30 mg/kg on only seven occasions (2.0% of all planned treatments). The volunteers' drug management skills were good, the response of the community was excellent, and adverse reactions were infrequent. Diagnosis of active trachoma, record-keeping skills, and knowledge of side-effects were found to need greater emphasis in any future education programme. Most people aged four years or older were able to swallow tablets. For those taking tablets, the correlation between the data gathered for height and weight shows that calculating azithromycin doses by height is a valid alternative to calculating it by weight. **CONCLUSION:** Trained community health volunteers have a potential role in identifying active trachoma and distributing azithromycin. To simplify training and logistics, it may be better to base dosage schedules on height rather than weight for those taking tablets, which included most people aged four years or more in the population studied

N2 - The hyperinsulinism-hyperammonemia syndrome (HHS) has been shown to result from 'gain-of-function' mutations of the glutamate dehydrogenase (GIDH) gene, *GLUD1*. In the original report, all mutations were found in a narrow range of 27 base pairs within exons 11 and 12 which predicted an effect on the presumed allosteric domain of the enzyme and all these mutations were associated by a diminished inhibitory effect of guanosine triphosphate (GTP) on GIDH activity. We have investigated 14 patients from seven European families with mild hyperinsulinism. In four families, more than one member was affected. In eight cases hyperammonemia was documented, and eight cases had signs of significant leucine sensitivity. In one of the families, a novel heterozygous missense mutation in exon 6 [c.833C>T (R221C)] was detected, and in all other cases from six unrelated families the novel heterozygous missense mutation c.978G>A (R269H) was found in exon 7. When GIDH activity was measured in lymphocytes isolated from affected patients, both mutations were shown to result in a normal basal activity but a diminished sensitivity to GTP. It is the first time that this effect is reported for mutations located in the presumed catalytic site and outside the GTP allosteric domain of the enzyme. The observation of the high prevalence of the exon 7 mutation both in familial and sporadic cases of HHS suggests a mutation hot spot and justifies a mutation screening for this novel mutation by mismatch PCR-based restriction enzyme digestion in patients with hyperinsulinism

N2 - **PURPOSE:** The primary aim was to provide experience with a functional evaluation instrument (modified Barthel index MBI) that assures the quality of work and identify its deficiencies, familiarize our staff with the feasibility of its application on our local inpatients and educate our personnel in the field of stroke rehabilitation. The secondary aim was to collect data that are measurable and reproducible, identify specific local factors that adversely affect outcomes and serve as a feedback system to our national organizations. **METHODS:** In this prospective/retrospective study we evaluated 80 hemiplegic patients with completed stroke, admitted to hospital during the year 1989 1990. They were assessed by a neurologist, physiatrist and physiotherapist on admission and discharge using the MBI. All patients received comprehensive inpatient rehabilitation. The study was interrupted at the beginning of the Gulf crisis. However, the data were revived and retrospectively studied in the year 1994-1995. **RESULTS:** The MBI proved to be fully acceptable and easily applicable in our community. The rehabilitation staff became rapidly familiarized with its application and the reproduction of its data. The goals of rehabilitation were achieved through the reduction in the number of individuals in the more severe MBI scores and the increase in the number of individuals in the less severe ones. Significant improvements occurred in dressing of the upper and lower body, washing, grooming, care of perineum, transfer chair, toilet and walking on a level of 50 yards ($p < \text{or} = 0.0005$). **CONCLUSIONS:** We conclude that MBI is simple, convenient, efficient, gives exact and accurate information about daily activities and ambulation and could be used in inpatient follow up sittings, in the Arab and culturally similar Middle East countries

N2 - We report the first case of peritonitis caused by *Curvularia* species in a child undergoing peritoneal dialysis. He presented with gray-black proteinaceous material obstructing the lumen of his Tenckhoff catheter. Although the peritoneal fluid was cloudy, the patient suffered neither significant abdominal tenderness nor systemic symptoms. Catheter removal and treatment with amphotericin B allowed complete recovery and return to peritoneal dialysis within 7 days. Outdoor play in a wooded environment may have allowed contact of this saprophytic fungus with the child's indwelling catheter transfer set

N2 - Human population data on air pollution and its effects on the immune system are scarce. A survey was conducted within the framework of the Central European Study of Air Quality and Respiratory Health (CESAR) to measure a panel of immune biomarkers in children of Bulgaria, Czech Republic, Hungary, Poland, Romania, and Slovakia. Seventeen cities were chosen to represent a wide range of exposure to outdoor air pollution. In each, ambient particulate matter of less than 10 microns diameter and less than 2.5 microns diameter (PM10 and PM2.5) were measured with a Harvard impactor. Blood was collected from 366 school children aged 9 to 11 yr between 11 April and 10 May 1996. The percentage of B, total T, CD4+, CD8+, and natural killer (NK) lymphocytes was determined by flow cytometry (Becton Dickinson); total immunoglobulins of class G, M, A

and E (IgG, IgM, IgA, and IgE) were measured in serum using nephelometry (Behring). Associations between PM and each log-transformed biomarker concentration were studied by linear regression, in a two-stage model. The yearly average concentrations varied from 41 to 96 micrograms/m³ for PM₁₀ across the 17 study areas, from 29 to 67 micrograms/m³ for PM_{2.5}, and from 12 to 38 micrograms/m³ for PM_{10-2.5} (coarse). Number of B, CD4+, CD8+, and NK lymphocytes increased with increasing concentration of PM, having adjusted for age, gender, parental smoking, laboratory of analysis, and recent respiratory illness. Differences in lymphocyte number were larger and statistically significant for exposure to PM_{2.5}. Similar results were found when we examined the association between PM and lymphocyte number separately for each laboratory. Total IgG was increased with increasing concentration of PM, significantly in the case of PM_{2.5}. When we repeated the analyses with two other statistical approaches the results did not differ from those reported here. The effect of coarse PM on lymphocyte numbers appears small in comparison to PM_{2.5}. One possible interpretation of our findings is that long-term exposure to airborne particulates leads to inflammation of the airways and activation of the cellular and humoral immune system

N2 - We studied the effect of ventilation and air filtration systems on indoor air quality in a children's day-care center in Finland. Ambient air nitrogen oxides (NO, NO₂) and particles (TSP, PM₁₀) were simultaneously

measured outdoors and indoors with automatic nitrogen oxide analyzers and dust monitoring. Without filtration nitrogen oxides and particulate matter generated by nearby motor traffic penetrated readily indoors. With chemical filtration 50-70% of nitrogen oxides could be removed. Mechanical ventilation and filtration also reduced indoor particle levels. During holidays and weekends when there was no opening of doors and windows and no particle-generating activity indoors, the indoor particle level was reduced to less than 10% of the outdoor level. At times when outdoor particle concentrations were high during weekdays, the indoor level was about 25% of the outdoor level. Thus, the possible adverse health effects of nitrogen oxides and particles indoors could be countered by efficient filtration. We also showed that inclusion of heat recovery equipment can make new ventilation installations economical

N2 - OBJECTIVE: Higher rates of outdoor injuries are found in older children, boys and children from more deprived areas. Some of the causes of these variations have been studied in some age groups and in different situations. To study children's perception of safety and danger and parents' views on the level of risk that their children attach to outdoor activities comparing age groups, boys and girls, and the less economically well off with the better off in order to understand outdoor accidental injuries. **METHODS:** A cross-sectional study, obtained information from children aged 7 and 9 (n=471) and their parents (n=416) were living in Newcastle upon Tyne by self-completed questionnaires. Nine schools in different socio-economic areas were selected. Children were asked to paste different stickers on to the pictures in the classrooms. The parents' questionnaires were delivered by children and then returned to school after completion. The deprivation of an individual was accessed by Z-score of the households. **RESULTS:** Older children compared to younger ones, boys versus girls and more economically deprived children compared to less deprived children had less perception of the dangers of outdoor activities. For example, older children compared to younger ones were more likely to perceive crossing a busy road with their friends (38.0% vs. 26.4%, P=0.007) as being safe. Boys compared to girls were more likely to perceive climbing wall (31.5% vs. 13.2%, P<0.001) as being safe. More economically deprived children were more likely to perceive cycling without a helmet (25.8% vs. 11.2%, P<0.001) as being safe than less economically deprived children. **CONCLUSION:** These findings may partly explain the higher rate of accidental injuries among older children, boys and more deprived children. The results may inform how education of primary schoolchildren about dealing with activities such as crossing a busy road, climbing walls and playing in street and how parents should be conscious of their children's outdoor activities

N2 - Education programs for intensive insulin therapy were found to be valuable in improving glycemic control, but, due to low prevalence of type 1 diabetes in children and adolescents, access to those programs varies considerably in rural areas. We report on a telemedical care program that overcomes geographical isolation of patients on intensive insulin therapy. Sixty-one children and adolescents under the age of 26 participated in a telemedical care program. They stored daily information on blood glucose, injected insulin, meals and exercise in a glucometer with electronic memory and transferred the data via modem to a remote diabetes center outside of the region. By individual telephone consultations from home, they reviewed the data with a diabetologist at the diabetes center and adjusted their intensive insulin therapy in order to achieve predefined treatment goals. Patients were trained for 19 (6-48) weeks in the program and measured blood glucose 4.9 (1.7-4.9) times daily. Compared to the run-in-period, mean blood glucose had decreased (167 to 158 mg/dL, $p < 0.01$), standard deviation of blood glucose had decreased (81 to 70 mg/dL, $p < 0.001$), and frequency of hypoglycemia had decreased (5.2 to 3.3 in 4 weeks, $p = 0.01$) at the end of the program. The proportion of blood glucose values within the target range (80-180 mg/dL) had increased (47-55%, $p < 0.001$). HbA1c was reduced by 0.4% (-3.8 to +2.2%, $p < 0.05$). Telemedical care for intensive insulin therapy is safe, can improve glycemic control, and reduce the number of hypoglycemia in children and adolescents with type 1 diabetes

N2 - The enormous amount of data concerning outdoor pollution has allowed quantifying the damage caused by single pollutants. On the basis of these data, and knowing the concentration of a pollutant in a given area, to date it is possible to foresee the expected risk for a given disease in our community. For instance, in an average size town like Parma, it can be calculated that in the middle of the winter, suspended particulate pollution (PM10), one day/three, will increase by 30% the number of symptomatic asthmatic children. In the long term, in a town like Parma, PM10 and NO2 pollution increases the number of children with more than 4 episodes of bronchitis or persistent cough by 30-50%. With regard to the typical summer pollution by O3, extremely harmful as it expands outside towns, in Parma and surroundings in August one should expect in 1/3 days double the number of symptomatic asthmatic patients, and every other day a 25% reduction of the respiratory function in asthmatic children exercising. With regard to indoor pollution besides the well known and severe problem of passive smoking, and that of volatile organic compounds still under investigation, one must consider NO2 pollution originating from the burning processes for heating and cooking. As this latter is extremely important in Italy, as gas is used in practically every house, the Author has done a specific research in which it is shown that if this kind of pollution was eliminated one could reduce the incidence of asthma in childhood from 7 to 5%, and noticeably the severity of the disease in affected subjects. Thus, paediatricians have two new aims. The first is to identify in pollution one of the possible causes of respiratory problems in each single patient, giving recommendations (ex. advise asthmatic children to avoid physical activity in the open and in the sunny hours during the summer, or avoid having children in the kitchen while cooking, or have boilers, heaters, etc. checked). Second, paediatricians should make aware, using the local actual data on pollution, not only the local administrators, but also and may be more important the parents of children with respiratory problems. These are in fact the ones who can and must become the most active in facing the big problem of pollution

 N2 - To evaluate the *Toxocara* spp. eggs environmental contamination of the soil of the urban or suburban area Ancona (Italy), 22 public playgrounds were selected and several cores of soil were taken from any selected areas. To study the *Toxocara* seroprevalence in the inhabitants of Ancona, blood samples were collected from selected groups of individuals. One hundred and sixty-three blood samples were tested using an enzyme linked immunosorbent assay (ELISA) technique (Lofarma Lab, Milan, Italy) for the detection of IgG-specific antibodies to *T. canis* excretory-secretory antigens. *Toxocara* spp. eggs were found in the soil samples from 14 (63.6%) playgrounds. *Toxocara* seroprevalence was detected in blood specimens from six (8.1%) out of 74 symptomatic individuals and from one (1.1%) out of 89 asymptomatic controls. Among symptomatic individuals, the association between *Toxocara* seroprevalence and eosinophilia resulted statistically significant ($p = 0.029$). The high environmental contamination frequency found make necessary to prompt preventive public health measures, such as control of stray animals, treatment of infected pets and hygiene education of the population

N2 - A 7-year-old girl had injured her maxillary primary incisors in a playground. One of the already-mobile incisors had been avulsed. The child who had a cough and breathing difficulties during sleep was diagnosed as suffering from upper respiratory infection and was treated with antibiotics. A few days later because her body temperature was elevated a chest radiograph was taken. The radiograph revealed an aspirated tooth in her right bronchus with atelectasis of the lower lobe. The tooth was removed by bronchoscopy. Dentists should suspect any tooth that has been avulsed and not found as possibly aspirated

N2 - There are sandboxes in public elementary school playground areas in Brazil, which can be harmful to children. They are at risk of cutaneous and visceral larva migrans infection caused by *Ancylostoma* spp. and *Toxocara* spp., respectively. The study was designed to investigate contamination by *Toxocara* spp. and/or their eggs and *Ancylostoma* spp. larvae in sand samples collected from the schools' sandboxes. Five hundred and thirty-five sand samples from 28 public elementary schools were collected during summer and winter and analyzed by both Baerman's method and centrifugal flotation technique. *Ancylostoma* spp. larvae were found in 35.7% (10/28) schools in summer time and in 46.4% (13/28) schools in the winter time. Eggs of *Toxocara* spp. could not be recovered from the samples analyzed and eggs from *Ancylostoma* spp. were seen in 0.56% (3/535) of the samples

N2 - We surveyed and analyzed cases of food-dependent exercise-induced anaphylaxis (FDEIA) in the Japanese literature. We found 167 cases which were reported as FDEIA since 1983. Analyzing these case, following characteristic features were revealed: 1) Recent upward trend in the number of reports of FDEIA was noted. 2) Male cases were more frequent than female cases, while about half of the cases were teenager. 3) More than half of the cases were proved to be induced by wheat followed by shrimp. In those under 20, shrimp was the most popular cause rather than wheat. 4) Skin test and/or IgE RAST showed positive results in most cases, suggesting that the response itself is linked to type I allergic reaction. 5) About 40% of the patients had history of atopic disease, indicating that atopic condition may play some role in FDEIA. 6) All cases who performed provocation test with aspirin responded to food challenge and/or exercise in combination with aspirin. This indicates that aspirin plays a key provoking factor in FDEIA. 7) In 17 cases FDEIA attacks were observed during noon recess or physical education class after lunch at school. We stress here the importance of a nation-wide education to school teachers the potential danger of this disorder

N2 - BACKGROUND: Low levels of physical activity is associated with major health problems. However, no overview of the level of physical activity outside work or school in Norway has been made, which is important in order to implement targeted interventions. MATERIAL AND METHODS: Based on published as well as unpublished data, we present data on physical activity in Norway--among children and adolescents, adults and elderly people. RESULTS: Results from different studies differ markedly. However, the main findings are these: The level of physical activity increases in childhood up until about 13 years of age. Approximately 70% of adolescents are active two hours or more a week beyond school-hours. The proportion of physical active youngsters then decreases towards young adulthood. Adults and elderly people get more inactive with increasing age. Data on physical activity from the past 10-15 years suggest a slight increase in the proportion of moderately active Norwegians. INTERPRETATION: Research on physical activity is impeded by the fact that different studies have operationalized physical activity differently and used different age grouping. There is a need for surveys in representative samples with standardised and validated questions, with uniform age classification, covering the full spectre of physical activity. In addition, we need smaller studies with more comprehensive measures of physical activity in Norway. [References: 40]

N2 - Stimulants are a key element in the treatment of ADHD. Carefully designed trials of stimulants have found substantial improvement in ADHD core behaviours in 65-75 % of subjects with ADHD. Most standard stimulants are rapidly absorbed, with their behavioural effects appearing within 30 minutes, reaching a peak within one to three hours and disappearing within five hours. Doses at school are often necessary, in spite of the risk of peer ridicule and added adult supervision requirements. The mechanism by which stimulants act to reduce hyperactivity is not completely understood, but they improve impulsivity and activity levels. Several controlled evaluations made over periods of time greater than a year show a clear persistence of medication effects over time. A carefully crafted programme of treatment with methylphenidate is more effective in the reduction of hyperactivity symptoms than an intensive programme of behavioural and cognitive intervention. The combination of stimulants with psychosocial interventions in ADHD offers few advantages over medication alone. Unchallengeable guides to practice that would be appropriate everywhere are difficult to propose. It is imperative that clinicians prescribing stimulants should monitor the use of the drug properly, making sure that it is not being abused by the child's family, peers or those dispensing medication at school. Polypharmacy should only be embarked on by a specialist service and the combination of methylphenidate and clonidine should be used cautiously. Apart from ADHD, stimulants are useful in narcolepsy, resistant depression and partial syndromes of attention and hyperactivity. Major gaps in knowledge remain; pharmacokinetics, pharmacodynamics and pharmacogenetics of stimulant effects need further study. Details of stimulant administration regimes seem to have a major effect on the response achieved. Further research is needed, preferably in realistic practice settings, comparing different forms of combination with psychological interventions, investigating the effects in groups of children outside the core of schoolaged children with typical ADHD: preschool children, adults, those with partial syndromes (such as inattentiveness) and those with co-morbid disorders. N2 - Contaminated site cleanup decisions may require estimation of dermal exposures to soil. Telephone surveys represent one means of obtaining relevant activity pattern data. The initial Soil Contact Survey (SCS-I), which primarily gathered information on the activities of adults, was conducted in 1996. Data describing adult behaviors have been previously reported. Results from a second Soil Contact Survey (SCS-II), performed in 1998-1999 and focused on children's activity patterns, are reported here. Telephone surveys were used to query a randomly selected sample of U.S. households. A randomly chosen child, under the age of 18 years, was targeted in each responding household having children. Play activities as well as bathing patterns were investigated to quantify total exposure time, defined as activity time plus delay until washing. Of 680 total survey respondents, 500 (73.5%) reported that their child played outdoors on bare dirt or mixed grass and dirt surfaces. Among these "players," the median reported play frequency was 7 days/week in warm weather and 3 days/week in cold weather. Median play duration was 3 h/day in warm weather and 1 h/day in cold weather. Hand washes were reported to occur a median of 4 times per day in both warm and cold weather months. Bath or shower median frequency was seven times per week in both warm and cold weather. Finally, based on clothing choice data gathered in SCS-I, a median of about 37% of total skin surface is estimated to be exposed during young children's warm weather outdoor play

N2 - The purpose of this manuscript is to describe the practical strategies developed for the implementation of the Minnesota Children's Pesticide Exposure Study (MNCPEs), which is one of the first probability-based samples of multi-pathway and multi-pesticide exposures in children. The primary objective of MNCPEs was to characterize children's exposure to selected pesticides through a combination of questionnaires, personal exposure measurements (i.e., air, duplicate diet, hand rinse), and complementary monitoring of biological samples (i.e., pesticide metabolites in urine), environmental samples (i.e., residential indoor/outdoor air, drinking water, dust on residential surfaces, soil), and children's activity patterns. A cross-sectional design employing a stratified random sample was used to identify homes with age-eligible children and screen residences to facilitate oversampling of households with higher potential exposures. Numerous techniques were employed in the study, including in-person contact by locally based interviewers, brief and highly focused home visits, graduated subject incentives, and training of parents and children to assist in sample collection. It is not feasible to quantify increases in rates of subject recruitment, retention, or compliance that resulted from the

techniques employed in this study. Nevertheless, results indicate that the total package of implemented procedures was instrumental in obtaining a high percentage of valid samples for targeted households and environmental media

N2 - **BACKGROUND:** We assessed the efficacy of preseasonal local allergoid immunotherapy in a group of children with asthma and/or rhinitis and/or rhinoconjunctivitis due to grass pollen. **METHODS:** We randomly assigned 24 children allergic to grass pollen to receive local allergoid immunotherapy for 3 months before the pollen season and 24 such patients to receive identically appearing placebo. The immunotherapy consisted of tablets of monomeric allergoid grass pollen allergens held in the mouth until they dissolved and then swallowed. The study was double-blind. Symptoms and medications were scored on diary cards during the pollen season. Nasal eosinophil cationic protein levels were measured by the monoclonal antibodies EG1 and EG2 outside the pollen season and at low and at high pollen concentration during the pollen season. **RESULTS:** The active-treatment group had a statistically significant reduction of total symptoms ($P < 0.05$), especially bronchial symptoms ($P < 0.05$), in comparison with the placebo group. Immunotherapy was well tolerated and compliance was good. Nasal levels of EG2 and EG1 increased significantly during the pollen season, but there was no difference between groups. EG2/EG1 increased significantly only in the placebo group during natural allergen exposure ($P < 0.01$). **CONCLUSIONS:** Our results suggest that this immunotherapy is effective for the treatment of asthma due to grass pollen in children

N2 - **BACKGROUND:** In inland NSW, Australia, allergic sensitization to the fungi *Alternaria* and *Cladosporium* and to pollen is common and an important risk factor for asthma. **OBJECTIVE:** We report the results of a series of experiments designed to assess the nature of personal exposure to these airborne allergenic particles. We have tested the effect of exposure conditions and level of activity on measurements of the personal exposure. **METHOD:** Personal Air Samplers (PAS) and Nasal Air Samplers (NAS) were employed. NAS are fitted just inside the nose and collect inhaled particles by impaction, while the PAS use a pump-operated filter with constant air flow (2 L/min). Thirty-three subjects (adults and children) used both NAS and PAS simultaneously for four one hour periods during which they performed activities or rested, both inside and outside their homes. Samples were analysed by light microscopy. *Alternaria* spores, *Cladosporium* spores, grass pollen and nongrass pollen were counted. **RESULTS:** Both samplers detected substantial variation in exposure between subjects. Between members of the same household, the intrahouse correlation coefficient ranged from $< 0 - 0.38$. Levels of pollen grains and fungal spores inhaled were higher during periods of activity than during rest, and higher while subjects were outdoors than indoors. During the active outdoor period, the number of *Alternaria* spores inhaled ranged from 4 to 794 (median 11) spores/hr, *Cladosporium* from 0 to 396 (median 4) spores/hr, grass pollen from 0 to 81 (median 1) grains/hr and nongrass pollen from 0 to 72 (median 5) grains/hr. **CONCLUSION:** This is the first study to quantify individual inhaled levels of allergenic fungal spores and pollen under normal domestic circumstances. Exposure can be substantial and highly variable between individuals. The amount of particles inhaled relates both to location of the individual and activity being performed, independent of age group

N2 - Transplantation activity is dependent upon organ procurement; although great efforts are made to enlarge the cadaver donors' pool, it still remains far too small to meet the recipients' need. Waiting time is a particular problem for paediatric patients, and mortality on the waiting list for liver transplantation is very high. The number of paediatric donors is far too small to satisfy the request. To enlarge the liver pool, the split-liver procedure was introduced in several Transplant Centers. In November 1997, the North Italy Transplant program (NITp) Working Group for Liver Transplantation decided to start an official Split-liver Program. A protocol was therefore defined and criteria for donor's and recipient's eligibility were established to minimize the risk. The Working Group also standardized the technical procedure and defined collaboration between centers. Out of 410 cadaver liver donors used in the NITp, from 1 November 1997 until 31 May 1999, 49 patients (37 males and 12 females) were chosen for the split-liver procedure. Mean age was 29.9 +/- 17.5 years. Mean ICU stay of the donors was considerably short (2.5 +/- 2.1 days), and the other conditions foreseen for donor eligibility were met. In all cases (except two) an "in situ" technique was performed. Forty-nine adult recipients and 43 children were transplanted by the split-liver technique in our Transplant Centers. One right lobe and five left liver lobes were sent to Transplant Centers outside the NITp. Adult recipient age ranged from 18 to 60 years (mean 46.4 +/- 11.7 years), and the paediatric one from 2 to 144 months (mean 24.8). Mean patient follow-up was 8.3 +/- 5.5 months. In the paediatric group, the graft was successful in 34 cases (79%), five patients (10.2%) died and four (9.3%) were re-transplanted. In the adult group, graft survival was 67.3%, 11 (22%) patients died and 5 (10%) were re-transplanted. On 1 November 1997, 30 paediatric patients were on the liver waiting list. In the preceding 19 months, 52 patients were newly enrolled, and 36 transplants were performed. The mean waiting time of paediatric patients was 259 days (range 1-919 days). From 1 November 1997 to 31 May 1999, 61 paediatric patients were newly enrolled. In this period 70 patients were transplanted. The mean waiting time was 185 days (1-1010 days). At present, the liver waiting list includes eight paediatric patients. Split-liver transplantation is a successful procedure, effective in reducing waiting time for paediatric patients. It should be established if this may be a tool to enlarge the organ pool also for adult liver transplantation

N2 - The challenge for helping others enjoy a healthy and active life is to move the focus of instruction from physical fitness toward physical activity. Participation in regular physical activity offers a number of benefits including reduction of the risk of premature mortality. coronary heart disease, diabetes mellitus, hypertension, and colon cancer. The physical fitness of American children has not declined over the years even though teachers and parents often believe it to be true. A significant amount of fitness test performance is explained by heredity. Both the response to training and genetic limitations are limiting factors outside the control of individuals. Not all people can reach a high fitness level, but all can be physically active. The Children's Lifetime Physical Activity Model (C-LPAM) offers guidance in how to prescribe activity for youth. Guidelines suggest youngsters should receive at least 60 minutes or more of physical activity on a daily basis

N2 - PURPOSE: To examine the possible factors related to the progression of myopia in Singapore children.
 METHODS: One hundred fifty-three Singapore children aged 6 to 12 years were recruited to participate in a concurrent cohort study of the risk factors for the progression of myopia. Socioeconomic status, outdoor activity, and near-work activity were documented in a face-to-face clinic interview. The changes in cycloplegic subjective refraction and autorefraction were ascertained with the use of a Nidek ARK 900 over a 2-year period.
 RESULTS: The average rate of progression of myopia as measured by subjective refraction was -0.59 D per year (95% confidence interval -0.52, -0.66). Younger children and children who were more myopic at the beginning (refractive error worse than -2.0 D) of the study had higher myopia progression rates.

CONCLUSIONS: Myopia progression was faster for younger children and for children who had more severe myopia at baseline. Socioeconomic status and near-work activity were not related to myopia progression

N2 - This study set out to explore the contexts in which preschool children use private speech, or self-talk, in the naturalistic setting of the preschool classroom, and age-related changes in the contexts in which preschoolers talk to themselves. A total of 2752 naturalistic observations of fourteen three-year-old and fourteen four-year-old children were conducted using a time-sampling procedure in two preschool classrooms over the course of one semester. Results from logistic regression analyses revealed that both age groups were (a) more likely to use private speech during the self-selected activity classroom context as opposed to both large group and outside free play classroom contexts, and (b) most likely to talk to themselves when alone, next likely in the presence of peers, and least likely when in the presence of a teacher. Although the probability of private speech among three-year-old children did not vary as a function of the child's immediate activity, four-year-old children's private speech was more likely to occur during sustained and focused goal-directed activity as opposed to rapidly-changing and non goal-directed activity. The findings suggest that private speech appears systematically in young children and that, in several ways, four-year-old children use private speech more selectively than three-year-olds

N2 - The physical activity levels of 47, 5- to 7-year-old children were assessed before and after a school playground was painted with fluorescent markings. Children's physical activity was measured using heart rate telemetry during three playtimes before and after the markings were laid down. Children in the experimental and control groups spent 27 and 29 min, respectively, in moderate to vigorous physical activity (MVPA) before the intervention, increasing to 45 and 36 min, respectively, during the intervention period. MVPA, vigorous physical activity (VPA) and mean heart rate remained relatively stable in the control group compared to respective increases of 10 and 5% of playtime and 6 beats min⁻¹ in the experimental group during the intervention period. The ANCOVA analysis revealed significant interactions and main effects for the intervention for MVPA, VPA and mean heart rate. Conversely there were no main effect differences between groups. These results suggest that while playground markings had a significant and positive influence on children's physical activity, factors other than playground markings may also influence children's physically active play

N2 - Longitudinal studies are needed to increase understanding of the causes of childhood obesity. To identify 1- and 2-year predictors of excess weight gain among preadolescents, the authors conducted a prospective cohort study of fourth- and fifth-grade students in 16 elementary schools located in multiethnic, low-income neighborhoods in Montreal, Quebec, Canada, that were participating in the evaluation of a school-based heart health promotion program. Subjects included 2,318 children aged 9-12 years with baseline and 1-year follow-up data and 633 children aged 9-11 years with baseline and 2-year follow-up data. One-year predictors of highest decile of change in body mass index (BMI) identified in logistic regression analyses included baseline BMI of 90th percentile or more (odds ratio (OR) = 2.66, 95% confidence interval: 1.80, 3.94) in boys and baseline BMI of 90th percentile or more (OR = 2.34, 95% confidence interval: 1.46, 3.76), no sports outside school (OR = 1.90, 95% confidence interval: 1.18, 3.06), and playing video games everyday (OR = 2.48, 95% confidence interval: 1.04, 5.92) in girls. Two-year predictors included baseline BMI of 90th percentile or more (OR = 3.26, 95% confidence interval: 1.52, 7.01), no sports outside school (OR = 2.14, 95% confidence interval: 0.96, 4.77), and least active (OR = 2.18, 95% confidence interval: 1.01, 4.71) in boys; only baseline BMI of 90th percentile or more (OR = 2.22, 95% confidence interval: 1.02, 4.81) was significant in girls. Results suggest the need for interventions to promote increased physical activity in children

N2 - Epidemiological studies have associated adverse health impacts with ambient concentrations of particulate matter (PM), though these studies have been limited in their characterization of personal exposure to PM. An exposure study of healthy nonsmoking adults and children was conducted in Banska Bystrica, Slovakia, to characterize the range of personal exposures to air pollutants and to determine the influence of occupation, season, residence location, and outdoor and indoor concentrations on personal exposures. Twenty-four-hour personal, at-home indoor, and ambient measurements of PM₁₀, PM_{2.5}, sulfate (SO₄(2-)) and nicotine were obtained for 18 office workers, 16 industrial workers, and 15 high school students in winter and summer.

Results showed that outdoor levels of pollutants were modest, with clear seasonal differences: outdoor PM₁₀ summer/winter mean = 35/45 microg/m³; PM_{2.5} summer/winter mean = 22/32 microg/m³. SO₄(2-) levels were low (4-7 microg/m³) and relatively uniform across the different sample types (personal, indoor, outdoor), areas, and occupational groups. This suggests that SO₄(2-) may be a useful marker for combustion mode particles of ambient origin, although the relationship between personal exposures and ambient SO₄(2-) levels was more complex than observed in North American settings. During winter especially, the central city area showed higher concentrations than the suburban location for outdoor, personal, and indoor measures of PM₁₀, PM_{2.5}, and to a lesser extent for SO₄(2-), suggesting the importance of local sources. For PM_{2.5} and PM₁₀, ratios consistent with expectations were found among exposure indices for all three subject groups

(personal>indoor>outdoor), and between work type (industrial>students>office workers). The ratio of PM_{2.5} personal to indoor exposures ranged from 1.0 to 3.9 and of personal to outdoor exposures from 1.6 to 4.2. The ratio of PM₁₀ personal to indoor exposures ranged from 1.1 to 2.9 and the ratio of personal to outdoor exposures from 2.1 to 4.1. For a combined group of office workers and students, personal PM₁₀/PM_{2.5} levels were predicted by statistically significant multivariate models incorporating indoor (for PM_{2.5}) or outdoor (for PM₁₀) PM levels, and nicotine exposure (for PM₁₀). Small but significant fractions of the overall variability, 15% for PM_{2.5} and 17% for PM₁₀, were explained by these models. The results indicate that central site monitors underpredict actual human exposures to PM_{2.5} and PM₁₀. Personal exposure to SO₄(2-) was found to be predicted by outdoor or indoor SO₄(2-) levels with 23-71% of the overall variability explained by these predictors. We conclude that personal exposure measurements and additional demographic and daily activity data are crucial for accurate evaluation of exposure to particles in this setting

N2 - Recent experimental findings in animals and humans indicate adverse respiratory effects from short-term exposures to particulate air pollutants, especially in sensitive subpopulations such as asthmatics. The relationship between air pollution and asthma has mainly been determined using particulate matter (PM) measurements from central sites. Validated tools are needed to assess exposures most relevant to health effects. Recently, a personal passive particulate sampler (personal Data-RAM, pDR, MIE Inc., Bedford, MA) has become available for studying personal exposures to PM with time resolution at 1 min. The pDR measures light scatter from PM in the 0.1-10 microm range, the significant range for health effects. In order to assess the ability of the pDR in predicting gravimetric mass, pDRs were collocated with PM_{2.5} and PM₁₀ Harvard Impactors (HI) inside and outside nine homes of asthmatic children and at an outdoor central Air Pollution Control District site. Results are presented of comparisons between the HI samplers and the pDR in various modes of operation: passive, active, and active with a heated inlet. When used outdoors at fixed sites the pDR readings exhibit interference from high relative humidity (RH) unless operated with a method for drying inlet air such as a heater, or if readings at times of high RH are adjusted. The pDR correlates more highly with the HI PM_{2.5} than with the HI PM₁₀ ($r^2 = 0.66$ vs. 0.13 for outdoors, $r^2 = 0.42$ vs. 0.20 for indoors). The pDR appears to be a useful tool for an epidemiologic study that aims to examine the relationship between health outcomes and personal exposure to peaks in PM

CY - NETHERLANDS

N2 - BACKGROUND: As part of its examination of federal support for immunization services during the past decade, the Institute of Medicine (IOM) Committee on Immunization Finance Policies and Practices (IFPP) commissioned eight case studies of the states of Alabama, Maine, Michigan, New Jersey, North Carolina, Texas, and Washington; and a two-county study of Los Angeles and San Diego in California. Specifically, the IOM Committee and these studies reviewed the use of Section 317 grants by the states. Section 317 is a discretionary grant program that supports vaccine purchase and other immunization-related program activities.

These studies afforded the Committee an in-depth look at local policy choices, the performance of immunization programs, and federal and state spending for immunization during the past decade. **METHODS:** The case-study reports were developed through interviews with state and local health department officials, including immunization program directors, Medicaid agency staff, budget analysts, and Centers for Disease Control and Prevention public health advisors to the jurisdiction. Other sources included state and federal administrative records and secondary sources on background factors and state-level trends. The case studies were supplemented by site visits to Detroit, Houston, Los Angeles, Newark, and San Diego. **OBSERVATIONS:** The nature of immunization "infrastructure" supported by the Section 317 program is shifting from primarily service delivery to a broader set of roles that puts the public effort at the head of a broad immunization partnership among public health, health financing, and other entities in both the public and private sectors. The rate and intensity of transition vary across the case-study areas. In the emerging pattern, service delivery increasingly takes place in the private sector and is related to managed care. "Infrastructure" is moving beyond supporting a core state staff and local health department service delivery to include such activities as immunization registries, quality improvement, and coordination with programs outside public health agencies. At the same time, the recent decline in federal Section 317 support is forcing difficult choices between old and new activities at the state and local levels. **CONCLUSIONS:** Immunization programs function as an organic component of the local health care financing and delivery systems of which they are a part. Immunization efforts are organized and conducted within distinctive state and local fiscal, economic, and health care contexts. Section 317 Financial Assistance grants, while playing a vital role in supporting immunization "infrastructure," have been too unstable and unpredictable to elicit the strategic planning, programming, and own-source spending that would be optimal for state and local programs. The predominant immunization function of state and local public health agencies is becoming assurance of age-appropriate immunization throughout the lifespan. To be successful in this emerging role, the health agencies must be supported with appropriate staffing, interagency collaboration, and clearly articulated authority

N2 - Opportunities for children to be physically active during school time are sparse and becoming increasingly so. The purpose of this investigation was to determine if children would compensate for school days (9 a.m.-3 p.m.) of restricted physical activity opportunities by increasing activity levels after school (3 p.m.-7:30 p.m.). Third and fourth grade children (N = 76) each wore a CSA accelerometer for 4 nonconsecutive days. Two days were categorized as active--during school, all children participated in outdoor recess and physical education class. Two days were categorized as restricted--all children spent their recess time indoors at a computer terminal, and no physical education class was scheduled. Dependent t tests revealed that children did not compensate for a sedentary school day by increasing their levels of physical activity after school. In fact, average movement counts per minute were higher in the 3 p.m.-7:30 p.m. period following the active day (525 counts.min⁻¹) versus the restricted day (186 counts.min⁻¹). These findings suggest cause for concern if children's opportunities to be active within school time are limited. Several reasons are given as to why children did not compensate or "make up" for the physical activity opportunities missed during the restricted school day

N2 - AIMS: Asthma is one of the most frequently encountered chronic illnesses in children. The aim of the present study was to investigate the problem of integration of asthmatic subjects at school by assessing the reactions of parents and teachers, and also by considering the medical aspects. **POPULATION AND METHODS:** A cross-sectional random study was carried out during autumn 1994 including 4,251 primary school children aged between five and 14 years, and including teachers from 188 classes and 26 schools in Grenoble and its inner suburbs. The first screening questionnaire was completed by the parents, and data on 3,799 children were obtained; from this, 191 currently asthmatic children were identified. One hundred and forty-six parents of the identified asthmatics subsequently answered a second questionnaire on the severity of the illness and its effects on school attendance and educational activities. The 186 teachers from the schools involved were interviewed about their knowledge of the disorder, and about what they knew of the treatment and management of asthmatic children in school. **RESULTS:** It was found that the cumulative prevalence of asthma amounted to 7.6%, and that the prevalence over the previous 12-month period was 4.3%. Sixteen percent of the asthmatic children reported an asthma-associated school absence of more than six days during the six preceding months. In 45.2% of cases, physical exercise was responsible for an asthmatic attack, but premedication was used in only 21% of cases. Nine percent of the children had obtained a medical certificate which exempted them from participating in sports activities and physical exercise. Seventy-three percent of the parents had informed the teachers of their child's illness, but the information communicated was incomplete. It was found that the teachers did not have a thorough knowledge of the disorder, but that many of them (92.7%) would appreciate further information on the subject and on its management. Eighty-three percent of the teaching staff were unaware that the ministerial circular No. 93-248 of 22 July 1993 had been issued on the proposed management of chronic disorders at school, advocating a combined effort on the part of the parents, the child's physician, the school doctors and the teachers in setting up a concerted plan of action. **CONCLUSIONS:** This study has demonstrated that the school integration of asthmatic children remains problematical both as regards treatment and the pursuit of indoor and outdoor school activities. Integration could be improved by using parent-doctor-teacher liaison forms, thereby maintaining closer communication regarding the child's needs. When this is not sufficient, an individualized asthma management plan could be introduced in collaboration with the parents, doctors and teachers, which might result in improved treatment and integration of asthmatic children in school

N2 - What role can the criminal law play in the battle against child sexual abuse? Should sexual relations of and with, persons under a certain age be criminalized regardless of the circumstances, even if they are consensual ("age of consent," "minimum age")? Where should such a minimum age-limit be fixed? Should there be a special, higher age-limit for particular conditions (e.g., "seduction," "corruption")? Should sexual contacts with minors within a relationship of authority be criminalized generally, or just if authority is abused? Should criminal proceedings be instituted ex officio or upon complaint only? Should authorities be provided with a power of discretion or should they be obliged to prosecute and sentence in each case? In answering these questions, it is highly beneficial to have a look across the borders to the solutions other countries have reached. This study presents an overview on the criminal law governing the sexual behavior of, and with, children and adolescents in all European jurisdictions and in selected jurisdictions outside of Europe. It shows which categories of offences exist and from which age onward young people can effectively consent to various kinds of sexual behavior and relations in the different countries. All states in Europe and all of the studied jurisdictions overseas have minimum age limits for sexual relations, and punish sexual relations with persons under a certain age. Nowhere is this age set lower than 12 years. In Europe, in one-half of the jurisdictions, consensual sexual relations with 14-year-old adolescents are legal; in three-quarters, with 15-year olds; in a majority, this is also the case when the older partner has started the relation (and also when the initiative contains an offer of remuneration). In nearly all jurisdictions, such relations are legal from age 16 onward. Most states apply a higher age limit for contacts in relationships of authority. If the authority is not misused, the age limit in most jurisdictions is set between 14 and 16; if it is misused, between 16 and 18. Most states make no difference between heterosexual and homosexual relations

N2 - OBJECTIVE: To report a case of delayed elimination of high-dose methotrexate (MTX) associated with concomitant omeprazole administration. CASE SUMMARY: Delayed MTX elimination was observed in an 11-year-old white boy who concomitantly received high-dose MTX and omeprazole. The patient's serum creatinine and liver function tests were normal during treatment and follow-up. The only medication we suspected of inhibiting MTX elimination was omeprazole 20 mg every 12 hours. Twenty-four hours after the first high-dose MTX cycle (15 g), omeprazole was discontinued. Thereafter, the patient received one high-dose MTX cycle without omeprazole every month for five months; MTX elimination was normal throughout MTX cycles 2 to 5. DISCUSSION: MTX is actively secreted in the distal tubules. The renal hydrogen/potassium adenosine triphosphatase (H⁺/K⁺)-ATPase pump makes the urine more acidic, by secreting hydrogen ions into the renal tubule and reabsorbing potassium ions. Active tubular secretion of MTX requires the activity of this pump because MTX is excreted with hydrogen ions. Omeprazole can inhibit renal elimination of the hydrogen ion and block the active tubular secretion of MTX. Therefore, the elimination half-life of MTX increases, which may result in potentially toxic concentrations of MTX. At a pH of approximately 5, as found in the renal tubules, pantoprazole is more slowly activated than omeprazole, reducing the incidence of unwanted reactions with sulfhydryl groups and adverse effects occurring outside of the gastric hydrogen pump. CONCLUSIONS: Based on the Naranjo probability scale, a probable drug interaction was observed. Omeprazole may delay MTX elimination; therefore, when prescribing MTX, an alternative to omeprazole should be considered

N2 - As a tribute to Freud's genius, he was able to recognize not only the importance of implicit unconscious learning but also the way it currently impacts on the patient in psychoanalytic therapy. He prevented the patient from viewing the analyst's facial expressions by placing the patient on the couch. In addition, the analyst was instructed not to say too much, to be neutral, nonjudgmental, and calmly reflective. Thus the patient's response to the facial expressions and voice tone of the analyst, even when subliminally perceived, were minimized. This may be even more significant in women, who seem to be more sensitive to nonverbal cues of emotional states. Ferenczi further elaborated on the importance of establishing a connective empathic relationship, using a kindly, soothing voice tone and being emotionally available. Sandler and Sandler (1994) also emphasized the importance of tolerance and acceptance when making interpretations. These clinical instructions diminish external threats to survival and thereby minimize the activation of the amygdala. These procedures in psychoanalytic treatment seem similar to a subliminal MIO message and to the subliminal exposure of a happy face, as mentioned above in the fMRI study by Whalen et al. (1998). The empathic responses of the therapist need to create a condition of safety. In turn, this decreases the patient's vigilance and defensiveness and allows for the emergence of unconscious material that can be worked through verbally and rectified by explicit memory. Another fascinating finding is that Freud (1914) became aware, in his paper on the repetition compulsion, that repressed traumatic and conflictual relationships are acted out behaviorally outside of conscious awareness. He then considered that the focus of analysis should be on analyzing the transference relationship, where this enactment was manifested. Brockman (1998) notes that modern empirical findings confirm Freud's clinical hypotheses regarding the repetition compulsion. Repressed traumatic emotional memories are encoded in the amygdala, and they are unconsciously enacted through behavior, especially in the transference. In summary, childhood and other traumatic memories become encoded in the amygdala and are later enacted and expressed behaviorally, especially in the transference relationship. Working through of the emotional trauma makes these implicit memories explicit and exposes them to adult judgment. When the therapist creates a condition of safety, old memories are reexperienced and detoxified. The memories are experienced as nonthreatening now, thus calming the amygdala and diminishing its activity. Biologically, new neural pathways from the cortex to the amygdala can be established, since the cortex is plastic. This process is slow and may account for the need to repeatedly work through in analysis old conflicted relationships that had threatened security and survival. As imaging techniques improve, we may soon be able to evaluate therapy outcomes scientifically by measuring these actual brain changes. We are on the threshold of establishing a scientific psychoanalysis, as empirical research is providing us with data that integrate the mind and the brain. Subliminal stimulation and brain imaging techniques provide us with important tools for developing an empirical base for psychoanalytic theory and treatment. These techniques were not available to Freud at the turn of the last century, and as we center the new millennium Freud's dream of psychoanalysis having a firm scientific foundation is becoming a reality

N2 - In eastern Indonesia, malaria control activities mainly depend on residual spraying but the situation is almost unchanged since the past decade. Understanding the socioeconomic and human behavior determinants is needed to implement an effective malaria control in accordance with the local condition and development. Hence we conducted an unmatched case control study. Two hundred samples were recruited from all, 11 villages surrounding the centre in Bacan Island, Maluku. For children aged 0 to 15 years old, the association of socioeconomic determinants: crowding and poor type of houses with malaria remained significant in the multivariate analysis. Meanwhile for persons above 15 years old, younger persons and regular going outside at

night remained significant in the multivariate analysis. And for persons above 15 years old, a higher proportion of controls (14%) than cases (4%) slept under mosquito net regularly. The Indonesia Family Program should be promoted. There was a better quality of life in small family. For persons above 15 years old, going outside at night should be discouraged because exposed to mosquito bites. The malaria control strategy use of effective personal, regular use of mosquito net could be used as a completion for the present activities. Considering the low malaria knowledge among samples, inhabitants should be enhanced the malaria knowledge on causation, transmission, prevention and to provide proper knowledge on residual spraying

N2 - The weekday UV exposures to anatomical sites were evaluated for outdoor workers, home workers, adolescents, indoor workers, school staff and students in south-east Queensland, Australia. Additionally, the UV exposures at weekends of school staff, school students, indoor workers and outdoor workers were evaluated. The weekday exposures per day ranged from 1.0 to 11.0 SED for winter to summer respectively. During spring, the ratios of the personal exposures divided by the ambient exposures at the weekend to the personal exposures divided by the ambient exposures on the weekdays to the neck, hand and left arm were at least 3.4, 2.0 and 0.67 for the indoor workers, school staff and students and outdoor workers respectively. The same ratios for the erythema UV exposures over the year, estimated from the exposures on four days in each of the four seasons, were at least 2.3 for the school staff and at least 1.3 for the 13 to 19 year old school students. These results reinforce the importance of targeting prevention programmes to both weekend and weekday exposures

N2 - The study examines gender-related injury frequency by the type of school activity. Data were taken from an injury register created during the school year 1996/97 with the help of 79 Swedish public-sector schools. Injury ratios (IRs) by gender, type of municipality, and type of school were computed for injuries during all types of activities, for sports-related injuries, and for injuries sustained during recess periods. IRs were higher among boys for recess activities, and among girls for sports activities. IRs showed major variation by type of school, and minor variation by type of municipality. Schools catering for pupils aged 7-12 years had the highest IRs for all groups of injuries, both on aggregate and by gender. Gender-related injury-event occurrence at school

clearly varies with kind of activity, but less so with age of pupils. The extent to which this reflects individual differences rather than varying exposure is uncertain

N2 - A study was conducted in the Makati area of Metro Manila, the Philippines. The study evaluated the significance of playground soil lead intake to the total daily lead burden in preschool children. The lead concentration was measured in residential playground soils, food, water, and hair samples by atomic absorption spectrometer and the data were used to draw conclusions. All of the playground soils were contaminated with lead levels ranging from a minimum of 34.54 microg/g to a maximum of 283.13 microg/g in comparison to the naturally occurring lead level of 15 microg/g in soils. Further, the study conducted a lead analysis on the hair of the study population to determine the accumulated lead intake. Ingestion of 25 mg/day of soil contributed to 4% of the total lead intake per day by children exposed to the study sites. Food (83%) was found to be the major source of lead compared to other sources. The study also includes economic valuation and cost benefit analysis from reducing lead in gasoline

N2 - OBJECTIVES: To assess general practitioners' attitudes to and involvement in child public health activities and identify barriers affecting their participation. DESIGN: Cross-sectional written questionnaire survey of a representative sample of actively practising GPs. SETTING: General practices in the State of Victoria. PARTICIPANTS: 840 GPs returned questionnaires (65% response rate), and, of these, 792 (94%) saw children 0-12 years. MAIN OUTCOME MEASURES: Attitudes to and involvement in public health promotion; predictive factors for GPs' involvement. RESULTS: The odds of GPs' involvement in child public health issues were increased by being female (odds ratio [OR], 1.88), receiving basic medical qualifications outside Australia (OR, 1.55), attending continuing education and postgraduate training (OR, 1.60), and having confidence in dealing with newborns and infants (OR, 1.93) and preschool children (OR, 2.94) (both $P < 0.05$). Older GPs,

compared with younger GPs, had significantly lower odds of involvement ($P < 0.01$). After adjustment, GPs had higher odds of involvement if they agreed it was important for them to take part in health promotion, or in screening and surveillance (OR, 2.76 and 1.94, respectively; $P < \text{or} = 0.05$); and lower odds if they agreed that screening and surveillance should be mainly done by maternal and child health nurses (OR, 0.60). The most common barriers to involvement were insufficient time, inadequate financial reimbursement for long consultations, inappropriateness of raising these issues in children presenting with illness, and lack of community resources. CONCLUSIONS: Increasing GPs' involvement in child public health will require attention to barriers (time, remuneration and perceived appropriateness), continuing education and changes in workforce composition and patterns

N2 - BACKGROUND: The majority of laboratories measure total phenytoin concentration for therapeutic drug monitoring. However, there are substantial interindividual variations in free phenytoin concentrations, the pharmacologically active component. **METHODS:** We describe the process and data used to implement monitoring of free phenytoin only in an urban medical center. Over a 6-week period, total and free phenytoin concentrations were measured, clinical charts reviewed, and indications for alterations in the percentage of free phenytoin fraction were determined. **RESULTS:** Of the 189 phenytoin requests from 139 patients, 136 data points were analyzed. Free phenytoin concentrations were 6.8-35.3%, with 50% outside the expected range of 8-12%. Clinical indications likely responsible for variations were hypoalbuminemia, drug interactions, uremia, pregnancy, and age. Overall, 30% of patients demonstrated a discrepancy between therapeutic, subtherapeutic, or supratherapeutic concentrations between free and total phenytoin concentrations. The largest discordance (53%) occurred in the patient group with free phenytoin <8% or >12%. **CONCLUSIONS:** This study supports previous clinical findings that monitoring total phenytoin is not as reliable as free phenytoin as a clinical indicator for therapeutic and nontherapeutic concentrations. Thus, we recommend that therapeutic monitoring should use free phenytoin concentrations only

N2 - PURPOSE: To identify risk and protective factors for initiation of sexual intercourse before age 16 years at the level of the individual, family, and school. METHODS: A longitudinal study based on a cohort of 1020 people born in Dunedin, New Zealand in 1972/73 and followed up to age 21 years. Demographic characteristics of the sample were similar to the New Zealand population of that age, except that a smaller proportion (3%) were Maori or Pacific Island Polynesian. Information on individual, family and school factors was collected by interview with parents at ages 3, 5, 7 and 9 years and then by postal questionnaire two-yearly up to 15 years. Subjects were assessed two-yearly from age 3 years and interviewed about their behaviours and ambitions at ages 11, 13, and 15 years. Questions about age at first intercourse were asked by computer at age 21 years. Multivariate logistic regression was used to model associations with age of first intercourse less than 16 years. RESULTS: Data on age at first intercourse were available for 926/1020 (91%) of surviving members of the cohort assembled at age 3 years. Overall 27.5% of males and 31.7% of females reported sexual intercourse before age 16 years. In multivariate analyses the independent predictors for early sexual initiation for males were: not having outside home interests at age 13 years, no religious activity at age 11 years, not being attached to school at age 15 years, a low reading score, and a diagnosis of conduct disorder in early adolescence. For females, independent predictors were: socioeconomic status in the middle range, mother having her first child before age 20 years, IQ in the middle range, not being attached to school, being in trouble at school, planning to leave school early, cigarette smoking and higher self-esteem score. CONCLUSIONS: Individual and school factors appear to be more important than family composition or socioeconomic status in the decision to have sexual intercourse before age 16 years. The lowering of age at first intercourse may be partly a cohort effect related to high rates of teenage childbearing in the mothers' generation, and to changes in social acceptability of early sexual behaviour

N2 - Over a 5-year period, three children with psoralen-induced burns were seen. All children were on treatment for vitiligo with a psoralen oil and burns were sustained from unsupervised sun exposure while playing outdoors. The burn wound was partial thickness and involved 6-40% of the total body surface area. All wounds healed without infection or contracture with topical silver sulfadiazine. However, the previously normal skin in phototoxic areas became significantly hyperpigmented while the areas with vitiligo remained hypopigmented. Differences between psoralen-induced burns and other second degree sunburns unrelated to psoralens are discussed

N2 - This paper reviewed the nature of children's physical activity patterns and how the unique nature of children can impact the assessment of physical activity. To accurately assess children's activity patterns, an

instrument must be sensitive enough to detect, code, or record sporadic and intermittent activity. Care also must be used to select criterion measures that reflect appropriate physical activity guidelines for children. A number of different measurement approaches have been described for assessing children's activity, but no specific method can be identified as the best option for all studies. Selection of an appropriate instrument depends on the specific research question being addressed as well as the relative importance of accuracy and practicality (Baranowski & Simons-Morton, 1991). For example, accurate measures of energy expenditure using doubly-labeled water, indirect calorimetry, or heart rate calibration equations may be needed for certain clinical studies, but the cost and inconvenience would make them impractical for field-based assessments on larger samples. The "accuracy-practicality" trade-off presents a more challenging predicament with children than for adults. In adults, a number of self-report instruments have been found useful for large epidemiological studies or interventions where less precision is needed. Because of developmental differences, especially in ability to think abstractly and perform detailed recall (Going et al., 1999; Sallis, 1991), children are less likely to make accurate self-report assessment than adults. Though self-report methods are still likely to be a principal source of information for many studies, other approaches (or the use of combined measures) may be needed to better characterize children's activity levels. While objective instruments (e.g., direct observation or activity monitoring) require more time and resources than self-report, there are options available to simplify data collection. One approach may be to focus assessments on key times or places that allow children to be active. The time after school, for example, appears to be a critical period that defines their propensity for physical activity (Hager, 1999). Monitoring of entire groups for discrete periods of time (e.g., recess or physical education) may also be useful to understand variability in activity patterns since children would all be exposed to the same stimulus or opportunity to be active. Proxy measures may also be useful in studying activity in children. For example, several studies (Baranowski, Thompson, DuRant, Baranowski, & Puhl, 1993; Sallis et al., 1993) have demonstrated that time spent outside is strongly predictive of activity in children. Involvement in community sports programs may also be a useful proxy measure as sports programs have been found to account for approximately 55–65% of children's moderate to vigorous activity (Katzmarzyk & Malina, 1999). Another option for improving assessments in children is to employ multiple measures of physical activity. A number of studies (Coleman, Saelens, Wiedrich-Smith, Finn, & Epstein, 1997; McMurray et al., 1998; Sallis et al., 1998; Simons-Morton et al., 1994) have reported differences in levels of activity when activity monitors were compared with self-report data. The method of measurement has also been shown to influence the results of studies on the determinants of physical activity in children (Epstein, Paluch, Coleman, Vito, & Anderson, 1996). While we do not currently know which measure is most accurate, reporting the results with different instruments provides a more complete description of children's activity and permit a triangulation of outcomes. In summary, there remains no single way of obtaining a highly accurate account of physical activity or energy expenditure in children. The nature of children's movement patterns, the various types of activities engaged in, and the inherent limitations of each assessment tool limit the ultima [References: 96]

N2 - OBJECTIVES: To assess book-sharing activities within first-generation Hispanic immigrant families, and to assess the effect of pediatricians giving books to their patients. DESIGN: Survey. PARTICIPANTS: Convenience sample of 122 predominantly Hispanic immigrant parents of children aged 2 months to 5 years. Of these parents, 56 had received children's books from the pediatrician, and 66 had not. SETTING: House staff continuity clinic at a university children's hospital. MAIN OUTCOME MEASURE: Frequent Book Sharing (FBS) was defined as a parent's reporting more than 3 days per week of sharing books with the child. Main independent variables included the following: (1) exposure to the Reach Out and Read program, defined as having received a children's book from the pediatrician; (2) socioeconomics, as measured by parents' years of education and Medicaid enrollment; (3) acculturation, as defined by 4 questions relating to parents' proficiency with the English language; (4) parent's country of origin; (5) parent literacy, as measured by a parent's reporting more than 3 days per week of reading alone; (6) parent's age; (7) marital status; (8) household size; (9) child's age; (10) child's sex. RESULTS: Ninety percent of the parents were born outside of the United States (71% in Mexico), 85% spoke Spanish in the home, and 63% had completed less than a high-school education. Seventy-five percent of children's medical insurance was provided by Medi-Cal (Medicaid), and 9% of children were uninsured. Sixty-seven percent spoke exclusively Spanish at home, and 84% of parents want their children to learn to read in both English and Spanish. High FBS was reported among parents whose children had received books from the physician when compared with parents whose children had received no books. The odds ratio (OR) was 3.62 (95% confidence interval [CI], 1.40-9.37; $P < .05$). Also associated with FBS were parents reading frequently to themselves (OR = 9.52; 95% CI, 2.09-43.27; $P < .05$) and national origin outside Mexico (OR = 5.54; 95% CI, 1.59-19.27; $P < .05$). These findings were independent of parent's educational level, parent's employment, parent's age, acculturation, and family size. CONCLUSIONS: Pediatricians can promote literacy development among Hispanic immigrant children through the provision of free books at well-child visits. Our findings also suggest the independent effects of adult literacy and child age. Further research is needed to understand the effect of pediatric literacy programs on Hispanic immigrant children, their bilingual environments, and their readiness for school entry. N2 - This study explores the knowledge, attitudes and perception of tuberculosis (TB) and how they affect adherence to preventive treatment. A qualitative study of 24 subjects taking preventive therapy for TB was undertaken. Interviews were conducted in English using a structured questionnaire in a private room adjoining the outpatient clinic before the subject's appointment. The questionnaire included; (i) demographic details; (ii) background information on TB; (iii) knowledge and perception of TB and chemoprophylaxis. Data was analysed descriptively and thematically and subjected to statistical evaluation where appropriate. Outcome was assessed >6 months after the start of preventive treatment. The sample was representative of the ethnic mix of those attending the clinic. Knowledge of TB was gained outside the family and covered transmission but few symptoms of active TB were recognized. The perceived threat from TB was high, although the estimated risk was low. Knowledge of preventive therapy exceeded the general knowledge of TB, although the latter was associated with better adherence. Most denied knowledge of the risk of hepatitis from isoniazid. Defaulters failed to attend their first appointment, attributed more side effects to isoniazid and perceived a longer waiting time in clinic. Adherence is better with a general knowledge of TB and attendance at the first appointment and could be improved by a single daily tablet, warnings about dizziness and discussion of the difficulties of taking a 6 month course of treatment

N2 - **PURPOSE:** Nonlinear EEG analysis is valuable in characterizing the spatiotemporal dynamics of the epileptogenic process in mesial temporal lobe epilepsy. We examined the ability of the measure neuronal complexity loss (L^*) to characterize the primary epileptogenic area of neocortical lesional epilepsies during the interictal state. **METHODS:** Spatial distribution of L^* (L^* map) was extracted from electrocorticograms ($n = 52$) recorded during presurgical assessment via subdural 64-contact grid electrodes covering lesions in either frontal, parietal, or temporal neocortex in 15 patients. The exact location of recording contacts on the brain surface was identified by matching a postimplant lateral x-ray of the skull with a postoperatively obtained sagittal MRI scan. Reprojecting L^* maps onto the subject's brain surface allowed us to compare the spatial distribution of L^* with the resection range of the extended lesionectomy. **RESULTS:** In each of the six patients who became seizure-free, maximum values of L^* were restricted to recording sites coinciding with the area of resection. In contrast, L^* maps of most patients who had no benefit from the resection indicated a more widespread extent or the existence of additional, probably autonomous, foci. The mean of L^* values obtained from recording sites outside the area of resection correctly distinguished 13 patients (86.7 %) with respect to seizure outcome. **CONCLUSIONS:** Relevant information obtained from long-lasting interictal

electrocorticographic recordings can be compressed to a single L* map that contributes to a spatial characterization of the primary epileptogenic area. In neocortical lesional epilepsies, L* allows for identification and characterization of epileptogenic activity and thus provides an additional diagnostic tool for presurgical assessment

N2 - The objective of this study was to identify current action for skin cancer risk reduction in English schools and thus set a baseline for future skin cancer risk reduction interventions. A postal questionnaire survey was sent to 1295 primary, 59 middle and 216 secondary school headteachers, a 10% sample of schools in England in 1998. Since the Health Education Authority/Department of Health/British Association of Dermatologists introduced the Sun Awareness Guidelines for Schools in 1995, seven items from the Guidelines, i.e. education, uniform, shade, outdoor activities, sunscreens, staff awareness, and parent and governor alliances were chosen as outcome measures. The results of the survey showed that most schools had taken at least one of the seven actions (mean 2.67, SD 0.88). Of the schools which addressed sun protection, the majority started to do so after the release of the Sun Awareness Guidelines in 1995. Judging from the length of time schools had been covering sun awareness issues, the proportion of schools which were just beginning to implement sun protection in 1995 was greater than those who began in the previous year. Teaching in the curriculum was the most frequent action taken, but the approach used was usually information giving. Brimmed hats and long sleeves were rarely part of summer school wear. Most schools had less than 25% of their outdoor break areas in shade, but action was being taken to increase this. Sports days were usually scheduled for the afternoon. Sunscreen use was allowed in over 80% of schools, but its application presented teachers with a dilemma. Few staff manuals

contained sun awareness issues; few staff had attended in-service courses on the subject; two-thirds of headteachers would support their staff attending them. Few schools had developed parent and governor alliances. We conclude that help is needed for schools in the form of materials, courses, funds and clear Government policy if their action is to play a major role in reducing the incidence of skin cancer

N2 - Air pollution produces adverse health effects. The consequences of lifelong daily exposures to atmospheric pollutants upon the respiratory apparatus of healthy children are of considerable clinical importance. We investigated the association between exposure to a highly polluted urban environment with a complex mixture of air pollutants-ozone and particulate matter the predominant ones-and chest x-ray abnormalities in 59 healthy Mexican children who are lifelong residents of Southwest Metropolitan Mexico City (SWMMC), with a negative history of tobacco exposure and respiratory illnesses. Their clinical results and x-ray findings were compared to those of 19 Mexican control children, residents of a low-pollution area, with a similar negative history of tobacco exposure and respiratory illnesses. Ozone concentrations in SWMMC exceeded the U.S. Environmental Protection Agency (U.S. EPA) National Ambient Air Quality Standard (NAAQS) for O(3): 0.08 ppm as 1-h maximal concentration, not to be exceeded more than 4 times a year, on 71% of days in 1986 and 95% in 1997, with values as high as 0.48 ppm. Ozone maximal peaks are usually recorded between 2 and 5 pm coinciding with children's outdoor physical activities. Children in the control group reported no upper or lower respiratory symptomatology. Every SWMMC child complained of upper and/or lower respiratory symptoms, including epistaxis, nasal dryness and crusting, cough, shortness of breath, and chest discomfort. Children aged 7-13 yr had the most symptomatology, while 5- to 6-year olds and adolescents with the lowest number of statistically significant outdoor exposure hours had less respiratory symptoms. Bilateral symmetric mild lung hyperinflation was significantly associated with exposure to the SWMMC atmosphere ($p = .0004$). Chronic and sustained inhalation of a complex mixture of air pollutants, including ozone and particulate matter (PM), is associated with lung hyperinflation, suggestive of small airway disease, in a population of clinically healthy children and adolescents. Small airways are a target of air pollutants in SWMMC children, with ozone and PM being most likely responsible, based on experimental animal, controlled-chamber, and epidemiological data available. Our main concern is the potential likelihood for the development of chronic lung disease in this highly exposed population

N2 - A 3-year-old medically fragile girl who refused to eat after prolonged and frequent hospitalizations was started on a feeding program in the home and school settings. She exhibited food aversions and received all nourishment via a gastronomy tube. Preevaluation observations of her feeding behavior revealed that she refused all presented drinks and foods. Treatment was two-fold. First, food acceptance was followed by social praise and access to preferred toy play, and second, food refusal and disruptive behaviors were ignored. Gagging, vomiting, and crying occurred periodically during initial feedings. In addition, there were medical complications during the course of treatment necessitating continuous modifications of the program. Results of a multiple-phase design showed marked increases in the amount of food consumed at home, which then generalized to the school setting

N2 - Eleven schools in the south of England took part in a trial of 'Safe in the Sun', a curriculum programme for primary school aged pupils. Case study methodology and the 'draw and write' technique were combined to evaluate changes in pupils' perceptions of the effects of the sun on their skin. Teachers were free to use the materials, consisting of a teacher's handbook and video, as they wished. Pupils in all schools showed higher levels of awareness of sun-safety measures in post-intervention studies compared with the levels recorded 4 months earlier. Chi-square analysis revealed that those pupils whose teachers had used the materials as recommended by the authors had significant increases in awareness and knowledge about keeping safe in the sun, compared with other levels of intervention. More pupils also appeared able to transfer their awareness to the context of the school playground, although the differences were not significant for any level of intervention. The discussion focuses on the value of the 'draw and write' technique as a tool for illuminative evaluation, on the factors which contributed to the pupils increased awareness of sun safety and on the importance of a whole school approach to sun safety

N2 - To help address the Food Quality Protection Act of 1996, a physically based probabilistic model has been developed to quantify and analyze dermal and nondietary ingestion exposure and dose to pesticides. The Residential Stochastic Human Exposure and Dose Simulation Model for Pesticides (Residential-SHEDS) simulates the exposures and doses of children contacting residues on surfaces in treated residences and on turf in treated residential yards. The simulations combine sequential time-location-activity information from children's diaries with microlevel videotaped activity data, probability distributions of measured surface residues and exposure factors, and pharmacokinetic rate constants. Model outputs include individual profiles and population statistics for daily dermal loading, mass in the blood compartment, ingested residue via nondietary objects, and mass of eliminated metabolite, as well as contributions from various routes, pathways, and media. To illustrate the capabilities of the model framework, we applied Residential-SHEDS to estimate children's residential exposure and dose to chlorpyrifos for 12 exposure scenarios: 2 age groups (0-4 and 5-9 years); 2 indoor pesticide application methods (broadcast and crack and crevice); and 3 postindoor application time periods (< 1, 1-7, and 8-30 days). Independent residential turf applications (liquid or granular) were included in each of these scenarios. Despite the current data limitations and model assumptions, the case study predicts exposure and dose estimates that compare well to measurements in the published literature, and provides insights to the relative importance of exposure scenarios and pathways

 N2 - Interventional cardiology (n = 108) and cardiac angiography (n = 481) procedures in pediatrics performed between January 1996 and December 1998 were reviewed. Means (SD) of duration of anesthesia for interventional cardiology and cardiac angiography were 245 (130) and 152 (48) minutes, respectively (P < 0.001). Incidences of long operations requiring over 6 hours of anesthesia were 12 and 0%, respectively (P < 0.001). Incidences of hemodynamic derangements were 17 and 2.9%, and catheter-related complications were 7.4 and 0.83%, respectively (P < 0.001). Incidences of ICU admission were 7.4 and 0.62% those of emergency surgery were 4.6 and 0%, and those of blood transfusion were 4.6 and 0%, respectively (P < 0.001). Incidences of cardiopulmonary resuscitation, and cardioversion were also higher in interventional cardiology (P < 0.05), and all these emergency cases were rescued successfully. The risk of cardiac angiography is higher compared with general surgery, and the risk of interventional cardiology is higher than cardiac angiography in pediatrics. This study reconfirms that anesthesiologists should play an active role in care of pediatric patients undergoing high-risk procedures outside the operating room

N2 - The distance telescope has a historical reputation for causing difficulties in prescribing and adaptation. Hence, we considered that a retrospective survey of patients at Nottingham Low Vision Clinic might elucidate specific attributes that influence an individual patient's success in using a distance telescope. From 142 patients prescribed distance telescopes since the Clinic's inception, 133 apparently remained users and were mailed a preliminary three-question enquiry about usage of their distance telescopes. The 87 respondents were followed up with questionnaire 2, requesting explicit information about usage, namely frequency, degree of ease or difficulty, and purpose. Older patients required higher magnification ($p < 0.025$). Seventeen of 74 respondents to questionnaire 2 had various adaptational problems, which are discussed; 57 of 74 patients found their distance telescopes easy to use, and 49 of 57 were frequent users. Thus, ease and frequency are linked ($p < 0.05$). People tended to use their distance telescopes outdoors and indoors with similar frequency ($p > \text{or} = 0.29$). Adaptation was found to be unrelated to visual acuity, binocularity/monocularity, ocular pathology, or restricted mobility; magnification seemed to be influential, although not significantly. Aging did not significantly impede adaptation. We infer that the universal criterion for selecting treatable patients seems to be personality type. We conclude that adaptation to a device is dependent upon active recognition of its benefits, paralleled with a tolerance of its constraints, which combine to make usage easy and regular on at least one common task

N2 - **BACKGROUND:** Children with tularemia are, irrespective of severity of disease, usually subjected to parenteral treatment with aminoglycosides. Based on available susceptibility testing, quinolones might be effective oral alternatives of parenteral therapy. These drugs cause arthropathy in immature animals, but this risk is currently regarded to be low in humans. **PATIENTS AND METHODS:** In 12 patients (median age, 4 years; range, 1 to 10) with ulceroglandular tularemia, a 10- to 14-day course of oral ciprofloxacin, 15 to 20 mg/kg daily in 2 divided doses, was prescribed. Microbiologic investigations included identification of the infectious agent by PCR and culture of wound specimens, as well as determination of antibiotic susceptibility of isolates of *Francisella tularensis*. **RESULTS:** Defervescence occurred within 4 days of institution of oral ciprofloxacin in all patients. After a median period of 4.5 days (range, 2 to 24), the patients were capable of outdoor activities. In 2 cases, treatment was withdrawn after 3 and 7 days because of rash. In both cases a second episode of fever occurred. All children recovered without complications. In 7 cases *F. tularensis* was successfully cultured from ulcer specimens and tested for susceptibility to ciprofloxacin. MIC values for all isolates were 0.03 mg/l. **CONCLUSION:** In our sample of 12 patients ciprofloxacin was satisfactory for outpatient treatment of tularemia in children

 N2 - A longitudinal study of malarionometric indicators and their association with potential risk factors was conducted during August 1997-July 1998 at Padre Cocha, a village of 1,400 residents in the Peruvian Amazon. The incidence of Plasmodium falciparum infections during the study year was 166/1,000 persons; that of P. vivax was 826/1,000 persons. The mean duration of symptoms prior to diagnosis was 2 days; presenting geometric mean parasite densities were 3,976 parasites/microl for P. falciparum infections and 2,282 parasites/microl for P. vivax. There were no malaria-associated deaths. Consistent with the epidemic nature of malaria in the area, the incidence of both parasite species increased with age and there were no age-specific differences in mean parasite densities. No specific occupational risks for malaria were identified. Activities significantly associated with malaria risk reflected local vector behavior and included strolling outdoors after 6:00 PM and arising before 6:00 AM for adults, and attending evening church services for children

N2 - CONTEXT: Skin cancer is the most common form of cancer in the United States, and it is one of the most preventable. Interventions for young children and their parents can help prevent future cases of skin cancer.

OBJECTIVE: To determine whether a skin cancer prevention program implemented at outdoor recreation sites improved children's sun-protection behaviors and site sun-protection policies. DESIGN: Randomized trial of 14 outdoor recreation sites on the island of Oahu, Hawaii. The trial had three arms: control, education only, and education/environment. INTERVENTION: The education arm included staff training, on-site activities, take-home booklets, behavior-monitoring boards, and incentives. The education/environment arm included all education components plus provision of sunscreen and promotion of sun-safe environments. PARTICIPANTS: Children 6 to 8 years of age and their parents. OUTCOME MEASURES: Reports from parents of children's sun-protection behaviors and the sun-protection policies of recreation sites. The cohort for analysis from baseline to 6 weeks after testing had 383 participants; the cohort from 6 weeks after testing to 3 months of follow-up had 285 participants. RESULTS: Program implementation was high in the education only and the education/environment sites. Compared with control sites, children's sun-protection behaviors and, in particular, the use of sunscreen improved significantly at sites where the two interventions were implemented. In addition, sun-protection policies of recreation sites were markedly higher at intervention arm sites. The education/environment intervention was not superior to education alone. Changes were partly maintained at 3 months of follow-up. CONCLUSION: A creative, engaging, multicomponent skin cancer prevention program in outdoor recreation settings can lead to modest improvements in children's sun-protection behaviors

N2 - We describe a family in which the mother died of unresolved lung disease and whose 5 children, some of whom had previous signs of asthma, were subsequently affected by extrinsic allergic alveolitis caused by contact with wild city pigeon antigens. The children received systemic corticosteroids for 1 month and inhaled steroids for 24 months, while antigen exposure was reduced as much as feasible. This was followed by a quick clinical recovery and a slow normalization of chest radiographs and pulmonary function indices, especially of diffusion capacity, during a follow-up of 24 months. Because pigeon-breeder's lung caused by free-roaming city pigeons has not been previously described, it remains unclear whether this family developed the disease because of high antigen exposure or because of increased susceptibility. None of the supposedly high-risk human leukocyte antigen types were found in the children. Whether human leukocyte antigen B7 in 1 child played a role in the course of the illness remains speculative. It is unknown to what extent pigeon-breeder's lung caused by nondomestic birds remains undetected and misdiagnosed as difficult or steroid-resistant asthma. The question remains whether free-roaming city pigeons are indeed a public health risk. We suggest that atypical outdoor antigens be considered in all patients with nonresolving chest disease or therapy-resistant asthma

N2 - **BACKGROUND:** Understanding the factors that influence physical activity can aid the design of more effective interventions. Previous reviews of correlates of youth physical activity have produced conflicting results. **METHODS:** A comprehensive review of correlates of physical activity was conducted, and semiquantitative results were summarized separately for children (ages 3-12) and adolescents (ages 13-18). The 108 studies evaluated 40 variables for children and 48 variables for adolescents. **RESULTS:** About 60% of all reported associations with physical activity were statistically significant. Variables that were consistently associated with children's physical activity were sex (male), parental overweight status, physical activity preferences, intention to be active, perceived barriers (inverse), previous physical activity, healthy diet, program/facility access, and time spent outdoors. Variables that were consistently associated with adolescents' physical activity were sex (male), ethnicity (white), age (inverse), perceived activity competence, intentions, depression (inverse), previous physical activity, community sports, sensation seeking, sedentary after school and on weekends (inverse), parent support, support from others, sibling physical activity, direct help from parents, and opportunities to exercise. **CONCLUSION:** These consistently related variables should be confirmed in prospective studies, and interventions to improve the modifiable variables should be developed and evaluated. N2 - Videotapes of children engaging in injury-risk activities on a playground were shown to mothers, who were asked to intervene by stopping the tape and saying whatever they would to their child in the situation shown. Results revealed that mothers of daughters were more likely to judge behaviors as posing some degree of injury risk, and they intervened more frequently and quickly than mothers of sons. Mothers' speed to intervene positively correlated with both children's injury history and their risk-taking tendencies, indicating that mothers of children who were previously injured and who often engaged in injury-risk behaviors had a higher degree of tolerance for children's risk taking than mothers of children who experienced fewer injuries and less frequently engaged in injury-risk behaviors. Mothers' verbalizations to children's risk taking revealed that daughters received more cautions and statements communicating vulnerability for injury, whereas sons received more statements encouraging risk-taking behavior.  N2 - Although children are exposed to a variety of environmental hazards, including pesticides, there is a scarcity of information available to estimate exposures realistically. This article reports on one of the first attempts to measure multi-pathway pesticide exposures in a population-based sample of urban and non-urban children. A design strategy was developed to assess multi-pathway pesticide exposures in children using personal exposure measurements in combination with complimentary measurements of biological markers of exposure, concentrations in relevant environmental media, and time spent in important microenvironments and participating in exposure-related activities. Sample collection and analysis emphasized measurement of three insecticides (i.e., chlorpyrifos, diazinon, and malathion) and one herbicide (i.e., atrazine). These compounds were selected because of their frequent use, presence in multiple environmental media, expected population exposures, and related hazard/toxicity. The study was conducted during the summer of 1997 in Minnesota and involved a stratified sample of households with children ages 3-12 years. Participants resided in either (a) the cities of Minneapolis and St. Paul (urban households), or (b) Rice and Goodhue Counties just south of the metropolitan area (non-urban households). Results from a residential inventory documenting storage and use of products containing the target pesticides were used to preferentially select households where children were

likely to have higher exposures. The study successfully obtained pesticide exposure data for 102 children, including measurements of personal exposures (air, hand rinse, duplicate diet), environmental concentrations (residential indoor/outdoor air, drinking water, residential surfaces, soil), activity patterns (obtained by questionnaire, diary, videotaping), and internal dose (metabolites in urine)

N2 - This study examined theoretical, methodological, and statistical problems involved in evaluating the outcome of aggression on the playground for a universal preventive intervention for conduct disorder.

Moderately aggressive children were hypothesized most likely to benefit. Aggression was measured on the playground using observers blind to the group status of the children. Behavior was micro-coded in real time to minimize potential expectancy biases. The effectiveness of the intervention was strongly related to initial levels of aggressiveness. The most aggressive children improved the most. Models that incorporated corrections for low reliability (the ratio of variance due to true time-stable individual differences to total variance) and censoring (a floor effect in the rate data due to short periods of observation) obtained effect sizes 5 times larger

than models without such corrections with respect to children who were initially 2 SDs above the mean on aggressiveness

N2 - A case control study design was used to determine the risk factors for severe injuries associated with falls from playground equipment. Children presenting to the Hospital for Sick Children in Toronto because of falls from playground equipment (1995-1996) were identified through daily review of admissions and emergency department visits. Cases were defined as children with a severe injury (AIS > or = 2), whereas, controls were children with a minor injury (AIS < 2). Data on age, sex, socioeconomic status, prior experience on the equipment, previous playground injury, type of equipment, height of fall, undersurface, nature of injury, body part involved, and disposition were collected via telephone interview, field trip measurement, and mailed questionnaire. A total of 126 children were studied--67 cases and 59 controls. There were no differences between the two groups on age, sex, socioeconomic status, prior exposure to the equipment, or previous playground injury. Extremity fractures predominated in the case group, while, facial lacerations predominated in the control group. The median height of fall for cases was 199 cm, compared with 160 cm for controls (P = 0.021). Cases were also more likely to have fallen from a height of > 150 cm (73%), compared with controls (54%), P = 0.027. The majority of cases (82%) and controls (86%) fell onto an impact absorbing undersurface (P = 0.540). The median depth of impact absorbing undersurface, however, for both case and control injuries was 3 cm--well below the recommended safety standards. Height of fall was an important risk factor for severe injury associated with falls from playground equipment. Above 150 cm, the risk of severe injury was increased 2-fold

N2 - This paper reports an outbreak of cutaneous larva migrans in children of a school located in Campo Grande, MS. Six out of the 16 students (37.5%) acquired this parasitic dermatitis in two playgrounds contaminated by cat feces, in which ancylostomid larvae were found. The serpiginous lesions and/or papules were located in the hands, feet, buttocks, thighs, vulva and scrotum. Control measures of this parasitosis are discussed

N2 - The aim of this study was to assess prevalence of asthma and allergy in the non-polluted mountain area of Upper Hallingdal, Norway. All schoolchildren (7-16 years) who in a previous questionnaire survey (n = 1177) reported 'sometime' asthma were enrolled in group I (n = 80), the 59 who reported asthma-like symptoms in the past 12 months formed group II, and 77 of the healthy controls were randomly selected as group III. All 216 children underwent clinical examination, skin prick test, spirometry, bronchial provocation (PD20 metacholine) and treadmill exercise test. Subsequently they were reclassified as (1) healthy, never had asthma or symptoms, (2) symptoms not confirmed as asthma, (3) previous asthma, now healthy, (4) current asthma. Lifetime asthma prevalence was 10.2%. Based upon clinical examination, the specificity and sensitivity of the questionnaire for asthma diagnosis were 88 and 74%, respectively. Forced vital capacity was significantly higher among the asthmatics (group 4 versus 1), whereas forced expiratory volume in one second (FEV1) and forced expiratory flow at 50% of vital capacity were similar in all groups. More than 10% reduction in FEV1 following treadmill-run was found in 20% of children. Children with current asthma compared to controls had significantly; lower mean values of PD20 (9.1 versus 16.5 micromol), higher eosinophil cationic protein (13.4 versus 7.7 micromol)

and more frequent sensitization to animal dander (56% versus 10%). In conclusion, despite a favorable climate, little mite sensitization and low outdoor pollution, asthma prevalence was surprisingly high in Upper Hallingdal. Sensitization to animal dander was the most important contributing factor for current asthma

N2 - This study aimed to identify typical features of burns in rural areas and to improve their prevention by comparing the characteristics of burnt patients and their burns in rural and urban areas. A cross-sectional survey was conducted in 19 of the 23 French burns units over one year, using a structured questionnaire. We analysed the resulting database. Of the 1422 patients, excluding 188 burnt in unclassified areas, 420 (34%) were burnt in rural areas. Burns were more frequent in rural than in urban areas. Occupational burns were more frequent in rural than in urban areas. The characteristics of patients and burns did not differ between the areas. Patients burnt during everyday activities were older and more frequently had predisposing factors in rural than in urban areas. Burns occurred outdoors more often in rural than in urban areas and were frequently due to flames or explosions or to the use of barbecues or open fires. The hands and perineum were burnt more frequently in rural than in urban areas. Rural burns were more severe than urban burns: they were deeper, involved a larger body surface area and caused more deaths. Preventive measures in rural areas should take into account occupation and everyday activities. They should be specifically adapted to the profiles of burnt patients

N2 - Sensitive individuals are at risk of adverse health effects from exposure to even modest levels of ozone. Such individuals are likely to develop respiratory symptoms and are more likely to be hospitalized when exposed to ozone at currently accepted levels. A review of scientific documents regarding the health effects of ozone has led the DHHS to agree with the EPA that the primary ambient air standard for ozone should be changed from 0.12 ppm (1-hour average) to 0.08 ppm (8-hour average). Achieving the proposed 0.08 ppm standard should decrease physician visits, hospitalization, and use of respiratory medications. In addition, because very susceptible healthy individuals may experience adverse health effects of the current standard, it is clear that the current standard provides little or no margin of safety, particularly for sensitive individuals. In order to avoid exposure to unhealthy levels of ozone, people should take precautions to minimize exposure from 2:00 to 6:00 pm on days when ozone levels are high. This is especially so for children, adults who are active outdoors, those with respiratory disease such as asthma, and people with unusual susceptibility to ozone

N2 - An epidemiological study was performed of endemic alveolar hydatid disease (AHD, multilocular echinococcosis), Rebun Island, Hokkaido and the period of AHD infection of patients was estimated. Death certificates of the residents of the island were analyzed, and 74 deaths (43 males and 31 females) by AHD were found out of the 3,126 deaths that occurred during the period from 1948 to 1990. The red fox population of the island was estimated on the basis of past researchs. The deaths due to AHD distributed around a major peak ($n = 67$) between 1948-1975 and there were 7 sporadic cases between 1976-90. The red fox population on the island had been estimated to be largest in 1935. The mean infection period from initial AHD infection to death was estimated to be 26 ± 7 years ($x \pm SD$) on the basis of the period between the year in which the peak red fox population was observed (1935) and the major peak of patient death (1962). The mean symptomatic period was 5 ± 5 years, and the mean latent period from infection to the onset of AHD was 21 ± 7 years. Sex ratio (M/F = $28/13 = 2.15$) was higher ($P < 0.05$) at the age groups below 10 and 26-45 years than the other age groups ($15/18 = 0.83$), and playing outdoors during childhood and working outdoors in the prime of life were assumed to be the causes of infection

N2 - OBJECTIVE: To identify predictors of participation in school activities from two sets of functional variables using classification and regression tree analysis. DESIGN: Relational study. PARTICIPANTS: A nationwide sample of 341 children with various disabling conditions, including physical and cognitive/behavioral types of impairment and various severity levels. Children attended public elementary school in 40 states in the United States. MAIN OUTCOME MEASURE: Overall participation in elementary school, combining children's participation in six different environments (transportation, transitions, classroom, cafeteria, bathroom, and playground), as measured by the newly developed School Function Assessment. The children were dichotomized into full ($n = 117$) and limited ($n = 224$) participation categories. RESULTS: Two

classification trees were developed identifying a small set of predictors from variables measuring performance of functional tasks and discrete activities. Final predictive models included physical and cognitive-behavioral variables, suggested important interactions among predictors, and identified meaningful cut-off points that classified the sample into the outcome categories with about 85% accuracy. CONCLUSIONS: Limited participation was predicted by information about children's physical capabilities. Full participation was predicted by a combination of physical and cognitive-behavioral variables. Findings underscore the relative utility of functional performance compared with impairment information to predict the outcome, and suggest pathways of influence to consider in future research and intervention efforts

N2 - The Harvard Southern California Chronic Ozone Exposure Study measured personal exposure to, and indoor and outdoor ozone concentrations of, approximately 200 elementary school children 6-12 years of age for 12 months (June 1995-May 1996). We selected two Southern California communities, Upland and several

towns located in the San Bernardino mountains, because certain characteristics of those communities were believed to affect personal exposures. On 6 consecutive days during each study month, participant homes were monitored for indoor and outdoor ozone concentrations, and participating children wore a small passive ozone sampler to measure personal exposure. During each sampling period, the children recorded time-location-activity information in a diary. Ambient ozone concentration data were obtained from air quality monitoring stations in the study areas. We present ozone concentration data for the ozone season (June-September 1995 and May 1996) and the nonozone season (October 1995-April 1996). During the ozone season, outdoor and indoor concentrations and personal exposure averaged 48.2, 11.8, and 18.8 ppb in Upland and 60.1, 21.4, and 25.4 ppb in the mountain towns, respectively. During the nonozone season, outdoor and indoor concentrations and personal exposure averaged 21.1, 3.2, and 6.2 ppb in Upland, and 35.7, 2.8, and 5.7 ppb in the mountain towns, respectively. Personal exposure differed by community and sex, but not by age group

N2 - BACKGROUND: Women physicians may have a multiplicity of domestic roles (eg, cook, housekeeper, child care provider) that are of inherent interest and that may affect their professional lives, but are largely unstudied. DESIGN, SETTING, PARTICIPANTS, AND MAIN OUTCOME MEASURES: We report data from respondents (N = 4501) to the Women Physicians' Health Study, a cross-sectional, questionnaire-based study of a stratified random sample of US women MDs. RESULTS: Women physicians with children aged 0 to 17 years spent a median of 24.4 hours per week on child care. Women physicians typically spent half an hour per day cooking, and another half-hour per day on other housework. Little time was spent on gardening: a median of 0.05 hours (3 minutes) per week. Those performing more domestic tasks are likely to work fewer hours outside the home and to be on call less often. Women physicians who are married or widowed, have more children, have lower personal incomes, and have more highly educated and higher-earning spouses perform more domestic activities. We found no significant adverse relationship between time spent on any domestic activity and career satisfaction or mental or physical health. CONCLUSIONS: Women physicians spend little time on domestic activities that can be done for them by others, including cooking, housework, and especially gardening. Women physicians spend somewhat less time on child care and substantially less time on housework than do other US women. Despite abundant editorializing about role conflicts of women physicians, our measures of career satisfaction and mental health were not adversely affected by time spent on domestic obligations

N2 - **PURPOSE:** This study is intended to resolve the disparity and reach consensus on issues regarding the treatment of children with isolated spleen or liver injuries. To maximize patient safety and assure efficient, cost-effective utilization of resources, it was essential to determine current practice. **METHODS:** Data from the case records of 856 children with isolated spleen or liver injury treated at 32 pediatric surgical centers from July 1995 to June 1997 were collected. The severity of injury was classified by computed tomography (CT) grade and the data analyzed for intensive care unit (ICU) stay, length of hospital stay, transfusion requirement, need for operation, pre- and postdischarge imaging, and restriction of physical activity. Patients with grade V injuries (2.8%) were excluded leaving 832 patients for detailed review. These data and available literature were analyzed for consensus by the 1998 APSA Trauma Committee. **RESULTS:** Resource utilization increased with injury severity (see Table 2). Based on the data analysis, literature search, and consensus conference, the authors propose guidelines (see Table 3) for the safe and optimal utilization of resources in routine cases. It is important to emphasize that no recommendation falls outside the 25th percentile of current practice at participating centers. **CONCLUSIONS:** Diversity of treatment, with attendant variation in resource utilization in children with isolated spleen and liver injury of comparable severity is confirmed. This analysis has stimulated a prospective outcomes study with the objective of validating the evidence-based guidelines proposed. This evidence-based study design can bring order and conformity to patient management resulting in optimal utilization of resources while maximizing patient safety

N2 - BACKGROUND: Ultraviolet radiation (UVR) is known to be the most important risk factor for melanoma and non-melanoma skin cancers. Until today it has been impossible to measure reliably UVR in the frame of epidemiological studies. The recent development of a spore film containing spores of *Bacillus subtilis* resulted in a new method of UV measurement by personal dosimetry. METHODS: The practical application of dosimeters was tested in 18 study persons under different circumstances of UV exposure and in 4 different geographical regions. RESULTS: Eleven children carried dosimeters on their shoulders for 1 day, playing in- and outdoors on a sunny day in summertime. Their whole-day values ranged from 0.1 to 1.5 minimal erythema doses (MED) per day with a mean of 0.71 MED (+/-0.44). Four lifeguards in a public swimming-pool carried dosimeters on their shoulders for 11 days and received UV exposures ranging from 3.6 to 9.5 MED (mean 5.9 +/- 1.88). Three mountain guides with dosimeters attached to the lateral head in different mountain regions at 23 mountaineering activities received daily exposures of 4.44-17.07 MED (mean 11.9 +/- 3.8). CONCLUSION: *B. subtilis* spore film dosimeters can be applied to different study persons including children and mountain guides under different climatic conditions. A broad range of UV exposures can reliably be measured with this method. Copyright 2000 (R) S.Karger AG, Basel

N2 - We conducted a study to examine seasonal changes in residential dust lead content and its relationship to blood lead in preschool children. We collected blood and dust samples (floors, windowsills, and carpets) to assess lead exposure. The geometric mean blood lead concentrations are 10.77 and 7.66 microg/dL for the defined hot and cold periods, respectively ($p < 0.05$). Lead loading (milligrams per square meter) is the measure derived from floor and windowsill wipe samples that is most correlated with blood lead concentration, whereas lead concentration (micrograms per gram) is the best variable derived from carpet vacuum samples. The variation of dust lead levels for these three dust variables (floor lead loading, windowsill lead loading, and carpet lead concentration) are consistent with the variation of blood lead levels, showing the highest levels in the hottest months of the year, June, July, and August. The regression analysis, including the three representative dust variables in the equations to predict blood lead concentration, suggests that the seasonality of blood lead levels in children is related to the seasonal distributions of dust lead in the home. In addition, the outdoor activity patterns indicate that children are likely to contact high leaded street dust or soil during longer outdoor play periods in summer. Consequently, our results show that children appear to receive the highest dust lead exposure indoors and outdoors during the summer, when they have the highest blood lead levels. We conclude that at least some of the seasonal variation in blood lead levels in children is probably due to increased exposure to lead in dust and soil

N2 - The Sicilian province of Catania is an active foci for human visceral leishmaniasis (VL) in the Mediterranean area. Approximately 10 to 15 cases of VL are diagnosed via hospital admissions each year in this community. Recently, an increase in VL case reporting by Sicilian physicians was noted, with 38 and 37 VL cases in 1996 and 1997, respectively. Before 1995, there were no reported VL cases among U.S. military personnel or their family members living in Sicily. However, since 1996, there have been four cases referred to Walter Reed Army Medical Center for diagnosis and treatment, all involving the children of personnel assigned to Naval Air Station Sigonella. Exposure histories for all infected individuals excluded exposure to Leishmania parasites outside of Sicily. All patients lived in areas where vectoring sandflies are present. All had dogs as family pets. To evaluate the level of infection among dogs owned by Navy personnel and their families, U.S. Navy Environmental and Preventive Medicine Unit 7, in a collaborative study with the U.S. Army Veterinary Clinic, Naval Air Station Sigonella, and the Walter Reed Army Institute of Research, performed clinical evaluation and serological testing of 50 dogs residing with U.S. personnel assigned to Naval Air Station Sigonella. The data indicate a high exposure rate to Leishmania (60% of the animals tested had elevated immunoglobulin M antibody levels) in the study population, suggesting that they were infected with Leishmania infantum. Distribution of seropositive dogs by sex was equal. Most of the dogs studied appeared to be in good health. However, inapparent infection of dogs, seen by Italian veterinarians, has been observed throughout all areas of Catania. Sandflies responsible for vectoring L. infantum were trapped in the same locations as the dogs sampled in this study. The level of subclinical infection was 75% among seropositive dogs. The overall level of canine infection observed was higher than expected. This study demonstrates an increased risk to military working dogs and companion dogs of U.S. personnel for infection with L. infantum during a 2- to 3-year tour in Sicily

N2 - OBJECT: Changes in cortical representation in patients with cerebral lesions may alter the correlation between cortical anatomy and function. This is of potential clinical significance when the extent of cortical resection is based on surface anatomical landmarks. METHODS: Fifty-one patients with supratentorial lesions were studied. Nineteen harbored noncentral lesions (no involvement of pre- or postcentral gyrus), whereas 32 had central lesions. Control studies consisted of stimulation of the hand contralateral to the unaffected hemisphere. Positron emission tomography activation studies were performed using the [15O]H₂O tracer. Somatosensory stimulation of the hand or foot was performed using a mechanical vibrator. Motor activation consisted of hand clenching or foot tapping. The t-statistic volumes were generated from images showing the mean change in regional cerebral blood flow, and coregistered with a T1-weighted magnetic resonance image. At the threshold selected, exclusive contralateral primary sensorimotor cortex activation was elicited in 100% of the control studies. A different pattern of cortical activation was associated with central lesions in 35 (78%) of 45 patients, which occurred significantly more often than with noncentral lesions (eight [31%] of 26 patients). The most common difference in the pattern of activation with central lesions was activation of cortical regions outside the central area (including the supplementary sensorimotor area and the secondary somatosensory cortex). No sensorimotor activation was observed in gyri adjacent to the pre- or postcentral gyrus. CONCLUSIONS: Central lesions are more frequently associated with altered patterns in activation than lesions in noncentral locations. Characteristic patterns include activation of secondary sensorimotor areas. The absence of activation in gyri adjacent to the sensorimotor strip has clinical significance for the planning of resections in the central area

N2 - A significant response in a bronchodilation test is one of the main diagnostic criteria of asthma. However, it is not known what the significant bronchodilator response (BDR) is by the interrupter technique (IR), measuring respiratory resistance (Rint) during tidal breathing. Fifty children with symptoms suggestive for asthma underwent an 8 min free running test outdoors. Flow-volume spirometry (FVS) and IR measurements were performed before and 10 min after running. Thereafter, all children received a salbutamol inhalation, and pulmonary function measurements were repeated 15 min later. The study population was classified into three groups according to the post-exercise pulmonary function: FEV1 > 100% of predicted (group I, n=15), FEV1 86-99% of predicted (group II, n=20) and FEV1 < 85% of predicted (group III, n=15). There were no differences in BDRs between groups I and II; the mean increases in FEV1 were 4-6% and in MMEF 20-23%, and the mean decreases in Rint were 23-26%. The mean changes in group III were significantly higher: 15% (P=0.004) in FEV1, 55% (P=0.021) in MMEF and 38% (P=0.014) in Rint. BDR was positive (FEV1 rise >10%) in 15 children; five were in group II and 10 in group III. For MMEF and Rint, the best combination of sensitivity and specificity was achieved by a limit of 35%. By this limit, MMEF identified 14 and Rint 17 positive cases. The IR technique agreed with both FEV1 and MMEF in 73% of the cases. The IR technique provides an alternative to conventional ventilatory function measurements in bronchodilation tests in children. We suggest a decrease of 35% or more in Rint as diagnostic in post-exercise bronchodilation tests

N2 - Activating missense mutations of the GNAS1 gene, encoding the alpha subunit of the stimulatory G protein (Gs), have been identified in patients with the McCune-Albright syndrome (MAS; characterized by polyostotic fibrous dysplasia, cafe au lait skin pigmentation, and endocrine disorders). Because fibrous dysplasia (FD) of bone also commonly occurs outside of the context of typical MAS, we asked whether the same mutations could be identified routinely in non-MAS FD lesions. We analyzed a series of 8 randomly obtained, consecutive cases of non-MAS FD and identified R201 mutations in the GNAS1 gene in all of them by sequencing cDNA generated by amplification of genomic DNA using a standard primer set and by using a novel, highly sensitive method that uses a protein nucleic acid (PNA) primer to block amplification of the normal allele. Histologic findings were not distinguishable from those observed in MAS-related FD and included subtle changes in cell shape and collagen texture putatively ascribed to excess endogenous cyclic adenosine monophosphate (cAMP). Osteomalacic changes (unmineralized osteoid) were prominent in lesional FD bone. In an in vivo transplantation assay, stromal cells isolated from FD failed to recapitulate a normal ossicle; instead, they generated a miniature replica of fibrous dysplasia. These data provide evidence that occurrence of GNAS1 mutations, previously noted in individual cases of FD, is a common and perhaps constant finding in non-MAS FD. These findings support the view that FD, MAS, and nonskeletal isolated endocrine lesions associated with GNAS1 mutations represent a spectrum of phenotypic expressions (likely reflecting different patterns of somatic mosaicism) of the same basic disorder. We conclude that mechanisms underlying the development of the FD lesions, and hopefully mechanism-targeted therapeutic approaches to be developed, must also be the same in MAS and non-MAS FD

N2 - The Stage of Change (SC) paradigm was adapted to assess readiness to be or stay physically active among fifth and sixth graders. Students completed a four-item SC survey, the Past Year Leisure Time Physical Activity Questionnaire, and the Modifiable Physical Activity Questionnaire for Adolescents. Precontemplation, contemplation, and preparation stages were grouped as "pre-action" (PRE), and action and maintenance as "post-action" (AX) stages. Nearly 40% of all students were in PRE, compared to 60% of students in AX stages. Twenty-two percent of all students were in the sedentary precontemplation or contemplation stages.

Significantly more boys were in maintenance than girls, and more girls than boys were in contemplation.

Students averaged 14-21 hours/week of television, video, or computer work, and 1.6 hours/week of physical activity outside of school. Interventions may be targeted at a specific SC to enable a child to move forward along the SC continuum toward an active lifestyle

N2 - "Troo, the Traumaroo" bicycle and playground safety education program created for kindergarten, first, and second grade students, was provided to a convenience sample of seven elementary schools in a Southwestern city. Favorable principal, classroom teacher, and school nurse evaluations indicated that the "Troo, the Traumaroo" program was successful in providing young children with bicycle and playground safety in a fun and entertaining way. Results of this pilot study indicated that kindergarten children pre-tested for bicycle safety knowledge prior to participating in the program, had significantly higher bicycle safety knowledge scores 30 days after participating in the program ($p < .0001$)

N2 - BACKGROUND: Sensitivity and exposure to indoor allergens constitutes a risk factor for the development and persistence of asthma in children. **OBJECTIVE:** Our purpose was to evaluate the relationship between sensitivity and exposure to inhalant allergens and lung function and bronchial responsiveness in a group of children (n = 1041) aged 8.9 +/- 2.1 years with mild to moderate asthma enrolled in the Childhood Asthma Management Program (CAMP). **METHODS:** With use of the extensive CAMP baseline cross-sectional data on spirometry, bronchial responsiveness, allergen sensitivities, and household allergen levels, the relationship of sensitization and exposure to allergens to lung function and methacholine sensitivity was evaluated. Children who enrolled in CAMP stopped all antiasthma medication except rescue use of albuterol and prednisone for exacerbations during the 5- to 16-week screening period. During the last 2 of these weeks they underwent spirometry and methacholine challenge. Indoor allergen exposures were determined from questionnaires completed by the parent. Household levels of indoor allergens (mite, cat, dog, cockroach, mold) were determined on house dust samples. Allergen sensitivity was determined by percutaneous skin testing with a standard battery of allergens plus locally important pollen and fungal spores. Lung function and bronchial hyperresponsiveness were compared for children sensitive and not sensitive to both indoor and outdoor allergens on skin testing and, if sensitive, for exposed and not exposed to the allergens to which they were positive on skin testing. **RESULTS:** There was a strong direct correlation between increased sensitivity to inhaled methacholine and skin test sensitivity to tree, weed, Alternaria, cat, dog, and indoor molds. When the relationship was examined by stepwise regression, the skin test sensitivities showing the strongest associations with the concentration of methacholine that caused a 20% fall in FEV(1) were dog (P =.003), Alternaria (P =.01), and cat (P =.05). Children sensitive to any one of the aeroallergens tested were compared for the presence or absence of exposure to that allergen at the time that the methacholine challenge was performed. Those who were sensitive and exposed to weed and cat had greater methacholine sensitivity than those similarly sensitive but not exposed (P =.003 and P =.02, respectively). **CONCLUSIONS:** Sensitivity to dog or cat dander or Alternaria by skin testing was associated with increased bronchial responsiveness but not decreased lung function in children with mild to moderate asthma. These findings support the important role that sensitization to certain allergens plays in modulating bronchial responsiveness

N2 - Ninety-two daycare centers (23 public, 10 charitable, and 59 private) were identified in the municipality of Pelotas, RS, Southern Brazil. These centers were studied in relation to their organization, services, child-care practices, and infrastructure. All public centers worked full-time, while most private centers operated in the afternoon and received a smaller proportion of children under the age of two. The child-to-attendant ratio was similar in both types of centers, and the nurseries were the classes most frequently above the recommended maximum. Group and center sizes were larger in the public centers. Attendant schooling was higher in the private centers, but task specificity was lower. The infrastructure deficiencies most commonly observed in the public centers were lack of an internal recreational area and playground equipment. Private centers lacked adequate diapering facilities and exclusive toilets for the children. A small proportion of centers had staff trained to handle fire emergencies and administer first aid, revealing insufficient concern over safety issues

N2 - This study describes the main social, economic, biological, and demographic characteristics of children and families who participate or have participated in the Children's Pastoral as compared to the overall urban population of Criciuma (Southern Brazil). A population-based cross-sectional study with a probabilistic sample of 2208 children under three years of age was conducted; 16.7% of the mothers confirmed having participated in the Pastoral at any given time, of whom 4.8% were currently participating, while the rest had dropped out. Black children and those over 12 months old or with two or more older siblings participated more frequently in the Pastoral. The main family factors associated with participation were mother's age (over 25), mother not working outside the home, low per capita income, low parental schooling, living in the neighborhood for more than 4 years, and death of sibling before age five. Reasons most often given by mothers for dropping out were migration, lack of time, and interruption of the Pastoral's activities in the neighborhood. The conclusion was that the Pastoral should prioritize the poorest of the poor and adopt measures to reduce drop-out rates

N2 - **PURPOSE:** To describe the prevalence and correlates of physical inactivity and of participation in organized sports at and outside school among elementary schoolchildren in multiethnic, low income, urban neighborhoods in Montreal, Canada. **METHODS:** As part of the evaluation of a school-based heart health promotion program, baseline data on physical activity behaviors and potential correlates of these behaviors, were collected from 2285 students aged 9-13 in all 130 grade 4 to 6 classes in 24 inner-city elementary schools from May to June 1993. **RESULTS:** One-fifth of boys (20.5%) and 24.4% of girls were inactive; 40.0% and 33.3% of boys and girls respectively, participated in school sports teams; 82.5% and 74.7% participated in organized sports outside school. Declines in activity levels with age were apparent in both genders. Children who participated in organized sports programs at and outside school, those with higher perceived self-efficacy for physical activity, and those with more parental support for engaging in physical activity were more active. Children of Asian family origin were less active. Socioeconomic status was related to participation in organized sports outside school. **CONCLUSIONS:** To reach children in socio-economically disadvantaged areas and to prevent age-related declines in activity levels, interventions promoting physical activity should focus on increasing availability and access to community-based organized sports programs at and outside school. Also they should include components to increase parental support and to improve perceived self-efficacy for physical activity

N2 - OBJECTIVE: Increasing prevalence of skin cancer over the past few decades and their relationship with childhood sun exposure, show that educational campaigns on sun protection are urgently needed. The aim of this study is to estimate the degree of children's sun exposure in the south of France (43 degrees latitude north) and to study sun protection behaviors according to phenotypic characteristics. POPULATION AND METHODS: The population was a randomly selected sample of 573 schoolchildren between 3 and 15 years of age living in Montpellier. The questionnaire provided information about sociodemographic characteristics, summer sun exposure and sun protection. Phenotypic characteristics, reactivity to sunlight and number of sunburns since birth were also reported. RESULTS: Exposure time was very high: half of children spend over 6 hours per day outside in summer. The youngest children were the most protected either by sunscreen, or by shirt. On the beach, sunscreens were used more than half of the time of exposure by 70 p. 100 of the children. At the swimming pool, sunscreens were used by 45 p. 100 of the children and only by 14 p. 100 of them during

other outdoor activities. A tee-shirt was only worn by 50 p. 100 of the children when playing on the beach, and by 75 p. 100 of them at the swimming pool. In addition, the application of sunscreen varied by body site. The adolescents, although they were exposed less than the youngest children, were very poorly protected. Light skinned children who do not tan easily had highest risk of sunburns, although they were generally more protected. CONCLUSION: The parents are able to identify highly sensitive children according to phenotype, but in practice the use of sunscreens and tee-shirt is very low. Parents and adolescents must be the target population but also insufficiently protected children. Health education at school must be an important measure for prevention

N2 - BACKGROUND: One-third of children diagnosed with autism spectrum disorders (ASDs) are reported to have had normal early development followed by an autistic regression between the ages of 2 and 3 years. This clinical profile partly parallels that seen in Landau-Kleffner syndrome (LKS), an acquired language disorder (aphasia) believed to be caused by epileptiform activity. Given the additional observation that one-third of autistic children experience one or more seizures by adolescence, epileptiform activity may play a causal role in some cases of autism. **OBJECTIVE:** To compare and contrast patterns of epileptiform activity in children with autistic regressions versus classic LKS to determine if there is neurobiological overlap between these conditions. It was hypothesized that many children with regressive ASDs would show epileptiform activity in a multifocal pattern that includes the same brain regions implicated in LKS. **DESIGN:** Magnetoencephalography (MEG), a noninvasive method for identifying zones of abnormal brain electrophysiology, was used to evaluate patterns of epileptiform activity during stage III sleep in 6 children with classic LKS and 50 children with regressive ASDs with onset between 20 and 36 months of age (16 with autism and 34 with pervasive developmental disorder-not otherwise specified). Whereas 5 of the 6 children with LKS had been previously diagnosed with complex-partial seizures, a clinical seizure disorder had been diagnosed for only 15 of the 50 ASD children. However, all the children in this study had been reported to occasionally demonstrate unusual behaviors (eg, rapid blinking, holding of the hands to the ears, unprovoked crying episodes, and/or brief staring spells) which, if exhibited by a normal child, might be interpreted as indicative of a subclinical epileptiform condition. MEG data were compared with simultaneously recorded electroencephalography (EEG) data, and with data from previous 1-hour and/or 24-hour clinical EEG, when available. Multiple-dipole, spatiotemporal modeling was used to identify sites of origin and propagation for epileptiform transients. **RESULTS:** The MEG of all children with LKS showed primary or secondary epileptiform involvement of the left intra/perisylvian region, with all but 1 child showing additional involvement of the right sylvian region. In all cases of LKS, independent epileptiform activity beyond the sylvian region was absent, although propagation of activity to frontal or parietal regions was seen occasionally. MEG identified epileptiform activity in 41 of the 50 (82%) children with ASDs. In contrast, simultaneous EEG revealed epileptiform activity in only 68%. When epileptiform activity was present in the ASDs, the same intra/perisylvian regions seen to be epileptiform in LKS were active in 85% of the cases. Whereas primary activity outside of the sylvian regions was not seen for any of the children with LKS, 75% of the ASD children with epileptiform activity demonstrated additional nonsylvian zones of independent epileptiform activity. Despite the multifocal nature of the epileptiform activity in the ASDs, neurosurgical intervention aimed at control has led to a reduction of autistic features and improvement in language skills in 12 of 18 cases. **CONCLUSIONS:** This study demonstrates that there is a subset of children with ASDs who demonstrate clinically relevant epileptiform activity during slow-wave sleep, and that this activity may be present even in the absence of a clinical seizure disorder. MEG showed significantly greater sensitivity to this epileptiform activity than simultaneous EEG, 1-hour clinical EEG, and 24-hour clinical EEG. The multifocal epileptiform pattern identified by MEG in the ASDs typically includes the same perisylvian brain regions identified as abnormal in LKS. When epileptiform activity is present in the ASDs, therapeutic strategies (antiepileptic drugs, steroids, and even neurosurgery) aimed at its control can lead to a significant

N2 - The purpose of this research was to examine the peer processes that occur during bullying episodes on the school playground. These processes were examined from a social learning perspective, allowing us to consider the effects of various types of reinforcement among bullies, victims, and peers. Fifty-three segments of video tape were examined. Each segment contained a peer group (two or more peers) that viewed bullying on the school playground. Peers were coded for actively joining or passively reinforcing the bully, and for actively intervening on behalf of the victim. On average, four peers viewed the schoolyard bullying, with a range from two to 14 peers. Averaged across all episodes, peers spent 54% of their time reinforcing bullies by passively watching, 21% of their time actively modelling bullies, and 25% of their time intervening on behalf of victims. Older boys (grades 4-6) were more likely to actively join with the bully than were younger boys (grades 1-3) and older girls. Both younger and older girls were more likely to intervene on behalf of victims than were older boys. The results were interpreted as confirming peers' central roles in the processes that unfold during playground bullying episodes. We discuss the results in terms of the challenges posed to peer-led interventions. Peers' anti-bullying initiatives must be reinforced by simultaneous whole-school interventions. N2 - Puppet script training was used to teach the social skills of greeting, responding to conversations, and initiating conversations to a preschool child with visual impairments. Susie and four peers without disabilities were taught social skills utilizing puppets enacting sociodramatic scripts within group training sessions. Training sessions were immediately followed by free-play activities among peers without disabilities to assess skill generalization. A single-case study using a multiple-baseline design demonstrated that the intervention increased performance of social skills during recess with peers. Results demonstrated that Susie learned the target behaviors and generalized their use to free-play activities with her peers

N2 - There is strong evidence that sun exposure during childhood and adolescence plays an important role in the etiology of skin cancer, in particular cutaneous melanoma. Between the age of 6 and 18, most children and adolescents will spend around 200 days per year at school and may receive a substantial fraction of their daily total solar ultraviolet radiation (UVR) exposure while at school. This study estimated the average daily erythemally effective dose of 70 grade 8 students from a high school in Townsville during 5 school days in July 1998. Through UV measurements of shade locations at the school and a combination of frequency counts and a questionnaire of grade 8 students, it was possible to determine the fraction of solar UVR reaching under the shade structures during lunch breaks and routine outdoor activities. Also, a routinely operating UV-Biometer provided the annual variation of the daily dose that was used to calculate exposure levels for the 70 students. Our results suggest that up to 47% of the daily total dose fell within the time periods where students were outdoors during school hours. For students not seeking shade structures during the breaks (which usually was the case when involved in sport activities such as basketball or soccer), the average daily dose could have been as high as 14 SED (standard erythemal dose). Using results from the questionnaire of 70 grade 8 students, their average annual dose while at school was 414 SED or 2 SED per school day. However, the distribution of average daily erythemal effective dose per grade 8 student over the whole year showed that on 31% of all school days in 1998, this dose was exceeded. Because most previous attempts to change arguably poor sun-protective behavior of young Australian children and adolescents at school showed little success, one way of decreasing the amount of harmful UVR reaching unprotected skin is the more careful design of shade structures at schools

N2 - BACKGROUND: The design of childhood injury prevention programmes is hindered by a dearth of valid and reliable information on injury frequency, cause, and outcome. A number of local injury surveillance systems have been developed to address this issue. One example is CHIRPP (Canadian Hospitals Injury Reporting and Prevention Program), which has been imported into the accident and emergency department at the Royal Hospital for Sick Children, Glasgow. This paper examines a year of CHIRPP data. **METHODS:** A CHIRPP questionnaire was completed for 7940 children presenting in 1996 to the accident and emergency department with an injury or poisoning. The first part of the questionnaire was completed by the parent or accompanying adult, the second part by the clinician. These data were computerised and analysed using SPSSPC for Windows. **RESULTS:** Injuries commonly occurred in the child's own home, particularly in children aged 0-4 years. These children commonly presented with bruising, ingestions, and foreign bodies. With increasing age, higher proportions of children presented with injuries occurring outside the home. These were most commonly fractures, sprains, strains, and inflammation/oedema. Seasonal variations were evident, with presentations peaking in the summer. **CONCLUSIONS:** There are several limitations to the current CHIRPP system in Glasgow: it is not population based, only injuries presented to the accident and emergency department are included, and injury severity is not recorded. Nevertheless, CHIRPP is a valuable source of information on patterns of childhood injury. It offers local professionals a comprehensive dataset that may be used to develop, implement, and evaluate child injury prevention activities

N2 - Prior research with contrived play groups suggests that how children interact with one another can influence their social relationships, but few studies have been carried out to determine if this is the case in naturalistic settings. This study examined the concurrent and longitudinal links between four observational measures of 8- to 9-year-old children's (N = 89) playground behaviors/peer contacts (Alone, Conversation, Group Size, and Network) and three sociometric measures of their peer relationships (Social Preference, Bully, and Victim). The latter were assessed at 2 points within a school year, the first corresponding with the playground observations and the second 5 months later. Several of the concurrent correlations were found to be significant. For boys, Group Size was positively correlated with Bully Score and Social Preference Score, but negatively correlated with Victim Score; and time Alone was positively correlated with Victim Score. For girls, time Alone was positively correlated with Victim Score; Network was negatively correlated with Bully Score but positively correlated with Social Preference Score; and Group Size was positively correlated with Social Preference Score. The longitudinal analyses indicated that for boys, elevated levels of time Alone and, separately, Conversation, predicted the highest increases in Victim Score. For girls, low levels of time Alone predicted the sharpest increases in Social Preference Score. There was also some marginally significant evidence, $p < .06$, that among girls, high levels of time Alone predicted the greatest increases in Bully Score, and high levels of Conversation predicted the greatest increases in Social Preference Score. The theoretical and practical importance of these links between children's nonaggressive playground behaviors and their emerging peer relationships are discussed

N2 - The nutritional status of Brazilians has improved over the last three decades. Still, little is known about the role played by nutritional assistance programs that public institutions and philanthropic organizations provide for low-income preschool children, who face greater nutritional risk. Therefore, we carried out a quasi-experimental study to evaluate the nutritional impact of the municipal preschool nutritional assistance program in the city of Sorocaba, Sao Paulo, Brazil. Over the course of a year, we performed quarterly measurements of weight and height on 444 children, whose ages ranged from 3 months to 6 years. In this population, 164 children were assisted by the preschool nutritional program (intervention group), and 280 children were not (nonintervention group). The children in the nonintervention group were identified by a special census for that purpose; they did not attend the preschool but lived nearby. After obtaining informed consent and carrying out a pretest, professionals and university students interviewed the mothers of the participating children, following standard techniques and conditions. Anthropometric measurements were done by teams of two interviewers, one of whom was a permanent member of the team, using equipment calibrated by the appropriate regional technical organization. The correspondence between the first measurement and subsequent measurements was evaluated by stratifying the population into three groups by z scores for weight-for-age and for weight-for-height, using U.S. National Center for Health Statistics reference curves. The z score groupings were established at the

beginning of the study for three different age groups: younger than 24 months, 24-36 months, and older than 36 months. The two study groups (intervention and nonintervention) were similar sociodemographically, with the following exceptions: maternal employment (more of the mothers of children in the intervention group had jobs outside the home); age (children in the intervention group were significantly older); nutritional status (it was worse in the intervention group); and prevalence of hospital admittance (it was higher in the intervention group). After just the first three months of the study, 32% of the children in the intervention group had moved to a higher nutritional stratum, whereas only 13% of children in the nonintervention group had shown improved nutritional status. The difference in favor of the intervention group increased with the length of the intervention and was higher among older children. These results show that the preschool nutritional assistance program helped to improve the assisted children's nutritional status

N2 - INTRODUCTION: This paper describes the evaluation of a skin cancer prevention program for preschools and daycare centers. The intervention was targeted primarily at staff of child care centers, with the aim of increasing use of sun protection practices for young children while attending these centers. Secondary target groups included parents and the children themselves. The intervention, which adopted the slogan, "Block the Sun, Not the Fun," included workshops for child care center staff, and information/activity packets for parents. **METHODS:** Twenty-seven preschools and daycare centers were randomly assigned to an intervention or wait-list control group. The intervention group received the intervention during the spring of 1994; the wait-list control group received the intervention during the spring of 1995. Evaluation consisted of interviews with center directors, observations of practices, and review of written policies before the intervention (in summer, 1993) and after the intervention (in summer, 1994). A survey of 201 parents was conducted during late summer 1994. **RESULTS:** While the intervention did not appear to change the sun protection attitudes or practices of parents, or use of clothing and shade at child care centers, results suggested significant changes in the sun protection knowledge/attitudes of center directors and the use of sunscreen at child care centers. Additionally, parents with children attending centers in the intervention group were more likely to be satisfied with sun protection practices at their centers. **CONCLUSION:** This low-intensity intervention appears to be effective at changing sun protection attitudes and sunscreen use at child care centers, and can be easily replicated. However, high staff turnover at child care centers would suggest that "boosters" will be necessary to sustain the impact. More intensive efforts directed at social norms are likely to be necessary to change clothing and outdoor play practices

N2 - BACKGROUND: "Kidskin" is an intervention study involving children at 33 primary schools in Perth, Western Australia. This study includes measurement of changes in implementation of schools' sun protection policies. This paper reports on measurement of observable aspects of sun protection. METHODS: Hat use was assessed from videos of children in the playground. Shade use was measured using UVR-sensitive polysulfone badges worn by a random sample of children. Shade provision was measured from aerial photographs of the schools. Principals were surveyed about school policies and practices. RESULTS: Eighty-seven percent of children wore a hat during lunch time at school, although only 14% wore the most protective styles of hats. The mean proportion of ambient UVR exposure received by Year 1 children was 15.5%; children spent less time in the sun on sunnier days. On average, 14.5% of the playground was shaded; this was not associated with children's sun exposure. Correlations between these results and the principals' estimates were poor. CONCLUSIONS: Children should be encouraged to wear more protective styles of hats and to avoid sun exposure, even on less sunny days during spring and summer. Principals' estimates of shade provision and children's sun protection behavior at school are of little value. Copyright 1999 American Health Foundation and Academic Press

N2 - The pathogenesis of allergy depends on the interaction between the time and amount of allergen exposure and the presence of nonspecific "adjuvant" factors in genetically susceptible individuals. There seems to be a period in early life during which the individual is particularly susceptible to sensitization, and there are variations in susceptibility over time. Allergens are almost ubiquitous, but the relative importance of the individual allergens varies between regions. In many temperate regions, house-dust mites used to be absent but are now more common. This may be due to modern methods of building houses. Differences in the prevalence of a particular allergy cannot explain variations in the prevalence of allergy in general. Various environmental factors that may enhance sensitization include tobacco smoke, NO₂, SO₂, ozone, and diesel particles. Passive smoking is by far the best established risk factor, particularly in early childhood. The indoor environment probably plays a larger role than outdoor air pollution in the development of allergic disease. The mother is not only a source of genetic information, but also an "environmental factor", as there is a close immunologic interaction between the mother and her offspring, mediated through the placenta and the breast milk, which may affect the likelihood of allergic disease. The concepts of "lifestyle" and "environment" should be expanded to include, for example, dietary changes, the microbial environment, and extensive traveling, as all the currently suspected risk factors taken together can only explain a small proportion of the geographic differences in and increasing prevalence of allergy. The future search for significant environmental factors should be interdisciplinary and be directed toward areas that have not yet been explored, thus giving "lifestyle" a broader interpretation

N2 - **OBJECTIVE:** This study was conducted to describe changes in prescription practices outside the hospital, to evaluate the adaptation of such prescriptions to current scientific knowledge, and to compare medical practices in France with those in other European countries. **METHODS:** Data were collected from several sources: analysis of the literature, surveys conducted in the Loiret department and in the Rhone-Alps region, ten-year health surveys (INSEE), data from the Sentinel network, sales statements from pharmaceutical firms, the Permanent Survey of Medical Prescription (EPPM) of the Medical Information and Statistics (IMS) firm. Comparisons between France, the United Kingdom and Germany were conducted by the French Medicine Agency's Pharmaco-economic Studies and Information Department using data furnished by the IMS firm and by pharmaceutical firms. **RESULTS:** In France, antibiotic sales increased by a mean annual rate of 2.1%, expressed in antibiotic units, and 2.6%, expressed in turnover (manufacturer price) between 1991 and 1996. The majority of these antibiotics were prescribed for respiratory and ENT infections with a presumed viral etiology such as rhino-pharyngitis and acute bronchitis. The results of the different surveys were in agreement showing that antibiotic prescriptions are made in approximately 40% of all consultations for rhino-pharyngitis and in 80% of those for acute bronchitis. Antibiotics were prescribed in more than 90% of cases of pharyngitis whatever the age of the patient. The situation was different for acute middle ear infections as the number of consultations has remained relatively unchanged over the last 10 years while antibiotic prescriptions have strongly increased, reaching 80% of the consultations. The number of consultations for pharyngitis and acute rhino-pharyngitis appears to be greater in France than in the United Kingdom and in Germany. Likewise, the proportion of patients using antibiotics after consulting for presumed viral conditions would be higher in France with different antibiotic classes being used. **CONCLUSIONS:** There is a gap between official guidelines (product description documents, therapeutic information documents, good practice guidelines, consensus conferences) and the state of current practices. Excessive and poorly-adapted antibiotic prescription favors the disturbing phenomenon of resistance which is all the more alarming because the emergence of resistant strains is difficult to predict and concerns bacteria causing the most common infections. To improve medical practices and achieve a persistent reduction in the use of antibiotics for viral infections, validated recommendations should be distributed to physicians. An effort should be made to prescribe the most appropriate active substance at optimal dose and treatment duration to limit the development of bacterial resistance. In addition, patients and the general public should be informed of the absence of any beneficial effect and the individual and collective risks involved in using antibiotics for viral infections in order to help them better understand and comply to their physician's prescription. N2 - Townsville, in Queensland, Australia, experiences very high levels of ambient solar ultraviolet radiation (UVR) throughout the year and has a predominantly white population which is prone to developing skin cancer. The UVR exposure of 1-year-old and 2 1/2-year-old children raised in Townsville was measured using UVR-sensitive polysulphone film badges. In two separate exposure studies undertaken for 7 days in October 1995 and 5 days in April 1997, exposure at the chest and shoulder for each subject was determined. The chest exposures for the 1-year-olds were significantly higher at weekends than on weekdays, whereas for the 2 1/2-year-old children the shoulder exposures were significantly higher at weekends than on weekdays. The median daily total exposure for 1-year-old infants was 0.4 SED (standard erythemal dose) for the chest and 0.4 SED for the shoulder. The median daily total exposure for 2 1/2-year-olds was 0.6 SED for the chest and 0.9 SED for the shoulder. Although the median daily total exposures were comparatively low, the maximum values for the chest and shoulder were 6.5 SED and 2.4 SED, respectively, for the 1-year-old infants, and 20.6 SED and 8.4 SED, respectively, for the 2 1/2-year-olds. While the 2 1/2-year-old children spent most of their time outside between 9 am and 4 pm, the 1-year-old infants spent more time outside before 9 am and after 4 pm. Exposure increases with age in early childhood. Increased mobility and a greater tendency to play outdoors is likely to account for the higher exposure levels in 2 1/2-year-old children, compared to 1-year-old infants

N2 - The main objective of the present study was to determine whether a structured, laboratory-based exercise task would modify the energy expenditure (EE) and the pattern of spontaneous physical activity (PA) of obese boys on the day of an exercise laboratory visit and on the following day. Fourteen 10- to 15-y-old moderately obese (36.6+/-3.3% fat) boys volunteered. They each had three laboratory visits, 1 wk apart. In one visit, they performed a strenuous 50-min cycling task; in another, a 30-min medium-intensity cycling task; and in another (which served as placebo), they did not exercise. PA was monitored the day before (d 1), during (d 2), and after (d 3) each laboratory visit by use of a heart rate monitor and a 12-h recall interview. EE was calculated from minute-by-minute heart rate and each child's predetermined relationship between oxygen uptake and heart rate. EE and PA were analyzed from 1300 to 1900 h each day using 15-min intervals. EE tended to decrease ($p < 0.087$) in the afternoon of all d 2 compared with d 1, and it increased on d 3 after the medium-intensity exercise ($p < 0.0005$). EE during d 2 and 3 combined, compared with d 1, decreased after the high-intensity exercise (534.2 versus 564.3 kJ/h, $p < 0.05$). It increased after the medium-intensity exercise (561.8 versus 526.7 kJ/h, $p = 0.052$) and was not affected after the placebo visit (589.4 versus 574.3 kJ/h). Time spent outdoors was consistently reduced on the day of laboratory visit compared with the day before and after the visit, regardless of the contents of intervention. In conclusion, a single laboratory visit is followed by a reduction in EE and PA on the day of intervention. However, its effect on EE the following day may be dose dependent: medium-intensity exercise induces an increase in EE, but high-intensity exercise causes a decrease in EE. One implication is that intervention by physical training should employ medium-intensity exercise to enhance the EE of obese boys

N2 - OBJECTIVE: To measure the incidence of childhood fractures in a defined population. SETTING: Accident and emergency (A&E) departments covering the Swansea and Neath Port Talbot areas of South Wales in 1996. METHODS: Linkage of data from A&E departments with population data to produce fracture incidence rates by anatomical site and cause in children aged 0-14 years. RESULTS: During 1996, 2463 new fractures occurred in 2399 residents yielding a fracture rate of 36.1/1000 children. Fractures were more common in boys than girls and increased with age in both groups. Sports and leisure activities accounted for 36% of fractures, assaults for 3.5%, and road traffic accidents 1.4%. Fractures of the radius/ulna were most frequent (36%). CONCLUSIONS: The fracture rate in South Wales children is twice the rate reported in previous studies. Further research is required to elucidate the reasons behind this high rate. Many fractures could be prevented by the use of safer surfaces in school playgrounds, and wrist protection in in-line skaters and possibly in soccer players

N2 - OBJECTIVES: A community intervention trial was carried out to evaluate the relative effectiveness of two methods of reducing playground hazards in schools. The study hypotheses were: (1) a health promotion programme addressing barriers to implementing the New Zealand Playground Safety Standard will reduce playground hazards and (2) the intervention programme will be more successful than providing information alone. METHODS: Twenty four schools in Wellington, New Zealand were randomly allocated into two groups of 12 and their playgrounds audited for hazards. After the audit, the intervention group received a health promotion programme consisting of information about the hazards, an engineer's report, regular contact and encouragement to act on the report, and assistance in obtaining funding. The control group only received information about hazards in their playground. RESULTS: After 19 months, there was a significant fall in hazards in the intervention schools compared with the control schools (Mann-Whitney U test, $p = 0.027$). No intervention schools had increased hazards and eight out of 12 had reduced them by at least three. In contrast, only two of the control schools had reduced their hazards by this amount, with three others increasing their hazards in that time. CONCLUSIONS: It is concluded that working intensively with schools to overcome barriers to upgrading playground equipment can lead to a reduction in hazards, and that this form of intensive intervention is more effective than providing information alone

N2 - Each year approximately 211,000 U.S. children receive emergency department care for injuries sustained on playground equipment, making the use of this equipment the leading cause of injuries to children in school and child care environments. In response to the problem, the National Program for Playground Safety (NPPS) at the University of Northern Iowa (UNI) developed a national action plan that focuses on four areas of playground injury prevention: supervision, age-appropriateness of equipment, suitable fall surfaces, and equipment maintenance. During 1998-1999, NPPS surveyed a sample of the nation's child care, elementary school, and park playgrounds. This report summarizes the survey results, which indicate that playground injuries could be reduced by measures such as resilient surfacing below equipment, better equipment maintenance, improved supervision, and use of age-appropriate equipment

N2 - OBJECTIVES: To describe the incidence of severe traffic injuries before and after implementation of a comprehensive, hospital-initiated injury prevention program aimed at the prevention of traffic injuries to school-aged children in an urban community. **MATERIALS AND METHODS:** Hospital discharge and death certificate data on severe pediatric injuries (ie, injuries resulting in hospital admission and/or death to persons age <17 years) in northern Manhattan over a 13-year period (1983-1995) were linked to census counts to compute incidence. Rate ratios with 95% CIs, both unadjusted and adjusted for annual trends, were calculated to test for a change in injury incidence after implementation of the Harlem Hospital Injury Prevention Program. This program was initiated in the fall of 1988 and continued throughout the study period. It included 1) school and community based traffic safety education implemented in classroom settings in a simulated traffic environment, Safety City, and via theatrical performances in community settings; 2) construction of new playgrounds as well as improvement of existing playgrounds and parks to provide expanded off-street play areas for children; 3) bicycle safety clinics and helmet distribution; and 4) a range of supervised recreational and artistic activities for children in the community. **PRIMARY RESULTS:** Traffic injuries were a leading cause of severe childhood injury in this population, accounting for nearly 16% of the injuries, second only to falls (24%). During the preintervention period (1983-1988), severe traffic injuries occurred at a rate of 147.2/100 000 children <17 years per year. Slightly <2% of these injuries were fatal. Pedestrian injuries accounted for two thirds of all severe traffic injuries in the population. Among school-aged children, average annual rates (per 100 000) of severe injuries before the intervention were 127.2 for pedestrian, 37.4 for bicyclist, and 25.5 for motor vehicle occupant injuries. Peak incidence of pedestrian and bicyclist injuries occurred during the summer months and afternoon hours, whereas motor vehicle occupant injuries showed little seasonal variation and were more common during evening and night-time hours. Age-specific rates showed peak incidence of pedestrian injuries among 6- to 10-year-old children, of bicyclist injuries among 9- to 15-year-old children, and of motor vehicle occupant injuries among adolescents between the ages of 12 and 16 years. The peak age for all traffic injuries combined was 15 years, an age at which nearly 3 of every 1000 children each year in this population sustained a severe traffic injury. Among children hospitalized for traffic injuries during the preintervention period, 6.3% sustained major head trauma (including concussion with loss of consciousness for ≥ 1 hour, cerebral laceration and/or cerebral hemorrhage), and 36.9% sustained minor head trauma (skull fracture and/or concussion with no loss of consciousness ≥ 1 hour and no major head injury). The percentage of injured children with major and minor head trauma was higher among those injured in traffic than among those injured by all other means (43.2% vs 14.2%, respectively; $\chi^2 = 336$; degrees of freedom = 1). The percentages of children sustaining head trauma were 45.4% of those who were injured as pedestrians, 40.2% of those who were injured as bicyclists, and 38.9% of those who were injured as motor vehicle occupants. During the intervention period, the average incidence of traffic injuries among school aged children declined by 36% relative to the preintervention

period (rate ratio:.64; 95% CI:.58,.72). After adjusting for annual trends in incidence, pedestrian injuries declined during the intervention period among school aged children by 45% (adjusted rate ratio:.55; 95% CI:.38,.79). No comparable reduction occurred in nontargeted injuries among school-aged children (adjusted rate ratio:.89; 95% CI:.72, 1.09) or in traffic injuries among younger children who

N2 - Efforts to increase the sun-protective behaviors of children were extended to outdoor recreational sports and youth soccer settings in this study. The pretest results of a pilot survey of coaches (n = 12), parents (n = 50),

and youths (n = 61) on eight soccer teams in south Georgia were used to guide the development of a health education program for coaches. In the pilot programs, half the coaches were trained to be involved in soccer-playing youths' sun protection by acting as positive role models and promoting sun protection to youths and their parents. The pilot demonstrated coaches' willingness to participate in sun protection promotion to youth: Youths indicated that coaches and parents were more likely to tell youths to wear sunscreen after the training than before, and coaches perceived getting youths to wear sunscreen to be less difficult than before

N2 - Any discussion of obesity in youth must consider physical activity level or energy output. Many suggest that increasing levels of obesity among children is the direct result of declining levels of physical activity. There is accumulating evidence that physical activity among youth has declined over the past several decades. Less time is spent on physical education classes in school and many popular activities among youth such as television and computer games, involve minimal physical exertion. These observations are confirmed by studies of physical fitness and endurance. These measures have also declined among youth. Much has been learned about the factors associated with physical activity among youth. These factors were used to develop several innovative school-based programs which demonstrate increased physical activity and performance. Recommendations are made for increasing physical activity both in the school curriculum and outside the school day. Potential health benefits and likely effects on obesity are substantial. N2 - Evaluation of health promotion interventions aimed at behavioural or environmental change involves assessing change that occurs as a result of the program. Direct observational methods can be used for this purpose and this paper describes three such methods that we pilot tested for use in a 5-year intervention study aimed at reducing sun exposure in primary school children. (1) Monitoring 'No hat, no play' policies. This method involved video taping children in selected school play areas during lunch time and analysing the content of the videos to assess the proportion of children wearing various types of hats. (2) Assessing shade provision in the playground. This method involved taking aerial photographs of each school and using them to estimate the proportion of shade in play areas available to children at lunchtime. (3) Shade use. This involved children wearing polysulphone film badges to measure the amount of UV-B exposure they received during one lunch period, relative to the total possible dose registered on index badges. Each method was implemented successfully, and we demonstrated that the video and aerial photography methods produced highly reproducible results and that all three methods were feasible. These three methods will be used in our intervention study to assess longitudinal change in schools' sun-protection policy and practice

N2 - Assessing personal exposure to ozone has only been feasible recently with the introduction of passive ozone samplers. These devices are easy to use, but changes in air velocity across their collection surfaces can affect performance. The Harvard active ozone sampler (AS) was developed in response to problems with the passive methods. This active sampler has been tested extensively as a microenvironmental sampler. To test for personal sampling, 40 children attending summer day-camp in Riverside, California wore the active ozone sampler for approximately 2.6 h on July 19 and 21, 1994, when ozone concentrations were about 100 ppb and 140 ppb, respectively. The children spent 94-100% of the sampling period outside, staying within a well-defined area while participating in normal camp activities. Ambient ozone concentrations across this area were monitored by two UV photometric ozone monitors. The active sampler was worn in a small backpack that was also equipped with a passive ozone sampler. Device precision, reported as the percent difference between duplicate pairs of samplers, was +/- 3.7% and +/- 4.2% for the active and passive samplers, respectively. The active sampler measured, on average, 94.5 +/- 8.2% of the ambient ozone while the passive samplers measured, on average, 124.5 +/- 18.8%. The samplers were worn successfully for the entire sampling period by all participating children

N2 - **BACKGROUND:** Playground equipment resulted in >200 000 injuries from 1990 to 1994, according to the Consumer Product Safety Commission; 88% were attributable to climbers (monkeybars/jungle gyms [MB/JGs]), swings, and slides. Equipment-specific injury requiring emergency department (ED) evaluation has not been reported previously. **OBJECTIVE:** To describe the spectrum of significant MB/JG-related injuries. **METHODS:** A 2-year retrospective chart review was performed using the computerized charting system at a large urban Children's Hospital/Regional Pediatric Trauma Center with 50 000 ED visits per year. A telephone survey also was conducted after the chart review to obtain additional information concerning the injury location, the surface type below the equipment, and the presence of adult supervision. **RESULTS:** A total of 204 patients were identified. Mean age was 6.2 years (range, 20 months to 12 years); 114 (56%) were male. A seasonal variation was noted with June to August accounting for 43% of visits. Injuries included fractures in 124 (61%), contusions in 20 (10%), neck and back strains in 17 (8%), lacerations in 16 (8%), closed head injuries in 10 (5%), abdominal trauma in 5 (3%), genitourinary injuries in 5 (3%), and miscellaneous injuries in the remainder. Among fractures, 90% were fractures of the upper extremity; 48 (40%) were supracondylar fractures. One child sustained a C7 compression fracture. Abdominal injuries included 1 child who sustained a splenic laceration. All genitourinary injuries (2 vaginal hematomas, 1 vaginal contusion, 1 penile laceration, and 1 urethral injury) were from straddle-type injuries. Fifty-one (25%) patients were admitted to the hospital. Of these, 47 (92%) required an operative procedure (orthopedic reduction or vaginal examination under anesthesia). Analysis of the telephone data revealed that the surface did not influence the injury type. Of the 79 fractures, 30 occurred on "soft surfaces." Injury type was associated significantly with chronologic age. Younger children (1 to 4 years of age) sustained more long-bone fractures than did older children. The presence of adult (at least 18 years of age) supervision, did not influence the occurrence of fractures. **CONCLUSIONS:** These data suggest that 1) a significant proportion (25%) of MB/JG-related injuries that are evaluated in the ED require hospitalization; 2) most of the injuries resulting in admission will require operative intervention (92%); 3) the surface below the equipment has no influence on the type or severity of the injury; 4) younger children are more likely to sustain

long-bone fractures than are older children; and 5) adult supervision does not influence the injury pattern. These data identify the need for additional investigation of means of making MB/JGs safer for child use

N2 - The latest available data indicate that an estimated 83 400 trampoline-related injuries occurred in 1996 in the United States. This represents an annual rate 140% higher than was reported in 1990. Most injuries were sustained on home trampolines. In addition, 30% of trampoline-related injuries treated in an emergency department were fractures often resulting in hospitalization and surgery. These data support the American Academy of Pediatrics' reaffirmation of its recommendation that trampolines should never be used in the home environment, in routine physical education classes, or in outdoor playgrounds. Design and behavioral recommendations are made for the limited use of trampolines in supervised training programs

N2 - The free running test is a useful method for evaluation of exercise-induced bronchospasm in children. In young children this test simulates real-life circumstances and can be done more easily than histamine or methacholine challenges. The interrupter technique is a noninvasive method for measuring airflow resistance during tidal breathing. This approach requires minimal cooperation, and is therefore promising for use in young children. Fifty children aged 5-15 years with asthma symptoms were tested by exercise challenge consisting of free outdoor running for 8 min at 85% of maximal predicted heart rate for age. Pulmonary function was measured by using the interrupter technique (IR), with a Wright's peak flow meter (WPEF), and by flow-volume spirometry (FVS). The measurements were done before and 10 min after exercise. In addition, WPEF was measured at 5, 15, and 20 min after exercise. A fall of 15% or more in WPEF associated with wheezing or cough symptoms was considered a positive test. The exercise challenge was positive in 16 (32%) of the 50 children. Measurements at 10 min by WPEF identified 9 positive cases. At the same time point the IR identified 10 positive cases; a rise in resistance of 15% or more was considered positive, giving it 80% sensitivity and 93% specificity. The repeatability coefficient (CoR) for the interrupter technique was 0.06 kPa x L(-1) x s (13%) before and 0.07 kPa x L(-1) x s (14%) after exercise. The IR provides a useful alternative for estimation of airway obstruction in children following exercise challenge. The results were comparable with the current reference methods of forced expiratory volume in 1 s and peak flow measurements

N2 - **BACKGROUND:** Children with Crohn's disease may have an impaired quality of life. **METHODS:** A validated questionnaire was mailed to the parents of all child members of Crohn's in Childhood Research Association (CICRA) (age range, 5-17 years). It investigated aspects of the quality of life of children with Crohn's disease. Sixty-four questionnaires were returned together with another 35 from those outside the defined age range. Patients in the latter group were not included in the analysis. **RESULTS:** Of the children investigated, 60% had significant absences from school, with a mean of 3+/-2.8 months' absence in the previous year. Most (53%) thought that their teachers knew nothing about Crohn's disease, and 50% thought that teachers were unsympathetic. Of the 24 who had taken examinations 80% thought they had underachieved because of ill health. Sixty-seven percent of children were unable to participate in sports on a regular basis, 60% felt unable to leave the house, and 50% were unable to play with their friends. Information about Crohn's disease had predominantly come from doctors (89%), information booklets (83%), and nursing staff (42%). The commonest questions asked by the children were: what is Crohn's disease (50%), why me (64%), will it affect my schooling (52%), and will it affect my chances of getting a job (67%). **CONCLUSION:** Children with Crohn's disease have a significantly impaired quality of life. They fear everyday childhood activities and fear for their future. These children need sympathetic management, and effort should be concentrated on improving their day-to-day existence to enable them to lead as normal a life as possible

N2 - OBJECTIVE: To compare playground hazards in high- and low-income neighborhoods. DESIGN: Forty-five playgrounds were randomly selected from the 9 New York City community districts that met our study criteria and were divided into high-and low-income groups based on comparison to the median incomes (\$24452 per year) of the 9 districts. Playgrounds are maintained by the City of New York Parks and Recreation Department and were assessed by one of us (S.A.S.) using a standardized on-site survey based on the US Consumer Product Safety Commission's guidelines for public playground safety. MAIN OUTCOME MEASURES: Total hazards per play area were subdivided into 3 categories: park design hazards, equipment maintenance hazards, and equipment hazards relating to fall injuries. A play area was defined as an individual set of equipment. RESULTS: Twenty-five (56%) of the parks were located in low-median-income districts and contained 98 (53%) of the total play areas. High- and low-income playgrounds did not differ significantly in the amount or type of equipment, mean fall injury hazards per play area, or mean park design hazards per play area. Low-income districts had a significantly higher mean total hazards per play area (6.1 vs. 4.2; P = .02) and mean equipment maintenance hazards per play area (2.1 vs. 1.0; P = .02). CONCLUSION: Significantly more hazards per play area were identified in the low-income group compared with the high-income group

N2 - This study examined the correlates of mothers' and fathers' knowledge about the daily experiences of their firstborn (M = 10.9 years) and secondborn (M = 8.3 years) children in 198 nondivorced, predominantly dual-earner families. Results revealed between- and within-family differences in knowledge as a function of mothers' work involvement, sibship composition (i.e., sex, birth order), children's personal qualities (e.g., temperament), and parents' personal qualities (e.g., education, gender role attitudes). Mothers' knowledge did not vary as a function of how much they worked outside the home, but fathers knew more about their children's activities, whereabouts, and companions when their wives worked longer hours. Parents knew more about their younger than their older offspring. Both mothers and fathers knew more about offspring of the same sex than about opposite-sex children, leading to greater within-family differences in families with mixed-sex siblings. Perhaps because parental involvement and monitoring are more "scripted" for mothers than fathers, fathers' knowledge was more consistently related to their children's characteristics than was mothers.'

N2 - OBJECTIVE: To describe the home literacy environment and to identify financial, human, and social capital variables associated with the presence or lack of Child Centered Literacy Orientation (CCLO) in families with young children who regularly attend pediatric primary care clinics. **DESIGN:** Cross-sectional case-control analysis of structured parent interviews conducted in two hospital-based and four community-based pediatric clinics in New England. **SUBJECTS:** Parents of 199 healthy 1- to 5-year-old children whose mean age was 30 +/- 15 (SD) months were interviewed. Parents were primarily mothers (94%) with a mean age of 28 +/- 7 (SD) years 60% of whom were single. Educational levels of study parents varied: 43% had not graduated from high school, 29% had a high school equivalency, and 28% had at least a year of college or vocational training. This was a multiethnic parent group. Sixty-five percent were bilingual or non-English speaking. Fifty-eight percent were born outside of the continental United States. Parents were primarily of low-income status with 85% receiving Women, Infant, and Children (WIC) food supplements, Aid to Families With Dependent Children, and/or Medicaid. **RESULTS:** Half of the parents interviewed reported that they rarely read books. Sixty percent of children had fewer than 10 books at home and two-thirds of these households contained fewer than 50 books total. When asked open-ended questions, 28% of parents said that sharing books with their child was one of their three favorite activities together, 14% said that looking at books was one of their child's three favorite things to do, and 19% reported sharing books at bedtime at least six times each week. Thirty-nine percent of families had at least one of these three literacy-related responses present and so were said to have a CCLO. A backwards stepwise multiple logistic regression on CCLO was performed with family financial, human, and social capital variables. Parents married or living together (odds ratio [OR] 2.56, 95% confidence interval [CI] = 1.21-5.42), higher adult-to-child ratios in the home (OR 1.92, 95% CI = 1.20-3.05), households speaking only English (OR 2.67, 95% CI = 1.24-5.76), parents reading books themselves at least a few times a week (OR 2.86, 95% CI = 1.38-5.91), and homes with more than 10 children's books (OR 3.3, 95% CI = 1.6-6.83), were all independently and significantly associated with the presence of CCLO. Older child age and higher parent education remain in the model but were not significant at the P < .05 level. Ethnicity and income status were dropped for lack of additional significance from this model, which described 24% of the variance in CCLO. **CONCLUSION:** Although two-parent families and higher adult-to-child ratios in the home appear to be social capital variables with protective effects, low-income, single-parent, and minority or immigrant families are at significant risk for lacking both children's books and a CCLO. We suggest that CCLO may itself be another form of social capital reflecting parental goals and expectations for their children. We speculate that interventions which provide children's books and information about reading with children to impoverished families with young children may facilitate more parent-child book sharing. Pediatricians and other primary care

providers serving underserved populations may have a unique opportunity to encourage activities focusing on young children and promoting literacy

N2 - BACKGROUND: Obesity in childhood increases the risk of obesity in adulthood. Obesity in adulthood is a risk factor for chronic diseases such as hypertension and atherosclerosis. Therefore, it is important to eliminate factors influencing the development of obesity in children from the viewpoint of preventive medicine. The purpose of this study is to elucidate the relationship between obesity and lifestyle in 3-year-old children in a case-control study. **METHODS:** Subjects were selected from the Toyama study at health checkups for 3-year-old children which are done routinely by local governments in Japan on all children of that age. A special questionnaire consisting of items on lifestyle and environmental factors of the children and past histories of parents was distributed to the Toyama study participants beforehand and was collected at the checkup. Matched-pair comparisons were performed between obese children whose body mass index was 18 or more (N = 427) and control children (N = 854) matched by sex and birth month. Multivariate stepwise conditional logistic regression analysis was also applied to assess the influence of confounding factors. **RESULTS:** The following six factors significantly influenced the development of obese 3-year-old children using the Mantel-Haenszel method: the mother's job, limited playtime outdoors (1 hour or less), snacking irregularity, an overweight father (body mass index ≥ 24), an overweight mother (body mass index ≥ 24), and overweight at birth (birth weight $\geq 3,500$ g). An overweight mother or father, limited playtime outdoors, overweight at birth, and snacking irregularity were significantly related to obesity in 3-year-old children after adjusting for confounding factors by multivariate stepwise conditional logistic regression analysis. **CONCLUSIONS:** We have suggested several factors influencing the development of obesity in 3-year-old Japanese children: parental overweight and overweight at birth as host factors, physical inactivity and snacking irregularity as behavioral factors, the mother's job as an environmental factor. N2 - **BACKGROUND:** In June, 1997, 21 children from a single community in Germany were hospitalized with aseptic meningitis. An epidemiologic investigation was conducted to determine the extent of the outbreak and risk factors for illness. **METHOD:** The extent of the outbreak was assessed with a cross-sectional survey of every 10th child listed in the town register among the 2240 town children < 16 years old. A case-control study determined risk factors for illness. Sixty-two cases were identified through the cross-sectional survey from hospitalized persons and from persons seen by local physicians. Controls were 114 asymptomatic persons identified from the cross-sectional survey. **RESULTS:** The overall attack rate was 16%, with the highest attack rates (24%) among the 6- to 8-year olds. Onsets occurred during a 37-day period. Among the 2240 town children <16 years of age, an estimated 353 met the case definition for enteroviral illness, 168 visited a doctor and 21 were hospitalized. Data from the case-control study indicated that contact with an ill household member [odds ratio (OR) = 6.3; 95% confidence interval (CI) 2.6 to 15.5], day-care attendance (OR = 2.6; 95% CI 1.1 to 6.2) and playground use, either two to three times per week (OR = 3.7; 95% CI 1.3 to 10.2) or daily (OR = 4.3; 95% CI 1.6 to 11.3), were risk factors for illness. **CONCLUSION:** Echovirus 30 caused substantial morbidity during this community outbreak caused by person-to-person spread. Household contacts, day-care centers and playgrounds were prominent risk factors for transmission

N2 - **PURPOSE:** To report the results of a Phase II study of hyperfractionated craniospinal radiation therapy, with and without adjuvant chemotherapy for primitive neuroectodermal brain tumors (PNETs) and malignant ependymomas. **METHODS AND MATERIALS:** Newly diagnosed PNET or malignant ependymomas were treated with hyperfractionated craniospinal radiation therapy. The primary tumor site was treated to a dose of 72 Gy, with 30 Gy given to the rest of the craniospinal axis. The fraction size was 1.0 Gy, given twice a day. Patients with poor risk factors also received adjuvant chemotherapy with CCNU, cisplatin, and vincristine. Patients had follow-up for survival, time to tumor progression, and patterns of relapse. **RESULTS:** A total of 39 patients (21 males/18 females) were treated between March 12, 1990 and October 29, 1992. The median age was 16 years (range 3-59 years). Tumor types included 25 medulloblastomas, 5 pineoblastomas, 5 cerebral PNETs, 1 spinal cord PNET, and 3 malignant ependymomas. Twenty cases were staged as poor-risk and received adjuvant chemotherapy following radiation. Three-year progression-free survival (PFS) was 60% and 63% for poor-risk and good-risk patients, respectively. Overall 3-year survival for these groups was 70% and 79%, respectively. For the 25 patients with medulloblastoma, there were 16 good-risk and 9 poor-risk patients. Three-year PFSs were 63% and 56%, respectively. The 5-year survival for good-risk medulloblastoma was 69% with 43.7% of these patients having failures outside the primary site. **CONCLUSIONS:** Survival in patients with good-risk medulloblastoma was no better than that seen in previous studies with single-fraction radiation, and the rate of failure outside the primary site is excessive. Those with poor-risk features had comparable survival to that seen in patients with good risk factors, but these patients were treated with chemotherapy, and the role that hyperfractionated radiation played in their outcome is uncertain

N2 - This study examined the effects of beverage composition on the voluntary drinking pattern, body fluid balance, and thermoregulation of heat-acclimatized trained boys exercising intermittently in outdoor conditions (wet bulb globe temperature 30.4 +/- 1.0 degreesC). Twelve boys (age 13.4 +/- 0.4 yr) performed two 3-h sessions, each consisting of four 20-min cycling bouts at 60% maximal aerobic power alternating with 25-min rest. One of two beverages was assigned: unflavored water (W) or flavored water plus 6% carbohydrate and 18 mmol/l Na (CNa). Drinking was ad libitum. Total intake was higher (P < 0.05) during CNa (1,943 +/- 190 g) compared with W (1,470 +/- 143 g). Euhydration was maintained with CNa (+0.18% body wt), but a mild dehydration resulted with W (-0.94% body wt; P < 0.05). Sweat loss, much higher than previously published for children of similar age, was similar between conditions (CNa = 1,644.7 +/- 117.5; W = 1,750.2 +/- 152.7 g). The increase in rectal temperature (CNa = 0.86 +/- 0.3; W = 0.76 +/- 0.1 degreesC), heart rate, and all perceptual variables did not differ between conditions. In conclusion, a flavored carbohydrate-electrolyte drink prevents voluntary dehydration in trained heat-acclimatized boys exercising in a tropical climate despite their large sweat losses. Because hydration changes were minor, the thermoregulatory strain observed was similar between conditions

N2 - Exhaled nitric oxide (NO) is increased in exhaled breath of asthmatic patients. The aim of this study was to investigate the longitudinal changes of exhaled NO outside and during the pollen season in pollen-allergic asthmatic children. Twenty-one children (age 6 to 16 yr), with a seasonal allergic asthma sensitive to grass pollen, underwent measurements of exhaled NO and pulmonary function before (March), during (May), and after (November) the pollen season. Exhaled NO was measured by a tidal breathing method with a chemiluminescence analyzer and NO steady-state levels were recorded. The timing of the measurements during

the pollen season was based on the atmospheric pollen count. Exhaled NO values of asthmatic children were compared with those of 21 sex- and age-matched healthy children. Pulmonary function and symptoms of asthma were also evaluated at each visit. The mean value of exhaled NO before the grass season was 12.7 +/- 5.1 ppb (mean +/- SD), significantly higher when compared with controls (7.8 +/- 2.7 ppb, $p < 0.001$). In the pollen season there was a significant ($p < 0.001$) twofold increase in exhaled NO (21.4 +/- 7.6 ppb) that, after the season, returned to values similar (12.8 +/- 5.8 ppb, $p = \text{NS}$) to those found before the season. There were no significant changes in FEV1 before and during the season (98.6% predicted versus 101% predicted, $p = \text{NS}$). We conclude that natural allergen exposure is related to an increase of exhaled NO in asthmatic grass pollen-allergic children even in absence of significant changes in airways function. We speculate that measurement of exhaled NO could be a sensitive noninvasive marker of asthma disease activity

N2 - OBJECTIVE: To determine if kindergartens' environmental status can influence children's lead exposure.

METHODS: Environmental specimens, such as floor dust, peeled-off paint chip, soil and drinking water, as well as children's hand dust and blood samples, were collected and measured for their lead levels in 19 kindergartens, to analyze the relationship between children's blood lead levels and their environmental lead

exposure. RESULTS: Geometric means of lead concentrations in indoor floor dust, peeled-off paint chip, dust fallout, outdoor floor dust, soil and drinking water were 86.5 microg/m(2), 235.5 microg/g, 445.9 microg/g, 172.4 microg/m(2), 70.1 microg/g and 12.5 microg/L, respectively. Lead level on children's hands averaged 3.4 microg at both hands. Blood lead levels in children correlated positively with the lead concentrations of outdoor floor dust and their hand dust, with correlation coefficients of 0.5186 and 0.2206, respectively. Multiple regression analysis showed that hand dust lead level in children entered the regression model with a largest standardized partial regression coefficient of 0.3842 and a coefficient of determination of 0.673 for the full equation with $F = 6.52$ and $P < 0.01$. CONCLUSION: Status of environmental health in kindergartens plays an important role in children's lead exposure. It is necessary to offer health education for children and make them wash their hands often and overcome unhealthy behavior of sucking their fingers

N2 - GTP cyclohydrolase I (GTPCH) catalyzes the rate-limiting step of tetrahydrobiopterin (BH4) biosynthesis. GTPCH has been associated with two clinically distinct human diseases: the recessive hyperphenylalaninemia (HPA) and the dominant dopa-responsive dystonia (DRD). We found a recessive GTPCH mutation (R249S, 747C-->G in a dystonia patient. Her PHA-stimulated mononuclear blood cells had a normal amount of GTPCH mRNA, but low GTPCH activity. Arginine 249 is located at the C-terminus of GTPCH, outside the catalytic site. E. coli expressed recombinant R249S mutant protein possessed normal enzyme activity and kinetics. However, in transfected eukaryotic cells, R249S mutant protein expression level was lower than the wild-type protein. Therefore, this is suspected to be a destabilizing mutation. Our data suggest that DRD could be either dominantly or recessively inherited, and the inheritance might be determined by the mechanism of mutation

N2 - Many parents in Japan today are very concerned and have daily problems with their children over the following kind of issues concerning video games, multimedia, and similar devices. 1) Is children's enthusiasm for video games actually harming their growth (physically or mentally)? 2) Is there any way that video games can help children in the future? For example, will playing these games help children learn to use computers or develop their power of thought? 3) Will excessive enthusiasm for TV games undermine our basic lifestyle? Is the time they spend studying at home or playing outside actually decreasing? 4) Will the methods of communication brought about by computers, pagers, and cellular phones weaken human relations among children? 5) Will being immersed in a virtual world created by computers result in a diminished sense of reality? The causes of this uneasiness may be traced to parents' own anxieties and concerns about the exceedingly rapid growth of the "information society" of today, together with the fact that their children are directly caught up in the deluge of this information and multimedia society. The development of media has coincided with the growth of today's adults, but children are immersed in a media-filled environment from the day they are born. In Japan, there are now children who can play video games before even learning to write. No one can predict what kind of adults these children will grow to be in the future, and it is fair to say that the most parents and children in Japan are being tossed about on the waves of this information explosion. At this international symposium, we hope to hear the many views that are held around the world concerning children and multimedia

N2 - Rectal diazepam is widely used in the treatment of acute seizures in children but has some disadvantages. Nasal/sublingual midazolam administration has been recently investigated for this purpose but never at home or in a general paediatric hospital. The aim of this open study was to determine the efficacy, the tolerance and the applicability of nasal midazolam during acute seizures in children both in hospital and at home. We included known epileptic children for treatment at home and all children with acute seizures in the hospital. In all, 26 children were enrolled, 11 at home and 17 in the hospital (including two treated in both locations); only one had simple febrile seizure. They had a total of 125 seizures; 122 seizures (98%) stopped within 10 minutes (average 3.6 minutes). Two patients in the hospital did not respond and in three, seizures recurred within 3 hours. None had serious adverse effects. Parents had no difficulties administering the drug at home. Most of those who were using rectal diazepam found that nasal midazolam was easier to use and that postictal recovery was faster. Among 15 children who received the drug under electroencephalogram monitoring (six without clinical seizures), the paroxysmal activity disappeared in ten and decreased in three. Nasal midazolam is efficient in the treatment of acute seizures. It appears to be safe and most useful outside the hospital in severe epilepsies, particularly in older children because it is easy for parents to use. These data should be confirmed in a larger sample of children. Its usefulness in febrile convulsions also remains to be evaluated. Copyright 1999 European Paediatric Neurology Society

N2 - For field studies of asthma, portable hand-held pulmonary function testing devices are required. Other than for peak flow measurements, little has been done to validate their use in children. Fifty children aged 5-15 years having asthma symptoms were examined using an exercise challenge (8 min free running outdoors) and a bronchodilation test (salbutamol inhalation at a dose of 0.15 mg/kg). Pulmonary function was measured with a turbine spirometer, with a Wright peak flow meter (WPEF) and with a flow-volume spirometer (FVS). A fall of 15% or more in peak expiratory flow associated with wheezing or cough was considered diagnostic for bronchial hyper-responsiveness to exercise (BHRE). A rise of 15% or more from baseline in peak expiratory flow after salbutamol inhalation was considered as a positive bronchodilator response (BDR). BHRE was present in 16 children (32%). Using the limit of a 15% or greater fall in FEV1, turbine spirometry identified 12 as BHRE-positive and no additional cases, giving a sensitivity of 75% and a specificity of 100%. The turbine spirometer showed lower FEV1 values than the FVS, the difference increasing with airway obstruction. BDR was positive in eight children (16%). Using the limit of a 10% or greater rise in FEV1, turbine spirometry was positive in six cases. FEV1 measured by turbine spirometry could not be used interchangeably with conventional FVS. However, the turbine spirometer offers the possibility to measure FEV1 repeatedly in field conditions, such as during exercise challenges outdoors

N2 - As the primary community institution in the lives of children, schools have much to contribute to plans for addressing the needs of today's youngsters during the time when classes are not being held. In recent years, demands have escalated for after-school child care, educational enrichment, and safe havens that also foster positive youth development. Many programs that respond to these needs are housed in school buildings. Some are operated by the schools, some by community-based organizations, and others by partnerships between schools and outside groups. New public funding for after-school programs often flows through the school system. This article reports the prevalence of school-based programs and discusses extracurricular activities, child care and extended-day programs, enrichment programs, and ambitious efforts to transform the schools into full-time community hubs offering something for residents of all ages. Implementation challenges accompany program expansion, and this article also examines major issues that arise in school-based programs: governance, space, program quality, funding, and accountability. If these programs fulfill their promise, the school of the future may, indeed, be open extended hours for the enrichment of the children and the sustenance of the family

N2 - OBJECTIVE: To determine the prevalence of alcohol and drug consumption and its relationship to sociodemographic variables, leisure activities, antisocial behavior, family norms and conflicts, among others. MATERIAL AND METHODS: Data derive from a representative survey of 1,929 students of junior high and high school, conducted in 1996 in the city of Pachuca, Hidalgo, Mexico. Of these, 44.9% were boys and 52.5% were girls; mean age was 14. A self-applied questionnaire, prepared by the WHO together with some countries, among them Mexico, was completed by the studied subjects, and included indicators of alcohol and drug consumption. RESULTS: Of the total sample, 47.9% had tried alcohol, and 12.6% had drunk large quantities--5 drinks or more per sitting--during the month previous to the survey. Preferred drinks are beer and "coolers", which they buy at shops where no identification is required and drink at home or at friend's homes. With respect to drugs, 5.1% had tried illegal or medical drugs without prescription, in particular inhalants, marihuana and tranquilizers. More boys consumed illegal drugs, and more girls medical drugs without prescription. Boys, who are also older, more frequently consumed alcohol and drugs and were more often employed during the previous year at part-time jobs. High alcohol level and drug consumers were characterized by their frequent report of being bored in their free time, drinking with friends and enrolling in antisocial behavior. With respect to family norms, they follow them less and show less interest in doing so. An elevated percentage informed that their parents fight frequently, that they have sought help for this reason and have intended separation. CONCLUSIONS: Groups who drink more alcohol and use other drugs, in contrast with nonusers, presented more behavioral problems, more outdoors activities that included drinking with friends, more antisocial behavior, had a distant relationship with their families sharing few activities with them, an showed little interest in following family rules and perceiving conflicts within their families

N2 - This study examined whether the relative reinforcing value of physical activity (RRVPA) measured in the laboratory predicted physical activity measured in the natural environment in 32 6-11-year-old children.

RRVPA correlated with physical activity level ($r = .42, p < .05$), and contributed to the prediction of physical activity level along with child obesity. RRVPA was related to the number of moderate to vigorous physical activity exercise bouts ($r = .35, p < .05$), not to the duration of those bouts. These results suggest that RRVPA is a determinant of child physical activity level, and that it may be naturally more reinforcing for children to engage in multiple, short exercise bouts than fewer, more extended bouts

N2 - OBJECTIVE: To carry out a door-to-door survey in rural areas of the Cordillera Province, Santa Cruz Department, Bolivia, to determine the prevalence of neurologic diseases (epilepsy, stroke, parkinsonism, and peripheral neuropathy) in a sample of approximately 10,000 inhabitants. **METHODS:** A team of nondoctor health workers administered a standard screening instrument for neurologic diseases—a slightly modified version of the World Health Organization protocol. All subjects found positive during the screening underwent a neurologic examination. **RESULTS:** On screening, the authors found 1,130 positive subjects, of whom 1,027 were then investigated by neurologists. On the basis of the definition proposed by the International League Against Epilepsy, we detected 124 epileptic patients (prevalence, 12.3/1,000), 112 of whom had active epilepsy (prevalence, 11.1/1,000) on the prevalence day (November 1, 1994). Peak age-specific prevalence occurred in the 15 to 24-year age group (20.4/1,000). Sex-specific prevalence was higher in women (13.1/1,000) than men (11.4/1,000). Eighty-nine patients (71.8%) underwent a standard EEG recording. Considering both EEG and clinical data, partial seizures were the most common type (53.2%) based on the classification of the International League Against Epilepsy. The mean age at onset was 20.7 years for partial seizures and 13.6 years for generalized seizures. Only 10.5% of patients had received specific treatment for more than 2 months of their life. **CONCLUSION:** This report on epilepsy prevalence in Bolivia confirms that epilepsy is a major health problem in rural areas of developing countries

N2 - To assess body proportions in girls with Turner syndrome (TS) during long term GH treatment, height, sitting height (SH), hand (Hand) and foot (Foot) lengths, and biacromial (Biac) and biiliacal (Biil) diameters were measured in 68 girls with TS participating in a GH dose-response trial. These previously untreated girls with TS, aged 2-11 yr, were randomly assigned to 1 of 3 GH dosage groups: group A, 4 IU/m² x day; group B, first year 4 and thereafter 6 IU/m² x day; group C, first year 4, second year 6, and thereafter 8 IU/m² x day. Seven-year data were evaluated to assess the effect of GH treatment on body proportions during childhood. In addition, data from all girls who had reached adult height were evaluated to determine the effect on the adult body proportions. All results were adjusted for age and sex and expressed as SD scores using reference values of healthy Dutch girls. To describe the proportions of SH, Hand, Foot, Biac, and Biil to height, these values were adjusted for the SD score of height and were expressed as shape values, using the formula, e.g. for SH: shape SH = (SH SD score - height SD score)/square root(2 - 2 x correlation coefficient between SH and height in the reference population). Furthermore, SD scores using references of untreated girls with TS were calculated for height and SH. Values less than -2 or more than +2 were considered outside the normal range. At baseline, the shape values of all measurements were significantly higher than zero, but most mean shape values were still within the normal range. Seven-year data of 64 girls and adult height data of 32 girls showed that an increase in height was accompanied by an even higher increase in Foot, resulting in mean SD scores above zero and shape values of +2 and higher. The increase in the shape value of Foot was significantly higher in groups B and C compared to that in group A after 7 yr of GH treatment, but there were no significant differences between the GH dosage groups in the girls who had reached adult height. The shape values of SH had decreased to values closer to zero after reaching adult height, especially in group A. A similar pattern in the relationship of SH to height was seen using references of girls with TS. No significant changes in the other proportions were found after reaching adult height. In conclusion, on the average, untreated girls with TS have relatively large trunk, hands, and feet, and broad shoulders and pelvis compared to height. The increase in height after long term GH

treatment is accompanied by an even higher increase in Foot and a moderate improvement of the disproportion between height and SH. Recently published reference data from untreated adults with TS and the results of a different patient group receiving a comparable GH dosage suggest that the disproportionate growth of feet has to be considered a part of the natural development in TS, but might be influenced by higher GH dosages. The development of large feet can play a role in the decision of the girl to discontinue GH treatment in the last phase of growth

N2 - Autosomal dominant holoprosencephaly is a rare but well documented entity and it can be the result of mutations in the Sonic Hedgehog gene (SHH). The transmitting parent may be normal or have a single maxillary central incisor. We describe a skewed sex ratio among the transmitting parents with SHH mutations, with more mothers than fathers having the mutation ($p=0.002$). The mechanism underlying this skewed sex ratio is not clear; the SHH mutations do not involve triplet repeats, imprinting is plausible but untested, and there is no evidence that the risk of holoprosencephaly is greater among males carrying such a mutation ($p=0.15$). We considered the possibility that males with such a mutation are at greater risk of other malformations outside the

central nervous system, which could reduce their reproductive fitness. To avoid ascertainment bias in identifying children with various malformations in kindreds with familial holoprosencephaly, we reviewed the reports of people with single maxillary central incisor and no other congenital malformations. Of the 16 cases identified, 13 were female ($p=0.0085$). We suggest that boys with mutations associated with autosomal dominant holoprosencephaly may be at greater risk of major malformations outside the central nervous system than girls

CY - UNITED STATES

N2 - PURPOSE: The purpose was to describe current levels of physical activity and inactivity among adults and young people in the United States. METHODS: Estimates of participation in regular physical activity were derived from three national surveys for adults (National Health Interview Survey, National Health and Nutrition Examination Survey, and the Behavioral Risk Factor Surveillance System) and from the Youth Risk Behavior Survey for high school students. RESULTS: Overall, 63.8% of high school students surveyed on the 1997 YRBS reported participating in vigorous physical activity for at least 20 min on 3 or more days per week. Participation in vigorous activity was higher for boys (72.3%) than girls (53.5%), whites (66.8%) compared with blacks (53.9%) and Hispanics (60.4%), and decreased with advancing grade. Among adults, 27.7% meet recommended levels of either moderate or vigorous physical activity, whereas 29.2% report no regular physical activity outside of their work. Gender differences in participation in physical activity are less pronounced than

in youth, and age-related patterns were complex. Whites are more active than blacks and Hispanics, and persons with higher family incomes and more education report being more physically active. There have been only minor changes in reported participation in leisure time physical activity over the past 15 yr. CONCLUSION: National estimates of physical activity appear to be reliable and valid for adults but may be less so for adolescents and are poor measures for children. Research is needed to determine the role that objective monitoring with accelerometers may play in surveillance. Reliable and valid measures of occupational, household, and transportation-related physical activity and sedentary behaviors are needed to better characterize the range of activity that is associated with health. N2 - OBJECTIVES: (1) To describe the pattern of injury in preschool-aged children in 4 child care centers as compared with the results of other studies; (2) to compare injury rates by sex, age, and child care center; and (3)

to examine environmental and child factors contributing to injury severity. DESIGN: A 2-year cohort study of 362 preschool-aged children attending 4 urban child care centers. Teachers completed standardized injury forms on the type of injury, body location, site of injury, and contributing factors. RESULTS: During the 2 years of the study, 1886 injuries were reported. The mean and median child injury rate was 6 and 4 injuries per 2000 exposure hours (equivalent to 1 full-time child care year), respectively. The majority of injuries (87%) were minor, occurred during free play (81%) and on the playground (74%), and were precipitated by child-related factors (59%), such as being pushed. Boys had significantly higher median injury rates than girls. Age-adjusted injury rates for each child care center were significantly different by center ($F_3 = 61$, $P < .001$). While moderate to severe injuries were more often precipitated by combinations of child and environmental factors ($\chi^2(4) = 20$, $P < .001$), minor injuries were usually precipitated by child-related factors. CONCLUSIONS: Injury data from child care centers are important for identifying common risk factors for frequent or severe injury events and for designing injury prevention programs. More research is needed to identify factors contributing to injuries, such as children's behavior and the child care centers' physical and socioemotional environments

N2 - Holocarboxylase synthetase (HCS) deficiency is a metabolic disorder that causes a biotin-responsive multiple carboxylase deficiency. We analyzed the kinetic properties of seven mutant HCS proteins. Two of these enzymes harbored mutations within the putative biotin-binding region of HCS and showed elevated Km values for biotin compared with that of the wild-type form (Km mutant; Gly581Ser: 45 times, delThr610: 3 times). The remaining five mutations (Arg183Pro, Leu216Arg, Leu237Pro, Val333Glu, and Val363Asp) were located outside the biotin-binding region. The enzymes containing these mutations showed normal or low Km values for biotin (non-Km mutant). Symptoms of patients who have the non-Km, mutants, as well as those of patients who have the Km, mutants, responded to biotin therapy. This is probably because the Km value for biotin of normal HCS is higher than the physiologic concentration of biotin in human cells. The Vmax values of all mutant HCS proteins were considerably decreased, but to a variable degree. The responsiveness to biotin supplementation of propionyl-CoA carboxylase activity in cultured cells bearing the mutations correlated well with the degree of reduction in the Vmax of HCS. Patients who have mutant HCS proteins with lower Vmax showed poorer clinical and biochemical responses to biotin therapy. These observations suggest that the reduction of Vmax is an essential factor for pathophysiology and prognosis of HCS deficiency under treatment with large amounts of biotin. The determination of HCS genotype can be valuable for characterizing the clinical phenotype in HCS deficient patients

N2 - We measured personal exposure to nitrogen dioxide (NO₂), nitrogen monoxide (NO), and ozone (O₃), using personal passive samplers during three 4-day periods, in a panel study of asthmatics continuing the normal activities of everyday life. Fifty-five adults, mean age 42 years, 53% men, and 39 children, mean age 11 years, 67% boys, wore two Ogawa passive samplers simultaneously: one for O₃, the other for NO₂ and NO. Mean outdoor pollution was measured at a regional monitoring network. Personal exposure levels were scattered; they were (on average) higher than stationary-site levels for NO and lower for NO₂ and O₃. In adults, 41% of the variance of personal exposure to NO₂ was explained by mean stationary-site measurement levels (P<0.0001). Twenty-one percent additional variance was explained by living near a main road, not having an extractor fan over the cooker, older age, and male sex. NO and O₃ personal exposures correlated poorly with stationary-site measurements. In panel studies of the health effects of air pollution, personal exposure to NO₂ and NO can be measured satisfactorily by passive samplers: such measurements are necessary for NO but not for NO₂. For O₃, accurate personal exposure measurement remains a challenge and further technical development is required. Copyright 1999 Academic Press

N2 - This report describes program effects of the Tri-Ministry Study a school-based, longitudinal trial carried out over a 5-year period to assess the effectiveness of classwide social skills training (SS), partner reading (RE), and a combination of both (SS & RE) to reduce maladjustment among children in the primary division (up to grade 3) of Ontario schools. It also places these effects in the context of other school-based prevention studies and discusses them in view of important methodological and programmatic issues. The incremental effects attributable to the intervention programs were small and sporadic. There were statistically significant increases in prosocial behaviour observed in the playgrounds of intervention schools with no differentiation by program type. Furthermore, there was some evidence--a reduction in teacher and parent-rated externalising problems--that the combination of SS & RE and SS alone may have had modest beneficial effects. A review of nine other school-based studies, which evaluated universally delivered mental health prevention programs in general populations of students, revealed similar mixed results. There are both methodologic and programmatic issues implicated in the weak findings that have been reported to date. These issues need to be addressed to advance knowledge about the potential impact of mental-health prevention initiatives delivered universally through school-based programs. A companion paper gives the specific details on the programs, randomisation of schools, selection of subjects, measurements, and analysis

N2 - A population-based randomized intervention trial for the prevention of conduct problems (i.e., oppositional defiant disorder and conduct disorder) is described. The LIFT (Linking the Interests of Families and Teachers) intervention was designed for all first- and fifth-grade elementary school boys and girls and their families living in at-risk neighborhoods characterized by high rates of juvenile delinquency. The 10-week intervention strategy was carefully targeted at proximal and malleable antecedents in three social domains that were identified by a developmental model of conduct problems. From 12 elementary schools, 671 first and fifth graders and their families participated either in the theory-based universal preventive intervention or in a control condition. The intervention consisted of parent training, a classroom-based social skills program, a playground behavioral program, and systematic communication between teachers and parents. A multiple measure assessment strategy was used to evaluate participant satisfaction and participation, fidelity of implementation, and the immediate impacts of the program on targeted antecedents

N2 - Information on human time-activity patterns is often required to interpret environmental exposure data fully and to implement exposure assessment models. Data on short-term time-activity patterns for individuals, such as 1-day measurements, are relatively abundant. The reliability of such data for use in chronic exposure (e.g., 1 or more years) assessments performed for evaluation of health risks is not well understood. As part of the NHEXAS-Maryland investigation, daily time budget data for seven microenvironments were collected from 80 people during as many as six 1-week Cycles over a 12-month period. The data were summarized and analyzed statistically by sampling Cycle, day of week, and individual to characterize long-term average microenvironmental time budgets and to identify their determinants. Median times spent in transit, indoors at home, outside at home, indoors at work or school, outdoors at work or school, indoors at other locations, and outdoors at other locations were found to vary significantly, although not substantively in many cases, by time of year (i.e., Cycle), by day of week, and by individuals. Time budgets for most of the microenvironments also exhibited significant variability by gender, age group, education level, annual household income, and work status. The results indicate that short-term (e.g., 1-day) measures of microenvironmental time budgets for individuals are unlikely to be representative of their long-term patterns. Thus, health risk or epidemiological assessments performed for a population mean or specific quantile may be relatively insensitive to when time budget data were collected. However, the accuracy of such assessments performed for individuals is likely to be greatly improved by collection of time budget data from numerous points in time

N2 - Within the context of the National Human Exposure Assessment Survey (NHEXAS), metals were evaluated in the air, soil, dust, water, food, beverages, and urine of a single respondent. Potential doses were calculated for five metals including arsenic. In this paper, we seek to validate the potential dose calculations through spatial analysis of the data. Others report elevated arsenic concentrations in biological and environmental samples from residents of mining towns, particularly Ajo, Arizona. These reports led us to expect potential arsenic doses above the 90th percentile of the NHEXAS exposure distribution to be from residents of mining communities. Arsenic dose was calculated using media concentrations, time activity patterns, and published exposure factors. Of the 179 homes evaluated, 54 were in mining communities; 11 of these were considered separately for reasons of population bias. Of the 17 homes with the greatest potential arsenic doses, almost half (47%) were in mining communities. We evaluated the potential doses by media from nonmining and mining areas using the nonparametric Mann-Whitney U test. Statistically significant ($p = 0.05$) differences were found between mining ($n = 43$) and nonmining sites ($n = 122$) for total exposure and for each of the following media: house dust, yard soil, outdoor air, beverage consumed, and water consumed. No differences were found in either food or indoor air of mining and nonmining areas. We eliminated outliers and repeated the test for all media; significance increased. Dietary, organic arsenic from fish consumption contributed to elevated arsenic exposure among people from nonmining communities and acted as an initial confounder. When controlling for fish consumption, we were able to validate our potential dose model using arsenic, particularly in Ajo. Further, we identified three mining communities lacking elevated arsenic exposure. Additional work is needed speciating the arsenic and evaluating health risks. The utilization of Geographic Information System facilitated spatial this project and paves the way for more sophisticated future spatial analyses

N2 - The appropriateness of recess in the elementary program continues to be questioned although generally it is believed to be useful by elementary principals despite a dearth of supportive data. This study was a developmental study of the effects of physical activity on concentration. Comparison of passive and directed physical education activities on the concentration of second-, third-, and fourth-grade children was made. The Woodcock-Johnson Test of Concentration showed better performance by the fourth grades and within Grade 4 in favor of the physical activity group. A structured physical activity or a classroom activity immediately prior to a concentration task was not detrimental to children in Grades 2 and 3. Fourth-grade children performed significantly better on a test of concentration after engaging in a physical activity

N2 - A Computerised Mapping Programme (CMP) was created step by step to cover all the needs of a cross sectional population survey conducted in eight villages of Fokida, a rural area of central Greece. The maps of Greece (boundary) and the topographical maps of the eight villages were created using the CMP. A volunteer sample of 1121 out of 2607 inhabitants of the study area participated in the population survey. The participants were tested for brucellosis using serological tests (ELISA and Rose Bengal) and the intradermal reaction test. A questionnaire was used to obtain information concerning the risk factors for brucellosis. The risk factors found through statistical analysis were occupation (RR: 5.81, $p < 0.00001$), consumption of raw milk (RR: 1.98, $p < 0.001$) and unpasteurised fresh cheese (RR: 2.13, $p < 0.01$). The same factors were indicated by the CMP. The CMP also indicated manure-contaminated playgrounds in residential yards as a potential risk factor for children. The origin and dissemination were delineated using time space association display. The CMP proved to be a useful tool in this epidemiological study

CY - CROATIA

N2 - Starting from the beginning of January 1998, school health service in Croatia became exclusively a preventive activity. This change provoked a lot of controversial discussions among general public and medical profession. This paper gives an outline of the historic course, the aims and content of school health in different countries. From its very beginning in the middle of the 19th century, school health started to develop as a preventive activity directed primarily towards organic etiology dominant in the morbidity of school children at that time (infectious diseases, tuberculosis, malnutrition). The morbidity has changed over time. Nowadays, the problems of psychosocial etiology have emerged into the first plane. Moreover, schooling has been prolonged. It covers a great part of childhood and almost the entire adolescence. The problems of adolescents are different and complex. Health care of school children and adolescents is functionally bound to the school as their natural environment. The most efficient health care is provided in close cooperation between medical personnel and teachers. Besides, the classical model of school health offers, particularly with respect to current problems, large possibilities for health promotion of children and adolescents, and in the long run, of the whole population. Health care of school children is not equally organized in different countries. The main difference depends on whether the school health team is directed only towards preventive and specific activities or towards comprehensive primary health care. In Croatia, traditionally, the integrated health care has developed. Beside preventive health care, the school doctors provided curative care for students in their schools. Within the reorganization of health care a new situation has arisen. Compulsory integration of preventive and curative activities at the school level is completely incompatible with the right to a free choice of primary care physician. However, by the strict interpretation of the principle of indivisibility of preventive and curative care, one school should cooperate with numerous personal doctors for its students. The essential principle of school health would be lost. The school represents a community which is exposed to the same health risks but keeps a great potential for health promotion. So, if this advantage is to be utilized, preventive care must be organized at the school level. This is the very nature of the reorganization in school health service which is performed in Croatia under the auspices of the Ministry of Health. Providing the preventive and specific health care for all school children and adolescents is the responsibility of school doctors who have become the employees of the Institutes of Public Health, while the curative care is provided by the personal physician of a student's or his parents' choice

N2 - We studied 10 patients who had neurological disorders with a MRI-based diagnosis of perisylvian dysgenesis based on the fact that the parasagittal and centrifugal extremity of the sylvian fissure was abnormally mesial. This abnormality was bilateral in seven cases; in the other three patients, the contralateral sylvian fissure appeared either normal (two cases) or enlarged (open operculum). The perisylvian cortex had a polymicrogyric appearance in most patients. Potential aetiopathogenic factors were determined in four patients. In two of them, ischaemia at mid-gestation was ascribed to death of a co-twin in a context of monozygotic twinning. In the other two patients, who were siblings, genetic factors were suspected. Pseudobulbar palsy was found in eight patients

and epilepsy in five patients. We used PET with [18F]fluorodeoxyglucose to test the hypothesis that, despite this clinical and MRI heterogeneity, regional cerebral glucose distribution could have common features in these patients. The analysis of PET data was performed by visual inspection in two cases and by using statistical parametric mapping (SPM) in eight patients compared with a control group. Segmented grey matter MRIs of seven out these patients were also analysed using SPM. We found that the abnormal perisylvian cortex had normal grey matter activity in eight patients and in the other two there was a heterogeneous pattern with areas of preserved metabolism and of decreased metabolism. Metabolic changes were also detected outside the polymicrogyric-like cortex; three patients had hypometabolic areas in cortical regions where the MRI appeared normal and had a normal intensity. When polymicrogyria extended into the white matter, this ectopic dysgenetic cortex was associated with a grey matter pattern within the white matter territory, and was detected by SPM as areas of PET hypermetabolism and MRI hyperintensity. In order to detect possible metabolic changes undetected by the individual analyses, the group of patients was compared with the control group. This comparison revealed bilateral hypometabolism in the frontal opercular cortex. We propose that these PET data be considered in light of the presumed cyto-architectonic pattern of perisylvian dysgenesis, i.e. polymicrogyria. In this malformation, two dense cell layers are separated by a necrotic sparse cell layer. We speculate that the amount of synaptic activity preserved in these dense cell layers depends on the importance and timing of the necrotic process; this hypothesis accounts for the large range of metabolic patterns found, from profoundly decreased glucose metabolism to nearly normal activity

 N2 - Four-hundred seventy-five permanent residents of Wisconsin were tested for antibodies to the agent of human granulocytic ehrlichiosis (HGE) by indirect immunofluorescent antibody (IFA) testing with Ehrlichia equi as antigen marker. Each resident completed a standard survey questionnaire about outdoor activities, animal and tick exposure, and any febrile illness during the preceding 12 months. Seventy-one serum samples (14.9%) contained E. equi antibodies. The mean IFA titer for seropositive residents was 250 (range, 80-10,240). Seropositive residents were older than seronegative ones (62 vs. 56 years; P = .019). None of the seropositive residents had a history suggestive of ehrlichiosis. There was no association between the IFA test outcome and specific demographic variables or history of tick bites. HGE appears to be a common subclinical or mild infection among residents in northwestern Wisconsin

N2 - Tobogganing is a very popular outdoor winter recreational activity. In order to elucidate the patterns of injuries associated with tobogganing all patients with an injury caused by falls from or collisions while on or being hit by a sled were sampled prospectively between the period of November 1996 and March 1997. 50 patients were included in this study, aged from 7 to 69 years (mean 25.5 years). Of these, 14 (= 28%) patients required admission to hospital lasting from 1 to 31 days (mean 13.5 days), 11 (22%) needed an operation. Over all we could register 55 injuries; the lower extremity was the region most commonly injured (63.6%), followed by upper extremity with 21.8%. The most common injury was the sprain of the knee. The most severe injuries could be found at the lower limb and at the vertebral column, including four fractures of the lower leg and 8 ankle-joint fractures as well as two fractures of the lumbar spine. The most common single procedure was the open reduction and internal fixation of a fibular fracture. In 48.6% of the cases the riders struck an object (tree, wall, post), while 32.4% fell from the toboggan caused by environmental conditions such as a bump or a ditch. The most important risk factor was an unadjusted speed referred to the environmental circumstances. Preventive strategies include tobogganing in adequate environmental conditions with no trees, no post or other stationary objects that could result in a collision. Speed should be adapted to the slope conditions

N2 - INTRODUCTION: Physical inactivity has been identified as an important public health concern for youth. School and community settings can be important infrastructures for promoting physical activity (PA). This paper reviews studies of physical activity in school and community settings among preschool through college-aged persons to determine characteristics and effects of interventions. Studies in progress are included.

METHODS: Studies from 1980 to 1997 testing physical activity interventions in schools and community settings were identified by computerized search methods and reference lists of published reviews. Studies needed to have used a quantitative assessment of PA, used a comparison or control group, included participants who were preschool through college age, and be conducted in the United States or foreign school or community settings. Significance of effects was examined overall and for various types of interventions. RESULTS: Twenty-two school-based studies were reviewed, 14 completed and 8 in progress. Three studies were in countries other than the United States. The 8 studies in progress were all in the United States. Only 7 community studies were reviewed, all in the United States. Four studies were in progress. Several community studies involved a high percentage of African-American or Hispanic youth and their families. Studies showing the best results used randomized designs, valid and reliable measurements, and more extensive interventions. Some follow-up results showed PA was sustained after interventions ended. CONCLUSIONS: The collection of school and community studies is limited for several age groups with none below third grade and only three at college age. There are few community studies. The most is known about upper-elementary-age-students, including the first multicenter randomized trial to report significant results for increasing moderate to vigorous physical activity (MVPA) in physical education (PE) and increase vigorous PA outside of school. A number of older study designs were weak and assessments less than optimal, but studies in progress are stronger. Special attention is needed for girls, middle schools, and community settings for all youth. More objective assessments are needed for measuring PA outside of school and in younger children, since they cannot provide reliable self-report. [References: 108]

N2 - BACKGROUND: Giardia infection is an ongoing problem in Tasmania and occurs throughout the state. It has been postulated that part of the problem is the reservoir of infection in native animals which is suggested to contribute to infections in humans. To date, however, no detailed study on the epidemiology of giardiasis in Tasmania has been carried out. METHODS: Information regarding the prevalence of Giardia infection in humans and the risk of intrafamilial transmission was obtained from the Department of Community and Health Services and from the direct examination of human or animal fecal samples. RESULTS: Giardia has been found to be present in a wide range of native and domestic animals and in humans of all ages from all over the state. CONCLUSIONS: Giardiasis is endemic in Tasmania and poses a risk to locals as well as to visitors to the state, especially those who participate in wilderness activities such as bushwalking. These people must be aware of the possible risk of Giardia infection and should take precautionary measures to avoid infection

N2 - In order to evaluate the load on the low back of teachers in kindergartens, basic activity and working posture were analyzed for four teachers by means of video recording. The trunk inclination angle (TIA) was also measured continuously during full workshifts for 12 kindergarten teachers by means of an inclination monitor. The kindergarten teachers spent 67% of the workshift on activities in contact with children, "indoor group childcare", "indoor free playing", "outdoor childcare", "preparation and clearing away" and "help and care", and did not take a recess during the workshift. They spent 36% of the workshift in three working postures with the load on the low back, "standing bent forward", "squatting" and "kneeling". Cumulative time at a TIA of 20 degrees or more represented 43% of the workshift. The frequency of trunk-lifting from severe bending forward (TIA > 45 degrees) was 95 times/hr on average. A comparison of the kindergarten teachers and nursery teachers in 4-5 year age classes showed that the time distributions of basic activities were generally similar to each other. Although the time distributions of working postures were also similar, time spent "standing bent forward", "squatting" and "kneeling" was longer in the kindergarten teachers than in the nursery teachers. Cumulative time at a TIA of 45 degrees or more was significantly longer in the kindergarten teachers. Although the frequency of trunklifting was not significantly different, the kindergarten teachers tended to lift their trunk more frequently. The present study found that the load on the low back was considerably great in the kindergarten teachers

N2 - It is clear from experimental studies in mice that T cell maturation can occur outside the thymus, especially in the intestine. There is little sound evidence so far that extrathymic T cell maturation occurs to any significant extent in human gut, and, postnatally, there is abundant evidence that the gut mucosa is an immune effector organ. Here, we describe a large population of T lymphocytes in human fetal intestinal mucosa that are proliferating (Ki67+) in the absence of foreign Ag (CD3+, Ki67+ lamina propria lymphocytes (LPL) 22 +/- 1.8% and CD3+, Ki67+ intraepithelial lymphocytes (IEL) 9.1 +/- 1.4%), that express the T cell activation markers CD103, HLA-DR, and L-selectin(low), and that express mRNA transcripts for pre-TCR-alpha. There is also a substantial proportion of CD7+ LPLs that do not express CD3 (CD3-7+, 14 +/- 7% of all LPLs) in the fetal gut that may be differentiating into CD3+ cells. Rearranged TCR-beta transcripts of fetal LPLs, IELs, and paired blood lymphocytes were cloned and sequenced, and virtually no overlap of clonality was observed between blood and intestine, suggesting that gut T cells may not be derived from the blood. In addition, 30 days after engraftment of SCID mice with fetal intestine, CD3-7+ cells, proliferating T cells, and pre-TCR-alpha transcripts were abundant, and there is a threefold increase in CD3+ IELs. These data show that in the human intestine before birth a population of precursor T cells exists that may be differentiating into mature T cells in situ

N2 - We evaluated the GH-releasing effect of hexarelin (Hex; 2 microg/kg, i.v.) and GHRH (1 microg/kg, i.v.) in 18 patients (11 males and 7 females, aged 2.5-20.4 yr) with GH deficiency (GHD) whose hypothalamic pituitary abnormalities had been previously characterized by dynamic magnetic resonance imaging (MRI). Ten patients had isolated GHD, and 8 had multiple pituitary hormone deficiency. All patients were receiving appropriate hormone replacement therapy. Twenty-four prepubertal short normal children (11 boys and 13 girls, aged 5.9-13 yr, body weight within +/-10% of ideal weight) served as controls. MRI studies revealed an ectopic posterior pituitary at the infundibular recess in all patients. A residual vascular component of the pituitary stalk was visualized in 8 patients with isolated GHD (group 1), whereas MRI showed the absence of the pituitary stalk (vascular and neural components) in the remaining 10 patients (group 2), of whom 8 had multiple pituitary hormone deficiency and 2 had isolated GHD. In the short normal children, the mean peak GH response to GHRH (24.8 +/- 4.4 microg/L) was significantly lower than that observed after Hex treatment (48.1 +/- 4.9 microg/L; $P < 0.0001$). In the GHD patients of group 2, the mean peak GH responses to GHRH (1.4 +/- 0.3 microg/L) and Hex (0.9 +/- 0.3 microg/L) were similar and markedly low. In the patients of group 1, the GH responses to GHRH (8.7 +/- 1.3 microg/L) and Hex (7.0 +/- 1.3 microg/L) were also similar, but were significantly higher than those observed in group 2 ($P < 0.0001$). In the whole group of patients, a significant correlation was found between the GH peaks after Hex and those after GHRH ($r = 0.746$; $P < 0.0001$). In this study we have confirmed that the integrity of the hypothalamic pituitary connections is essential for Hex to express its full GH-releasing activity and that Hex is able to stimulate GH secretion in patients with GHD but with a residual vascular component of the pituitary stalk

N2 - Experimental research in humans and animals points to the importance of adverse respiratory effects from short-term particle exposures and to the importance of proinflammatory effects of air pollutants, particularly O(subscript)3. However, particle averaging time has not been subjected to direct scientific evaluation, and there is a lack of epidemiological research examining both this issue and whether modification of air pollutant effects occurs with differences in asthma severity and anti-inflammatory medication use. The present study examined the relationship of adverse asthma symptoms (bothersome or interfered with daily activities or sleep) to O(3) and particles (less than or equal to)10 micrometer (PM10) in a Southern California community in the air inversion zone (1200-2100 ft) with high O(3) and low PM (R = 0.3). A panel of 25 asthmatics 9-17 years of age were followed daily, August through October 1995 (n = 1,759 person-days excluding one subject without symptoms). Exposures included stationary outdoor hourly PM10 (highest 24-hr mean, 54 microgram/m(3), versus median of 1-hr maximums, 56 microgram/m(3) and O(3) (mean of 1-hr maximums, 90 ppb, 5 days (greater than or equal to)120 ppb). Longitudinal regression analyses utilized the generalized estimating equations (GEE) model controlling for autocorrelation, day of week, outdoor fungi, and weather. Asthma symptoms were significantly associated with both outdoor O(3) and PM(10) in single pollutant- and co-regressions, with 1-hr and 8-hr maximum PM(10) having larger effects than the 24-hr mean. Subgroup analyses showed effects of current day PM(10) maximums were strongest in 10 more frequently symptomatic (MS) children: the odds ratios (ORs) for adverse symptoms from 90th percentile increases were 2.24 [95% confidence interval (CI), 1.46-3.46] for 1-hr PM10 (47 microgram/m(3)); 1.82 (CI, 1.18-2.81) for 8-hr PM10 (36 microgram/m(3)); and 1.50 (CI, 0.80-2.80) for 24-hr PM10 (25 microgram/m(3)). Subgroup analyses also showed the effect of current day O(subscript)3 was strongest in 14 less frequently symptomatic (LS) children: the ORs were 2.15 (CI, 1.04-4.44) for 1-hr O(3) (58 ppb) and 1.92 (CI, 0.97-3.80) for 8-hr O(3) (46 ppb). Effects of 24-hr PM10 were seen in both groups, particularly with 5-day moving averages (ORs were 1.95 for MS and 4.03 for LS; p(less than or equal to)0.05). The largest effects were in 7 LS children not on anti-inflammatory medications [5-day, 8-hr PM10, 9.66 (CI, 2.80-33.21); current day, 1-hr O(3), 4.14 (CI, 1.71-11.85)]. Results suggest that examination of short-term particle excursions, medication use, and symptom severity in longitudinal studies of asthma yields sensitive measures of adverse respiratory effects of air pollution

N2 - Total exposure assessment identifies the various sources of exposure to air pollution which affect each individual, thus functioning as a useful tool in clinical and environmental exposure management. A cross sectional survey was performed in order to create a total exposure model of inhaled particulates. This survey involved 544 subjects located within the Mexico City Merced monitoring station, an area covering three kilometers in diameter. Two questionnaires were developed one on housing and the other on respiratory symptoms. A diary on daily activity was kept, and an outdoor monitoring station was also installed. A new technology was adapted and incorporated for personal and indoor monitoring. A correlation of up to 0.38 was identified between the environmental concentrations. Exposures at home and at other extramural activities are most predictive of personal exposure. It was determined that 8.8% of the subjects studied had chronic bronchitis, and that this percentage increases with greater levels of exposure and outdoor sports. These findings conclude that the models are useful for risk assessment and management in Mexico

N2 - Outbreaks of yellow fever (YF) have never been recorded in Kenya. However, in September 1992, cases of hemorrhagic fever (HF) were reported in the Kerio Valley to the Kenya Ministry of Health. Early in 1993, the disease was confirmed as YF and a mass vaccination campaign was initiated. Cases of suspected YF were identified through medical record review and hospital-based disease surveillance by using a clinical case definition. Case-patients were confirmed serologically and virologically. We documented 55 persons with HF from three districts of the Rift Valley Province in the period of September 10, 1992 through March 11, 1993 (attack rate = 27.4/100,000 population). Twenty-six (47%) of the 55 persons had serologic evidence of recent YF infection, and three of these persons were also confirmed by YF virus isolation. No serum was available from the other 29 HF cases. In addition, YF virus was isolated from a person from the epidemic area who had a nonspecific febrile illness but did not meet the case definition. Five patients with confirmed cases of YF died, a case-fatality rate of 19%. Women with confirmed cases of YF were 10.9 times more likely to die than men ($P =$

0.010, by Fisher's exact test). Of the 26 patients with serologic or virologic evidence of YF, and for whom definite age was known, 21 (81%) were between 10 and 39 years of age, and 19 (73%) were males. All patients with confirmed YF infection lived in rural areas. There was only one instance of multiple cases within a single family, and this was associated with bush-clearing activity. This was the first documented outbreak of YF in Kenya, a classic example of a sylvatic transmission cycle. Surveillance in rural and urban areas outside the vaccination area should be intensified

N2 - We designed a semiautomated method for the objective detection of abnormal regions of tracer accumulation in the brain. The purpose of the present study was to examine the diagnostic performance of this method by applying it to patients with clinically intractable epilepsy of unilateral origin; they underwent [F-18] deoxyglucose positron emission tomography (PET) prior to surgical resection of epileptic foci. A semiautomated method for assessment of asymmetries in the brain cortex was developed that compares activity concentrations in homotopic cortical areas. When these differences exceeded a predefined threshold, the areas with lower activity were marked and 3-dimensional surface rendered images were created to guide placement of intracranial electrodes (ECoG) followed by surgical resection. The normal amount of asymmetry between small (0.5-0.7 cm²) homotopic cortical regions was determined as 5.9 +/- 4.0% (mean +/- SD). The false-positive fraction was determined for cutoff thresholds of 1 SD (10%), 1.5 SD (12%), and 2 SD (15%) outside the mean and was found to be 89, 44, and 0%, respectively. The obtained sensitivity-specificity pairs for correct localization of epileptogenic lobes based on the ECoG results were best for the 15% threshold (80/94%, accuracy 0.90). This objective PET method allows the accurate determination of cortical asymmetries, and it proved to be highly efficient in guiding epilepsy surgery

N2 - INTRODUCTION: Campfires, bonfires and barbecues play a prominent role in outdoor activities and serve a variety of decorative and functional purposes. Given all of it's various forms, uses and benefits, the outdoor fire can turn dangerous in a matter of seconds: a stumble or fall (the child running that trips) leads to direct contact with the flames and subsequent burn injury. With it's everyday occurrence, we were surprised to find a paucity of information regarding this type of burn in the literature, including the NBIE analysis.

METHODS: A retrospective review of 107 patients admitted to the Maricopa Medical Bum Center, from 1987 to 1996, was conducted. Each chart was analyzed for the patient demographics, mechanism of injury, percent total body surface area burned, operative versus non-operative treatment and overall outcome. RESULTS: An average burn injury involved 5.7% TBSA, with a wide range from 1 to 47%. The majority of our population involved either small children or intoxicated adults and a total of 50 patients required 92 operations. Severe morbidity, including 4 amputations and 2 mortalities, were seen. The average hospital stay was 14.3 days, ranging from 1 to 52 days. CONCLUSIONS: Recreational outdoor burns were extremely common injuries leading to loss of functional employment and prolonged physical therapy requirements. Small children and intoxicated adults comprised the majority of our study population. The impact and severity of such outdoor fires could be greatly affected by appropriate attention to prevention

N2 - UNLABELLED: Due to the large number of differential diagnostic possibilities, the etiology of endogenous uveitis is still hard to determine. One reason for uveitis may be the occurrence of parasites. However, too little attention is paid to this underlying disease. **METHODS:** To identify certain sources of infection, oviscopic probes of 98 dog feces from the urban area of Halle were taken. The material was collected from children's playgrounds, parks and swimming pools. A retrospective analysis of patient case data from the records of the University Eye Hospital for the years 1986-1995 complemented the environmental and parasitological examination of patients with *Toxocara canis* and *T. cati* infections. **RESULTS:** From the oviscopic examinations, 16% of the fecal samples contained *T. canis* eggs. Seventeen percent contained coccidial sporocysts. Eggs of *Trichuris vulpis* and not clearly identifiable nematodal larvae were found in 1% of the samples. The reasons for the morphology was, in one instance, suspected *Echinococcus* eggs. The fact that 12 or 15 parasitologically positive dog excrement samples were taken from the immediate vicinity of children's playgrounds and another three directly from these grounds should be regarded as particularly critical. The investigated patient case data records revealed for the period studied nine uveitic patients with *T. canis* infection. The diagnosis was based on the larva precipitation test in all cases. After correct diagnosis and appropriate treatment, the prognosis was favorable. The specific treatment had to be repeated in two patients. **CONCLUSIONS:** The environmental parasitological study presented proves the relatively high prevalence of pathogenic causal agents in dog excrement samples from the area of urban recreation and leisure grounds, in particular, children's playgrounds. Parasite infestation is a mirror of the efficiency of hygienic and social measures. Public health education must be reinforced. Differential diagnosis of chronic endogenous eye diseases must pay more attention to infections by parasites

N2 - **BACKGROUND:** The Food and Drug Administration (FDA), in its 1996 regulations to restrict certain forms of cigarette advertising likely to appeal to adolescents, prohibited outdoor tobacco advertising within 1,000 feet of schools and playgrounds. No published studies have determined the density of outdoor tobacco advertising within the FDA's prescribed 1,000-foot buffer zone around schools. **OBJECTIVE:** To determine the prevalence, type, and proximity to public schools of all stationary, outdoor tobacco advertising in six Boston neighborhoods. **DESIGN:** A cross-sectional field survey conducted in six Boston neighborhoods with varying ethnic, cultural, and socioeconomic characteristics. The main outcome measure was advertising density within buffer zones around public schools. **RESULTS:** Youth in the six neighborhoods are heavily exposed to stationary, outdoor cigarette advertising. This exposure is intense in areas close to public schools, and more intense in neighborhoods with more children, with significant Black and Hispanic/Latino populations, and with low socioeconomic status. Advertising strategies employed by the tobacco industry are in line with accepted professional marketing practice that targets adolescents for other products. **CONCLUSIONS:** Given the pervasive nature of the outdoor tobacco advertising we observed in the present study, it appears that the only way to protect youth from exposure is by eliminating it from the community

N2 - This study examined the effects of a student-mediated conflict resolution program on primary school (junior kindergarten to grade 5) playground aggression. Mediation teams of grade 5 students (approximately age 10) participated in 15 hours of training according to the model developed by Cunningham, Cunningham, and Martorelli (1997). Following baseline observations, mediation was introduced onto the playgrounds of three schools according to a multiple baseline design. Mediators successfully resolved approximately 90% of the playground conflicts in which they intervened. Direct observations suggest that the student mediation program reduced physically aggressive playground behavior by 51% to 65%. These effects were sustained at 1-year follow-up observations. Teacher and mediator satisfaction questionnaires provided strong support for impact, feasibility, and acceptability of this program

N2 - OBJECTIVE: To examine the relationship between the number of male sexual partners of adolescent males and the frequency of victimization at school, missed school because of fear, used drugs at school, and engagement of fighting and weapon carrying both in and out of school. STUDY DESIGN: Sexually active male adolescents (N = 3886) in 8th through 12th grades were administered the 1995 Vermont Youth Risk Behavior Survey. RESULTS: A total of 8.7% of male adolescents reported one or more male sexual partners. Alcohol, marijuana, and smokeless tobacco use at school, not attending school because of fear, having been threatened or injured with a weapon at school, and weapon carrying at school accounted for 15.8% of the variation in the number of male sexual partners ($p < 0.0001$). Suicide attempts, school absence because of fear, cigarette smoking, alcohol use, and smokeless tobacco use at school, frequency of fighting requiring medical treatment, carrying a weapon, and carrying a weapon at school accounted for 17.2% out of 100% of the variation in the number of male sexual partners ($p < 0.00001$). CONCLUSION: The number of male sexual partners reported by sexually active male adolescents correlated with a higher frequency of victimization, use of violence and drug use at school. Frequency of suicide attempts and fighting outside of school were also correlated with the number of same-sex sexual partners

N2 - The social, behavioural, and school adjustment of 41 9-year-old children in long-term residential group care in Greece was compared with that of children of the same sex and age brought up in two-parent families. Observational, interview, and questionnaire measures were employed. Observations in school classrooms showed that compared with their classmates, the group care children were more inattentive, participated less often in the classroom activities, were more likely to be passive, and tended to be involved in alternative and nonproductive activities. In the playground, they rarely interacted with non-institutional children. On both parent and teacher scales the group care children showed significantly more overall disturbance. The boys showed poor task involvement in the classroom and more emotional difficulties, conduct problems, and hyperactivity, whereas the between-group differences for girls were statistically significant only for emotional disturbance and poor task involvement in the classroom. Both boys and girls in long-term residential care showed less harmonious, confiding relationships with peers than those reared in families, and were more affection-seeking with teachers

N2 - Second only to traffic accidents, accidental falling is the most significant cause of death in children.

Included in this category is a special group of accidents--falling from a height--where preventative measures would give good results. Cases of child abuse have also been found in this group. From 1989 to 1994 64 children, 19 girls and 45 boys, were treated in our surgical department after accidental falls. There were 99 injuries in all, most of them caused by falls from heights less than 2.5 m. Only two children suffered penetrating injuries. Two of the 64 children died from cerebral injuries after falling from great heights. One child died from heart tamponade, caused by rupture of the right auricle after falling down a steep staircase. One child survived a fall from a great height despite multiple injuries. In such cases, treatment is dependent on a multiple trauma team being available on a 24-hour basis. Measures to prevent falls in the home, as well as in children's playgrounds and in kindergartens are not only very important, but also easy to apply. Suspicion of child abuse must be raised where unusual injuries are observed in children who have reportedly fallen from low heights

N2 - OBJECTIVE: To evaluate the effectiveness of a skills training program in improving safe cycling behavior, knowledge, and attitudes in young children. METHODS: Grade 4 children from six elementary schools in East York (a borough of Metropolitan Toronto) participated. The intervention--playground based instruction on bicycle handling skills by certified instructors--was randomly allocated to three schools. Altogether 141 children participated: 73 in the intervention group and 68 in the control group, with follow up evaluations available on 117 (83%). The primary outcome was safe cycling behavior (straight line riding, coming to a complete stop, and shoulder checking before a left turn). A self report questionnaire collected data on knowledge and attitudes. Baseline assessments were made in June, with follow up evaluations in September, 1995. RESULTS: The prevalence of safe cycling behaviors at follow up in the intervention and control groups respectively, were: straight line riding (90% v 88%; $p = 0.782$), coming to a complete stop (90% v 76%; $p = 0.225$), and shoulder checking (0% v 2%; $p = 1.000$). Over time (from baseline to follow up) children in both groups were more likely to maintain straight line riding, less likely to ride on the sidewalk, and less likely to consider that a car had more right to the road. CONCLUSIONS: This brief skills training program was not effective in improving safe cycling behavior, knowledge, or attitudes among grade 4 children

N2 - OBJECTIVES: To assess the impact of potentially modifiable environmental factors on the risk for pedestrian and cyclist injuries among school age children. SETTING: Population of school age children in Dusseldorf (population 570,000) in the west of Germany. All pedestrian and cyclist injuries involving children between 6 and 14 years brought to the attention of the police between January 1993 and March 1995 were eligible. METHODS: A case-control design was used, with controls matched by age and sex. Criteria for inclusion of cases were: residence in Dusseldorf, and injury within 500 meters from home. A random sample of 174 cases was selected. For each an age-sex matched child, resident in Dusseldorf, was randomly selected from a list of all school age children. The environment within a radius of 500 meters around the homes of cases and controls was analysed by blinded on site investigators. These used a standardized questionnaire to assess the number of streets with speed limits of 30 kph, the number of pedestrian crossings with traffic lights per street with speed limits of 50 kph or above, and the number of playgrounds for children. RESULTS: Complete information was available for 170 cases and 168 controls. There were significantly more streets with a speed limit of 30 kph around the homes of controls ($p = 0.0003$; mean 9.5; 95% confidence interval (CI) 8.8 to 10.1) than cases (mean 7.8; 95% CI 7.3 to 8.3). For every five streets with a speed limit of 30 kph injury risk was reduced by nearly 50% (odds ratio 0.57; 95% CI 0.43 to 0.76). There were also significantly more pedestrian crossings with traffic lights on streets with a speed limit 50 kph or above around the homes of controls ($p = 0.0004$; mean 2.7; 95% CI 2.4 to 2.9) compared with cases (mean 2.1; 95% CI 1.9 to 2.3). Finally there were significantly more playgrounds around the houses of controls ($p = 0.04$; mean 1.9; 95% CI 1.7 to 2.2) compared with the houses of cases (mean 1.7; 95% CI 1.4 to 2.0). CONCLUSIONS: Significant associations with injury risk were identified for some prespecified modifiable environmental factors

N2 - QOL assessment in pediatric oncology is seriously understudied, especially compared with the adult population. The limited progress is due to the methodological complexity of the task, which should not be viewed as insurmountable. Given a precise study question, the methodological issues can be clarified simply, piece by piece. Researchers must consider very carefully the specific characteristics that define a study population in order to choose an instrument that is domain-appropriate and valid for the assessment paradigm. The first priority should be that a researcher must identify the means of accessing the information of interest. In the pediatric population, information about children's status may be elicited from parents, medical personnel, teachers, or the children themselves. Clearly, the type of instrument to be used for assessment is dependent on the choice of reporter. Researchers must also account for developmental age and disease; in assessing generic and disease-specific functioning, the "functional scale" against which an individual is compared must implicitly reflect the types of activities and/or levels of functioning that are realistic norms for the patient. Equally important is the analysis of independent domains in order to characterize the dynamics/divergence of clinical status and functional status. What are the merits of conducting QOL research for the pediatric cancer-survivor population? The policy implications are profound and pervasive both for the individual survivors (regarding treatment, care, and his/her ultimate ability to reintegrate into society) and for society (regarding resource allocation, cost planning, and productivity). Commensurate with the rapid advancement of oncologic therapy, there is now an expanding cohort of pediatric cancer survivors. Current estimates suggest that, by the turn of the century, 200,000 children will be in this category. The long-term survivorship of this cohort is still poorly defined. However, as the survivors mature, it is likely that their needs will evolve as well—whether for treatment of secondary malignancies, long-term morbidities, and fertility issues or for neuropsychological dysfunction, emotional counseling, or occupational issues. Children, as survivors, are unique, in that their future (the context within which long-term outcome is defined) spans decades. Based on a median age at diagnosis of 6 years, survivors can expect to live an additional 66 years. From a cost or policy perspective, children represent enormous future potential. The implications of children's long-term outcomes must be considered regarding the change in future potential secondary to survivorship. Pediatric QOL research plays a role both inside and outside the health care system. Clearly, in the provision of health care, QOL data may be used to improve or modify patient care by supplementing information about the clinical status of individual patients. Information about an individual's general functioning, particularly as it diverges from disease-specific functioning, complements clinical data to facilitate comprehensive care. Information about the long-term outcomes of pediatric cancer, as a whole, will influence the policies of health care institutions and the allocation of health care resources. By expanding the scope of survivorship (or cure) to include long-term clinical and general "costs" the "cost of cure" is shifted: this shift will ultimately impact estimations of cost effectiveness, with ramifications for the evaluation of hospital-wide protocols, utilization priorities, and cost policies. Outside of the hospital, the implications of QOL research are equally ubiquitous. Pediatric survivors will live an estimated 7 decades after "cure," during which time they will exist almost entirely outside the realm of health care; yet, their condition as a survivor, with or without the long-term clinical toxicities secondary to treatment, will continue to affect some or all of thei

N2 - This paper contains the findings of a scientific research which was done on post-traumatic paraplegics who live in the area of Athens. Greece, and measured the impact of pressure sores and UTIs on their everyday life activities. The target population was 127 individuals out of which 98 were observed and interviewed. A semi-structured questionnaire which consisted of two parts used; the first part of the questionnaire included general questions whereas the second contained the Sarno Functional Life Scale (SFLS) which is a tool measuring the level of independence of disabled people. Sixty-two per cent of the population was male. The mean age of the sample population at the time they had the accident which caused the paraplegia was 31.5, while the median was 28.5. The majority of the subjects comes from the lower socioeconomic class. Traffic accidents accounted for the 55% of the occurrences of paraplegia, falls for 37%, surgical complication for 4% and athletic activities for the remaining 4%. Forty-nine percent of the sample had been hospitalised in a rehabilitation centre. However, the multiple regressions used did not reveal any statistically significant relation between the hospitalisation in a rehabilitation centre and the paraplegic's scores in any of the Sarno Functional Life Scale's (SFLS) variables. Instead, the multiple regressions employed yielded paraplegics' scores in the SFLS's everyday life activities that were negatively related to age ($P = 0.004$) and pressure sores ($P = 0.021$).

The paraplegics' scores on the SFLS's indoors activities are positively related to the years since injury ($P = 0.048$) and health education on daily fluid consumption ($P = 0.003$). The scores of the subjects on the SFLS's outdoor activities are positively related to the years of education ($P = 0.008$), the years since injury ($P = 0.011$), while are negatively related to pressure sores ($P = 0.034$) and UTIs ($P = 0.044$). The subjects' scores on the SFLS variables regarding social relations had a negative relation to sex, (female) ($P = 0.0001$), age ($P = 0.001$) and pressure sores ($P = 0.019$), while they have a positive relation with the years since injury ($P = 0.024$)

N2 - The Welfare of Sick Children in Hospital' was the formal title of a report published in Britain in 1959 which came to be known as the Platt Report, after Sir Harry Platt, the chairman of the parliamentary committee which investigated the care of children in hospital. The committee found the hospitals were miserable places for children, where they were expected to conform to ward routines, not allowed to play; where to lie quietly was the accepted norm, and where, under no circumstances, were the parents allowed to visit outside the declared visiting hours. Subsequent to the publication of the Platt Report a revolution occurred in children's hospitals in Britain and other western countries, including Australia. This paper explores these changes, and discusses implications for paediatric care in hospitals and paediatric nursing education today

N2 - Southern California children (10 to 12 years old) participated in a two-season study to assess the potential acute respiratory effects of ambient ozone (O₃). Asthmatic (n = 49), wheezy (n = 53), and healthy (n = 93) children completed a four-day (Friday through Monday) study protocol, once in spring and again in summer, that included the use of daily activity and symptom diaries, heart rate recording devices, personal O₃ samplers, and maximal effort spirometry several times per day. Data from regional monitoring stations were used to establish ambient hourly O₃ concentrations. Analyses revealed that the children spent more time outdoors and were more physically active in the spring. Girls spent less time outdoors and were less physically active than boys. Personal O₃ samplers correlated poorly with, and generally gave lower readings than, outdoor ambient monitors. Higher personal O₃ exposures were associated generally with increased inhaler use, more outdoor time, and more physical activity. Children with asthma spent more time outdoors and were more active in the spring on high-O₃ days (measured by personal sampler), and had the most trouble breathing, the most wheezing, and the most inhaler use on these days. Activity pattern data suggested that children with asthma protected themselves by being less physically active outdoors during the summer on high-O₃ days. Wheezy children had the most trouble breathing during the summer on low-O₃ days (measured by personal sampler). Observed relationships between O₃ and pulmonary function were erratic and difficult to reconcile with existing knowledge about the acute respiratory effects of air pollution. We conclude that although asthmatic and wheezy

children behave differently from their healthy peers with regard to symptoms and patterns of activity when challenged by ambient ozone, the nature of these changes remains inconsistent and ill-defined

N2 - A normally healthy 6-year-old woke in an agitated state, limp, and moving only her left extremities. Upon arrival at the emergency department, a blood glucose measurement was 34 mg/dL. The child was lethargic, not responding to questions appropriately, and not moving her right extremities. The right arm was flexed, and the right leg was flexed and abducted. Pupils were equal and reactive, and eyes were deviated to the left. Six loose tablets of the grandmother's glyburide were found at home in the child's outdoor playhouse. Administration of glucose produced no change in the child's clinical condition. Intravenous glucose was begun at 4 mg glucose/kg/min, and the blood glucose level did not fall below 74 mg/dL after that. Over the next 48 h, the hemiparesis and mental status changes resolved without sequelae. The events of the case suggest a hypoglycemia-induced seizure with subsequent Todd's paralysis. Early direct medical evaluation in suspected glyburide ingestions in children is suggested

N2 - The validity of the 600-yard walk/run, the 20-m shuttle run, and a modified 16-m shuttle run was determined to measure aerobic capacity (VO₂peak) in children with mild and moderate mental retardation. Practice sessions for all tests were conducted. All field tests were very reliable, and VO₂peak was significantly related to them all. A stepwise multiple regression showed that field test performance, body mass index (BMI), and gender, but not age, were also significant predictors of VO₂peak. All field tests were valid and reliable indicators of aerobic capacity, suggesting that these tests can be used to predict VO₂max in children with mild and moderate mental retardation

N2 - To monitor personal exposure to biologically effective solar-UV radiation, Bacillus subtilis spores on a membrane filter and UV-coloring labels were incorporated into a monitoring badge. The samples were covered with one of three types of filter sheet, dependent on the season, to reduce the amounts of exposure to measurable levels. Five fifth- or sixth-grade classes of primary schools, each consisting of 30-40 children, were chosen in northern (Sapporo), central (Tsukuba and Tokyo), and southern (Miyazaki and Naha) cities in Japan. In all four seasons, each child wore a badge on an upper arm for the entire waking hours, changing it daily, for a week. Upon collection of the badges, the survival of spores and the extent of coloration of the label were determined. The results were used to estimate the amount of daily exposure to biologically effective UV radiation, expressed as the value of spore inactivation dose. Unexpectedly, the average amounts of exposure were not directly correlated with the outdoor UV irradiance: in the two southern cities, despite high outdoor irradiance from spring to autumn, the average amounts of exposure were less than 3.1% of the average irradiance. Highly concentrated exposures occurred in two central cities on three days when extensive outdoor exercise took place. These results contradict the simple notion that children's exposure is in proportion to the outdoor UV irradiance, and support the view that the extent of solar-UV exposure is primarily determined by life-style rather than living location

N2 - OBJECTIVE: To determine the risk for injury associated with environmental hazards in public playgrounds. SETTING: One hundred and seventeen playgrounds operated by municipalities or school boards in and around Kingston, Ontario, Canada. METHODS: A regional surveillance database was used to identify children presenting to emergency departments who were injured on public playgrounds; each case was individually matched (by sex, age, and month of occurrence) with two controls--one non-playground injury control, and one child seen for non-injury emergency medical care. Exposure data were obtained from an audit of playgrounds conducted using Canadian and US safety guidelines. Exposure variables included the nature of playground hazards, number of hazards, frequency of play, and total family income. No difference in odds ratios (ORs) were found using the two sets of controls, which were therefore combined for subsequent analysis. RESULTS: Multivariate analysis showed strong associations between injuries and the use of inappropriate surface materials under and around equipment (OR 21.0, 95% confidence interval (CI) 3.4 to 128.1), appropriate materials with insufficient depth (OR 18.2, 95% CI 3.3 to 99.9), and inadequate handrails or guardrails (OR 6.7, 95% CI 2.6 to 17.5). CONCLUSION: This study confirms the validity of guidelines for playground safety relating to the type and depth of surface materials and the provision of handrails and guardrails. Compliance with these guidelines is an important means of preventing injury in childhood

N2 - **OBJECTIVES:** To assess the exposure to toxic metals and to evaluate its possible association with essential elements and socioeconomic status in children from the town of Bytom in the Katowice area; this area is one of the most polluted industrialized regions in Poland. **METHODS:** Concentrations of lead, cadmium, mercury, selenium, magnesium, copper, and zinc were determined in whole blood of 211 children aged 9 years. The samples were analyzed using inductively coupled plasma mass spectrometry (ICP-MS). Information on socioeconomic factors was collected using questionnaires. Concentrations of trace elements in the blood of 24 Swedish children aged 9-10 years were used for comparisons. **RESULTS:** The concentrations of lead detected in the blood of the Polish children ranged from 0.09 to 1.9 $\mu\text{mol/l}$, with the median value being 0.27 $\mu\text{mol/l}$. Statistically significant associations were found between lead and such socioeconomic factors as the number of siblings, trips outside the region, maternal smoking, playing outdoors, and apartment standard. The average blood lead level was about 3 times higher in the Polish children than in the Swedish group. The median blood concentration of cadmium found in the Polish children was 3.4 nmol/l (range 1.1-41 nmol/l ; almost 3 times higher than that detected in the Swedish children), and that of mercury was 3 nmol/l (range 0.5-11 nmol/l). The median blood levels and ranges of the essential elements were 1.1 (0.7-2.0) $\mu\text{mol/l}$ for selenium, 1.5 (1.2-1.9) mmol/l for magnesium, 17 (13-22) $\mu\text{mol/l}$ for copper, and 78 (54-104) $\mu\text{mol/l}$ for zinc, respectively. The concentrations of selenium and magnesium were significantly lower in the Polish group as compared with the Swedish children. **CONCLUSIONS:** In all, 7% of the Polish children had blood lead levels exceeding 0.5 $\mu\text{mol/l}$, the concentration above which negative effects on mental development have been reported. However, the findings indicate a decrease in lead exposure during recent years among the Bytom children

N2 - This study was carried out to determine the concentrations of eosinophil cationic protein (ECP) and tryptase in the nasal lavage fluid (NLF) of 24 children (C) with grass pollen rhinitis as well as rhinitis symptoms before and after nasal provocation tests with or without a levocabastine (anti-H1 topical antihistamine) pretreatment. All C were monosensitized to grasses only. Twelve patients (Active Group = AG) were tested with a nasal provocation test with grass pollen (NPT) carried out by the insufflation of increasingly higher doses of an allergenic extract powder, while the other 12 patients (Placebo Group = PG) underwent just a nasal provocation test with lactose (placebo) (NPTp). The prechallenge NLF, obtained both before (C) and after (AG) levocabastine pretreatment, was compared to that obtained after periods of 2 and 24 hours postchallenge. In the AG, before and after levocabastine pretreatment, the tryptase concentrations had not significantly increased, whereas the ECP concentrations were found to be significantly higher ($p < 0.05$) in just the 24-hour postchallenge samples. In the PG the rhinitis symptoms were not induced by the NPTp and there was no significant change in either ECP or tryptase concentrations. In the AG a levocabastine pretreatment induced a significant increase ($p < 0.05$) in the cumulative allergen doses administered by the NPT. There was a reduction of the nasal symptoms in 7 patients, while in 3 subjects there was only a slight improvement, but in 2 subjects no effect was encountered. In conclusion this study shows that a levocabastine pretreatment before an NPT in patients with grass pollen rhinitis, outside the grass pollen season, induces a significant increase in the cumulative allergen doses (administered by the NPT) which provoked rhinitis symptoms but is not able to demonstrate any significant reduction in the ECP concentrations of the NLF

N2 - **STUDY OBJECTIVE:** To describe the prevalence of smoking in junior secondary school students in Hong Kong and to analyse the relationship between a range of risk factors and ever-smoking experience, including tobacco advertisements. **METHODS:** Cross-sectional survey using an anonymous standardised self-administered questionnaire. **SETTING:** 61 randomly selected secondary schools in Hong Kong.

PARTICIPANTS: 6,304 form 1 to 3 Chinese students from 172 classes (51% girls and 49% boys; 90% were aged 12 to 15 years). **RESULTS:** The smoking status (95% confidence interval) was: (1) never smoker, 71.1% (70.0%-72.2%), (2) tried only, 15.5% (14.6%-16.4%), (3) used to smoke but not now, 4.2% (3.7%-4.7%), (4) smoked < 1 cigarette per week, 2.9% (2.5%-3.4%), (5) smoked 1-6 per week, 1.7% (1.4%-2.0%), and (6) smoked > 6 per week, 4.5% (4.0%-5.0%). In a backward stepwise logistic regression model, ever-smoking (including categories 2 to 6 above) was independently associated with thirteen factors, including gender (boys), increasing age, place of birth (outside Hong Kong, mainly China), poor knowledge of the hazards of smoking, positive attitudes to smoking, smoking in family members, participation in tobacco promotional activities, and perception of cigarette advertisements as attractive. Among the strongest associations observed was the youth's perception of cigarette advertisements as attractive, with the adjusted odds ratio (95% confidence interval) of 2.68 (2.33-3.07). **CONCLUSIONS:** Smoking among young people is an important public health problem.

Although the causes are multifactorial, in Hong Kong environmental tobacco advertising is an important risk factor that can be removed by banning all forms of tobacco promotion to young people

N2 - A comprehensive review of 487 emergency dental trauma visits seen at a children's hospital during a 3-year period was performed to investigate aspects of trauma care that have not been previously reported. Patient characteristics, diagnoses, and injury treatment were analyzed. General patient characteristics and diagnoses were consistent with other studies. Young children were often injured in falls within the home whereas older children were often injured in sports and activities outside the home. The emergency visit was the first contact with the dentist for 80% of children 3.5 years old and younger. Maxillary incisors accounted for 84% of primary tooth injuries: examination and extraction were common treatments. Maxillary incisors accounted for 87% of permanent tooth injuries: bandage restorations and splint placement were frequent treatments. An assistive restraint device was used most often for children 4 years and younger who required extractions. The restraint

was used more frequently during clinic hours with support staff present than after hours with a sole provider. Hospital facilities were not essential for treatment of the patients in this study

N2 - OBJECTIVE: To map the frequency (prevalence) of torture victims among parents in asylum seeking Middle Eastern refugee families, to map the occurrence (prevalence) of experiences of war and other forms of organised violence among the children in these families, to map the occurrence (prevalence) of emotional symptoms and behavioural problems among the children, and to identify risk indicators and modifying factors for anxiety symptoms among the children. DESIGN: Interview with parents using a structured interview questionnaire developed for this study. Validated through a blinded semi-structured interview conducted with approximately 1/3 of the families. AUSPICES: The study has been carried out by the Rehabilitation and Research Centre for Torture Victims (RCT) in cooperation with the Danish Red Cross. MATERIAL: Structured interviews with parents regarding 311 children aged 3-15 from 149 families, all registered as asylum seekers from the Middle East between February 1, 1992 and April 30, 1993. The response was 90.4%. PRINCIPAL VARIABLES: Background (past-past)--social and demographic data; trauma complex (past)--war-related life circumstances (conditions) and experiences of war and other forms of organized violence such as loss,

separation, direct exposure to violence and witnessing acts of violence (specific events and changes of life conditions); present life context (past-present)--family circumstances upon arrival in Denmark; effect (present)--the child's current psychological state. RESULTS: 28% of the parents (44% of the fathers and 13% of the mothers) had been tortured, to the effect that 51% of the children were part of a family including a survivor of torture. The most frequent specific types of violence-related events or circumstances were 'lived in a refugee camp outside the home country' (92%), 'lived under conditions of war' (89%) and 'been on the run with parents' (89%). Twenty percent of the children had lost one parent, and another 60% had been separated from one parent for more than a month. The highest prevalence of emotional symptoms were found within the anxiety dimension, as 67% of the children were assessed as being clinically anxious. The most important risk indicators for anxiety were 'lived in a refugee camp outside the home country', 'part of a torture surviving family', 'lack of opportunities for play with other children', 'beaten/kicked by an official', and 'loss of father'. Current parental behaviour was also an important risk indicator for anxiety, if the mother or father hit or punished the child more than was the case prior to arrival in Denmark. The most important anxiety-modifying factor was arrival in Denmark in the company of both parents. CONCLUSIONS: Asylum seeking refugee children from the Middle East have had many experiences of war and other forms of organised violence. The children frequently reacted with anxiety and with other symptoms of emotional instability. Prevalent anxiety symptoms correlated both with previous living conditions and present family situation. Living under prolonged conditions influenced by war and other forms of organised violence (prevalence) were found to a higher degree to be risk indicators for anxiety than were specific events or changes of life conditions (incidence)

N2 - OBJECTIVE: To identify the epidemiologic characteristics of tuberculosis (TB) in Montreal and the patterns of resistance to antituberculous drugs in order to improve TB control in the region. DESIGN: Descriptive analysis of surveillance data for TB cases reported in Montreal by physicians and laboratories between 1992 and 1995. SETTING: Region of Montreal, population 1,775,889. PARTICIPANTS: All cases of active TB among Montreal residents reported to the Department of Public Health between Jan. 1, 1992, and Dec. 31, 1995. OUTCOME MEASURES: Epidemiologic characteristics, proportion of cases resistant to antituberculous drugs and types of resistance. RESULTS: A total of 798 cases of TB (mean annual incidence 11.2 per 100,000) were reported in Montreal during the study period. Of these patients, 617 (77.3%) were born outside Canada. The annual incidence of TB in the foreign-born population (37.5 per 100,000) was 10 times the rate in the Canadian-born population, and the highest rate among foreign-born residents (62.8 per 100,000) occurred in those 15-29 years of age. In general, annual incidence in Montreal's foreign-born population reflected the reported incidence of TB in their regions of birth. In 8.7% of all cases, the disease was resistant to isoniazid, and the proportion of cases resistant to this drug was greater than 4% in almost all age groups, among both foreign-born and Canadian-born patients. CONCLUSIONS: TB remains a major problem in Montreal, as in other large cities. Surveillance data give opportunities to public health agencies to adapt their prevention and control strategies to local situations and can also help clinicians in their clinical decision-making

N2 - BACKGROUND: Children are at particular risk for sun exposure, a major cause of skin cancer. Parents and caregivers can help protect children by educating them about practicing safe sun habits, serving as role models, and providing supportive environments. OBJECTIVE: We evaluated SunSmart, a cancer prevention program for 6- to 8-year-old children, their parents, and outdoor recreation staff. METHODS: The intervention included staff training, on-site activities for children, interactive take-home booklets, behavior-monitoring scoreboards, incentives, providing sunscreen, and encouraging sun safe environments and policies. The program was evaluated by baseline and follow-up surveys of parents and recreation staff, monitoring forms, and on-site observations. RESULTS: There were positive changes in all major outcomes, including knowledge; sun protection habits of parents, children, and staff; readiness to change; sun protection policies; and sun protection norms. The changes ranged from improvements of 3% to more than 20%, and several changes were statistically significant. CONCLUSION: The results demonstrated the feasibility and short-term impact of Hawaii's SunSmart program and suggested areas for refinement and expansion

N2 - OBJECTIVE: To design a structured curriculum to teach pediatric residents about wilderness medicine. BACKGROUND: An increasing number of children are involved in more rigorous and potentially risky outdoor activities. Despite the breadth of exposure characteristic of most pediatric residences, we are aware of no formalized syllabus that prepares residents to both treat injuries sustained in outdoor pursuits, and help parents and children to prepare safely for such activities. METHODS: The first half of the course was designed to teach a broad range of topics in wilderness medicine through a series of readings, lectures, and field trips. The second half of the course involved a six-day course in wilderness skills. RESULTS: Over a three-week period, the major topics of wilderness medicine were thoroughly covered. The three residents involved in the planning and execution of the course felt that the course succeeded in filling an important gap in their pediatric residency training. CONCLUSIONS: The addition of a structured wilderness medicine elective to pediatric residencies, with or without a field component, may provide a valuable opportunity for pediatric residents to broaden their skills and knowledge base to include these increasingly important topics

N2 - Hettstedt, a city in eastern Germany with a long history of mining and smelting of non-ferrous ores, has multiple lead waste deposits and the remains of a former lead smelter and a copper-silver smelter. As part of a cross-sectional study, an analysis of lead concentrations in drinking water and in blood was undertaken to determine the impact of lead in drinking water on the internal burden of lead in children. The geometric mean of blood lead levels among children 5-14 years old was 35.0 micrograms/l with a 95% confidence interval (C.I.) of 33.4-36.7. The geometric mean of lead in the random tap water samples was 0.5 microgram/l (95% C.I., 0.5-0.6) and 0.7 microgram/l (95% C.I., 0.6-0.8) in the stagnant tap water samples. Blood lead levels were somewhat correlated with the random water measures but not the stagnant water measures (random sample: $r = 0.12$, $P = 0.012$; stagnant sample: $r = 0.04$, $P = 0.396$). After adjustment for relevant confounders, lead in drinking water (random sample) was not significantly associated with blood lead levels. Factors that were significantly associated with blood lead included gender, the city area of residence, lead in house dust, regular contact with dogs and dirtiness of the child after playing outdoors. Based on this study, lead in domestic tap water contributed little to the lead exposure of children in the lead contaminated region of Hettstedt

N2 - A study of personal exposure to respirable particles (PM10) and fine particles (FP) was conducted in groups of 50-70 year-old adults and primary school children in the Netherlands. Four to eight personal measurements per subject were conducted, on weekdays only. Averaging time was 24 hours. Method performance was evaluated regarding compliance, flow, weighing procedure, field blanks and co-located operation of the personal samplers with stationary methods. Furthermore, the possibility that subjects change their behavior due to the wearing of personal sampling equipment was studied by comparing time activity on days of personal sampling with time activity other weekdays. Compliance was high; 95% of the subjects who agreed to continue participating after the first measurement, successfully completed the study, and, except for the first two days of FP sampling, over 90% of all personal measurements were successful. All pre and post sampling flow readings were within 10% of the required flow rate of 4 L/min. For PM10 precision of the gravimetric analyses was 2.8 microgram/m³ and 0.7 micrograms/m³ for filters weighted on an analytical and a micro-balance respectively. The detection limit was 10.8 micrograms/m³ and 8.6 micrograms/m³ respectively. For FP, weighing precision was 0.4 micrograms/m³ and the detection limit was 5.3 micrograms/m³. All measurements were above the detection limit. Co-located operation of the personal sampler with stationary samplers gave highly correlated concentration ($R > 0.90$). Outdoor PM10 concentrations measured with the personal sampler were on average 4% higher compared to a Sierra Anderson (SA) inlet and 9% higher compared to a PM10 Harvard Impactor (HI). With the FP cyclone 6% higher classroom concentrations were measured compared to a PM2.5 HI. Adults spent significantly less time outdoor (0.5 hour) and more time at home (0.9 hour) on days of personal sampling compared to other weekdays. For children no significant differences in time activity were found

CY - KOREA (SOUTH)

N2 - The study was conducted from November 1995 to May 1996 at the one general hospital in Seoul. The total subjects of this study were 412 patients who have the experience of fall accident, among them 31 was who have fallen during hospitalization and 381 was who visited emergency room and out patient clinic. The purposes of this study were to determine the characteristics, risk factors and results of fall accident and to suggest the nursing strategies for prevention of fall. Data were collected by reviewing the medical records and interviewing with the fallers and their family members. For data analysis spss/pc+ program was utilized for descriptive statistics, adjusted standardized X²-test. The results of this study were as follows: 1) Total subjects were 412 fallers, of which 245 (59.5%) were men and 167 (40.5%) were women. Age were 0-14 years 79 (19.2%), 15-44 years 125 (30.4%), 45-64 years 104 (25.2%), over 65 years 104 (25.2%). 2) There was significant association between age and the sexes (X² = 39.17, P = 0.00). 3) There was significant association between age and history of falls (X² = 44.41, P = .00). And history of falls in the elderly was significantly associated with falls. 4) There was significant association with age and medical diagnosis (X² = 140.66, P = .00), chief medical diagnosis were hypertension (34), diabetes mellitus (22), arthritis (11), stroke (8), fracture (7), pulmonary tuberculosis (6), dementia (5) and cataract (5). 5) There was significant association between age and intrinsic factors: cognitive impairment, mobility impairment, insomnia, emotional problems, urinary difficulty, visual impairments, hearing impairments, use of drugs (sedatives, antihypertensive drugs, diuretics, antidepressants) (P < 0.05). But there was no significant association between age and dizziness (X² = 2.87, P = .41). 6) 15.3% of total fallers were drunken state when they were fallen. 7) Environmental factors of fall accident were unusual posture (50.9%), slips (35.2%), trips (9.5%) and collision (4.4%). 8) Most of falls occurred during the day time, peak frequencies of falls occurred from 1 pm to 6 pm and 7 am to 12 am. 9) The places of fall accident were roads (22.6%), house-stairs (16.7%), rooms, floors, kitchen (11.2%), the roof-top, veranda, windows (10.9%), hospital (7.5%), ice or snowy ways (5.8%), bathroom (4.9%), playground, park (4.9%), subway-stairs (4.4%) and public-bathrooms (2.2%). 10) Activities at the time of fall accident were walking (37.6%), turning around or reaching for something (20.9%), going up or down stairs (19.2%), exercise, working (17.4%), up or down from a bed (2.7%), using wheelchair or walking aids, standing up or down from a chair (2.2%) and standing still (2.2%). 11) Anatomical locations of injuries by falls were head, face, neck (31.3%), lower extremities (29.9%), upper extremities (20.6%), spine, thorax, abdomen or pelvic contents (11.4%) and unspecified (2.9%). 12) Types of injures were fracture (47.6%), bruises (13.8%), laceration (13.3%), sprains (9.0%), headache (6.6%), abrasions (2.9%), intracranial hemorrhage (2.4%) and burns (0.5%). 13) 41.5% of the fallers were hospitalized and average of hospitalization was 22.3 days. 14) The six fallers (1.46%) died from fall injuries. The two fallers died from intracranial hemorrhage and the four fallers died of secondary infection; pneumonia (2), sepsis (1) and cellulitis (1). It is suggested that 1) Further study is needed with larger sample size to identify the fall risk factors. 2) After the fall accident, comprehensive nursing care and regular physical exercise should be emphasized for the elderly person. 3) Safety education and safety facilities of the public place and home is necessary for fall prevention

N2 - The statuses of vector-borne diseases have changed over recent years. How a few such diseases have changed and the primary causes of change (urbanization, increased conflict, changes in water-resource management, ecological and environmental change, and reduced health service resourcing) are the subjects of the present review. The key impacts which these primary causes have on selected vectors and the infections they transmit are tabulated. The success of vector-control programmes against onchocerciasis and Chagas disease is discussed, and the methods used to evaluate the epidemiological impact of such controls are described. Bednet programmes for control of malaria are recognized as a potential future means of reducing morbidity and mortality in children. In contrast to the success achieved in limiting *Simulium* and *Triatoma* populations through vertical programmes, control of tsetse, whilst successful in Uganda, has not been utilized to stem recent epidemics of sleeping sickness in resource-stressed settings in Central Africa. Vector-borne diseases will continue to be a problem because of the adaptability of vectors, the potential problems of managing effective vector controls within decentralized health systems, and the influence of activities outside the health sector itself. Changes beyond the health sector can increase the problem posed by a vector and increase the frequency of transmission. [References: 59]

N2 - **OBJECTIVE:** To determine the seroprevalence of treponemal infection and possible risk factors among children aged 0-14 in the general population of a rural Tanzanian village. **METHODS:** The survey was conducted as a part of a cross section study of a total village population on HIV and sexually transmitted disease. Among 1708 registered children aged 0-14, the 553 first attending were tested for treponemal infection with both rapid plasma reagin test (RPR) and Treponema pallidum Haemagglutination test (TPHA). These children belonged to a household cohort--also including their parents, siblings, and other household members--with 1339 members; 1224 (91.4% participated in the survey and 82.1% of these were tested for treponemal infection. **RESULTS:** The overall prevalence for the TPHA test was 6.4% among girls and 1.1% among boys (odds ratio, OR = 6.5; 95% confidence interval, CI: 1.9-22.3). The sex difference was most pronounced in the age group 10-14; 11.1% among girls versus 1.0% among boys (OR = 12.8; CI: 1.6-101.9). Among the 20 children who were TPHA positive, we found two cases of active, congenital syphilis. There was a lack of association between positive serology in children and positive serology in their parents. **CONCLUSION:** The highly significant predominance of girls testing positive for TPHA, and the concomitant lack of association

between parents' and children's serostatus might point to sexual transmission as being the most common route of transmission of treponemal infection in girls during childhood in this village. The sources of infection for the seropositive girls are possibly found outside the family

N2 - OBJECTIVE: To determine whether intravenous home treatment with antimicrobial drugs of patients with an infection is feasible. DESIGN: Descriptive. SETTING: Academic Hospital, Leiden, the Netherlands.

METHODS: In October 1992 a programme for intravenous home treatment of patients with infectious diseases was started. The programme was based on self-administration of the intravenous antibiotic therapy by the patient. The hospital pharmacy provided the antibiotics and infusion devices, an infectious diseases specialist supervised the home treatment and the nursing staff of the First Aid Department was available to change

infusion cannulas. After assessment of their medical and psychosocial fitness in which the general practitioner was involved, thorough instruction on use of the infusion device and care of the infusion cannula, patients were sent home. RESULTS: In the period October 1992-September 1996, 162 patients (median age: 45.0 years (range: 3-82)) were treated at home for a median period of 15 days (1-221). Osteomyelitis, arthritis, Lyme disease, septicaemia with secondary foci, and herpes virus infections were the most frequent indications for home treatment. Penicillins and cephalosporins were given in 70% of the cases, teicoplanin and antiviral drugs in 12% and 14%, respectively. For intermittent administration bolus injection, a mechanical or elastomeric pump were used, for continuous infusion a syringe or cassette pump. The intention of the programme that the patient performed the home treatment as much as possible without extra professional help, was realised in 82% of the patients. In 60% of the cases the patients were fully self supporting, in 22% family or friends played an important role. CONCLUSION: Home treatment with antimicrobial drugs intravenously is quite feasible. If this were fully implemented, about 1400 patients in the Netherlands could be treated in this manner

N2 - OBJECTIVES: To describe factors that contribute to variations in health-related behaviours and attitudes among inner city 12-year-olds. To see if there was an identifiable patterning by ethnic group. DESIGN: Semi-structured interviews with a stratified sample of 12-year-old students and their parents from four ethnic groups, attending state secondary schools in two inner London boroughs. RESULTS: Bangladeshi young people were significantly more likely to receive school meals. There was no variation in reported snacking between the groups. Girls and Bangladeshi students were less likely to report exercising outside school (33% of Bangladeshi boys reported not exercising outside school compared to 5% of boys from all other groups). Bangladeshi boys and their parents were more likely to report that bullying or worries about racial violence prevented them from going out after school. White young people were more likely to report experimenting with and the regular use of cigarettes and alcohol. Use of alcohol and cigarettes was also associated with gender, religion and strength of religious observance. White parents were the least likely to report restricting their child's social activities as a way of influencing behaviour and expressed more concerns about their child's potential for health-damaging behaviour than parents in all other groups. CONCLUSION: This study shows that ethnicity alone is insufficient and inadequate in explaining variations in health behaviours among inner city teenagers. A complex mix of personal, cultural and social factors including ethnicity shape the behaviours and attitudes of these young people

N2 - OBJECTIVES: To investigate the validity of outdoor concentrations of particulate matter < 10 microns diameter (PM10) as a measure of exposure in time series studies, and to study the extent to which differences between personal and outdoor PM10 concentrations can be explained. **METHODS:** Four to eight repeated measurements of personal and outdoor PM10 concentrations were conducted for 45 children, aged 10-12 years, from four schools in Wageningen and Amsterdam, The Netherlands. Repeated PM10 measurements in the classrooms were conducted in three of the schools. Averaging time was 24 hours for the personal and outdoor measurements, and eight hours (daytime) and 24 hours for the classroom measurements. For each child separately, personal exposures were related to outdoor concentrations in a regression analysis. The distribution of the individual correlation and regression coefficients was investigated. Information about factors that might influence personal exposures was obtained by questionnaire. **RESULTS:** Median Pearson's correlations between personal and outdoor concentrations were 0.63 for children with parents who did not smoke and 0.59 for children with parents who smoked. For children with parents who did not smoke, excluding days with exposure to environmental tobacco smoke (ETS) improved the correlation to a median R of 0.73. The mean personal PM10 concentration was 105 micrograms/m³; on average 67 micrograms/m³ higher than the corresponding outdoor concentrations. The main part of this difference could be attributed to exposure to ETS, to high PM10 concentrations in the classrooms, and to (indoor) physical activity. **CONCLUSIONS:** The results show a reasonably high correlation between repeated personal and outdoor PM10 measurements within children, providing support for the use of fixed site measurements as a measure of exposure to PM10 in epidemiological time series studies. The large differences between personal and outdoor PM10 concentrations probably result from a child's proximity to particle generating sources and particles resuspended by personal activities

N2 - The aims of the study were to evaluate if the front-door concentrations of benzene, toluene, and xylenes can be used to classify the personal exposures of Danish children and to identify factors that affect their personal exposure. Average concentrations were measured over 1 week with diffusive samplers, and the personal exposures of 98 children and the concentrations outside the front doors of their homes were measured simultaneously. Time and activity patterns were noted in diaries. The front-door concentrations were significantly higher in Copenhagen than in rural areas (all $P < 0.0001$), but the personal exposures were only slightly higher. Even though the personal exposures were highly significantly associated with front-door concentrations in urban areas (all $P < 0.004$), use of the residential front-door concentration as an exposure surrogate would imply misclassification, as it cannot be used for rural children. Multiple regression analyses brought to light several factors that affect the exposure of children independently, including front-door concentration, riding in cars, and activities involving potential exposure to gasoline vapors like motocross, moped driving, and refueling of cars

N2 - Sporotrichosis is a subcutaneous fungal infection caused by the traumatic implantation of the dimorphic, pathogenic fungus, *Sporothrix schenckii*. It constitutes the most common subcutaneous fungal infection in the general population in South Africa. Sporotrichosis in South Africa dates back to 1914, when the disease was first diagnosed in the gold mines. Occupational and recreational circumstances of infection are well established, and the environmental requirements for contracting the disease are better understood. Sporotrichosis cases were recorded from 42 suburbs in the greater Pretoria area as well as from 23 towns outside the Pretoria municipal boundary. It occurred in 154 patients with ages ranging from less than 1 year to 90 years old, with males predominating. Females in the area seemed to be at lesser risk, mainly becoming infected through gardening injuries, insect bites or other minor injuries due to outdoor activities. Exposure to possible sources of the fungus, either from recreational or occupational activities in males, was the main determining factor in acquiring the disease. The lymphocutaneous and localized forms of the disease were most often recorded. Our study indicates that, while there is no pronounced seasonal variation, the onset of the disease seemed to be mainly in the cooler and dryer months of the year

N2 - AIM: To identify risk factors, particularly paint removal and clean up practices, for elevated blood lead levels in children, 12 to 24 months old, living in Wellington city. METHODS: Children living in residences more than 50 years old, where residential paint removal had taken place in the last two years, were recruited. Care givers were interviewed, a blood sample was taken from the child's arm and a dust wipe sample was collected from the kitchen floor. Blood and dust samples were analysed for lead content. RESULTS: Data were collected for 141 children (75% of those eligible). The mean blood lead level was 0.24 mumol/L (5.06 micrograms/dL). Higher blood levels were associated with lower income of the main family earner, playing outside, eating dirt and parental hobbies involving lead use. Children receiving regular medical treatment were at lower risk of lead absorption. With the exception of paint removal involving blow torches, none of the paint removal, clean up, or disposal practices was more strongly associated than the other methods with elevated blood lead levels in children living in the household. Dust wipes from the kitchen floor had little predictive value for blood lead level. CONCLUSIONS: High temperature methods of paint removal and parental hobbies involving lead are associated with higher lead levels in children. Given the availability of alternative means of paint removal, continuing use of high temperature methods is unnecessary. Further work is needed to assess lead absorption risks associated with hobbies involving lead

N2 - We conducted a cross-sectional study of tuberculin reactivity among residents of two northern California migrant-farm-worker housing centers. Participants completed a brief health questionnaire and were offered tuberculin skin testing with radiologic and medical follow-up. Four hundred and sixty-nine persons (estimated participation rate: 70%) completed questionnaires. All but one were Hispanic. Two hundred and ninety-six (63%) participants completed tuberculin skin testing and 49 (16.6%) showed reactivity (\geq or = 10 mm induration at 48-72 hours). Increased prevalence was seen for the 15-39-year age group (vs. persons younger than 15: OR 2.59; 95% CI 0.79-8.47), former smokers (vs. never smokers: OR 3.11; 95% CI 1.20-8.09), and persons born outside the U.S. (OR 2.09; 95% CI 0.66-6.61). Prophylaxis with isoniazid was recommended for 23 persons; nine (39%) completed therapy. No cases of active tuberculosis were found. Prevalence of tuberculin reactivity in this population is lower than reported among Hispanic farm workers in the eastern and midwestern U.S. Higher prevalence may obtain among California farm workers not included in the study population, including homeless, single, and highly mobile persons. Public-health efforts in this population should focus on ever-smokers, young adults, and persons born outside the U.S

N2 - Sleep/wake patterns were recorded by continuous 24-hour ambulatory polysomnography in 339 patients, who had episodes of altered consciousness. Patients were recorded while they were outside the hospital. From a seven-channel montage of electrodes affixed below the hairline, sleep polygraphic EEG was easily read from T3-T4, EOG from F2-F8 and EMG from T3-T6. Sleep was staged by analysis of aural signals on 60 times real time playback, augmented by continuous visual display and selected frozen frames. Patient major sleep period patterns reflected those reported for general populations. Unexpectedly, 47% of the patients took daytime naps and 44% of the nappers took more than one nap. Naps had a mean duration of 71 minutes. Those who took no naps slept significantly longer at night by 23 min. Napping reduced night sleep much more in patients who did not take CNS-acting medications. We conclude that excessive sleepiness may in part explain complaints of episodically altered consciousness

N2 - Communication is a process that begins at birth and continues throughout life. For young children with developmental delay or disability, the acquisition of expected communication skills may be compromised. Compromised communication skills, in turn, may lead to additional challenges when participating in daily activities and routines, forming social relationships, and developing independence. Assistive technology (AT) is one means by which a child's current communication skills can be expanded and enhanced within the child's natural environment. Increased awareness by both parents and professionals of the availability of AT has led to the inclusion of AT strategies within routine day-to-day early intervention practices. This article briefly highlights early aspects of communication development in typically developing infants and toddlers, then provides a framework through which AT strategies can be identified and utilized by parents and professionals to improve a child's existing communication skills

N2 - In preparation for large-scale investigations, we have conducted some methodological studies with small groups in order to determine patterns of stay and time activity patterns in various microenvironments at different times of the day. A diary technique was used. This paper reports some results of this methodological study: In one study we investigated a group of toddlers (n = 52, aged 2-3 years) attending a nursery school, and in a second study we compared two groups of medical students (n = 79 and 54, respectively). The reported data was analyzed by descriptive statistical methods. The toddlers spent an average of 87.6% of their time indoors (66.2% at home, 20.4% at nursery schools, 1% at other indoor areas), 11.2% of their time outdoors, and 1.2% of their time using various means of enclosed transportation. In the student study, time budgets of the two student groups differ only slightly. The students spent about 87% of their time indoors (about 66% at home, 14% in rooms connected with their study, 7% in other indoor areas), about 6% of their time using various means of enclosed transportation, and about 7% of their time outdoors. In order to describe the physical activity, the students were asked to evaluate their physical activity according to a low, medium or high physical strain. These evaluations were used to calculate a "mean activity coefficient" for each microenvironment and each hour of day. Not every individual in a group spent time in every given microenvironment during the period of investigation. Therefore, the mean over all the individuals of the group (the "group mean") and the mean over the individuals who in fact did spend time in any given microenvironment (the "actual doers mean") may be very different. There are two kinds of frequency distributions of time spent in various microenvironments: (1) The distribution of the individual's mean time spent in the microenvironment across the entire investigation period (distribution of the individual means) and (2) the distribution of the duration of time spent in the microenvironment for all participants at all days (distribution of the person-days). Both types of frequency distributions should be determined for the purpose of exposure and risk estimation for pollutants

N2 - **BACKGROUND:** Atopy is reported to play an insignificant role in wheezing during infancy in contrast to later childhood. For this reason skin testing may not be included in a workup of wheezing infants.

OBJECTIVE/METHOD: In order to evaluate the degree and evolution of skin sensitization to allergens in infants with asthma, we have retrospectively analyzed the skin test results from 40 referred asthmatic children less than 36 months of age, who had had more than three wheezing episodes and whose symptoms improved on treatment with beta-agonist and anti-inflammatory agents. **RESULTS:** Skin sensitization (epicutaneous) to common indoor and outdoor aeroallergens and foods were demonstrated in 23 (58%) of these patients.

Asthmatic children with the onset before 12 months of age and duration of less than 12 months were sensitive predominantly to foods. Those with later onset asthmas and longer duration developed sensitivity first to indoor and then to outdoor allergens. The most common food, indoor, and outdoor allergens were egg, dust mite, and pollens, respectively. Six of these patients had repeat skin tests later. Two demonstrated a decrease in skin sensitivities to foods, one gained a new sensitivity to grass, while three remained unsensitized. **CONCLUSION:** Skin sensitization to allergens was common in selected asthmatic infants and evolves in the order of exposures: foods, indoor allergens, and outdoor allergens. Repeat skin tests showed changing skin test patterns in some patients

N2 - The aims of the study were to evaluate the front-door concentration of traffic exhaust fumes as a surrogate for the personal exposure of children and to study factors in the behavior and the environment of children that affect their personal exposure to nitrogen dioxide (NO₂). The exposure to NO₂ of 103 children living in Copenhagen and 101 children living in rural areas of Denmark was studied by measuring average concentrations over 1 week with diffusive badge samplers placed outside the front door of the home, inside the child's bedroom, and on each child. Detailed information about the activities of the children involving potential exposure to NO₂ was noted in diaries. The results indicated that the front-door concentration of traffic pollution might be used to classify the personal exposure of urban children, although misclassification would be introduced. Multiple regression analysis showed several factors that affected the personal NO₂ exposure of the children independently, including the front-door concentration, the bedroom concentration, time spent outdoors, gas appliances used at home, passive smoking, and burning candles

 N2 - We investigated physical activity and encouragement for activity in a bi-ethnic cohort during recess. Activity and associated interactions of 287 children were recorded at preschool and again 2.2 years later. Children expended nearly twice as much energy at preschool recess than at elementary recess. Activity levels declined as recess time elapsed. At preschool, European-American children engaged in more moderate to vigorous activity than Mexican-Americans. As participants moved to elementary school, teachers' prompts to be active decreased and prompts from peers increased. Boys and girls received similar amounts of activity prompts at preschool, but prompts to boys increased over time. The findings suggest that school environments could be altered to promote healthful physical activity among young children

N2 - The authors examine the theoretical possibilities of human dental transplants: autologous, homologous and heterologous. They, then discuss-with reference to autologous transplants-an autotransplant as an alternative to prosthodontic treatment. This would apply both to traditional prosthodontic treatment and on implants or orthodontic treatment aiming at filling dental gaps. They show both general and local counterindications against this operational method the knowledge of which is necessary for an adequate selection of patients. They stress the determining factors for a successful autotransplant: 1) particular care with the choice of the germ to be transplanted taking into account its morphology and the stage of root development; 2) adequate surgical preparation of the receiving site in relation to the size of the germ to be transplanted; 3) suitable surgical technique entailing a particular care in the manipulation of soft and hard tissues and of the germ and appropriate conditions of sterilization; 4) use of appropriate retention means to ensure stability of the transplanted germ so as to favour cellular proliferation and reduce osteoclastic activity; 5) reduction of occlusal pressure on the transplanted germ. The authors describe for example's sake 3 out of 32 cases treated with the documentation of the achieved long-term success. They also analyse the possible causes of failure of such operational method (careless manipulation of the germ, incorrect surgical technique, removal of the germ in a too early stage of its development, too long exposure of the germ outside the oral cavity, poor oral hygiene, caries, periodontal disease, occlusal trauma

N2 - This prospective study examined characteristics of school-related injuries in grades K-6 and children's perceptions regarding prevention and environmental influences. Injuries were most likely to occur on the playground, were most frequent for first and second graders, and for boys. Only 30% of the sample perceived that they could have prevented their injury. This perception was more frequent for children in higher grades. Fifty percent perceived an environmental influence. The Health Promotion Model was used as the theoretical framework to guide this investigation and provide implications for practice. School nurses are in an ideal position to counsel children on taking responsibility for their safety through preventive thinking. [References: 28]

N2 - OBJECTIVES: This study evaluated a health-related physical education program for fourth- and fifth-grade students designed to increase physical activity during physical education classes and outside of school. METHODS: Seven schools were assigned to three conditions in a quasi-experimental design. Health-related physical education was taught by physical education specialists or trained classroom teachers. Students from these classes were compared with those in control classes. Analyses were conducted on 955 students with complete data. RESULTS: Students spent more minutes per week being physically active in specialist-led (40 min) and teacher-led (33 min) physical education classes than in control classes (18 min; $P < .001$). After 2 years, girls in the specialist-led condition were superior to girls in the control condition on abdominal strength and endurance ($P < .001$) and cardiorespiratory endurance ($P < .001$). There were no effects on physical activity outside of school. CONCLUSIONS: A health-related physical education curriculum can provide students with substantially more physical activity during physical education classes. Improved physical education classes can potentially benefit 97% of elementary school students

N2 - The aim of this paper is to describe an epidemiological model to investigate the relationship between respiratory diseases and environmental air pollution. In the Po Delta prospective study, subjects were investigated before and after a large thermoelectric power plant began operating, in 1980 to 1982 and in 1988 to 1991, respectively. The Pisa prospective study was performed in 1986 to 1988 and in 1991 to 1993, before and after the construction of a new expressway that encircles the city from the North to the Southeast. In each survey, subjects completed the interviewer-administered standardized CNR questionnaire on respiratory symptoms/diseases and risk factors, and performed lung function tests. In the second survey of each study, skin prick tests, total serum IgE determination, methacholine challenge test and biomarkers (such as sister chromatide exchanges, micronuclei, chromosomal abnormalities, DNA and hemoglobin adducts) were also performed. Concentrations of total suspended particulate and SO₂ in both surveys were higher in urban than in rural areas, as well as symptom/disease prevalences and bronchial reactivity. Subgroups of subjects from the two samples were enrolled to perform a specific study on the acute respiratory effects of indoor pollution; the daily presence of symptoms and measurements of peak expiratory flow (PEF), daily activity pattern, and assessment of the indoor air quality (particulates < 2.5 µ and NO₂) were evaluated. Higher symptom prevalences and PEF variability level were observed in subjects with the highest levels of NO₂ or particulates, especially asthmatics. In conclusion, these studies represent a basis for further analyses to better define the relationship between respiratory health and indoor/outdoor pollutant levels

N2 - Numerous epidemiological studies on risk factors of malignant melanoma confirm the etiologic role of excessive UV-exposure especially in childhood. Preventive educational campaigns directed to parents of pre-school children have been inaugurated in several countries. In Germany the information was distributed by the "Working group for Preventive Measures in Dermatology" in cooperation with different public health institutions and the media starting in 1993. To evaluate the influence of these efforts on the knowledge and behaviour of the parents, two successive cross-sectional studies at all 56 nursery schools using the same standardised questionnaire were performed. The first interview took place in spring 1993 (before the campaign) with 1341 evaluable questionnaires, the second in fall 1994 (after the campaign) with 1150 evaluable questionnaire. The knowledge of the parents on melanoma risk factors was significantly improved in the second interview. Also the parental behavior regarding sun-protective measures when their children were outdoor at the beach or in the garden definitely changed. In 1993 the best textile sun protection was used by 21% of the parents at the beach and 36% in the garden. These numbers rose to 34% (beach) and 57% (garden) by the second interview. The percentage of children with no sunburn recorded during the preceding summer rose from 39% to 51%. According to the child's gender the parental behavior was different between the sexes; boys were always better protected than girls. The design of this study with two cross-sectional surveys in the same populations does not provide a methodologically sound basis for attributing the observed positive changes to the campaign. Without any doubt it can be stated that the parental knowledge and their attention to sun protection in their children showed substantial improvement in the second survey after the campaign. Thus, these results provide some evidence for the success of the preventive activities and confirm the necessity to continue with such activities

N2 - OBJECTIVE: To describe the profile of injuries sustained by children in school accidents and suggest preventive measures. DESIGN: A five month prospective study of children attending an urban accident and emergency (A&E) department. SUBJECTS: 500 children who sustained injuries in school due to a variety of activities. RESULTS: 10 and 12 year old pupils suffered most injuries in school grounds/playgrounds, on concrete, or on grass/soil surfaces due to random activities resulting in striking or being struck by objects/persons, tripping or slipping, and sports (mainly football); 65.5% of these activities were not supervised and 67.4% occurred "out of lessons"; 22% sustained fractures or dislocations, 28.2% needed follow up treatment, and 1.4% were admitted. CONCLUSIONS: Injuries to children in school are a cause for concern. Effective preventive measures should concentrate on (a) specific target areas using schemes based on individual school, and (b) establishing a credible system of monitoring of their effectiveness

N2 - Toxocara (the cause of visceral larva migrans in humans) and allergy have in common both elevated immunoglobulin E (IgE) levels and eosinophilia. In the present study, we investigated: 1) associations between Toxocara seropositivity and allergic manifestations; 2) risk factors for Toxocara infection; and 3) differences in Toxocara seroprevalence, allergic manifestations and the associations between these two, in children from urban and rural environments. Blood samples from 1,379 Dutch urban and rural elementary schoolchildren, were examined for Toxocara antibodies, eosinophil numbers, total IgE concentrations, and the occurrence of inhaled allergen-specific IgE. Questionnaires investigating respiratory health and putative risk factors for infection were completed. It was found that 8% of the children had Toxocara antibodies, occurring significantly less often in

females than in males. The means of total serum IgE levels and blood eosinophils were significantly higher in the Toxocara-seropositive than in the seronegative group. Allergic asthma/recurrent bronchitis was found in 7% of the children, allergic reaction on animal contact in 4%, and IgE to at least one inhaled allergen in 16%. These variables were associated with Toxocara seroprevalence. Inhaled allergen-specific IgE and asthma/recurrent bronchitis occurred significantly less often in rural than in urban areas, and significantly less often among girls than among boys. Furthermore, occurrence of allergen-specific IgE increased significantly with age. No association existed between Toxocara seroprevalence and assumed risks, i.e. contact with pet animals and public playgrounds. In conclusion, our results indicate that allergic manifestations occur more often in Toxocara-seropositive children. A relationship with an already existing allergic condition is plausible

N2 - Physical performance of preschool children and elementary school pupils (N = 2309, age: 61 to 108 mo.) was related to characteristics of physical growth and cognitive performance and to ecological variables.

Correlations between measures of physical growth and physical performance and between physical and cognitive performance were positive and significant. Measurements of physical fitness and body coordination increased across ages. Significant differences were found between boys and girls; however, boys exceeded on some items, girls on others. Children of higher socioeconomic status performed better than children of lower status and children who participated in sports outside school outperformed those who did not

N2 - BACKGROUND: The safety of playgrounds is important to protect children from injury, but studies are mostly done mainly under laboratory conditions without epidemiological data. We investigated the safety of different playground surfaces, and types and heights of equipment in public playgrounds in the City of Cardiff,

UK. METHODS: We did a correlational study of 330 children aged between 0 and 14 years. All children were hurt when playing in playgrounds in Cardiff and presented to the Accident and Emergency Department in Cardiff Royal Infirmary during summer (April to September) 1992 and 1993, and the whole of 1994. We studied the children's hospital records to establish the type of injury and interviewed their parents to find out the playground and type of equipment involved. The main outcome measures were the number of children injured whilst playing, and injury rates per observed number of children on different surfaces, types, and heights of equipment. FINDINGS: Children sustained significantly more injuries in playgrounds with concrete surfaces than in those with bark or rubberised surfaces ($p < 0.001$). Playgrounds with rubber surfaces had the lowest rate of injury, with a risk half that of bark and a fifth of that of concrete. Bark surfaces were not significantly more protective against arm fractures than concrete. Most injuries were equipment related. Injury risk due to falls from monkey bars (suspended parallel bars or rings between which children swing) was twice that for climbing-frames and seven times that for swings or slides. The height of the equipment correlated significantly with the number of fractures ($p = 0.005$) from falls. INTERPRETATION: Rubber or bark surfacing is associated with a low rate of injuries and we support their use in all public playgrounds. Bark alone is insufficient, however, to prevent all injuries, particularly arm fractures. Rubberised impact-absorbing surfaces are safer than bark. We believe that playing on monkey bars increases the risk of injury in playgrounds and that they should generally not be installed. Safety standards should be based on physical and epidemiological data. Our data suggest that the proposed raising of the maximum fall height from 2.5 m to 3.0 m in Europe is worrying

N2 - Primary monosymptomatic nocturnal enuresis (PMNE) is often not openly discussed in Asian societies. We report the parental view of PMNE in Singapore, its impact on patients and their families and the traditional beliefs and its influence on subsequent management. A screening questionnaire was used in evaluating 30 children enrolled in a clinical trial on the use of oral Desmopressin for the treatment of PMNE. Primary monosymptomatic nocturnal enuresis was familial in 56.7% of patients. Fifty per cent of them were previously unevaluated. Earlier remedial attempts included bedtime fluid restriction and voiding (100%), incentive measures (43.3%), traditional practices (26.7%), punishment (20%), drugs (16.7%), psychotherapy (100%) and bladder training (3.3%). Perceived causes of PMNE were maturational delay (50%), deep sleep (50%), familial (43.3%), behavioural problems (43.3%) and excessive fluid intake (26.7%). Reasons for seeking treatment included restricted outdoor activities (90%), parental fatigue (86.7%), disrupted sleep for the household (46.7%) and fear of underlying pathology (26.7%). Perceived adverse effects on patients included social stigma (83.3%), disrupted sleep (33.3%) and impaired school performance (13.3%). Primary monosymptomatic nocturnal enuresis can thus be a chronic distressing problem in Asian communities

N2 - Injuries to children 0 to 12 years of age pose a national health problem. Injuries are a particular problem in child care settings. Both research and anecdotal reports confirm that most injuries in the child care setting are cuts, scratches, and abrasions caused by falls indoors and in playgrounds. Other injuries are caused by human bites and motor vehicle pedestrian injuries. Child development centers are an obvious focal point to direct injury prevention services by nurses. The nurse's role in injury prevention is to educate the child care providers about injuries and then teach them the skills to assess and monitor injury prevention strategies. This article discusses the problem of injuries in child care centers in general and discusses injury prevention strategies the nurse can share with the child care provider. Educational resources are included to help the child care providers assess and monitor their own center's injury risk. J Pediatr Health Care. [References: 24]

N2 - Orthodontic services for Finnish children and adolescents up to the age of 18 in 1992 were monitored by a questionnaire sent to all municipal health centres responsible for children's dental care in Finland, and 96% responded. All health centres provided some orthodontic treatment, but the percentage of 0 18-year-old children receiving treatment ranged from 1% to 19%. One-quarter of all dental visits of the 0 18-year-olds were in connection with orthodontics. The timing of treatment was early, the average age for starting was 9.5 years. In statistical analyses, the number of children receiving treatment was associated with the timing of treatment. At the age of 7, the most frequently used appliances were quad helix, removable appliance and orthopaedic headgear and, at the age of 13, fixed appliance and activator. Most treatments were provided by nonspecialists. The specialist expertise needed was usually purchased from an outside orthodontist by means of consultation contracts. Every fifth health centre, usually the largest, had employed one or more specialist orthodontists. The regional distribution of orthodontists was uneven, emphasizing regional variation in the delivery of orthodontic services

N2 - Gender differences in nutrient and food intake were examined in Mexican Nutrition CRSP (Collaborative Research Support Program) infants (N = 75), preschoolers (N = 80), and school children (N = 91). No significant gender differences in dietary quality or quantity were seen for infants and preschoolers. For school children, the contribution of various foods to total energy intake (dietary quality) was also quite similar for girls and boys. Equity in dietary quality remained even under conditions of economic and demographic stress. Nevertheless, school girls consumed significantly less energy per day than boys (-300 kcal/d or 1.3 mJ/d), and less of all micronutrients examined. Gender differences in estimated basal metabolic rates of school children were slight (-20 kcal/d), and body composition and size were similar. When energy intakes were expressed as a percent of estimated requirement (calculated from age, sex and weight using WHO/FAO/UNU equations), intakes were adequate and not significantly different between girls (mean = 111%) and boys (mean = 113%). Playground observations showed girls to be less active than boys, which may reflect both cultural and biological influences. Apparently due to this lower activity, school girls consumed less energy, and may have been at much higher risk than boys of micronutrient deficiency. The lower food intakes of girls did not appear to be due to purposeful dietary discrimination, but rather to culturally patterned sex roles involving lower activity

N2 - **OBJECTIVE:** To determine if a commonly used violence prevention curriculum, Second Step: A Violence Prevention Curriculum, leads to a reduction in aggressive behavior and an increase in prosocial behavior among elementary school students. **DESIGN:** Randomized controlled trial. **SETTING:** Urban and suburban elementary schools in the state of Washington. **PARTICIPANTS:** Six matched pairs of schools with 790 second-grade and third-grade students. The students were 53% male and 79% white. **INTERVENTION:** The curriculum uses 30 specific lessons to teach social skills related to anger management, impulse control, and empathy. **MAIN OUTCOME MEASURES:** Aggressive and prosocial behavior changes were measured 2 weeks and 6 months after participation in the curriculum by parent and teacher reports (Achenbach Child Behavior Checklist and Teacher Report Form, the School Social Behavior Scale, and the Parent-Child Rating Scale) and by observation of a random subsample of 588 students in the classroom and playground/cafeteria settings. **RESULTS:** After adjusting for sex, age, socioeconomic status, race, academic performance, household size, and class size, change scores did not differ significantly between the intervention and control schools for any of the parent-reported or teacher-reported behavior scales. However, the behavior observations did reveal an overall decrease 2 weeks after the curriculum in physical aggression ($P=.03$) and an increase in neutral/prosocial behavior ($P=.04$) in the intervention group compared with the control group. Most effects persisted 6 months later. **CONCLUSIONS:** The Second Step violence prevention curriculum appears to lead to a moderate observed decrease in physically aggressive behavior and an increase in neutral and prosocial behavior in school

N2 - This article examines heat-related illnesses and deaths that occurred in Wisconsin during the summer of 1995, which was among the warmest seasons on record. Death certificates that listed heat exposure as a contributing or underlying cause of 154 deaths and ambulance run reports for 454 heat-related emergency calls were analyzed. The time and place of these events and patient information were used to evaluate risk factors such as age, medical condition, physical activity, and environmental temperature. Three-fourths of the deaths and nearly half of the heat-related illnesses occurred during or shortly after two days of intense heat. Major risk factors for these heat-related illnesses and deaths included age, underlying chronic illness, physical exertion, and lack of air-conditioning. To reduce the number of illnesses and deaths that occur during future heat waves, all residents should be advised to install air-conditioning systems in their homes or apartments and encouraged to use them when indoor temperatures are uncomfortably warm. Summer weather forecasts should include heat index information. During periods of extreme heat, public health advisories should be issued encouraging residents to seek shelter in air-conditioned areas and to avoid strenuous outdoor activities and prolonged sun exposure. Region-specific criteria and procedures for issuing public health advisories should be developed jointly by the National Weather Service and the US Centers for Disease Control and Prevention

N2 - OBJECTIVE: To assess the exposure to violence of a representative sample of children living in an inner-city public housing development. DESIGN: Self-report survey. SETTING: Chicago public housing development that covers 4 census tracts; population, 95% African American, 75% below the poverty level. PARTICIPANTS: One hundred forty-six African American youth, aged 7 through 13 years, completed the survey; 53% were male, mean and median ages, 11 years. Seventy-two children (case subjects) are involved in a community-based health and recreation program. They completed the survey prior to participating in a peer-mentoring violence prevention curriculum. The other 74 children (control subjects) were recruited by a community member going door to door. Control subjects were matched to case subjects for age, sex, and census tract. RESULTS: The case and control subjects were similar in their exposure to violence and so were grouped for analysis. Of the 146 children, 42% had seen someone shot and 37% had seen someone stabbed; 21% lived with someone who had been shot and 16% lived with someone who had been stabbed. Forty-seven percent of the girls and 55% of the boys had witnessed violence ($P > .25$). Almost all subjects (90%) felt safe at home. Two thirds (65%) of the children were not afraid to play outside, but almost half (43%) worried about getting hurt at school. CONCLUSIONS: These data, which describe a representative sample of children from an inner-city housing project, confirm the results from older clinic- and school-based convenience samples. In this low-income community, children are frequently exposed to deadly violence. In contrast with other reports, girls here are not spared

N2 - This study investigated the prevalence of elevated blood lead (PbB) levels in children 1-6 years old in Kaduna, a medium size city in northern Nigeria. Mean PbB was found to be 10.6 micrograms/dl, and 2% of the children had PbB levels greater than 30 micrograms/dl. Highest average PbB levels were found in children 5 years old and was attributed to the tendency for this age group to play longer in contaminated outdoor environments. The strongest associations were found between PbB and whether the family owned a car or lived in a house on a tarred road. Potential sources of lead in the city as well as household and behavior risk factors likely to result in exposure of children to lead are discussed. This study provides additional data pointing to childhood lead poisoning as being a major public health problem in urban areas of Africa

N2 - BACKGROUND: Extensive print, radio, and television coverage about the dangers of sun exposure and benefits of sun protection occurred over the past decade. Illinois teen knowledge and attitudes about sun exposure/protection, sun-exposure/protection behavior, and information sources were determined by a summer telephone survey. METHODS: Telephone interviews with 658 teenagers between ages 11 and 19 included African-American, Asian, Hispanic, Native American, and white teenagers. RESULTS: Teens knew that too much sun was harmful as it caused skin cancer and sunburn. Sunburn was mentioned more often by those with skin types that burned easily and tanned poorly (I,II) ($P < 0.001$), was better known to girls than to boys ($P < 0.001$), and was recognized more by those with higher socioeconomic status ($P < 0.001$) but was not associated with age. Widely held sun exposure attitudes were socializing with friends and feeling better when outdoors. On weekdays, boys averaged 5.3 hr (SD, 1.65 hr) outside compared with 3.9 hr (SD, 0.75 hr) for girls ($P < 0.001$). Teenage boys were more likely to obtain occupational sun exposure, and girls sunbathed. Subjects with skin types I and II reported an average of 3.3 sunburns in the past year. During unprotected sun exposure, extensive numbers of teens with moderate-risk skin type experienced at least 1 sunburn per year. Indoor tanning use was more prevalent among older girls and those with skin types I and II. Sunscreen use was associated with water recreational activities (swimming, water sports, and going to the beach) by girls slightly more than by boys ($P < 0.001$). Hat-wearing was more common among boys than among girls. CONCLUSIONS: Teen knowledge that excessive sun exposure causes skin cancer and sunburns and that wearing sunscreens and hats were sun-protective methods did not enable sun protection that prevented burning. This is particularly troublesome because severe sunburns in youth are associated with an increased risk of melanoma. Existing teen sunscreen use could be broadened by educating teens to use adequate quantities of sunscreen prior to daily sun exposure to prevent painful burns. Messages to teens that emphasize the short-term consequence of painful sunburns because of inadequate protection during outdoor occupational and non-water-related recreational exposure would increase the relevance of the message and may enable behavioral change. Parents and physicians need to be included in messages that are directed to teens and to become part of their education. Parents could ensure an adequate sunscreen supply for daily use by the family, encourage teens not to deliberately tan, and serve as role models for the use of protective clothing

N2 - OBJECTIVES: To examine behavioral differences between children with attention-deficit hyperactivity disorder (ADHD) and tics and their peers and the extent to which methylphenidate (0.1, 0.3, and 0.5 mg/kg) normalized the behavior of probands and indirectly influenced the behavior of peers (treatment spillover).

METHOD: Thirty-four prepubertal children with ADHD and chronic tic disorder (who were participating in a double-blind, placebo-controlled methylphenidate evaluation) and their peers were observed for approximately 20 hours in the school setting (classroom seatwork activities, lunchroom, and playground). RESULTS: Children with ADHD and tics were more inattentive and more disruptive in the classroom and more aggressive in all school settings than their peers. Although treatment with methylphenidate made probands less easily distinguished from their peers (normalization), many children still scored in the deviant range for at least one ADHD behavior when receiving the 0.5-mg/kg dose. There was little evidence that peer behavior improved as a function of the proband's dose of medication. CONCLUSIONS: Although conventional doses of methylphenidate produced dramatic clinical improvement in ADHD-related behavior, complete behavioral normalization is often not attained

N2 - Work-related low back pain and cervicobrachial disorders have become increasingly common among nursing personnel with the increase in the number of social welfare institutions and workers. The aim of this study is to assess the burden on the low backs of personnel caring for children. We measured work content, working time, posture and muscular activity in 16 nursery workers in three different types of institutions for healthy and handicapped children. The working time and posture of 7 nursery teachers in a public nursery school for healthy children (A school), 7 nursing workers (4 nursery teachers and 3 nursery instructors) in a public daycare center for mentally and physically handicapped children (B center), and 2 nursery instructors in a private home for severely handicapped children (C home) were analyzed. The muscular activity of the erector spinae muscle of three subjects was measured using a newly developed EMG monitor (portable EMG monitor, PEMM). The following results were obtained. The average length of a lesson or activity in A school was greater than that in B center and C home. The time required by care for meals was longest in C home. The arrangement and rearrangement times were longest in the classes of children aged 3-5 in A school. The time occupied for clerical work and other work was relatively longer, while recess including lunch time was approximately one hour. The most commonly observed posture was sitting on the floor in all kinds of classes, with this occurring most often in C home. Hazardous postures such as bending forward, squatting, and kneeling appeared in 11-

18% (48-81 min) of a day's working time. The average muscular activity of the erector spinae muscle of three subjects throughout a day was approximately 10% of the maximum isometric contraction (% maximum work load, %MWL), when muscular activities were measured by PEMM. The relatively high %MWL values (19-27%MWL) were obtained at a slightly bending posture and a kneeling posture, while lower (1-9%MWL) values were observed at a sitting posture. The %MWL values at a sitting posture varied according to such conditions as duration of sitting, back rest, weight on the arms, twisting of the trunk, and hip movement. The risky nature of the sitting posture are also discussed

N2 - Childhood injuries are a major source of morbidity and mortality in industrialized countries, and many injuries occur on playgrounds. Our purpose was to examine childhood playground injuries in a metropolitan center in Canada. All children injured on playground equipment who were seen in the emergency department (ED) at The Hospital for Sick Children between March 1990 and July 1991 and were entered in the Children's

Hospital Injury Research and Prevention Project (CHIRPP) database were included. The type, body part, and mechanism of injury were determined as well as the type of equipment, location, and surface. Among the 289 children injured on playground equipment, the mean age was 5.9 years with 39% < 5 years (range: 1 to 18 years). The most common injuries included fractures (28%), lacerations (24%), and hematomas (14%). The head and neck were injured 43% of the time, the upper extremity 41%, lower extremity 10%, and the trunk 6%. Climbing apparatus injuries occurred in 29% of children < 5 years compared with 47% of those injured who were > or = 5 years ($P = 0.002$). Injuries related to slides occurred in 40% of children < 5 years compared to 26% of children > or = 5 years ($P = 0.033$). Of children < 5 years, 58% had head and neck injuries compared to 32% of children > or = 5 years ($P = 0.0006$). Of children < 5 years, 28% had upper extremity injuries compared to 49% of children > or = 5 years ($P = 0.0005$). There were no fatalities and the overall hospitalization rate was 18%. Of those children hospitalized, 77% had fractures, compared to 16% of those not hospitalized ($P = 0.00001$). Of all children hospitalized, 62% were injured on climbing apparatus, compared to 37% of those not hospitalized ($P = 0.0004$). There were no significant differences between nonprotective and natural protective surfaces with respect to hospitalization. We conclude that: 1) upper extremity injuries, especially fractures, accounted for the majority of hospitalizations resulting from injuries on playground equipment; 2) climbing apparatus-related injuries accounted for nearly two thirds of hospitalizations; 3) older children sustained more injuries on climbing apparatus, where younger children sustained more injuries on slides; and 4) younger children sustained more head injuries on playground equipment than older children, but most of these were minor

N2 - BACKGROUND: The amount of time children spend in play spaces (ie, physical locations that are appropriate for children's physical activity) near their homes is correlated with their level of physical activity. OBJECTIVE: To examine factors used in parents' decisions about the selection of play spaces for their children. SUBJECTS: Parents (primarily mothers) of 178 Mexican American and 122 white children who were a mean age of 4.9 years old at the first measurement. MEASURES: In individual interviews, parents rated 24 factors on their importance in selecting for their children a play space that is away from their home or yard. Decision factors were rated from 1 (ie, not important at all) to 5 (ie, very important). RESULTS: The most important factors, with ratings ranging from 4.8 to 4.2, were safety and availability of toilets, drinking water, lighting, and shade. Mexican American parents rated 8 of 24 items significantly higher than did white parents, including lighted at night, organized activities, play supplies, and drinking water. White parents rated 5 of 24 items significantly higher than did Mexican American parents, including distance from home, cost of admission, and child's friends go there. The rated importance of 7 of 24 items increased during 1 year, including play supplies, drinking water, distance from home, and parents' friends or relatives go there. CONCLUSIONS: These results indicate that parents can identify factors they use in selecting places for their young children to play, and selection factors differ somewhat by ethnicity or socioeconomic status. Further studies are needed to determine whether improvements on the most important selection factors might be effective in increasing the use of play spaces by children and their parents. Clinicians may be able to use the most highly rated decision factors to help parents assess the acceptability of play spaces in their areas

N2 - An ozone exposure assessment study was conducted in a Southern California community. The Harvard ozone passive sampler was used to monitor cohorts of 22 and 18 subjects for 8 weeks during the spring and fall of 1994, respectively. Ozone exposure variables included 12-hr personal O₃ measurements, stationary outdoor O₃ measurements from a continuous UV photometer and from 12-hr Harvard active monitors, and time-activity information. Results showed that personal O₃ exposure levels averaged one-fourth of outdoor stationary O₃ levels, attributable to high percentages of time spent indoors. Personal O₃ levels were not predicted well by outdoor measurements. A random-effect general linear model analysis indicated that variance in personal exposure measurements was largely accounted for by random error (59-82%), followed by inter-subject (9-18%) and between-day (9-23%) random effects. The microenvironmental model performs differently by season, with the regression model for spring cohorts exhibiting two times the R² of the fall cohorts (R² = 0.21 vs. 0.09). When distance from the stationary monitoring site, elevation, and traffic are taken into account in the microenvironmental models, the adjusted R² increased almost twofold for the fall personal exposure data. The low predictive power is due primarily to the apparent spatial variation of outdoor O₃ and errors in O₃ measurements and in time-activity records (particularly in recording the use of air conditioning). This study highlights the magnitude of O₃ exposure misclassification in epidemiological settings and proposes an approach to reduce exposure uncertainties in assessing air pollution health effects

N2 - Medical conditions may be exacerbated by environmental stresses or may limit tolerance to them. To advise patients who are planning foreign or wilderness travel of potential health risks, medical providers must first understand the interactions between physiologic demands from environmental factors and from exercise, and the patient's medical problems. This article considers medical limitations owing to specific environmental stresses and limitations imposed by specific medical problems. The challenge is to match the prospective participant with the proposed activity to minimize the risk of failure caused by medical problems. [References: 73]

N2 - We retrospectively reviewed the clinical and radiographic results of total hip arthroplasty with cement in patients with juvenile rheumatoid arthritis who were less than thirty years old at the time of the index procedure. Thirty-nine patients (sixty-six hips) were managed with this procedure at our institution between 1971 and 1983. Six patients (eleven hips) died before a minimum of ten years of follow-up; the remaining thirty-three patients (fifty-five hips) were followed for at least eleven years. Twenty-eight patients (forty-six hips) had at least one original component in situ after an average duration of clinical follow-up of 15.1 years, and twenty-three of these patients (thirty-eight hips) were followed radiographically for an average of 14.7 years. At the time of the latest follow-up examination, all twenty-eight patients were able to walk outside the home; twenty of these patients (thirty-five hips; 76 per cent) had no pain with activity, and eight patients (eleven hips; 24 per cent) had mild-to-moderate pain with activity. Over-all, twelve (18 per cent) of the sixty-six femoral components and twenty-three (35 per cent) of the sixty-six acetabular components were revised after an average of 12.8 and 11.8 years, respectively. The fifteen-year survival rate for the femoral components was 85 per cent with revision or radiographic loosening as the end point. The fifteen-year survival rate for the acetabular components was 70 per cent with revision as the end point and 61 per cent with revision or radiographic loosening as the end point. The benefits of total hip arthroplasty were maintained over the long term in most of our patients who had juvenile rheumatoid arthritis. However, the durability of the components in these young patients remains a concern

N2 - OBJECTIVE: To assess the effectiveness of a new multidisciplinary method for reconstructing the causal sequences that lead to child pedestrian injuries. **SETTING:** Subjects were 5-12 year old residents of Chicago, Illinois, USA, presenting for care due to pedestrian injury at one pediatric trauma center. **METHODS:** The interactions of medical, child, psychosocial, and traffic factors contributing to the injury were analysed. For 142 cases, information about the victim, his/her family, the injury site, and the activities just before the injury, was used in a structured manner by a multidisciplinary team to produce injury scenarios. Each scenario comprised a list of contributing factors, an estimate of the importance of each, and a narrative description of the causal sequence leading to the injury event. Face validity was assessed by two outside teams that performed a structured review of a subsample of cases (n = 11). Reliability was evaluated by comparison of the results of parallel teams assessing the same cases (n = 14). Process consistency and bias were assessed by analysis of the correlations of factor-importance rating patterns between members and over time. **RESULTS:** The outside team's agreement scores were based on a 1-5 Likert scale; these showed a mean of 3.6 and median of 4.0. Parallel teams consistently showed agreement greater than 85% on global attributes of cases. Intraclass correlation coefficient scores showed fair or better agreement for all classes of contributors, and excellent agreement for more than one third. Rating pattern analyses showed strong agreement by team members. Agreement did not increase over the period of the study. **CONCLUSIONS:** This causal sequence reconstruction method has acceptable face validity, reliability, and internal consistency. Although labor intensive and thus costly, it can produce unique, rich information for understanding injury causation and for guiding the search for promising interventions

N2 - OBJECTIVES: The purpose of this study was to determine adherence to selected recommended safety standards in North Carolina child care centers. METHODS: A self administered questionnaire eliciting information about safety practices in child care was mailed to a randomly selected sample of 409 North Carolina child care centers. RESULTS: One hundred and ninety five usable questionnaires were returned from child care centers in 75 counties. Results indicated that all of the standards included in the state's child regulations were being adhered to by at least 80% of the centers. However, adherence to recommended standards not included in the state's regulations was quite variable, with one standard implemented by less than 5% of the centers. The lowest rates of adherence were found for standards specifying that resilient surface material be used under playground equipment (4%) and that certain foods that may present a choking hazard to small children not be served (27%). CONCLUSIONS: Many hazards not addressed in North Carolina child care regulations are present in child care centers. Some safety standards are not adhered to due to lack of knowledge or limited resources. Inclusion of national standards in state child care regulations appears to reduce, but not eliminate, the likelihood of hazards being reported. Further research should include on-site inspections and attention to safety in family child care

N2 - OBJECTIVES: To prospectively determine the incidence rate of injuries that required medical attention among children in day care and to identify possible hazards related to these injuries. SETTING: King County, Washington. METHODS: Prospective cohort study of children in a sample of licensed day care facilities. RESULTS: From 1 July 1992 to 30 June 1993, 53 medically attended injuries were reported by 133 day care sites; incidence rate 1.9 per 100,000 hours of day care attendance. The rate of injury in 91 small family day care homes was essentially the same as that in 42 larger day care centers; relative rate 1.0 (95% confidence interval 0.6 to 1.9). Injuries that required sutures accounted for 39% of the cases, while 17% required a cast, splint, or sling. No child was hospitalized. Sixty nine sites were inspected and all had potentially correctable physical hazards, with a median of 15 hazards per site (range 7 to 26). These potential hazards had little relationship to the risk of injury and a case-by-case review identified only two injuries that might have been prevented by a more energy absorbent playground surface. CONCLUSIONS: The incidence of medically attended injuries found in this study is consistent with other studies from the United States. Most injuries were minor and had little relation to physical hazards at day care locations

N2 - OBJECTIVES: Despite the widespread promotion of safety standards no epidemiological studies have adequately evaluated their effectiveness in preventing injury in falls from playground equipment. This study evaluated the effectiveness of the height and surfacing requirements of the New Zealand standard for playgrounds and playground equipment. SETTING: Early childhood education centres and schools in two major cities in the South Island of New Zealand. METHODS: Data were collected on 300 children aged 14 years or less who had fallen from playground equipment. Of these, 110 (cases) had sustained injury and received medical attention, while 190 (controls) had not sustained injury requiring medical attention. RESULTS: Logistic regression models fitted to the data indicated that the risk of injury being sustained in a fall was increased if the equipment failed to comply with the maximum fall height (odds ratio (OR) = 3.0; 95% confidence interval (CI) 0.7 to 13.1), surfacing (OR = 2.3; 95% CI 1.0 to 5.0), or safe fall height (OR = 2.1; 95% CI 1.1 to 4.0) requirements. Falls from heights in excess of 1.5 metres increased the risk of injury 4.1 times that of falls from 1.5 metres or less and it was estimated that a 45% reduction in children attending emergency departments could be achieved if the maximum fall height was lowered to 1.5 metres. CONCLUSIONS: Although the height and surfacing requirements of the New Zealand standard are effective in preventing injury in falls from playground equipment, consideration should be given to lowering the maximum permissible fall height to 1.5 metres

N2 - PURPOSE: The purpose of this study was to determine how injury prevention awareness of children ages 3, 4, and 5, based on recognition of hazards in pictures differs in the United States, Belgium, East Germany and West Germany. METHODS: Children from these four countries were presented with 10 different pictures. Each picture represented a common injury producing situation to which children are exposed in traffic, home, and recreation. RESULTS: Results indicate that for pictures relating to home hazards, less than 22% of children from Belgium (21.5%), West Germany (4.7%), and the United States (20.3%) clearly recognized the essential hazards in the pictures, whereas over 40% of the East German children clearly recognized these dangers. A higher proportion of the children from all countries recognized the traffic hazards. Only 23.9% of all children had a clear recognition of the playground situations. The child's age had a bearing on ability to recognize hazards overall. CONCLUSIONS: Children need to be provided with better injury prevention education at an early age, especially those from West Germany

N2 - UNLABELLED: CENTERS: The growth in liver transplantation activity recorded by the Pitt-UNOS Liver Transplant Registry since October 1987 continued. However, for the first time since the establishment of the LTR, there was no net gain in the number of centers in 1995. The large differences in volume per center also diminished. PATIENTS: The age of pediatric recipients increased significantly in 1995, due to a decrease in the proportion of recipients under age one. For the first time, in 1995 fewer than half of transplantations in children were for biliary atresia. The addition of bone marrow transplantations, for which collection began in 1994, accounted for half of the multi-organ transplantations in 1995. Many of the characteristics examined for adult recipients changed between 1994 and 1995. The proportion of Hispanic recipients increased. The mean age of adult recipients continued to increase, but there was not a significant change in the prevalence of positive CMV serology. Reversing a trend, the proportion of adult recipients awaiting transplantation outside of the hospital decreased between 1994 and 1995. As with children, the proportion of adult multi-organ transplantations which included bone marrow increased. Hepatitis non-A, non-B, or C and alcoholic liver disease (ALD) were the most common reasons for LTX in 1995. While the proportion of recipients with ALD alone decreased slightly, the proportion with ALD and hepatitis C increased from 1994 to 1995. OUTCOME: The cumulative probability of surviving (without retransplantation) for 8 years after initial transplantation was .71 (.60) for pediatric recipients. The one-year survival for pediatric recipients changed significantly over time with the increase from 1994 to 1995 being similar to the increase between 1994 and prior years. Independent risk factors for survival among children included age, race, location awaiting transplantation, primary liver disease, and serum creatinine. Year of transplantation and bilirubin were independently associated with retransplantation-free survival, whereas multi-organ transplantation was associated with poorer patient survival. The cumulative probability of adults surviving (without retransplantation) for 7 years following LTX was .58 (.50). Independent risk factors were year of transplantation, age, location awaiting transplantation, primary liver disease, albumin, creatinine, and ABO match. Black recipients had poorer patient survival rates than other recipients whereas increased prothrombin time and CMV-positive donors were risk factors for retransplantation or death

N2 - The Burn Unit of Dona Estefania Hospital admitted a total of 454 patients from January 1992 to January 1995, 24 of these patients suffered from electric shock. Of these 24 patients 3 suffered burns in the mouth, 15 in one or both hands and 6 multiple burns. In 19 patients the burns were up to 1%. A description is made of 5 cases, male children between the ages of 9 and 13 years, which were deemed severe. The incidents occurred outdoors with different voltages and in activities considered of ludic or experimental nature: two on the roof of a house, two with railway cables and one with an electrical cable in a port zone. The burnt areas vary between 4% and 70%, all of them 2nd and 3rd degree, with hospitalization lasting from 36 to 116 days. In addition to early and coordinated medical and rehabilitative treatment, according to individual needs, a description is also made of the cutaneous sequelae (deforming cicatrices, bridles), neurologic and psychologic sequelae, with emphasis on a patient who underwent amputation of the lower left leg and 4th and 5th ranges of the right foot. It was concluded that measures should be taken in education and legislation to prevent these accidents. Relevance is given to the need for a multidisciplinary team and specialized center for the treatment of these patients

N2 - OBJECTIVES: To evaluate the pattern of fractures in children in the south eastern region of Nigeria, seeking to highlight the planning and designs of buildings, roads and playgrounds to prevent paediatric fractures. DESIGN: Retrospective review of paediatric patients with fractures who presented at the only tertiary referral centre in the region. SETTING: A university teaching hospital situated in the south eastern corner of Nigeria. SUBJECTS: 102 paediatric patients treated for fractures between January 1993 and December 1995. MAIN OUTCOME MEASURES: Causes of fractures and their anatomical distribution. RESULTS: 71 boys and 31 girls were treated for fractures. The commonest cause of fractures was road traffic accidents accounting for 50% of the patients, followed by falls and collapsing mud walls. Most of the fractures seen (58 patients) were of the green stick type. The femur was the commonly fractured bone (25 patients) followed by the radius (22 patients) and humerus (20 patients). Road traffic accident victims presented earlier at the hospital than victims of other causes. Also lower limb fracture patients presented earlier than patients with upper limb fractures. CONCLUSION: Paediatric fractures are amenable to conventional conservative therapy and open reduction became necessary in long neglected cases with associated malunion. Since the causes of fractures are largely preventable, public enlightenment campaigns, provision of pedestrian pathways, care on the part of school authorities and proper structural construction of the traditional houses may help reduce the number of cases of fracture in our environment

N2 - The assessment of health risk due to environmental contaminants depends upon accurate estimates of the distribution of population exposures. Exposure assessment, in turn, requires information on the time people spend in micro-environments and their activities during periods of exposure. This paper describes preliminary results including study methodology and population sampled in a large Canadian survey of time-activity patterns. A 24-hour diary recall survey was performed in 2381 households (representing a 65% response rate) to describe in detail the timing, location and activity pattern of one household member (the adult or child with the next birthday). Four cities (Toronto, Vancouver, Edmonton and Saint John, NB) and their suburbs were sampled by random-digit dialling over a nine-month period in 1994/1995. Supplemental questionnaires inquiring about sociodemographic information, house and household characteristics and potential exposure to toxins in the air and water were also administered. In general, the results show that respondents spend the majority of their time indoors (88.6%) with smaller proportions of time outdoors (6.1%) and in vehicles (5.3%). Children under the age of 12 spend more time both indoors and outdoors and less time in transit than do adults. The data from this study will be used to define more accurately the exposure of Canadians to a variety of toxins in exposure assessment models and to improve upon the accuracy of risk assessment for a variety of acute and chronic health effects known or suspected to be related to environmental exposures

N2 - We studied 269 school children from three Southern California communities of contrasting air quality in two successive school years, to investigate short-term effects of ambient ozone (O₃), nitrogen dioxide (NO₂), or particulate matter (PM) on respiratory health. We measured lung function and symptoms twice daily for one week each in fall, winter and spring; and concurrently assessed time-activity patterns and personal exposures. Average daily personal exposures correlated with pollutant concentrations at central sites ($r = 0.61$ for O₃, 0.63 for NO₂, 0.48 for PM). Questionnaire-reported outdoor activity increased slightly in communities/seasons with higher pollution. Lung function differences between communities were explainable by age differences. Morning forced vital capacity (FVC) decreased significantly with increase in PM or NO₂ measured over the preceding 24 hours. Morning-to-afternoon change of forced expired volume in one second (FEV₁) became significantly more negative with increase in PM, NO₂, or O₃ on the same day. Predicted FVC or FEV₁ loss on highest- vs lowest-pollution days was < 2%. Daily symptoms showed no association with current or prior 24-hour pollution, but increased with decreasing temperature. Parents' questionnaire responses suggested excess asthma and allergy in

children from one polluted community while children in the other polluted community reported more symptoms, relative to the cleaner community. We conclude that Los Angeles area children may experience slight lung function changes in association with day-to-day air quality changes, reasonably similar to responses seen by others in less polluted areas. Although short-term pollution effects appear small, they should be assessed in longitudinal lung function studies when possible, to allow maximally accurate measurement of longer-term function changes

N2 - This report uses data from the Kingston and Region Injury Surveillance Program (KRISP), a subset of the Canadian Hospitals Injury Reporting and Prevention Program (CHIRPP), to describe rates and identify patterns of injury among children aged 0-19 years in Kingston and area. During 1994, there were 7572 reported injury events, resulting in an overall rate of 173.6 injuries per 1000 children per year (males: 202 per 1000; females: 143.7 per 1000). Four major patterns of injury were identified as priorities for intervention: 1) household injuries among children aged 0-4 years; 2) injuries occurring on playgrounds to children aged 5-14 years; 3) sports injuries among 10-19-year-old children and youth; and 4) bicycle-related injuries among children 5-14

years of age. Discussion focuses on the use of the surveillance system in prioritizing interventions and evaluating injury prevention programs for this population

N2 - Vertical infection with human immunodeficiency virus-1 (HIV-1) causes profound changes in the proportions of subpopulations of lymphocytes in the peripheral circulation. In this study the percentages in whole blood of CD4 and CD8 cells, and of immunologically important subpopulations, were measured in 19 HIV-infected children over periods of up to 4 years and compared to our recently published ranges for normal children of various ages. The rate of CD4 decline and of CD8 increase differed between clinically fast and slow

progressors. On CD8 cells, cytotoxic, memory (CD11abright and CD45R0), and activation (HLA-DR) markers were raised soon after birth to levels outside the normal range, and compared favorably with HIV culture as a method for early diagnosis of HIV infection. Mean levels of naive (CD45RA) and memory (CD45R0, CD29) markers on CD4 cells became significantly altered after 48 months of age, suggesting that these are markers of more advanced disease. Despite different ages of enrollment into the study, in the cohort as a whole, the levels of the lymphocyte subpopulations studied changed consistently. Thus, their measurement could be useful both in the diagnosis and prognosis of HIV infection in individual children. This is the first report showing that lymphocyte subpopulation analysis can play a major role in the diagnosis of pediatric HIV infection

N2 - SETTING: Passive smoking-related respiratory disorders in children. OBJECTIVES: To assess the effect of passive smoking on the development of active pulmonary tuberculosis (PTB) in children immediately following infection by Mycobacterium tuberculosis within the family. DESIGN: An unmatched case-control study in which 93 contacts who became cases (active PTB diagnosed) and 95 contacts who did not become cases (tuberculin-positive children without evidence of active disease) were included. All were household contacts of a new case of pulmonary bacillary tuberculosis. Smoking habits were investigated by a questionnaire. Urinary cotinine was analysed. Odds Ratio (OR) was adjusted for age and socio-economic status using multiple logistic regression analysis. RESULTS: Passive smoking was a risk factor for PTB (OR: 5.29; 95% confidence interval (CI): 2.33-12.82; $P < 0.00005$). The adjusted OR was 5.39 (95% CI: 2.44-11.91; $P < 0.00001$). The risk increased when contacts were passive smokers both at home and outside the home within the family (OR: 6.35; 95% CI: 3.20, 12.72; $P < 0.00001$). Contacts 0-4 and 5-9 years old showed a significantly higher risk than those aged $> \text{ or } = 10$. There was a dose-response relationship between the risk of developing active PTB immediately following infection and the number of cigarettes smoked daily by the household adults ($P < 0.001$). Mean (SD) urinary cotinine detectable concentrations (ng/ml) were different between disease contacts (119.46 [68.61]) and non diseased contacts (91.87 [73.10]). The difference was statistically significant ($P < 0.001$). CONCLUSIONS: Passive exposure to tobacco smoke in children was associated with an increased risk of developing pulmonary tuberculosis immediately following infection. This is an association of great concern requiring health education programmes and antitobacco medical advice

N2 - The aim of this analysis is to evaluate the gonadal function in children with true undescended testes and in those with retractile testes, in order to verify a possible impairment of the testicular steroidogenesis due to the permanent or transitory anomalous position of the gonad outside the scrotum. The authors carried out a prospective study on 29 prepubertal children affected by true undescended testes (monolateral in 20 cases and bilateral in 9), as well as on 25 prepubertal children with retractile testes (monolateral in 10 cases and bilateral in 15), assaying the testosterone (T) levels, basal and 72 hours after stimulus with human chorionic gonadotrophin (HCG) administered in a single dose of 100 U/kg i.m. Further-more, to verify the hypothesis of a possible progressive reduction of the Leydig cells function, particularly in the gonads bilaterally affected, the authors also evaluated the testosterone response to gonadotrophic stimulus compared to age ($> 0 < 4$ years). This study in agreement with data already published, confirms the normality of gonadal function both in children with mono or bilateral true undescended testes and in those with retractile testes. The lower the age of the subject the higher is the peak of testosterone after stimulus, confirming the active steroidogenesis of the gonads in infants and small children and sustaining the "non quiescence" of this organ during infancy, even in cases of true undescended testes

N2 - This review summarizes studies comparing the epidemiology of asthma, allergic rhinitis, and atopic dermatitis in eastern versus western German populations. These studies clearly revealed that the prevalence of physician-diagnosed allergic rhinitis was higher in western Germany than in eastern Germany. The rate for asthma also tended to be higher in western than in eastern populations, whereas a tendency for less atopic dermatitis was found in western German children. When sensitization rates, as measured by RAST and skin-prick tests, were compared, a clear increase was found in western versus eastern young-adult German populations. This phenomenon may be related to exposure to different allergens, such as those associated with nutritional patterns or pet ownership, as well as to different environmental factors, such as outdoor and indoor pollutants. If lifestyle or environmental factors play a role in developing allergic sensitization, then one would expect the rates of sensitization in eastern and western Germany to converge as the two societies become more similar. N2 - Over a period extending from 1984 to 1993, 16 children ranging in ages from 2 months to 12 years with posterior fossa ependymoma were treated. Four of these tumors were classified as lateral ependymomas because of their configuration and suspected site of origin. These 4 patients' ages ranged from 2 months to 5 years. Signs and symptoms of increased intracranial pressure and cranial nerve dysfunction were the hallmark of their presentation. Their imaging evaluation included a preoperative and postoperative CT scan and/or MRI. A gross total surgical resection' was completed in the 4 children. At least a 1-year follow-up was available for all the patients. Intraoperative brain stem evoked potentials and facial and glossopharyngeal nerve monitoring were used in all the surgeries. Three children required a ventriculoperitoneal shunt postoperatively. Chemotherapy was used postoperatively in 3 children. The 4th child did not receive chemotherapy due to parental refusal and succumbed to a recurrence 1 years postoperatively. Radiation therapy was given to 2 children. Tumor recurrences developed in all children at 12 months, 18 months, 3 years and 4 years postoperatively in proximity to the original tumor site. Histologic sections in 3 patients, including those at the time of recurrence, were consistent with a low mitotic index. Only 1 child's histologic diagnosis was consistent with a high-grade ependymoma. The lower cranial nerve dysfunction transiently worsened in all the patients and was permanent in 2. The child's age, tumor histology and extent of resection play an important role in the prognosis of posterior fossa ependymoma. The lateral posterior fossa ependymoma has a particularly poor prognosis due to its location and its significant postoperative morbidity. The authors propose a combined midline and lateral suboccipital approach in order to expose the fourth ventricular floor, upper cervical spine, lateral recess, cerebellomedullary fissure, cerebellopontine and the cerebellomedullary cistern in an attempt at a "total' resection with a focus on the site of origin. The usage of neurophysiological monitoring appears to be useful in limiting and predicting the extent of postoperative complications. However, prolonged morbidity is likely and is commonly related to lower cranial nerve deficits. The author proposes a proactive approach in order to limit the sequelae of these complications

N2 - Unintentional injuries sustained on school playgrounds are a continual problem not only for children but also for the school nurses who are concerned with their safety. A group of school nurses organized by the local health department's pediatric nurse practitioner responded proactively to this problem by enlisting both school officials and students to accept joint responsibility for a safe play environment. The school nurses assisted the staff in providing a safe play environment and encouraged the students to behave in a safe and acceptable manner on the playground. The nurses developed (a) a Playground Safety Assessment Guide for the school staff to establish and maintain a safe play environment, (b) an in-service session for playground monitors to learn how to supervise children at recess, and (c) a student-oriented program for the children to improve behavior on the playground based on a program conceived by Utah State University (Daug & Fukui, 1988). School nurses and pediatric nurse practitioners can use this program as a model for other schools to improve the physical play environment and behavior of the children at recess

N2 - Elevated concentrations of polycyclic aromatic hydrocarbons (PAK) are often found in the soil of former waste disposal sites, industrial areas, etc. It is desirable and useful to determine orientation values to facilitate and unify the evaluation of contaminations under the aspects of present or planned uses of an area, health protection and decision-making on remedial measures. In the present paper we wish to draw attention to, and discuss problems resulting from, particular characteristics of PAK, e.g. the toxicological property "complete carcinogens" or the necessity of taking into account oral, inhalative and dermal exposure of children on a playground. Based on the discussion, orientation values for benzo[a]pyrene and PAK ("normal" pattern) of 0.5 mg/kg soil and 5 mg/kg soil, respectively, are recommended for top soil of vegetation-free playgrounds. In comparison, deductions carried out by other working groups are presented

N2 - The prevalence and level of sensitivity to indoor allergens were studied in relation to current exposure at home in 124 children with perennial asthma living in three climatic zones of Sweden. The house dust mite (HDM) allergen levels were higher in the South than in the North ($p < 0.001$), while cat and dog allergen levels tended to be higher in the North than the South (n.s.). Thirty-four percent of the children were sensitive to the HDM *Dermatophagoides pteronyssinus*, as determined by IgE antibodies in vitro, 27% were sensitive to *D. farinae*, 57% to cat and 55% to dog. Sensitivity to HDM was significantly more prevalent in Southern, than in Central and Northern Sweden ($p = 0.001$) where the children were more often sensitive to pets (cat $p = 0.005$, dog $p = 0.002$). A significant association between the concentration of Der p I and Der fI in the house dust and both the prevalence of sensitivity to HDM and the IgE antibody levels against mites was found even at concentrations well below the commonly suggested risk level for sensitisation of 2 micrograms/g dust. No relationship was found between pet allergen concentration in the home dust and sensitivity to pets, possibly because of exposure outside home, e.g. in schools and meeting places for leisure activities. Similarly, there was no consistent association between the level of mite or pet allergen exposure at home and asthma severity as judged by symptom and medication score. The study indicates that there is no threshold value for sensitisation to mite allergens in asthmatic children, and therefore, dust allergen levels at home should be kept as low as possible in homes of children at risk for asthma

N2 - To provide optimal management for the child with community-acquired pneumonia, the clinician must take multiple factors into consideration. The etiology of pneumonia is difficult to determine and initial choice of therapy is based on the frequency of pathogens in various age groups, local antibiotic resistance patterns of the organisms, clinical presentation, and epidemiological data. *Streptococcus pneumoniae* and *Haemophilus influenzae* remain the most common bacterial pathogens outside the newborn period. Increasing numbers of multidrug-resistant strains of *S pneumoniae* in the United States and Europe, the decline in *H influenzae* type b because of current vaccination strategies, and increasing recognition of nontypeable *H influenzae* as etiologic agents of pneumonia have prompted reconsideration of the drug of choice. Amoxicillin and its derivatives or oral cephalosporins are the drugs of choice for initial therapy for mild to moderate disease. For severe disease or if beta-lactamase producing organisms are a concern, extended spectrum cephalosporins are indicated.

Pneumococcal pneumonia unresponsive to penicillin therapy may warrant the use of extended spectrum cephalosporins or vancomycin. For older children in whom mycoplasma is a significant cause of pneumonia, the new macrolides have provided additional options for the clinician. Azithromycin and clarithromycin are efficacious, well tolerated, and require less frequent dosing intervals. The introduction of ceftriaxone, a third-generation cephalosporin with a broad spectrum of activity and prolonged half-life, allows once-a-day intramuscular therapy that can be administered on an outpatient basis. With the availability of parenteral outpatient therapy, hospital admission is no longer required for the treatment of most cases of serious community-acquired pneumonia

N2 - The aim of the present study was to replicate earlier findings of beneficial effects of ORG 2766, an ACTH-(4-9) analog, in autistic children. Fifty children with autism, 7-15 years old and with a Performance IQ of more than 60, participated in a double-blind placebo controlled parallel trial. Active treatment was 40 mg ORG 2766 for 6 weeks. The outcome was assessed on the basis of the Aberrant Behavior Checklist completed by parents and teachers, and by means of a detailed behavioral observation (30 subjects). ORG 2766 failed to improve social and communicative behavior at a group level. The rate of individual response, defined as a reliable change in social withdrawal at home and at school, to ORG 2766 (10 out of 30) and placebo (4 out of 20) was not significant either. The children who responded to ORG 2766, but not those who responded to placebo, manifested significant improvements outside the changes in the defining variables, including a decrease in hyperactivity at school. The responders to ORG 2766 were characterized mainly by a relatively lower PIQ; further by more initial hyperactivity, stereotypies and abnormal speech, and less initial eye contact. The responders to placebo could not be differentiated from the non-responders to placebo. Future studies should examine whether ORG 2766 differentially affects various subtypes of autism

N2 - **PURPOSE:** To study fixation patterns and reading rates in eyes with central scotomas from geographic atrophy (GA) of age-related macular degeneration and to compare fixation patterns with those of patients with Stargardt disease. **METHODS:** Scanning laser ophthalmoscope analysis of fixation patterns in eyes with 20/80 to 20/200 visual acuity. Included were 41 eyes of 35 patients with GA and 10 eyes of 5 patients with Stargardt disease. The patients with GA also were tested for maximum reading rate, and the size of the areas of atrophy were measured by fundus photograph analysis. **RESULTS:** Sixty-three percent of GA eyes fixating outside the atrophy placed the scotoma to the right of fixation in visual field space, 22% placed the scotoma above fixation, and 15% placed it to the left, regardless of the laterality of the GA eye. Fixation was stable in subsequent years of testing for scotoma placement to the right of or above fixation. All GA eyes fixated immediately adjacent to the atrophy. In contrast, seven of ten eyes with Stargardt disease fixated at a considerable distance from the scotoma border, with the dense scotoma far above the fixation site in visual field space. For the patients with GA, the maximum reading rate was highly correlated with size of the atrophic area, but not with age or visual acuity within the limited visual acuity range tested. There was a trend to more rapid reading with the scotoma above fixation and slower reading with the scotoma to the left. **CONCLUSION:** There is a preference for fixation with the scotoma to the right in eyes with GA. Patients with Stargardt disease use different strategies for fixation, perhaps due to subclinical pathology adjacent to the atrophic regions. The size of the atrophic area in GA plays the predominant role in reading rate for eyes that have already lost foveal vision

N2 - Risk factors for Lyme disease and/or infection with *Borrelia burgdorferi* in children are not defined. A case-control study was performed using Lyme disease patients from our Lyme Clinic population. Age- and sex-matched controls from the same neighborhood were identified by the Lyme patients' families. A site visit was made to each case/control neighborhood. Twenty-four environmental variables, especially the ecologic characteristics of the home environment were examined. Forty-five items were surveyed by parent questionnaire, including certain "high-risk" activities and behaviors, whether ticks or certain animals were present on the property, and whether antitick measures were used. Control subjects had serologic assays for antibodies to *B. burgdorferi*. Forty-four Lyme disease patients and 44 well-matched control subjects participated; 2 controls were seropositive. Significant associations with Lyme disease were found for deer ticks in the home environment, ground cover containing moist humus, and leaf litter in the yard. Among the 45 items

related to life-style, there was no correlation with Lyme disease for the use of any antitick measures or for any childhood activities; in fact, an inverse correlation was observed for camping and fishing. We conclude that conditions in the immediate home environment, including certain ecologic factors that favor the presence of Ixodes ticks, are associated with an increased risk for Lyme disease in children

N2 - This article examines trends in the nutritional status of children in EI Salvador between 1988 and 1993 (before and after the signing of a peace accord that ended the civil war.) The data derive from two national surveys, each of which included measurements of the height and weight of children aged 3-59 months. The prevalence of low weight-for-age (< -2 SD) dropped from 15% in 1988 to 10.5% in 1993. The prevalence of low weight-for-height (< -2 SD) was minimal in both surveys: falling from 3.9% to 2.9%. The prevalence of low height-for-age (< -2 SD) fell from 28.1% to 22%. These declines in malnutrition indicators resulted from an upward shift in the distributions of weight and height of children, not from thinner lower tails of the distributions. The quality of anthropometric data appears to be high for both surveys: < 1% of surveyed children had heights or weights outside the expected range. This analysis demonstrates the value of repeated surveys of nutritional status

N2 - Injuries and infectious respiratory, gastrointestinal and dermatologic diseases are common in day care settings. Most day care injuries are contusions, abrasions and cuts involving the head and extremities. Impact-absorbing surfaces under playground equipment, safely-proofing of all play areas, increased staff supervision, and staff and parental education might reduce injuries by as much as 75 percent. Respiratory illnesses are the most common day care infections. Chemoprophylaxis with rifampin is required for all close contacts of children infected with Haemophilus influenzae type B and Neisseria meningitidis. Diarrheal illness may be caused by viral pathogens, bacterial agents such as Shigella, Campylobacter or Salmonella, or parasitic infections caused by Giardia lamblia and Cryptosporidium. Strict hand-washing procedures, especially before food preparation and after toileting, may reduce diarrheal illness by 50 percent. Head lice (Pediculosis capitis) and scabies are common dermatologic infections spread by direct contact and through clothing, bedding and hair brushes. Screening and treating affected children with permethrin preparations and thoroughly washing bedding and clothing are necessary to stop outbreaks. Use of universal precautions for the handling of stool is essential to prevent the spread of both ordinary diarrheal illnesses and serious infections such as hepatitis A and B, human immunodeficiency virus and cytomegalovirus. N2 - **BACKGROUND:** Physical inactivity is a risk behavior for cardiovascular and other diseases. Schools can promote public health objectives by increasing physical activity among youth. **METHODS:** The Child and Adolescent Trial for Cardiovascular Health (CATCH) was a multicenter, randomized trial to test the effectiveness of a cardiovascular health promotion program in 96 public schools in four states. A major component of CATCH was an innovative, health-related physical education (P+) program. For 2.5 years, randomly assigned schools received a standardized PE intervention, including curriculum, staff development, and follow-up. **RESULTS:** Systematic analysis of 2,096 PE lessons indicated students engaged in more moderate-to-vigorous physical activity (MVPA) in intervention than in control schools (P = 0.002). MVPA

during lessons in intervention schools increased from 37.4% at baseline to 51.9%, thereby meeting the established Year 2000 objective of 50%. Intervention children reported 12 more min of daily vigorous physical activity ($P = 0.003$) and ran 18.6 yards more than control children on a 9-min run test of fitness ($P = 0.21$).

CONCLUSIONS: The implementation of a standardized curriculum and staff development program increased children's MVPA in existing school PE classes in four geographic and ethnically diverse communities. CATCH PE provides a tested model for improving physical education in American schools

N2 - The aim of this study was to determine the physical activity levels of a sample of young children. Data were collected using direct, continuous observation by trained observers. The observational method utilised a points system to differentiate intensity of physical activity. Observations were carried out during school break times, lunch times and physical education lessons and during free time outside of school. The sample consisted of 93 girls and 86 boys aged between 5 and 11 years. Only 38 children (21%) engaged in a sustained 20-min period of moderate to vigorous physical activity (MVPA), but nearly all children (95%) took part in a 5-min period of MVPA. The highest recordings of MVPA occurred during school break times but MVPA was less prominent during free time outside of school. One hundred and seventy eight children were observed during school physical education lessons. Sustained MVPA was particularly low during physical education lessons with only 13 children (8%) participating in at least one sustained 10-min period. There appeared to be no difference in activity levels between boys and girls or between children of differing ages. During all observation periods the main activity of the child was recorded. Soccer, brisk walking, general play and chasing games were the most common activities. The results are disturbing since preadolescent children appear to be engaging in very little sustained, playful physical activity during their free time outside of school. If childhood is considered

to be the most active stage of life there must be concern for the future. There is a need for health professionals to promote active lifestyles from birth

N2 - Papular urticaria is a common pruritic hypersensitivity reaction to the bites of insects of many different types, including fleas, mosquitoes, chiggers, and, more rarely, avian or rodent mites. Which particular insect is the cause varies with geographic location. In San Francisco, children with papular urticaria due to flea bites are part of dermatologic practice year round. With its relatively warm winters and wet, foggy summers, San Francisco is an environment where fleas thrive, and their bites afflict children at day care centers and park playgrounds, as well as in homes with pets. We review the clinical approach to papular urticaria in general, and focus on flea bite prevention and management. [References: 15]

N2 - OBJECTIVE: The "athletic triad" of amenorrhea, osteopenia, and eating disorders (EDs) has received increasing attention in the past decade. Adolescents may seek care for amenorrhea or other menstrual irregularity before disclosure of an eating disorder to a primary care clinician. The purpose of this study was to determine the prevalence of abnormal eating attitudes and behaviors in adolescent girls going to a clinic for reproductive endocrinology (RE) visits versus the prevalence in girls going for health maintenance (HM) visits. DESIGN: All patients aged 8-22 years going to RE or HM clinics were given a 26-item modified eating attitudes test (EAT) and two pages of questions on other eating issues and demographics. Informed consent was obtained from all participants, and also from the parents of those less than 18 years of age. SETTING: All subjects were seen at a hospital-based ambulatory (HM) or subspecialty (RE) clinic, with both clinics located on the same floor. PARTICIPANTS: The study included 53 girls from the RE clinic and 108 girls from the HM clinic. All demographics were similar except that the RE patients were slightly older and had significantly more parents with masters or doctorate degrees. MAIN OUTCOME MEASURES: Study variables were compared between RE and HM groups using either the Student's t test or the Chi-square test, with statistical significance defined as $p < 0.05$. A score of 20 or higher on the modified EAT was correlated with a high risk of EDs and was used as a measure of prevalence of abnormal eating attitudes and behaviors. RESULTS: Modified EAT scores were 11.8 +/- 8.9 in RE patients vs 7.0 +/- 7.2 in HM patients ($p < 0.001$), with 10 (18.9%) RE patients and 7 (6.5%) HM patients having scores of at least 20 ($p = 0.016$). No differences in daily exercise, dairy consumption, or use of vomiting or laxatives to control weight were found. As expected, RE patients were significantly more likely to experience menstrual irregularities than the HM patients ($p < 0.001$).

CONCLUSIONS: Adolescents attending a reproductive endocrinology clinic showed a higher prevalence of abnormal eating attitudes and behaviors than did those going to a clinic for HM visits. Early detection of eating disorders may occur both within and outside of the primary care setting through use of a modified EAT

N2 - Injuries sustained in schools account for 20-30% of all accident and emergency attendances in school age children. Little information has been available on the epidemiology of school accidents in the United Kingdom. Two years of routine school incident reports were analysed from Renfrew Sub-Region, an area with a school roll of 55,521 children attending 135 schools. Schools returned 1,660 report forms in the two year period, of which 1,440 referred to injuries to school children. The peak incidence of injuries was in the 10-12 year age group. The male:female ratio was 1.37:1. Cuts/ laceration and fractures were the commonest diagnoses reported for both Primary and Secondary Schools. Injuries to face and features were commonest in Primary, and upper limb injuries in Secondary Schools. Uncontrolled areas, e.g. playgrounds, stairways and corridors were the most frequent places of occurrence in Primary Schools (Relative Risk 5.24, 95% C.I. 3.28-8.35). Report accuracy was assessed by comparing one year of school reports in a Local Government District to records in the local District General Hospital. This identified 156 children who had attended hospital as the result of a school accident. Schools overestimated the number of fractures by 27%, but where schools had not provided a diagnosis, 15.4% were identified as fractures in hospital records. Each child seen at the hospital received an average of 2.1 X-rays. Nine children underwent manipulations under general anaesthetic. Seventeen children were admitted to hospital, and the group required 103 outpatient follow-up appointments

CY - NETHERLANDS

N2 - Diverse environmental exposure profiles exist in the Americas because of widely different climates, ambient pollutants, and bioaerosols in these continents. This paper reviews selected studies from the Americas that support the broad hypothesis that environmental factors contribute to respiratory hypersensitivity. Processes influenced by environmental factors include primary immunologic sensitization, the development and exacerbation of specific immunologic diseases and the activation of nonspecific mechanisms with tissue inflammation, injury and remodeling. Endpoints resulting from these processes include respiratory symptoms, diseases such as asthma, with measures of disease severity including medication use and hospitalization rates, and death due to cardiorespiratory disease. Studies associate sensitization rates to specific allergens with environmental factors such as humidity and indices of allergen exposure. Regional variation occurs with exposure to outdoor source pollutants such as ozone, but varies by household to bioaerosols such as dust mite, cat or cockroach allergen. Indoor allergens are associated with asthma while outdoor allergens are associated with allergic rhinitis. In a national survey, the atopic sensitization rate in the USA increased with urban residence (defined as towns of population > 2500) and varied by region. Controlled human challenge studies show that ozone increases the response of allergic subjects to allergen. Increased ambient photochemical pollution concentrations, of which ozone is an important component, are associated with increased emergency room visits for asthma in cities such as Toronto, New York, Atlanta, and Mexico City. In Sao Paulo, Brazil, mortality due to childhood respiratory disease was influenced by the ambient levels of NO₂. Epidemiologic studies including the recent meta-analysis of a large, longitudinal study population associate ambient concentrations of particulate matter < 10 microns and respiratory symptoms, disease severity and increased cardiorespiratory deaths. Toxicology studies show that individual variation in responsiveness is important in nonspecific inflammatory responses to irritant pollutants such as ozone and environmental tobacco smoke. These studies indicate that environmental factors influence primary allergen sensitization, secondary allergic responses, the activation of nonspecific inflammatory responses, and the severity of respiratory diseases, including asthma. N2 - BACKGROUND: Previous studies have shown an inconsistency in the association between maternal education and child nutritional status across socioeconomic levels. This may be because the beneficial effects of education are only significant when resources are sufficient but not abundant. METHODS: Associations were examined for differences across socioeconomic levels using data collected from 41 rural communities of Benin for 435 children aged 13-36 months. Village level indicators of household wealth were used together with child z-scores to partition the sample into three levels of socio-environment relative to conditions more or less conducive to child growth. RESULTS: Using an interactive linear regression model it was shown that for the population of children of women who had no more than 4 years of formal schooling, the association of maternal education and child weight differed significantly across the socio-environment. The relationship was flat and non-significant in the lowest socio-environment, positive and significant ($P < 0.05$) in intermediate conditions, and weakly positive under the best socio-environment conditions. Among children of mothers attaining higher levels of education, an unexpected negative association was found. It could be that maternal education had enabled women to participate in activities outside the home without simultaneously ensuring adequate child care

N2 - A longitudinal epidemiologic survey (1989-1991) plus a cross-sectional parasitologic, clinical, and sociodemographic survey (July-October 1990) were conducted in Candeias do Jamary, a village with approximately 7,000 inhabitants in Rondonia, Brazil. Analysis of the results revealed hypoendemic malaria with a complex epidemiology. Plasmodium vivax predominated over P. falciparum infections while infections with P. malariae were absent. Malaria is present throughout the year but was clearly seasonal with epidemic outbreaks in the dry season from June to August. Malaria prevalence was lower in children less than 10 years of age and significantly higher in young adult males, which represent the high-risk group. The incidence of locally acquired infections (autochthonous cases) was significantly lower in the rainy season as compared with the dry season. This is not true with respect to heterochthonous (imported) malaria cases, that is, malaria acquired elsewhere by Candeias residents, most of whom are male adults working outside the town. In both cases, however, the age and sex distribution of prevalence and its relationship with occupational activities indicate a predominance of outdoor transmission. The results of the cross-sectional survey are in agreement with those of the longitudinal passive survey and, in addition, disclose the absence of asymptomatic infection

N2 - Obesity and low levels of physical and metabolic fitness are risk factors for cardiovascular disease and diabetes. The purpose of this investigation was to attenuate obesity and improve physical and metabolic fitness in elementary school children. Schools have the opportunity, mechanisms, and personnel in place to deliver nutrition education, fitness activities, and a school food service that is nutritious and healthy. Cohorts from grades 3 to 5 in two school districts in rural Nebraska (Intervention/Control) participated in a 2-year study of physical activity and modified school lunch program. Data collection for aerobic capacity, body composition, blood chemistry, nutrition knowledge, energy intake, and physical activity was at the beginning and end of each year. Int received enhanced physical activity, grade specific nutrition education, and a lower fat and sodium school lunch program. Con continued with a regular school lunch and team sports activity program. At year 2, Int lunches had significantly less energy (9%), fat (25%), sodium (21%), and more fiber (17%). However, measures of 24-hour energy intake for Int and Con showed significant differences for sodium only. Physical activity in the classroom was 6% greater for Int compared to Con ($p < 0.05$) but physical activity outside of school was approximately 16% less for Int compared to Con ($p < 0.05$). Body weight and body fat were not different between schools for normal weight or obese children. No differences were found for cholesterol, insulin, and glucose; however, HDL cholesterol was significantly greater and cholesterol/HDL was significantly less for Int compared to Con ($p < 0.05$). It appears that compensation in both energy intake and physical activity outside of school may be responsible for the lack of differences between Int and Con

N2 - A case-control investigation of childhood acute lymphoblastic leukemia was conducted in the town of Carbonia (Sardinia, Italy). Parents of 9 cases diagnosed between 1980 and 1989 and 36 controls were interviewed at their respective residences. None of the risk factors analyzed was associated significantly with childhood acute lymphoblastic leukemia. The following were associated with an increased risk for childhood acute lymphoblastic leukemia: parents born outside of Carbonia, family history of cancer, alcohol consumption by fathers that exceeded 60 g/d, exposure of fathers to solvents at their workplaces, maternal smoking, use of anti-nausea medications during pregnancy, and presence of a well in the backyard. Chance and recall bias likely played a role in generating positive associations. The increases in childhood leukemia risk associated with the presence of a well and with use of anti-nausea medications during pregnancy are consistent with previous reports and require further investigation

N2 - The PTEAM Study was the first large-scale probability-based study of personal exposure to particles. Sponsored by the U.S. Environmental Protection Agency (EPA) and the Air Resources Board of California, it was carried out by the Research Triangle Institute (RTI) and the Harvard University School of Public Health (HSPH). HSPH designed and constructed a 4-lpm, battery-operated personal monitor for inhalable particles (PM10) that could be worn comfortably for up to 14 hours by persons from 10 to 70 years old. The monitor was worn for two consecutive 12-hour periods (day and night) during the fall of 1990 by 178 participants representing 139,000 nonsmoking residents of Riverside, California. Nearly identical monitors were employed to collect concurrent indoor and outdoor samples. The monitors were equipped with a different sampling nozzle to collect fine particles (PM2.5). Population-weighted daytime personal PM10 exposures averaged 150 +/- 9 (SE) micrograms/m³, compared to concurrent indoor and outdoor concentrations of 95 +/- 6 micrograms/m³. This suggested the existence of excess mass near the person, a "personal cloud" that appeared related to personal activities. Fourteen of 15 prevalent elements also were evaluated in the personal samples. The two major indoor sources of indoor particles were smoking and cooking; even in these homes, however, more than half of the indoor particles came from outdoors, and a substantial portion of the indoor particles were of undetermined indoor origin. Outdoor concentrations near the homes were well correlated with outdoor concentrations at the central site, supporting the idea of using the central site as an indicator of ambient concentrations over a wider area. Indoor concentrations were only weakly correlated with outdoor concentrations, however, and personal exposures were even more poorly correlated with outdoor concentrations. Elemental profiles were obtained for environmental tobacco smoke (ETS) (major contributions from potassium and chlorine) and cooking emissions (aluminum, iron, calcium, and chlorine). These profiles can be used in future source apportionment studies

N2 - OBJECTIVES: To determine the prevalence, causes and clinical features of short lasting recurrent limb pain (recurrent limb pain) in children. DESIGN: Population-based study in two stages, with an initial screening questionnaire followed by clinical interviews and physical examination of symptomatic children. SETTING: 67 primary and secondary schools in the city of Aberdeen. SUBJECTS: 2165 children representing a random 10% sample of all schoolchildren aged between 5-15 years. MAIN OUTCOME MEASURES: (a) The causes of limb pain in children, (b) the prevalence of recurrent limb pain in schoolchildren, (c) the relationship of recurrent limb pain to childhood migraine. RESULTS: Sports and playground injuries were the most common cause of limb pain, affecting 9% of all children. The prevalence rate of recurrent limb pain was 2.6% (95% confidence interval 1.9 to 3.4). Episodes of recurrent limb pain had similar trigger factors, associated symptoms, and relieving factors to episodes of headache in children with migraine. CONCLUSIONS: Recurrent limb pain is a common cause of limb pain, with a prevalence rate of 2.6%. The close clinical and epidemiological similarities between recurrent limb pain and childhood migraine suggest a common pathogenesis

N2 - The role of sun exposure in development of basal cell and squamous cell carcinomas among different populations from south Europe was investigated. Between 1989 and 1993 we interviewed incident cases and a random population sample of controls from five centres where a cancer registry was operating, whereas we selected a sample of hospital-based cases and controls from the other three centres. We gathered information on life-long exposure to sunlight during different activities. Results are analysed for 1549 basal cell carcinoma (BCC) cases and 228 squamous cell carcinoma (SCC) cases compared with 1795 controls. We observed a statistically significant increase of risk of SCC with increasing sun exposure beyond a threshold of 70,000 cumulated hours of exposure in a lifetime. Sun exposures during work and holidays were, however, inversely correlated. Odds ratios (ORs) of SCC were up to eight or nine times the reference for the highest exposures (200,000 cumulated hours or more). BCC exhibited a 2-fold increase of risk for lower exposure (8000-10,000 cumulated hours in a lifetime) with a plateau and a slight decrease of risk for the highest exposures (100,000 cumulated hours or more). Outdoor work showed a significantly increased risk of SCC (OR 1.6 for more than 54,000 cumulated hours of exposure in a lifetime), whereas recreational activities such as sun exposure during holidays at the beach (OR 1.6 for more than 2600 cumulated hours of exposure in a lifetime) or during water sports (OR 1.6 for more than 2600 cumulated hours of exposure in a lifetime) were associated with an increased risk of BCC. Risk patterns were different in poor or good tanners with a significant risk trend for good tanners, whereas poor tanners were on a plateau of increased risk at any level of exposure. Solar radiation is associated with a risk of BCC even for relatively short periods of exposure such as during holidays and sports, whereas SCC develops later if exposure continues. The skin's ability to tan modulates the risk of BCC; subjects who tan poorly have a steady risk increase, whereas people who tan easily develop cancer only after prolonged exposures

N2 - **OBJECTIVES:** To conduct the first nationwide investigation of violent deaths associated with schools in the United States, to quantify the risk of school-associated violent death, and to identify epidemiologic features of these deaths. **DESIGN:** Descriptive case series. **SETTING:** United States, July 1, 1992, through June 30, 1994. **METHODS:** School-associated violent deaths were identified by study collaborators and through 2 online news databases. Police reports, medical examiners' records, and interviews with police and school officials provided detailed information about each case. **RESULTS:** In a 2-year period, 105 school-associated violent deaths were identified. The estimated incidence of school-associated violent death was 0.09 per 100 000 student-years. Students in secondary schools, students of minority racial and ethnic backgrounds, and students in urban school districts had higher levels of risk. The deaths occurred in communities of all sizes in 25 different states. Homicide was the predominant cause of death (n = 85 [80.9%]), and firearms were responsible for a majority (n = 81 [77.1%]) of the deaths. Most victims were students (n = 76 [72.4%]). Both victims and offenders tended to be young (median ages, 16 and 17 years, respectively) and male (82.9% and 95.6%, respectively). Approximately equal numbers of deaths occurred inside school buildings (n = 31 [29.5%]), outdoors but on school property (n = 37 [35.2%]), and at off-campus locations while the victim was in transit to or from school (n = 37 [35.2%]). Equal numbers of deaths occurred during classes or other school activities (n = 46 [43.8%]) and before or after official school activities (n = 46 [43.8%]). **CONCLUSIONS:** School-associated violent deaths were more common than previously estimated. The epidemiologic features of these deaths were similar to those of homicides and suicides that occur elsewhere. A comprehensive approach that addresses violent injury and death among young people at school and elsewhere in the community is suggested

N2 - **OBJECTIVES:** To assess the distribution of personal exposures to nitrogen dioxide (NO₂) in school children, and to investigate factors that might influence personal exposure. **METHODS:** NO₂ exposures were assessed by use of passive diffusion tubes for 46 children aged 9-11 years, selected from two Southampton schools. The tubes were worn for seven days, and parallel measurements were made with static samplers in the child's kitchen, living room, classroom, and playground. Information about potential exposures was collected by questionnaire. **RESULTS:** Personal exposures to NO₂, averaged over seven days, ranged from 11 to 257 micrograms/m³ (6 to 137 ppb) with a geometric mean of 36 micrograms/m³ (19 ppb). Exposures correlated with concentrations of NO₂ recorded in the home, but the relation was far from exact. Factors associated with increased personal exposure included the use of gas appliances in the home, living with one or more smokers, and travel to school by means other than a car. However, together these variables only explained a small part of the variation in personal exposures. **CONCLUSIONS:** These findings reinforce the need for personal monitoring of exposure in studies investigating potential health effects of NO₂ in children

N2 - OBJECTIVE: To describe our experience with developing, implementing, and evaluating the educational effect of a school health experience for pediatric residents. DESIGN: Descriptive. SETTING: University-based pediatric residency program and five public elementary and middle schools in surrounding communities.

PARTICIPANTS: Eleven pediatric residents. INTERVENTION: A school health experience for pediatric residents was developed in response to the report of the American Academy of Pediatrics Task Force on Pediatric Education and the new training recommendations of the Residency Review Committee of the American Council for Graduate Medical Education. Residents spent 3 weeks in the schools engaged in teaching and observational activities. MAIN OUTCOME MEASURES: Questionnaires of residents' attitudes and knowledge, structured resident interviews, and teacher questionnaires. RESULTS: Positive effect on resident's knowledge of school structure, child development, communication with children, school-related problems, and special education. Positive effects on resident's attitudes about teamwork between teachers and pediatricians and roles of pediatricians in schools. Teacher feedback showed acceptance by the school community.

CONCLUSIONS: Pediatric residents benefit from exposure to children in school settings. Schools provide an opportunity to observe normal childhood development and behavior in a more natural setting than that provided in the hospital

N2 - BACKGROUND: Nodular fasciitis is characterized by a proliferation of spindle cells which may be misdiagnosed as sarcomas due to the rich cellularity, mitotic activity and variant morphologic patterns.

METHODS: This report includes 42 cases of nodular fasciitis and related conditions of skin and soft tissue from the pathology files of the Royal Brisbane Hospital, Queensland, Australia. There were 33 cases of nodular fasciitis, three cases of ossifying fasciitis, three cases of proliferative fasciitis, two cases of proliferative myositis and one case of intravascular fasciitis. Two-thirds of cases were referred from outside Royal Brisbane Hospital.

RESULTS: Nodular fasciitis and ossifying occurred most commonly in young adults with 16 patients (44%) between the ages of 20 and 29. However, the other variants of nodular fasciitis including proliferative myositis and intravascular fasciitis occurred in older people (six patients being older than 49 years) and more commonly occurring in men (n=5). A painless rapidly growing mass was most common. The lesions of nodular fasciitis were most often located in the upper extremity with the forearm most commonly affected. CONCLUSIONS: Nodular fasciitis and related conditions are benign. All patients are alive and well 3 months to 13 years (mean 7.2 years) after simple local resection

N2 - **BACKGROUND:** Cetirizine, a new once-daily highly specific H1-antagonist, has been shown in conventional studies to be efficacious in the treatment of seasonal and perennial allergic rhinitis and chronic idiopathic urticaria. **OBJECTIVE:** The efficacy, duration and onset of action, and safety of cetirizine, 10 mg once daily, was compared with that of loratadine, 10 mg once daily, and placebo in a field study of patients with seasonal allergic rhinitis. **METHODS:** This was a randomized, double-blind, parallel, double-dummy study conducted over 2 days in spring allergy season at outdoor parks in San Diego and Iowa City. Study medication was administered at 10:00 AM on both days. After screening, eligible patients completed rhinitis symptom diaries in the park hourly from 7:30 to 9:30 AM (baseline); at 10:30 AM and hourly from 11:00 AM to 4:00 PM (period I); at 6:00, 8:00, and 10:00 PM at home (period II); and the next day in the park hourly from 8:00 to 10:00 AM (period III), and from 11:00 AM to 4:00 PM (period IV). Major and total symptom complex scores, global efficacy and overall satisfaction, and adverse events were assessed. **RESULTS:** Of the 279 patients (140 men and 139 women; mean age, 29 years) randomized to treatment, 278 were included in the efficacy analysis. Cetirizine produced significantly greater mean reductions than loratadine or placebo in major symptom complex severity scores at all periods ($p < \text{or} = 0.05$), except period I for placebo. Cetirizine also produced mean reductions in total symptom complex severity scores that were superior to loratadine at every evaluation period ($p < 0.05$) and were statistically different from placebo at period II ($p < 0.01$). A rapid onset of action was observed with cetirizine, as was a better response pattern in the patient global assessment of efficacy compared

with loratadine. Study medications were well tolerated; no patient stopped treatment because of side effects. The incidence of somnolence with cetirizine was 13% versus 2% with placebo ($p < 0.05$); headache occurred more frequently with loratadine (23%) than with cetirizine (11%, $p = 0.03$). CONCLUSIONS: Cetirizine relieved rhinitis symptoms more effectively and quickly than loratadine and placebo in this field study of seasonal allergic rhinitis. Both active agents were generally well tolerated

N2 - OBJECTIVE: To evaluate the utility of the Centers for Disease Control and Prevention (CDC) Risk Questionnaire and a behavioral risk factor questionnaire in identifying children with blood lead concentrations of 0.48 $\mu\text{mol/L}$ (10 micrograms/dL) or more. DESIGN: Cross-sectional study of 463 urban Massachusetts children (6 to 72 months of age) screened for lead with venous blood. RESULTS: Twenty-two percent of the children had elevated blood lead concentrations. Of the five CDC questions, only one was significantly associated with an increased adjusted odds ratio for elevated blood lead: having a sibling, housemate, or playmate who was followed up or treated for lead poisoning (odds ratio, 2.7; 95% confidence interval, 1.7 to

4.2; $P < .001$). Children who had at least one positive or equivocal response to any of the five CDC questions ($n = 318$ [68.7%]) were not at higher risk than were children who displayed a negative response to all five questions (odds ratio, 1.1; 95% confidence interval, 0.7 to 1.8; $P = .69$). Of nine behaviors surveyed, two were associated with an increased adjusted odds for elevated blood lead: use of a pacifier (odds ratio, 2.4; 95% confidence interval, 1.3 to 4.4; $P = .01$) and playing near the outside of the home (odds ratio, 3.4; 95% confidence interval, 2.0 to 5.8; $P < .001$). CONCLUSIONS: In this population of children, the CDC risk questionnaire did not identify a group at higher risk for lead exposure. We suggest that practitioners in urban communities screen all children according to the same schedule. We conclude that risk factors differ by community and no risk questionnaire developed at the national level should be applied across communities to target screening

N2 - A model for the external exposure of the Ukrainian population after the Chernobyl accident was developed. It is based on extensive measurements of external gamma-exposure rates (EGER) in air and of external effective doses of members of five population groups. Questionnaires were used to determine the occupancy times of members of the population groups at three types of locations; inside houses, outdoors, and outside of the home settlement. Behavior factors are defined as the ratio of individual external doses to a

reference dose for a phantom standing permanently over an open field with the same average ^{137}Cs activity per unit area as in the settlement. The behavior factors were derived for five population groups (children younger than seven years, the age group from eight to seventeen years, employees, agricultural workers, and pensioners) by two methods: first from direct measurements of individual doses by thermoluminescent dosimetry and an experimental determination of the average ^{137}Cs activity per unit area in the settlement of interest; and second from external gamma-exposure rates in air at various types of locations and from the questionnaire data. The methods were found to be consistent and the results were used to calculate external exposures of the five population groups in the years 1987 through 1991

N2 - This paper reviews the use of exposure modeling by the Ambient Standards Branch (ASB) of EPA's Office of Air Quality Planning and Standards. The Branch uses exposure assessments to evaluate health risks associated with attainment of alternative National Ambient Air Quality Standards (NAAQS). This paper examines the history of the NAAQS Exposure Model (NEM) and probabilistic NEM (pNEM) models and the role that they have played in NAAQS reviews of lead, carbon monoxide, nitrogen dioxide, and oxygen. Trends in how the following substantive issues were addressed in the NEM series of models are reviewed: (1) exposure and dose metrics; (2) microenvironmental (μe) concentration estimation; and (3) human activity and breathing rate simulation. In response to an outside peer review of its recent exposure assessments, ASB is deemphasizing modeling the entire population in favor of limited modeling of narrowly defined "sensitive groups." In addition, ASB increasingly is focusing its exposure assessments on those human activities that lead to high intake dose, or high intake dose rate. Examples are provided that highlight these changes in emphasis

N2 - A review of the available information on the validity of a mother's history of measles in children and its importance in Indian context is presented. A history of measles was found to have a median sensitivity (SN) of about 60% ($n = 6$; range 33-75) and a median specificity (SP) of about 95% ($n = 5$; range 79-100). A subclinical infection seems to be the most plausible explanation for the low SN. Two mechanisms for the development of subclinical infection have been suggested: (i) In infants, exposure to the virus in the households when maternal antibodies are just sufficient to prevent the disease but not the infection. (ii) In older children, exposure to a mild dose of virus outside the households. However, due to the misclassification of non measles cases as measles, the

SN increases and SP decreases as the child grows older. The implications of low SN, high SP and varying predictive values of the mother's history of measles are discussed

N2 - To investigate the nature of exposure factors, and effectiveness of countermeasures in head injuries in children and adolescent of Taiwan area, we conducted a retrospective study on 820 children and adolescents with head injuries consecutively admitted to Chang Gung Memorial Hospital from January 1985 to December 1989. We analyzed the data by chart review and divided the cases into four age-groups: group A (0-4 years old), group B (5-9 years old), group C (10-14 year old) and group D (15-17 years old). The boy to girl ratio was 2.43. The largest proportions of head injuries were the adolescents in group D. The most common cause of head injury was traffic accidents (74%); while the falls were contributed the main cause in other studies. In all group A, B and D, the majority of traffic accidents were pedestrian injury; while in group D, the motorcyclists or car drivers were responsible for the accidents. Fall from height was the major cause of fall in all four age-groups, but it was fall from bicycle or during play or sports in group C. Injuries were most common in summer and clustered at afternoon in all patients. Majority of head injuries occurred outdoors. Most children and adolescents suffered from mild head injury, but there were still 203 cases with severe head injury (24%). Eighty-one cases (9.9%) were either discharged in critical condition or died at the hospital. There were no significant differences in mortality among four age-groups

N2 - Air pollutants have been documented to be associated with a wide variety of adverse health impacts in children. These include increases in mortality in very severe episodes; an increased risk of perineonatal mortality in regions of higher pollution, and an increased general rate of mortality in children; increased acute respiratory disease morbidity; aggravation of asthma, as shown by increased hospital emergency visits or admissions as well as in longitudinal panel studies; increased prevalence of respiratory symptoms in children, and infectious episodes of longer duration; lowered lung function in children when pollutants increase; lowered lung function in more polluted regions; increased sickness rates as indicated by kindergarten and school absences; the adverse effects of inhaled lead from automobile exhaust. These impacts are especially severe when high levels of outdoor pollution (usually from uncontrolled coal burning) are combined with high levels of indoor pollution. In developed countries, where indoor pollution levels are lower, increasing traffic density and elevated NO₂ levels with secondary photochemical and fine particulate pollution appear to be the main contemporary problem. By virtue of physical activity out of doors when pollution levels may be high, children may experience higher exposures than adults. Air pollution is likely to have a greater impact on asthmatic children if they are without access to routine medical care. [References: 49]

N2 - To determine Colorado American Academy of Pediatrics (AAP) pediatricians' involvement in community-based activities and awareness of and interest in the AAP Community Access to Child Health (CATCH) program, a 22-item survey was mailed to all general pediatrician AAP fellows and candidate fellows practicing in Colorado (n = 434). The return rate was 65%. Of the respondents, 73% provide direct patient care as their primary professional activity, 58% reported either current or past involvement in community-based programs outside of their practices, 91% of this community-based work was voluntary, and 80% of the respondents described this work as moderate to very rewarding. Half of the respondents (51%) were aware of the AAP CATCH program, and 68% were interested in attending a statewide CATCH meeting. We conclude that Colorado AAP pediatrician survey respondents participate heavily in community programs outside of their clinical practices and that among this group there is substantial interest in the AAP CATCH program

N2 - Stool disposal practices have been shown to be associated with childhood diarrhoea. However, efforts to promote improved hygiene behaviour are hampered by a lack of understanding of what determines those behaviours. Data from 2793 household interviews with mothers of children from the town of Bobo-Dioulasso in Burkina Faso were analyzed to examine what differentiated mothers who reported using safer stool disposal practices from those who did not. Three 'outcomes' were considered: where the child was reported to defaecate; where the mother reported disposing of the child stools; and whether excreta were observed in the compound. Regression models were developed to identify those factors with the strongest independent associations with the outcomes. There was a consistent association between the source of water and the outcomes. Mothers with access to a tap in the yard reported using safe hygiene practices three times more often than mothers using wells outside the compound and twice as often as mothers who used public standpipes or wells within the yard. The source of water showed a similar pattern of association with observations of faecal matter in the environment. Improved sources of water may contribute to safer stool hygiene by reducing the time spent on water collection or by encouraging mothers to conform to higher standards of hygiene. Other factors which played a role in predicting the hygiene behaviour of mothers were the husbands' occupation, the number of health education sessions that she had attended, her zone of residence and family ownership of certain valuable objects. These factors are likely to be related and to be, to some extent, proxies for the real determinants of her behaviour. A model of the cultural, psycho-social and infrastructural proximate determinants of hygiene behaviour is proposed. Data from focus group discussions suggested that the main purpose of hygienic behaviour is to conform to existing norms of social etiquette. Trials of interventions based on changing such norms are needed to test whether this is an effective means of promoting of safer hygiene practices

N2 - The acute effects of ozone (O₃) on the change in lung function before and after exercise was assessed in 22 boys and 18 girls from 7 1/2 to 11 yr of age tested up to eight times over a 1 1/2-yr period outdoors (under a tarpaulin) at a school in Mexico City. Ozone and particulates were monitored at an adjacent government station, in the school yard, and under the tarp. Subjects were selected to oversample children with chronic respiratory symptoms, although children with active asthma under regular medication or FEV₁ < 80% predicted were excluded. Of the participants, 21 had chronic cough, chronic phlegm, or ever wheeze with colds or apart from colds. Children performed two cycles of treadmill exercise (15 min) and rest (15 min) for a total of 1 h of intermittent exercise. Most subjects attained the target minute ventilation of 35 L/min/m². Subjects exercised alternately during low ozone hours (8:00-10:00 A.M.) and during peak O₃ hours (12:00-2:00 P.M.), to assure a range of exposures. On 85% of exercise days, the maximum daily 1-h average for ambient O₃ exceeded the Mexican guideline of 110 parts per billion (ppb). O₃ exposure during the hour of exercise was divided into quintiles, and the response was adjusted for repeated measures, subject having a cold, and prior outdoor exercise. Ambient O₃ in the fifth quintile (mean = 229 ppb) was associated with a percentage change in FVC (-1.43% +/- 0.70), FEV₁ (-2.85% +/- 0.79), FEF_{25-75%} (-6.32 +/- 1.87) and FEV₁ (-1.41% +/- 0.46). N2 - To identify risk factors for incident Lyme disease in California during the period June 1, 1991 to December 31, 1992, the authors compared the activities of 101 cases of physician-diagnosed erythema migrans ascertained via both active and passive surveillance with those of 107 controls matched on sex, age, and neighborhood. Questions asked by telephone pertained to location of home, presence of wildlife around the house, hours of outdoor work and outdoor leisure activities, pet ownership, precautionary measures to avoid tick bites, tick removal methods, and knowledge about Lyme disease. For cases, activities pertained to the month prior to the onset of erythema migrans; controls were interviewed about the same activities during the same one-month period. The observation of deer and lizards around the home and a history of exposure to ticks were associated with Lyme disease (deer, odds ratio (OR) = 2.53, 95% confidence interval (CI) 1.25-5.15; lizards, OR = 2.14, 95% CI 1.14-4.04). However, the only activity associated with Lyme disease was the use for more than 5 hours per week of wide maintained trails (OR = 11.33, 95% CI 1.33-123.5); this association occurred only in persons with other outdoor leisure activities. No other behaviors or activities were identified as risk factors for acquisition of Lyme disease in California

N2 - The purpose of this study was to examine tracking of physical activity at home and recess in young children. Three hundred fifty-one Mexican-American and Anglo-American children entered the study (mean

age = 4.4 yr), and 83% completed 2 yr of measurement. Physical activity was directly observed on 10 d over 2 yr. Measurement waves occurred every 6 months, and each wave consisted of 2 d of observation within 1 wk. Children were observed for 60 min at home on a weekday evening and up to 30 min during recess at preschool or school. Maximum likelihood procedures using a linear mixed-effects model indicated that most of the variance in home and recess physical activity was accounted for by short-term/weekly factors. Tracking of physical activity accounted for 15% of the total variance at home and 8% at recess. Pearson correlations for physical activity over time were higher at home than at recess. Tracking of home physical activity was $r = 0.15$ when single days were correlated and $r = 0.36$ when the means of 4 d were correlated. There was a small, but detectable, stable component of physical activity in young children, at least at home

N2 - The purpose of this study was to evaluate the validity of the Tritrac-R3D Activity Monitor, a new instrument designed to improve assessments of physical activity. Comparisons were made with a heart rate monitor and with a Caltrac Activity Monitor. Thirty-five children (ages 9-11 years) were monitored on 3 different school days with all 3 instruments. The Tritrac was moderately correlated with the heart rate monitor ($r = .58$) and highly correlated with the Caltrac monitor ($r = .88$). By taking advantage of the minute-by-minute timing capability of the Tritrac and the heart rate monitors, it was discovered that the correlations between these instruments were highest during free play situations (lunch/recess, recess, after school) and were lower when activity was more limited (class time) or structured (physical education). The ability of the Tritrac to assess activity on a minute-by-minute basis may greatly enhance its overall utility

N2 - Although clinicians have described the value of support groups in assisting children mourn the death of someone close, little is known about helping children with bereavement. By understanding what helps children mourn, nurses can better facilitate a healthy bereavement process. The purpose of this mini-ethnographic study, which used observation and participation procedures, was to identify what 16 children found helpful during their bereavement. Initially, the children's expressions of feelings were demonstrated both verbally and through art work. The patterns of the children's emotions were labeled as affective distress, somatic complaints, and for the boys, disruptive behavior. The children then described their mourning processes as being facilitated by out-of-door activity, yelling, and talking to others (e.g. God, mom, grandmother or grandfather)

N2 - The Harlem Hospital Injury Prevention Program (HHIPP) was established in 1988 with the goal of reducing injuries to children in central Harlem by providing safe play areas, supervised activities, and injury prevention education. To achieve this goal, a broad-based coalition was formed with state and local governmental agencies interested in injury prevention and with community groups, schools, parents, and hospital staff. An evaluation of the program in terms of both process and outcome formed a critical element of this effort. Since 1988 the HHIPP, as the lead agency for the Healthy Neighborhoods/Safe Kids Coalition, developed or participated in two types of programs: injury-prevention education programs and programs that provide safe activities and/or environments for children. The educational programs included Window Guards campaign; Safety City Program; Kids, Injuries and Street Smarts Program (KISS); Burn Prevention Curriculum and Smoke Detector Distribution; Harlem Alternative to Violence Program; Adolescent Outreach Program; and Critical Incident Stress Management Teams. The safe activities and environmental programs included the Bicycle Safety Program/Urban Youth Bike Corps; Playground Injury Prevention Program; the Greening of Harlem Program; the Harlem Horizon Art Studio; Harlem Hospital Dance Clinic; Unity through Murals project; baseball at the Harlem Little League; winter baseball clinic; and the soccer league. Each program was conceived using injury data, coupled with parental concern and activism, which acted as catalysts to create a community coalition to respond to a specific problem. Data systems developed over time, which monitored the prevalence and incidence of childhood injuries in northern Manhattan, including central Harlem, became essential not only

to identify specific types of childhood injuries in this community but also to evaluate these programs for the prevention of injuries in children

N2 - One hundred and eighty-five rural Bangladeshi children (80 boys and 105 girls) aged 4-27 months were observed to investigate developmental, behavioural, and environmental risk factors for diarrhoea during a 6-month period. Incidence of diarrhoea was found to be the highest among children aged 10-12 months. Children of this age group had the greatest exposure to environmental contaminants in the neighbourhood. Incidence of diarrhoea was the highest in hot, dry months. Risk factors for diarrhoea included: faecal contamination and garbage disposal in infant's outdoor play compound, crawling, contact of hand and mouth with contaminated materials, greater distance of household from water source, inadequate cleaning after defecation; dirt of child's face, presence of flies, feeding rotten food; insufficient washing of infant's and caretaker's hands before feeding rice meals or soft, wet foods; and lack of mothers' willingness to visit a modern (allopathic) health practitioner

N2 - The results of a 4-week summer camp for childhood obesity were reported. Twenty-one children with moderate to severe obesity, aged between 8-13 years, joined the program. Dietary restriction during the official hours and dietary self-control at home were implemented throughout the program. Exercise, swimming and group therapy were also implemented throughout the program. Weekly sight-seeing outside the camp was very interesting for the participants. After the program, all participants had lost weight which was about 5 per cent of their initial weight. Most of the weight loss was due to loss of body fat but not lean body mass. No complications occurred during the program. The 4-week summer camp is then practical for initiating weight loss for obese children. Long-term follow-up which is underway will be reported later

N2 - Exposure to chromium was assessed for 40 children living near chromium waste sites. Sampling was conducted in one Jersey City, New Jersey neighborhood during the summer and fall of 1991. Household dust samples from residences and urine samples from children living near chromium waste sites were collected and analyzed for chromium. During the summer and fall visits when the samples were collected, the children were also interviewed about lifestyle/activity patterns. Comparisons were made with similar samples collected from children and homes in other areas of New Jersey outside of Hudson County with no known chromium waste sites. Household dust masses and chromium loadings and concentrations in the dust showed a significant decline in this Hudson County neighborhood since the area was first sampled in 1990. Interim remediation of neighborhood sites and an active community education program in the interval between the first and second year of sampling may have contributed to the reduction in dust masses and chromium levels in dust. Children's urine chromium concentrations were consistent across the two sampling periods despite reported changes in activity patterns. Chromium concentrations in urine were found to be age-dependent and related to home location. In this sample of Jersey City children less than six years old, time spent playing outdoors was a weak secondary contributor to urine chromium levels

N2 - OBJECTIVES: To estimate and describe morbidity from sports and recreation injuries in children and adolescents. DESIGN: Survey conducted by the National Center for Health Statistics--the Child Health Supplement to the 1988 National Health Interview Survey. SETTING: The general community. PARTICIPANTS: Representative sample of the noninstitutionalized civilian US population. Five percent of the eligible households did not participate. The subject of this report is 11,840 children and adolescents aged 5 to 17 years. MAIN OUTCOME MEASURES: Medically attended nonfatal injuries resulting from sports and recreation, and serious sports injuries, defined as injuries resulting in hospitalization, surgical treatment, missed school, or half a day or more in bed. Sports and recreation injuries were defined as those occurring in a place of recreation or sports, or receiving any of the following International Classification of Diseases, Ninth Revision (ICD-9) E-codes: struck in sports, fall in sports, bicycle-related injury, riding an animal, water sports, overexertion, fall from playground equipment or other vehicles, primarily skates and skateboards. RESULTS: The estimated annual number of all injuries from sports and recreation in US children and adolescents is 4,379,000 (95% confidence interval = 3,147,000 to 5,611,000); from serious sport injuries, 1,363,000 (95% confidence interval = 632,000 to 2,095,000). Sports account for 36% of injuries from all causes. Cause and nature of injury are strongly related to age. Sports do not account for a disproportionate number of serious or repeated injuries compared with other causes of injuries. CONCLUSION: Sports activities account for a large number and substantial proportion of all injuries to children and youth

N2 - It has been suggested that all children with skull fractures require urgent CT scanning to exclude intracranial injury. Adhering to such a policy could both tax limited scanning facilities and result in unnecessary exposure to radiation. The aim of this study is to assess the level of consciousness in determining the need for urgent CT scanning, and the possible role of the mechanism of injury as a secondary risk factor. We identified 140 children admitted during a 7-year period with a skull fracture after falling outside the home. Thirteen children had a diminished level of consciousness. Scans were performed in nine, and seven of the scans revealed significant intracranial injuries. By comparison, all 127 children with a normal level of consciousness recovered fully. Scanning was performed in only eight of them; seven scans were normal and one revealed a small subarachnoid heamorrhage which did not require active treatment. In addition, all 13 children with a diminished level of consciousness had sustained their injuries by falling from greater than their own standing height. By comparison, none of the children who had sustained their skull fractures by tripping up had a diminished level of consciousness or a significant intracranial injury. We conclude that all children with a diminished level of consciousness need to undergo an urgent CT scan. Children with skull fractures and a normal conscious level may be managed initially by neuroobservations and the clinician may be further reassured if the child's injury resulted from tripping up

N2 - Southwest Metropolitan Mexico City (SWMMC) preadolescent children have been exposed to a highly polluted urban atmosphere most of their lives. The main objective of this study was to determine by nasal lavage (NAL) the acute inflammatory nasal influx elicited in these children upon exposure to three different polluted days. Ozone, the main criteria pollutant for SWMMC, varied both in the number of hours above the National Ambient Air Quality Standard (NAAQS), which is 0.12 ppm as a 1-h maximum concentration not to be exceeded more than once per year, and in the maximal concentrations in the preceding three NAL sampling dates. Nasal neutrophilic influx, the surface expression of the B2 integrin CD11b on the nasal polymorphonuclear leukocytes (PMNs), rhinoscopic findings, respiratory symptoms, and nasal cytologies were evaluated in the 38 exposed children and in the 28 control children living in a nonpolluted Pacific coast port. SWMMC children had an average daily outdoor exposure of 7.7 h and complained of nasal mucus secretion, epistaxis, intermittent nasal obstruction, diurnal cough episodes, and chest discomfort. Nasal mucosal atrophy by rhinoscopy was present in 37/38, and all children had an abnormal nasal cytology. Exposed children had significantly higher nasal PMNs and nasal PMN-CD11b expression than controls. PMN median values in exposed children were higher than controls on all sampling dates (November 12, $p < .001$; November 17, $p < .001$; and November 24, $p < .00001$). Interestingly, a lower nasal neutrophilic response ($p < .0004$) was recorded in the SWMMC children 18 h after exposure to the highest O₃ concentrations (up to 0.307 ppm) and the largest number of hours with O₃ > 0.12 ppm (7 h). The question of a competing inflammatory response at the bronchioalveolar level with structural damage is raised. These NAL findings underscore the need to restrict outdoor activity in SWMMC children during the months of greater potential exposure to ozone

N2 - OBJECTIVES: To measure the incidence of playground fall injuries among children attending licensed US day care centers and to evaluate how injury incidence varies with center characteristics and with the regulatory and enforcement climate in which centers operate. DESIGN: Telephone surveys of directors of day care centers and enforcement agencies and review of written day care regulations. SETTING: Probability sample of licensed day care centers in 50 states and the District of Columbia. PARTICIPANTS: Children attending day care centers with playgrounds. MAIN OUTCOME MEASURES: Medically attended playground fall injuries. RESULTS: Among the 1740 day care centers studied, a weighted total of 89.2 injuries occurred during the 2-month study period (0.25/100,000 child-hours in day care). The most important risk factor for injury was height of the tallest piece of climbing equipment on the playground in both bivariate ($P = .01$) and multivariate ($P = .02$) analyses. Neither regulations addressing playground safety or playground surfaces nor enforcement patterns were associated with lower injury rates. CONCLUSIONS: Additional effort is needed to develop and evaluate regulations and enforcement that reduce injury risks for children while minimizing burden on day care centers. In the meantime, limiting climbing equipment heights may reduce playground injury rates

N2 - Effective communication between Hispanic parents and teens about sexual issues may deter adolescent pregnancy, yet little is known about the prevalence or impact of such communication. The study examined this potential relationship in a cohort of urban Hispanic adolescents. A questionnaire was administered to a non-random sample of pregnant and non-pregnant Hispanic women aged 12-18 years attending inner city schools in Los Angeles to obtain demographic, sexual activity and communication information. Logistic regression analysis was used to evaluate the independent contribution of risk factors to teenage pregnancy. Good communication with one's mother was inversely related to pregnancy; the adjusted odds ratio of pregnancy if the mother told the daughter about sex was 0.3 (95% CI 0.2-0.6). Friends' love was also inversely related to pregnancy (odds ratio 0.7; 95% CI 0.6-0.8). In order of increasing strength, alcohol and drug use, favorable attitude toward premarital sex, receipt of welfare, older age at menarche, and older age were all significantly related to pregnancy. Pregnant Hispanic teenagers have poorer communication with their parents than do other Hispanic teens. Efforts to reduce the incidence of adolescent pregnancy among Hispanics may need to address not only family communication but also issues outside the home such as alcohol and recreational drugs

N2 - The study examines the role of several potential predictors of urinary cotinine levels in a cross-sectional sample of 1,072 nonsmoking children and adolescents in Latium, Italy, during 1990-1991. As expected, there was a strong relation between passive exposure to smoking and the amount of maternal and paternal self-reported smoking. The urinary cotinine level increased with a decreasing level of paternal education and with an increasing index of household crowding; self-report of recent exposure to smoking outside the home was a strong predictor of the biologic marker. The analysis was then restricted to 346 subjects whose parents claimed that they were nonsmokers and that there were no smokers at home. In this group, however, 57 children reported some active smoking at home by their parents. Those with parents suspected to be "deceivers" had higher level of urinary cotinine than did those truly not exposed. In addition, urinary cotinine in this group was clearly associated with duration of exposure to smoking outside home. The study indicates that both factors related to family circumstances and exposure outside the household setting are strong determinants of urinary cotinine levels. The finding may be considered a direct confirmation that passive smoking among children should be viewed as a specific community responsibility

N2 - Ethnography can be utilized to assess the impact of HIV/AIDS education simultaneous with the implementation of program activities. An ethnographic analysis based on field methods adapted in a Michigan program that targets migrant farmworkers highlights responses to showings of a bilingual AIDS education video; the things to which migrants attend while they are interacting with the educator and each other in HIV

education presentations; the tactics they employ to direct discussion when talking about HIV/AIDS, and the manner in which they use language to "distance" themselves from the topic of HIV infection and AIDS. Migrants in Michigan experience the same risks to health as farmworkers in other states; their pay is low, their hours are long, and the time they spend in the state is seasonal (summer). They engage in risk behavior while in the state (primarily consensual/contracted sex). Some migrants through use of drugs may come closer to exposure to the HIV virus outside the state than when they are working as migrants in Michigan

N2 - BACKGROUND: Ehrlichiosis due to *Ehrlichia chaffeensis* usually occurs sporadically or in small clusters, with an annual incidence estimated at 3 to 5 cases per 100,000 population in areas of endemic disease. The putative principal vector is the Lone Star tick (*Amblyomma americanum*). We investigated an outbreak of ehrlichiosis that occurred in June 1993 among members of a golf-oriented retirement community (community A) in Tennessee. The community is densely wooded and borders a wildlife-management area where deer are numerous. METHODS: We conducted a case-control study, using medical-history reviews, serologic testing, and testing with the polymerase chain reaction for *E. chaffeensis* infection. We also surveyed a sample of 10 percent of the households in community A and in another golf-oriented community (community B) more than 20 miles (32 km) from the wildlife-management area. Survey participants completed a questionnaire and provided specimens for serologic testing. In both communities, searches for ticks were undertaken. RESULTS: Eleven cases of symptomatic ehrlichiosis were identified in the case-control study, 10 of which were in community A (attack rate, 330 per 100,000). Of 311 surveyed residents of community A, 12.5 percent had serologic evidence of past *E. chaffeensis* infection, as compared with 3.3 percent of 92 in community B (relative risk in community A as compared with community B, 3.9; 95 percent confidence interval, 1.2 to 12.2). The risk of infection was associated with tick bites, exposure to wildlife, golfing, and among golfers, retrieving lost golf balls from the rough. Persons who never used insect repellent were more likely to have had infection than persons who did. In community A, thousands of Lone Star ticks were found; in community B, only three ticks were found. CONCLUSIONS: The high rate of *E. chaffeensis* infection in community A resulted from its proximity to a wildlife reserve. When outdoor recreational activities are common and concentrations of ticks are high, outbreaks of arthropod-borne zoonoses can be anticipated

N2 - BACKGROUND: Sudden death from cardiac arrest in a young person may occur during sports play after a blunt blow to the chest in the absence of structural cardiovascular disease or traumatic injury (cardiac concussion or commotio cordis). We studied the clinical features of this apparently uncommon but important phenomenon. **METHODS:** We identified cases from the registries of relevant agencies and organizations, as well as newsmedia accounts, and developed a clinical profile of 25 children and young adults, 3 to 19 years of age. **RESULTS:** Each victim collapsed with cardiac arrest immediately after an unexpected blow to the chest, which was usually inflicted by a projectile (such as a baseball or hockey puck). Incidents took place during organized competitive sports in 16 cases and in recreational settings at home, at school, or on the playground in 9. In each instance, the impact to the chest was not judged to be extraordinary for the sport involved and did not appear to have sufficient force to cause death. Twelve victims collapsed virtually instantaneously on impact, whereas 13 remained conscious and physically active for a brief time before cardiac arrest. Cardiopulmonary resuscitation was administered within about three minutes to 19 victims, but normal cardiac rhythm could be restored in only 2 (both incurred irreversible brain damage and died shortly thereafter). Seven victims (28 percent) were wearing some form of protective chest padding. **CONCLUSIONS:** We speculate that most sudden deaths related to impact to the chest (not associated with traumatic injury) are due to ventricular dysrhythmia induced by an abrupt, blunt precordial blow, presumably delivered at an electrically vulnerable phase of ventricular excitability. This profile of blunt chest impact leading to cardiac arrest adds to our understanding of the range of causes of sudden death on the athletic field and may help in the development of preventive measures

N2 - A cross-sectional study was carried out to determine whether environmental exposure of children to lead may cause renal effects. The study involved a total of 195 children aged 12 to 15 years. One hundred forty-four children (63 boys and 81 girls) were recruited from two schools in the vicinity of a lead smelter and 51 (25 boys and 26 girls) from a school in a rural area. Compared to their referents, boys and girls from the two schools in the polluted area had significantly higher levels of lead in blood (PbB) but similar levels of cadmium (CdB) and zinc protoporphyrins (ZPP). The functional integrity of the kidney was assessed by measuring the urinary excretion of beta 2-microglobulin, Clara cell protein, retinol-binding protein (RBP), albumin and beta-N-acetyl-D-glucosaminidase. The most significant and consistent finding of the study was that children from the two schools in the polluted area showed a significant elevation of the urinary excretion of RBP that paralleled the level of lead in blood or in the dust collected on the school playgrounds. A similar pattern was observed for the prevalence of elevated values of urinary RBP which increased from 3.9% in the control area up to 17% in the most polluted school. Urinary RBP was found to be associated with PbB (partial $r^2 = 0.046$, $P = 0.005$) in a stepwise regression analysis testing also the influence of age, sex, CdB, and ZPP. In conclusion, the present study suggests that lead contaminating the environment may cause slight effects on the proximal tubule function in children at exposure levels close to those associated with CNS deficit

N2 - We report the clinical manifestations and outcome of 82 patients with nontumoural parietal lobe epilepsy treated surgically at the Montreal Neurological Institute between 1929 and 1988. Patients with extensive resections extending outside the parietal lobe were excluded. Ninety-four percent exhibited auras: the most common were somatosensory, described by 52 patients; 13 of these also described pain. Other auras included disturbances of body image, visual illusions, vertiginous sensations and aphasia or dysphasia. A few patients exhibited complex visual or auditory hallucinations and elementary visual hallucinations. Intraoperative cortical stimulation reproduced the habitual auras in 44 patients. Often the clinical manifestations indicated ictal spread to the frontal, supplementary motor area, or temporo-limbic areas: 28% of patients exhibited tonic posturing of the extremities, 57% unilateral clonic activity, 17% oral or gestural automatisms and 4% complex automatisms. Sixty-one percent of patients with tonic posturing had epileptogenic zones which included the superior parietal lobe, and in 79% of patients with automatisms the epileptogenic zones extended to the inferior parietal lobe, suggesting different spread patterns. Forty-three patients underwent right, and 39 left parietal corticectomies. Postoperative sensory deficits were seen only when the corticectomy extended into the post-central gyrus. Early in the series extensive nondominant inferior parietal resections led to disturbances of body image in a few

patients. Follow-up ranging from 2 to 50 years was available for 79 patients. Sixty-five percent had a complete or nearly complete cessation of seizures. Those patients with no post-resection electrocorticographic epileptiform discharges had a more favourable outcome. [References: 63]

N2 - Diet, weight-bearing physical activity (WPA) and daylight hours spent outdoors (DE) were related to bone mineral density in the distal (BMDd) and ultradistal (BMDud) forearm of 495 healthy children (8-11 years) and adolescents (11-17 years). BMD was assessed by single photon absorptiometry. Using multiple regression, BMDd was predicted by saturated fat and BMDud by fiber in children. In adolescents, BMDd was predicted by saturated fat and vitamin C, and BMDud by calcium and vitamin C. WPA and DE were not related to BMD. In conclusion, our results showed that current intake of calcium, saturated fat, fiber and vitamin C were positively associated with forearm BMD in children and adolescents. These associations depended on age and bone type. If our findings are verified, dietary recommendations, especially when aimed at young people, may have to be reconsidered

N2 - We analyzed the relationship between daily high temperature and mortality in Kyushu, Japan, 1972-1990. Mortality rate was obtained by dividing the number of deaths in a certain daily high temperature category by person-days in the same category. The results were as follows: (1) With daily high temperature on the x-axis and mortality rate on the y-axis, the relationship between the two variables appeared to be V-shaped. The minimum mortality rate was observed at the 28 degrees C-33 degrees C level. (2) Among all deaths at 33+ degrees C level, the proportion of deaths from "excessive heat" never exceeded 0.4%. This suggested that heat stroke is not a major contributor to the V-shape formation. (3) The V-shape was observed even in 1990, suggesting that the rapid spread of air conditioners did not alter the relationship between daily high temperature and mortality rate. (4) For the 0-4 years age group, mortality was not temperature dependent. However, the 5-14 years age group showed high mortality rates at 33+ degrees C. This may be attributed to outdoor activities during summer. After 30 years of age, the overall mortality rates rose with age, with greater increases at lower ambient temperature levels. As a result, the 65+ years age group had the greatest temperature dependence. (5) Deaths from respiratory diseases, circulatory diseases, and senility were highly temperature dependent, whereas death from cancer was not temperature dependent. Deaths from digestive diseases, infectious diseases, and accidents showed moderate temperature dependence

N2 - Residential exposure to elemental mercury typically involves small amounts (e.g., the approximately 0.3 mL in a thermometer). During August 1994, five children residing in a neighborhood in Palm Beach County, Florida, found 5 pints of elemental mercury in an abandoned van. During the ensuing 25 days, the children shared and played with the mercury outdoors, inside homes, and at local schools. On August 25, 1994, a parent notified local police and fire authorities that her children had brought mercury into the home. On the same day, 50 homes were immediately vacated and an assessment of environmental and health impacts was initiated by the State of Florida Department of Environmental Protection, the Health and Rehabilitative Services of the Palm Beach County Public Health Unit, and the U.S. Environmental Protection Agency. This report summarizes the investigation of this incident.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - We present a hypothesis that the risk of childhood leukemia is related to exposure to specific combinations of static and extremely-low-frequency (ELF) magnetic fields. Laboratory data from calcium efflux and diatom mobility experiments were used with the gyromagnetic equation to predict combinations of 60 Hz and static magnetic fields hypothesized to enhance leukemia risk. The laboratory data predicted 19 bands of the static field magnitude with a bandwidth of 9.1 microT that, together with 60 Hz magnetic fields, are expected to have biological activity. We then assessed the association between this exposure metric and childhood leukemia using data from a case-control study in Los Angeles County. ELF and static magnetic fields were measured in the bedrooms of 124 cases determined from a tumor registry and 99 controls drawn from friends and random digit dialing. Among these subjects, 26 cases and 20 controls were exposed to static magnetic fields lying in the predicted bands of biological activity centered at 38.0 microT and 50.6 microT. Although no association was found for childhood leukemia in relation to measured ELF or static magnetic fields alone, an increasing trend of leukemia risk with measured ELF fields was found for subjects within these static field bands (P for trend = 0.041). The odds ratio (OR) was 3.3 [95% confidence interval (CI) = 0.4-30.5] for subjects exposed to static fields within the derived bands and to ELF magnetic field above 0.30 microT (compared to subjects exposed to static fields outside the bands and ELF magnetic fields below 0.07 microT). When the 60 Hz magnetic fields were assessed according to the Wertheimer-Leeper code for wiring configurations, leukemia risks were again greater with the hypothesized exposure conditions (OR = 9.2 for very high current configurations within the static field bands; 95% CI = 1.3-64.6). Although the risk estimates are based on limited magnetic field measurements for a small number of subjects, these findings suggest that the risk of childhood leukemia may be related to the combined effects of the static and ELF magnetic fields. Further tests of the hypothesis are proposed

N2 - Research in West Africa has begun to document the phenomenon of child fostering although little attention has focussed on other types of non-maternal child care arrangements and their impact on child health. Evidence from a sample of 77 weaned children under five in rural Mali found that over one third (35%) of children were not the prime responsibility of both their biological parents. Nineteen per cent (N = 15) of the sample were formally fostered children, known as sukaabe bambaabe, who lived neither with their biological mothers nor with their biological fathers. Others lived under flexible or semi-permanent non-maternal care arrangements both within and outside the agnatic family. Factors precipitating fostering are outlined and are divided into: (i) those under which the child is fostered away from its biological family through force of circumstance; and (ii) those under which the child is actively requested by its foster mother. Rather than fostering providing a universal option for over-burdened mothers with too many or too closely-spaced children, the field evidence shows that the movement of children within and between households is rigorously controlled by the female social hierarchy. Children are transferred in a uni-directional fashion from the care of their low status biological mothers to high status foster mothers. Their transfer serves to visibly reinforce socio-political

power differentials between these women who are at different stages of the female life-cycle and in different sets of household circumstances. Economic factors are not associated with the decision to keep the child or to foster it away, but do appear to determine whether the children living under non-maternal care are fostered out under a structured or unstructured fostering arrangement. Contrary to findings in other West African settings, fostering per se has little impact on children's nutritional outcomes as measured by their weight-for-age Z-Scores, probably because the use of surrogate or sibling caretakers is common in this environment even for children who are the full responsibility of their biological mothers. The context of the fostering, however, does influence fostered children's nutritional status. Those children who were requested by their foster mothers had better nutritional outcomes than those who were fostered in by force of circumstances. It is concluded that the concept of 'maternal and child health' and the 'maternal-child' dyad around which both health interventions and demographic evaluations are centred, may not always be appropriate in areas of high fostering prevalence

N2 - An ozone (O3) exposure assessment study was conducted in Toronto, Ontario, Canada during the winter and summer of 1992. A new passive O3 sampler developed by Harvard was used to measure indoor, outdoor, and personal O3 concentrations. Measurements were taken weekly and daily during the winter and summer, respectively. Indoor samples were collected at a total of 50 homes and workplaces of study participants. Outdoor O3 concentrations were measured both at home sites using the passive sampler and at 20 ambient monitoring sites with continuous monitors. Personal O3 measurements were collected from 123 participants,

who also completed detailed time-activity diaries. A total of 2,274 O3 samples were collected. In addition, weekly air exchange rates of homes were measured

N2 - OBJECTIVE: To determine the pattern of perineal injuries and frequency of hymenal involvement resulting from unintentional trauma in prepubescent girls. DESIGN: Prospective, multicenter. Observation by skilled observers. Determination of the circumstance and physical pattern of injury, with specific attention to the hymen. SETTING: Children's emergency department or acute care clinic. PATIENTS: Tanner stage 1 girls presenting with acute perineal injury. Criteria for unintentional injury: observation of the event or knowledge of the girl's engagement in a risky activity (eg, biking or climbing monkey bars) immediately before the injury. RESULTS: Fifty-six girls were evaluated. Age range: 1 to 12 years (median, 6 years; mean, 6.2 years). Associations: bicycle, 39%; other outdoor injuries, 25% (climbing apparatus, straddling an object, and falls); indoor injuries, 36% (straddling furniture and falls). Most injuries were minor. In each group the labia minora was the most frequent structure involved. The majority of injuries were anterior or lateral to the hymen. However, in 34% some or all of the injuries were posterior to the hymen. Thigh injuries were observed only in older children engaged in bicycle riding or outdoor play. In only one patient was the hymen involved. That patient was a 2 year old who fell outdoors, at a park, abducting her legs in a splits-type mechanism. She had a

pinpoint abraded area on the hymenal surface at three o'clock. Otherwise, no unique pattern of injury was associated with age or circumstance of injury. **CONCLUSIONS:** Hymenal injuries are rarely the result of unintentional injury. The presence of a hymenal injury should suggest sexual abuse. Involvement of other perineal structures was commonly associated with unintended injury. Given the limited resources for prevention, the relative infrequency of perineal injuries and the minor nature of most of these injuries, significant preventive efforts are not justified

N2 - The objectives of this research were to study the epidemiological characteristics and home-based treatment of childhood burns in the Ashanti Region of Ghana. Children aged 0-5 years with a burn history were identified through a community-based, multisite survey. A standard questionnaire was administered to mothers of 630 of these children to elicit information on their sociodemographic characteristics and the circumstances of the burn event. Ninety-two per cent of the burns occurred in the home, particularly in the kitchen (51 per cent) and the house yard (36 per cent), with most of them happening in the late morning and around the evening meal. The main causes of the burns were scalds (45 per cent), contact with a hot object (34 per cent) and flame (20 per

cent). 'Cool' water was applied to the burned area in 30 per cent of cases. Otherwise, treatment with a traditional preparation was the most popular first-aid choice. Since a considerable proportion of burns happened between meals when children 'play with fire' in the house yard, the provision of alternative play activities and community play areas may reduce the incidence of burns to these children. Secondly, we recommend that education on first-aid management of burns be intensified, with special emphasis on alternatives to the use of traditional preparations

N2 - The epidemiology of tuberculosis remains poorly understood. We investigated the relative importance of within-household and community transmission of infection among children aged 6 months to 14 years living in a Peruvian shanty-town. The prevalence of Mycobacterium tuberculosis exposure among 175 contact children (sharing a household with a person who had confirmed pulmonary tuberculosis) and 382 control children (living in nearby households free of active tuberculosis) was defined as the proportion of children with a positive purified protein derivative (PPD) skin-test. 97 (55%) contact children and 129 (34%) controls were PPD positive. Living in a contact household (odds ratio 1.74, 95% CI 1.11-2.73) and age (1.11, 1.06-1.18) were significant risk factors for PPD positivity. We calculated the community infection ratio (CIR) as the odds ratio of PPD-positive controls to PPD-positive contacts: $CIR = \frac{OR_{contact}}{OR_{community}}$. A low CIR therefore suggests mainly household spread of infection, whereas a high value suggests frequent transmission outside the household. The adjusted odds ratio (for age, sex, within-household correlation, and household size) was 0.40 (95% CI 0.26-0.64), compared with values of 0.18-0.37 in studies elsewhere. Currently recommended tuberculosis control strategies are suitable for areas with low CIRs. Different strategies may be needed for areas, such as that we studied, with high values

N2 - 31Phosphorus nuclear magnetic resonance spectroscopy was used to examine skeletal muscle in 29 patients with mitochondrial myopathy, 9 male and 20 female. Gastrocnemius was investigated in 15 patients and 30 normal subjects and finger flexor muscle (flexor digitorum superficialis, fds) in 24 patients and 35 normal controls. Both muscles were studied in 10 of the patients. Results were abnormal (outside the full range of normal values) in all but 2 patients. In 86% of patients (25/29) abnormalities were detected in resting muscle. In most cases there was a low phosphocreatine/ATP ratio, high calculated free [ADP] and low phosphorylation potential. At rest, abnormality was detected with equal ease in fds and gastrocnemius. Exercise and recovery increased the sensitivity of MRS in detecting abnormal metabolism. Finger flexion was better tolerated by patients than plantar flexion and gave bigger changes in metabolite concentrations and intracellular pH. Thus, results from fds were more easily differentiated from normal. Exercise duration was significantly shorter than in controls while phosphocreatine depletion was more rapid than normal, consistent with a shortfall in mitochondrial ATP synthesis. Nearly all patients (25/27, 93%) showed abnormalities during recovery from exercise. [ADP] was high during exercise and its recovery was delayed, providing increased drive for oxidative phosphorylation. Phosphocreatine resynthesis during recovery (which reflects oxidative ATP synthesis) was slow both in absolute terms and in relation to [ADP]. Recovery of intracellular pH after exercise was significantly more rapid than normal, consistent with an upregulation of proton efflux.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - Eighteen people with learning disabilities who moved from hospital to community-based homes were compared with a matched group of 18 who did not. A week-long time budget diary was used to record each occasion that the person left their home, the people accompanying them on each trip, their mode of transport and their destination. The diary was completed before they left the hospital and was repeated at least 1 year later. There was a strong correlation between the number of trips made from hospital wards at baseline and the number made at follow-up in both groups. Moving from the hospital had no significant effect on the number of trips made, but it did change their nature. Movers made more trips to unsegregated facilities; they made fewer trips alone and more in groups which included both staff and residents

N2 - No gamma-interferon production was observed in peripheral blood mononuclear cells (PBMC) cultures from 45 patients living in an endemic area of schistosomiasis in Brazil following in vitro stimulation with schistosomula or adult worm antigens from *Schistosoma mansoni* (4.9 +/- 2.4 and 1.0 +/- 3.4 pg/ml, respectively). This immunological abnormality was observed in patients both with a high degree of infection (> or = 400 eggs/g feces) and with a low degree of infection (< 400 eggs/g feces), and was independent of the degree of natural exposure to infection. This absence of gamma-interferon production was antigen specific since high levels of this cytokine were detected in the same patients when their cells were stimulated with PPD (247 +/- 179 pg/ml) or PHA (408 +/- 328 pg/ml). In two of four subjects cured of a previous *S. mansoni* infection and currently living outside the endemic area, gamma-IFN was produced when their PBMC were stimulated with adult worm antigen (75 +/- 2.5 pg/ml)

N2 - We assessed blood pressure responses of a multiethnic (Black and White) sample of 120 children of hypertensive families to orthostasis, video game, forehead cold, and dynamic exercise, and monitored the children's ambulatory pressure 24 hours later. Thirteen children were studied twice (1-year stability). The Black children exhibited higher 24-hour ambulatory systolic and diastolic pressures than the White children. Regardless of ethnicity, peak and mean systolic pressures during each task were generally positively correlated with mean systolic pressure while the children were awake and asleep. Associations between diastolic pressor responses and ambulatory measurements were somewhat dependent upon ethnicity and task. Relatively few reactivity-ambulatory correlations were significant, using pressor reactivity change scores. The children who participated twice exhibited significant 1-year stability for most ambulatory and pressor measurements. Children's pressor responses to laboratory tasks may generalize to the natural environment

CY - NORWAY

N2 - Two-hundred-and-fifty patients were registered in a population-based study of neuroblastomas in Denmark in the period 1943-80. The major epidemiological findings were an increased incidence with an unchanged mortality rate during the study period. The increase in incidence related solely to children 0-4 years of age and was most pronounced in infants under 1 year of age. Several reasons for the observed epidemiological rates include (i) changes in the composition of the population, (ii) improved diagnostic procedures, (iii) a shift in the diagnostic criteria, and (iv) an increase in environmental carcinogens of importance in the induction of neuroblastoma. Associated with an increased risk were lower socio-economic levels and young or advanced parental age, suggesting the importance of environmental as well as genetic factors for the induction of neuroblastoma. The epidemiological findings of an increased incidence with an unchanged mortality rate, which suggests the inclusion of borderline lesions in recent years, are of major importance in interpreting the results of mass screening for the disease. The clinical findings in 253 patients treated in Denmark from 1943 to 1980 (including 5 patients resident outside Denmark and excluding 2 patients without available hospital records) were analysed. The major finding was a zero-time shift, that is, earlier diagnosis of the disease during the study period, with increasing survival rates from decade to decade mostly due to a better age and stage distribution, a zero-time shift which was also apparent in the changes of the symptomatology. Independent prognostic variables were age, stage, and treatment with chemotherapy for children over 1 year of age with stage II disease, and for infants with stages III-IV disease. Analysis of data from a subset of the 253 children suggested that high proliferative activity detected by flow cytometry may be an important prognostic variable. The study also suggests that the pattern of metastatic spread might have changed as a consequence of prolonged survival obtained by improved treatment modalities, stressing the importance of a high frequency of autopsy among cancer patients. Hypotheses generated by the study included (i) that most neuroblastomas might be congenital, (ii) that the age influence on prognosis might be explained in terms of growth rate, cell cycle transit time, and duration of the disease, and (iii) that some neuroblastomas might be borderline lesions. N2 - This retrospective study was designed to document the etiology of traumatically ruptured globes in children and to determine the prognostic value of several clinical parameters with respect to visual outcome. Forty-six children 16 years of age and under seen in the emergency room over a 2-year period were found to have full thickness penetration of the globe. Fifty-nine percent of injuries occurred during recreational activities, and 59% occurred outside of the home. Boys outnumbered girls by a 6:1 ratio. For children, initial visual acuity proved to be less valuable as a prognostic indicator with regard to final vision than has been reported in adults. Smaller corneal wounds offered better visual outcomes. Four eyes were enucleated. Ten ruptures (22%) were related to activity involving guns. Four of six BB gun injuries were the result of a ricocheted BB. Visual outcomes in gun-related injuries were particularly poor

N2 - Consultation-liaison psychiatry emerged in a particular socio-historical context, following a major shift of medicine into a more scientific, hospital-based system. Psychiatrists realized that they needed to move outside of the asylum and reintegrate themselves with the new structures of medicine, especially the general hospital and the medical school. Psychosomatic theory and psychoanalytic influence shaped the emergence of consultation-liaison activities in the 1930s through 1950s as they shaped most psychiatric services in the United States at that time, but they were an epiphenomenon to this powerful underlying dynamic that dictated psychiatry's move into the medical hospital. The experience of other countries tends to confirm this hypothesis, though a comparative history is limited by the strong postwar US influence. Pediatric consultation-liaison had a somewhat different evolution, reflecting the later emergence of pediatrics itself as a field and its strong psychosocial and preventive medicine emphasis

N2 - Allergic sensitization and symptoms from the airways in relation to air pollution were compared in 10-12-year-old school children (n = 1113) from urban Konin in central Poland and both urban and rural parts of Sundsvall in northern Sweden. The measurements included parental questionnaires, skin-prick tests and serial peak flow measurements during 2 weeks with simultaneous monitoring of outdoor air pollutants. The skin-prick test technique was validated by IgE antibody determinations. The levels of common industrial pollutants, SO₂ and smoke particles were much higher in Konin than in urban Sundsvall and the levels of NO₂ were similar. Various respiratory symptoms were more often reported among school children in Konin (except for wheezing and diagnosed asthma). Multiple logistic regression analyses yielded the following increased odds ratios for children in Konin as compared with the reference group (rural Sundsvall): chest tightness and breathlessness 3.48 (95% confidence interval 2.08-5.82), exercise-induced coughing attacks 3.69 (95% confidence interval 1.68-8.10), recurrent episodes of common cold 2.79 (95% confidence interval 1.53-5.09) and prolonged cough 4.89 (95% confidence interval 2.59-9.23). In contrast, as compared with rural Sundsvall, the adjusted odds ratio for a positive skin-prick test was decreased in Konin, but increased in urban Sundsvall, 0.58 (95% confidence interval 0.37-0.91) and 1.67 (95% confidence interval 1.15-2.42) respectively. The study confirms that living in urban, as compared with rural areas, is associated with an increased prevalence of respiratory symptoms and sensitization to allergens. These differences could be explained by air pollution. Respiratory symptoms were more common in a similar urban group of Polish children who were exposed to even higher levels of air pollution. These children, however, had a much lower prevalence of sensitization to allergens, as compared with the Swedish children. This indicates that differences in lifestyle and standard of living between western Europe and a former socialist country influences the prevalence of atopy

N2 - Sixty preschoolers (30 deaf and hard of hearing, 30 hearing) were observed in their integrated school during "centers" and outdoor play. Half the children experienced auditory communication and half total communication modes of communication. All children had known their classmates for six months to three years. It was found that all children preferred to play and communicate with same-hearing status children, however 63% of all children communicated with children of other-hearing status. Amounts of social play and communication differed somewhat between the two communication environments, and context of interaction was related to the behavior and communication of children who were deaf and hard of hearing. Implications are discussed for the education of young children who are deaf and hard of hearing--specifically that educational and social benefits accrue to those who are integrated throughout the school day (across context) and have access to hearing classmates and classmates who are deaf and hard of hearing

N2 - This study analyzed 73 electrocochleographic recordings made in children with a normal hearing threshold, selected retrospectively from 1563 recordings made between 1973 and 1990. The aim of the study was to check the original findings for any correlation between the various response parameters which might be indicative of a pathological condition. Compound action potential (AP) latency and amplitude, presynaptic summation potential (SP) and cochlear microphonic (CM) amplitudes and AP rapid adaptation behavior were calculated and recordings were associated with clinical information on aetiologic diagnosis, otoscopic examination, impedance measurement data and the finding of any central nervous system (CNS) pathology. The trend of the amplitudes as a function of the intensity of all three potentials (input-output functions), CM and SP in particular, demonstrated unexpected scattered values especially towards the high intensities. This was found correlated to the presence of CNS pathology. The comparison between the two groups (with vs without CNS pathology) with the aid of the Student's t-test proved statically significant, especially for CM and SP amplitudes while rather less so for AP amplitude. In particular, all CM and SP amplitude values outside the confidence intervals (calculated as 95% of normal cases) revealed CNS pathology. It has been suggested that the influence of the CNS on cochlear function is due to a disturbed function of the olivocochlear bundle, which is known to have an inhibitory effect on cochlear dynamics; furthermore, there is also proof that it can be activated regardless of any ipso-and/or contra-lateral acoustic stimulation. The effects observed on the electrocochleography in cases with CNS disorders would thus be explained by an interruption of the olivocochlear bundle at the CNS level or a disruption of the CNS mechanism capable of controlling its activation

N2 - BACKGROUND: Oral azelastine, a nonsteroidal antiinflammatory respiratory investigational drug has demonstrated activity in the treatment of allergic rhinitis and asthma with a good safety profile. METHODS: Azelastine nasal spray was compared with sustained-release oral chlorpheniramine maleate and placebo for efficacy and safety in the treatment of seasonal allergic rhinitis in a double-dummy, two-center, 2-day, double-blind, randomized, dose-ranging, parallel-groups, onset and duration of action study. Two hundred sixty-four subjects reported to an outdoor park on Saturday morning during the height of the fall pollen season and remained there for 8 hours that day and the next to ensure maximal exposure to seasonal aeroallergens. Symptom diary cards were collected hourly Saturday from 8:00 AM to 10:00 AM (baseline period). Subjects who had sufficient symptoms were randomized into five groups and received medication at 10:00 AM and 10:00 PM on Saturday and at 10:00 AM on Sunday: azelastine 0.1% (1 spray [0.12 mg] per nostril every 12 hours, 2 sprays per nostril every every 12 hours, or 2 sprays per nostril once daily), Chlor-Trimeton Repetabs (12 mg twice daily), or placebo (twice daily). Diary cards were completed hourly (11:00 AM to 4:00 PM) and at 6:00, 8:00, and 10:00 PM on Saturday and again hourly on Sunday (from 8:00 AM to 4:00 PM) to evaluate rhinitis symptoms and adverse events. RESULTS: Two hundred fifty-nine subjects completed the study. The groups that received 2 sprays of azelastine per nostril once and twice daily and the chlorpheniramine group had statistically significantly more improvement in total rhinitis symptoms than the placebo group without serious adverse events. CONCLUSIONS: This study supports a once to twice daily dosing regimen for 2 sprays of 0.1% azelastine in the acute treatment of allergic rhinitis with onset of action within 2 to 3 hours

N2 - This report, which is based on laboratory reports and patient records, covers the epidemiology, etiology and antibiotic susceptibility of all bacteremic episodes at a community hospital during 1988-90. The overall incidence was eight episodes per 1000 patient admissions, though this figure varied considerably between departments and between age groups. Most organisms were community acquired, and we had few *Klebsiella* spp., *Pseudomonas* spp., anaerobic bacteria, fungi and polymicrobial episodes. There were fewer antibiotic resistant strains than reported from outside Scandinavia. The combination of benzylpenicillin and aminoglycoside (plus metronidazole in surgical wards) has a broad enough spectrum of activity for 95% of our patients with sepsis of unknown origin. Thus, our rather "old-fashioned" prescribing policy, with the new and broadspectrum cephalosporins and betalactam drugs constituting only a minor part, is still good practice. The study also shows that cumulative reports issued by the local microbiological laboratory bring awareness to these issues and affect the prescribing pattern in a positive way

N2 - The incidence and pattern of injuries to children in public playgrounds presenting to the accident and emergency department were reviewed over two six month summer periods in Cardiff. A total of 178 children (mean age 7.5 years) attended with a playground injury representing 1.1% of all the children attending. One hundred and five children fell from equipment, of which the commonest was the climbing frame; 125 children had playground surface related injuries, 86 on bark and 30 on concrete. The pattern of injuries on the playground surfaces was different: fractures and sprains were more common on bark surfaces and lacerations and abrasions on concrete surfaces. Comparison of total injury rates showed there were fewer injuries on modernised playgrounds than expected but these differences were not significant. Modernised playgrounds are more popular, have new exciting equipment, and offer good play opportunities for children. However, the high fracture rate on modernised bark playgrounds is concerning and requires further research

N2 - Toxocara seroprevalence and the relation between Toxocara seroprevalence and allergic asthma were investigated in Dutch schoolchildren aged 4-6 years. Data on Toxocara antibodies, allergen-specific immunoglobulin E, allergic manifestations, and risk factors (pets and playgrounds) were obtained from 235 children from The Hague and 477 from Rotterdam, the Netherlands. The surveys were carried out from September 1987 to January 1988 in The Hague and in March and April 1989 in Rotterdam. Logistic regression was used to evaluate putative relations. Toxocara seroprevalence was higher in The Hague (11%) than in Rotterdam (6%), but this difference was not quite significant. Seroprevalences varied widely among schools. No differences between socioeconomic categories or between the sexes were found. Occurrences of asthma/recurrent bronchitis and hospitalization due to asthma/recurrent bronchitis were significantly associated with seroprevalence. Furthermore, a marginally significant relation with eczema was found. Immunoglobulin E specific for inhaled allergens occurred significantly more often in the Toxocara-seropositive group. The risk factors investigated were not related to seroprevalence. It is suggested that Toxocara, among other environmental factors, may stimulate polyclonally immunoglobulin E production, including allergen-specific immunoglobulin E, and thus may contribute to the manifestation of allergic asthma and possibly of eczema in children predisposed to allergy

N2 - If we are committed to the health and development of children, we need to recognize that the vast majority of the world's women are working women. In Africa, 80% of the women are actively engaged in economic activities outside the home. The "economic miracle" in Southeast Asia was made possible by the nimble fingers of thousands of women working in textile and electronics factories. There is need for pre-day-care advocacy for infants, through promotion of breast feeding and maternity leave. When the mother returns to work, the standard of the International Labor Organization should be applied, namely" ...the care of children while the parents are working cannot be ignored because it forms a focal point on which three main concerns of development policy--work, health, and education--converge." Several principles emerged from the presentations in the international panel: 1. Child-care programs must be community based, using the resources of the families and the community organizations themselves. 2. Programs require the active involvement of the communities, women's groups, and other partners. 3. Programs are modified by innovations created by community organizations, universities, and other groups. 4. Programs require the mobilization of trained young men and women into the field of early childhood education and development. This international panel provided an overall uniting theme, that throughout the world the hope for the survival and better life for children unites parents of every country and every creed. This is one of the most powerful and strongest motivational resources in the world.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - **PURPOSE:** Standard practice in protecting against chemotherapy-associated infection has been chemotherapy dose modification or dose delay, administration of progenitor-cell support, or selective use of prophylactic antibiotics. Therapy of chemotherapy-associated neutropenic fever or infection has customarily involved treatment with intravenous antibiotics, usually accompanied by hospitalization. The hematopoietic colony-stimulating factors (CSFs) have been introduced into clinical practice as additional supportive measures that can reduce the likelihood of neutropenic complications due to chemotherapy. Clinical benefit has been shown, but the high cost of CSFs has led to concern about their appropriate use. The American Society of Clinical Oncology (ASCO) wishes to establish evidence-based, clinical practice guidelines for the use of CSFs in patients who are not enrolled on clinical trials. **METHODS:** An expert multidisciplinary panel reviewed the clinical data documenting the activity of CSFs. For each common clinical situation, the Panel formulated a guideline to encourage reasonable use of CSFs to preserve effectiveness but discourage excess use when little marginal benefit is anticipated. Consensus was reached after critically appraising the available evidence. Guidelines were validated by comparing them with recommendations for CSF use developed in other countries and by several academic institutions. Outcomes considered in evaluating CSF benefit included duration of neutropenia, incidence of febrile neutropenia, incidence and duration of antibiotic use, frequency and duration of hospitalization, infectious mortality, chemotherapy dose-intensity, chemotherapy efficacy, quality of life, CSF toxicity, and economic impact. To the extent that these data were available, the Panel placed greatest value on survival benefit, reduction in rates of febrile neutropenia, decreased hospitalization, and reduced costs. Lesser value was placed on alterations in absolute neutrophil counts (ANC). **CONCLUSIONS:** CSFs are recommended in some situations, eg, to reduce the likelihood of febrile neutropenia when the expected incidence is $>$ or $=$ 40%; after documented febrile neutropenia in a prior chemotherapy cycle to avoid infectious complications and maintain dose-intensity in subsequent treatment cycles when chemotherapy dose-reduction is not appropriate; and after high-dose chemotherapy with autologous progenitor-cell transplantation. CSFs are also effective in the mobilization of peripheral-blood progenitor cells. Therapeutic initiation of CSFs in addition to antibiotics at the onset of febrile neutropenia should be reserved for patients at high risk for septic complications. CSF use in patients with myelodysplastic syndromes may be reasonable if they are experiencing neutropenic infections. Administration of CSFs after initial chemotherapy for acute myeloid leukemia does not appear to be detrimental, but clinical benefit has been variable and caution is advised. Available data support use of CSFs in pediatric cancer patients similar to that recommended for adult patients. Outside of clinical trials, CSFs should not be used concurrently with chemotherapy and radiation, or to support increasing chemotherapy

dose-intensity. Further research is warranted as a means to improve the cost-effective administration of the CSFs and identify clinical predictors of infectious complications that may direct their use. [References: 256]

N2 - This study systematically compared the influence of naturalistic social behaviors and nonbehavioral variables on the development of peer status in 49 previously unfamiliar boys, aged 6-12 years, who attended a summer research program. Twenty-five boys with attention-deficit hyperactivity disorder (ADHD) and 24 comparison boys participated. Physical attractiveness, motor competence, intelligence, and academic achievement constituted the nonbehavioral variables; social behaviors included noncompliance, aggression, prosocial actions, and isolation, measured by live observations of classroom and playground interactions. As early as the first day of interaction, ADHD and comparison boys displayed clear differences in social behaviors, and the ADHD youngsters were overwhelmingly rejected. Whereas prosocial behavior independently predicted friendship ratings during the first week, the magnitude of prediction was small. In contrast, the boys' aggression (or noncompliance) strongly predicted negative nominations, even with nonbehavioral factors, group status (ADHD versus comparison), and other social behaviors controlled statistically. Implications for understanding and remediating negative peer reputations are discussed

N2 - **PURPOSE:** To assess the efficacy of interstitial brachytherapy in the treatment of patients with recurrent malignant astrocytoma. **METHODS AND MATERIALS:** Forty-six patients with recurrent malignant astrocytoma were treated with stereotactic high-activity temporary iodine-125 implants between September, 1986 and October, 1992. All patients had been initially treated for malignant astrocytoma (44) or low-grade astrocytoma (2) with surgery and external fractionated radiation. The median time between initial diagnosis and recurrence treated with brachytherapy was 12.5 months. Twenty-five patients received chemotherapy prior to brachytherapy. **RESULTS:** All but four patients have died; median survival time following brachytherapy is 46 weeks. Twelve patients underwent reoperation for radiation necrosis at a median interval of 6.5 months after treatment (26%). Five patients incurred complications directly due to brachytherapy (11%). Forty-four patients are evaluable regarding pattern of failure following brachytherapy. Six of these 44 patients (13.6%) recurred at a distance from the treatment volume (4 in brain and 2 in spinal subarachnoid space). **CONCLUSION:** Brachytherapy confers modest but meaningful prolongation of survival in selected patients with recurrent malignant astrocytoma, but complications are significant, reoperation frequently required, and recurrence outside the treatment volume common

N2 - **PURPOSE:** Television watching has been reported to be associated with obesity, resting energy expenditure, and lower daily physical activity among both children and adolescents. However, most of these studies were based on self report or data collected in laboratory settings. This study examined the relationship among observed time of television watching, observed physical activity level and body composition among 3- or 4-year-old children. **METHODS:** African-American (41.4%), Mexican-American (23%), and Anglo-American (35.6%) children (N = 191, males = 90) from the Texas site of the Studies of Child Activity and Nutrition program were observed from 6 to 12 hours per day up to 4 days over 1 year. Activity level each minute of the day was measured with the Children's Activity Rating Scale (interobserver reliability = .84 +/- .001). The interobserver reliability of time of television watching was .96 +/- .08. **RESULTS:** The median of the longest number of consecutive minutes of television watching was 15 (range = 1 to 79). The median percent of minutes of television watching of total observed minutes was 14.8% (0% to 58%) and the median percent of minutes of inside minutes was 17.9% (0% to 80.9%). There were no gender or ethnic differences in time

watching television or physical activity during television watching. Physical activity during television watching was lowest during the longest bout of television watching (mean = 1.48 +/- .28) compared to outside minutes (mean = 2.38 +/- .21), inside non-television minutes (mean = 1.96 +/- .13) and inside television minutes (mean = 1.65 +/- .18). The level of physical activity during television-watching times was highest ($P < .0031$) during October and November and lowest during March, April, June, and July. Longest bout of television watching and percent of minutes watching television to total observed minutes were inversely associated with mean physical activity, percent of minutes of physical activity levels 3, 4, or 5, and percent of physical activity levels 4 or 5. Percent of television watching to inside minutes was negatively correlated with physical activity levels 4 or 5. Television-watching behavior was not associated with body composition. CONCLUSIONS: Television watching was weakly negatively correlated with physical activity levels, and physical activity was lower during television-watching than non-television-watching time in this sample of children. Television viewing behavior was not associated with body composition

N2 - Serpentine asbestos from the Naslawice mine, which contains mineral impurities of the serpentinite group - chrysotile and antigortie, has been used to built school sports grounds as well as roads and playgrounds within residential areas. The study was aimed to measure concentrations of respirable mineral fibres in the atmospheric air at the time children were playing on one of the playgrounds as well as at four other sites of Wroclaw. Air samples were collected using individual dosimeters and distributions of length and concentration of fibres were measured by means of a laser fiber monitor FM7400. X-ray diffraction and infrared spectrometry were used to determine the mineral composition of raw material collected from the playground. Morphology of particles of dust from the atmospheric air was analysed by means of electronic microscopy. It was found that the concentration of mineral fibres in the air in question depended on the number of children playing, namely when 7 children were playing the concentration value was equal to 165 fibres/litre and 549 fibres/litre with the number of 20 children. The concentration of fibres in a flat in the vicinity of the playground covered with serpentinite was about 11 times higher than at a street crossing with heavy traffic of motor vehicles. Antigortie and chrysotile were found in samples of raw material used to cover the playground. Numerous particles of fibrous structure were observed in the electronic microscopy image of air dust samples collected from the playground

N2 - The Colorado Asthma Ski Day, an annual cross-country and alpine skiing event, encourages children with asthma to participate fully in outdoor winter sports. Since cold air and exercise can trigger bronchospasm, we examined the peak expiratory flow rates of 80 children who attended Asthma Ski Day 1992 or Asthma Ski Day 1993 to establish a safety profile for this event. Peak expiratory flow rates were measured prior to skiing, at lunchtime, and at the end of the day's activities. We asked the children to pretreat with their regular medications, as prescribed by their physicians, to use their bronchodilator inhalers p.r.n., and to report to our medical station if an episode of acute asthma occurred. The average age of the participants was 9.5 years, and the average baseline daytime peak flow rate was 100.03% of predicted. The average percent change in peak flow rates during the day was an increase of 5.00%. Our results demonstrate that with medical supervision, peak expiratory flow rate monitoring, and properly administered medications, peak flow rates can be stabilized and even improve during cold-weather exercise to an extent that safety concerns need not restrict children with asthma from engaging in exercise or cold-weather sports. The Colorado Asthma Ski Day can serve as a model event for other organizations that want to promote outdoor activities for children with asthma

N2 - Power mower trauma remains an alarmingly frequent cause of serious injury in young children. The patterns of mower-related injuries in children < 15 years old (n = 13) were compared with those of adults aged 15-64 (n = 16) and elderly victims > or = 65 years old (n = 6), who were similarly injured over the past 5 years. Children were more likely to be injured in accidents involving high-energy riding mowers. Of those children injured, 69% (9 of 13) were playing in the yard while 31% (4 of 13) were riding on the mower with a guardian when the injury occurred. Amputations in children were more frequent and more extensive than in the adults and included one forearm, two Symes, and three below-knee amputations. The need for transfusion was also significantly increased in children (62% vs. 6% adults, p < 0.005), who were also more likely to require prolonged hospitalization (11.8 days vs. 5 days in adults, p < 0.005). Aggressive efforts to increase public awareness regarding the cause and nature of power mower injuries are warranted to decrease the incidence of this debilitating but preventable trauma in young children

N2 - Representative isolates of *Pseudomonas cepacia* from 15 cystic fibrosis (CF) patients attending the Respiratory Unit of Alder Hey Childrens' Hospital were investigated by SDS-PAGE of whole-cell polypeptides and by pyrolysis mass spectroscopy (PMS). SDS-PAGE was less discriminatory than PMS. Eleven isolates were indistinguishable by PMS and considered to represent re-isolates of an endemic strain; four isolates were distinct from this group, and from one another. *P. cepacia* was first isolated on the unit in July 1989 from a patient who had attended a UK selection meeting for a Canadian CF camp. A ward and outpatient segregation policy was introduced, but colonisation of further patients occurred. In August 1991, the Adult CF Association recommended that all social activities involving colonised patients should cease. This, and an increased awareness amongst older CF patients of the risks of person-to-person transmission, was associated with a marked decline in new cases. Social activity and hospital admissions were compared for colonised patients during the year before colonisation with *P. cepacia*, and matched patients who did not acquire the endemic strain. This showed a significantly higher attendance at CF social events for colonised patients, but no significant association between colonisation and hospital admission. These results are strong indirect evidence that transmission of *P. cepacia* occurs through social contact outside the hospital environment

N2 - The needs and clinical decisions of care centres are related to patients' ability to carry out daily living activities. Most of the functional scales are not easy to use. This study examined the inter-rater agreement of the Functional Independence Measure (FIM) and a subjective uniform continuous scale (UCS) (the rating varied between 0 = complete dependence and 9 = complete independence) between 'educators', physiotherapists and occupational therapists. Two hundred and fifty-four patients aged below 20 in a rehabilitation centre were rated by professionals who were most familiar with them. For the two scales, inter-rater agreement was very good for all activities except for locomotion outside the centre for the UCS. The rating differences were slightly smaller for the FIM than for the UCS. Physiotherapists rated similarly to occupational therapists. The educators rated slightly though significantly lower than the other raters. The differences could be explained by their professional activities

N2 - Acute Respiratory Infections (ARI) are a major cause of death in children under five in rural Bangladesh. A popular strategy for lowering ARI mortality in such settings includes detecting and managing pneumonia in children at the community level. The success of programs using this approach requires a well-trained community-based cadre of health workers and the appropriate utilization of services provided. Determinants of health care seeking behavior are clearly of interest in this regard. A qualitative study was conducted in Matlab, Bangladesh to describe community perceptions of signs and symptoms of ARI, case management behavior, and constraints to service utilization. Mothers recognized pneumonia and thought it to be caused by "exposure to cold." They were able to identify labored breathing, chest retractions, lethargy, and inability to feed as signs of severe disease needing treatment outside the home. Nevertheless, similar illnesses were sometimes believed to be due to attack by evil influences. In these cases, spiritual healers were sought and allopathic treatment was avoided or delayed. The mothers' observance of purdah and "proper" behavior were reported to play a role in prevention of child death from disease. Implications of this belief and its impact on service utilization are discussed. Suggestions for program managers are made in addition to recommendations for further research

N2 - Knowledge of how deaf children use speech outside the classroom or therapy room many enhance our ability to improve their speech in a variety of situations and with a variety of communication partners. Past research has shown that deaf children's interactions in informal settings with their mothers and hearing peers create situations that can foster improved linguistic skills. In the current study, the amount and intelligibility of spoken language output in 15 deaf children ages 4-5 to 9-8 years during 15 minutes of free play with their mothers was compared with output and intelligibility during a similar session with a self-selected hearing peer. The results, which indicated that significantly more speech was produced during the children's interaction with their mothers, are discussed in terms of future research

N2 - 4 types of after-school care (formal after-school programs, mother care, informal adult supervision, and self-care) were examined for 216 low-income children (M age = 9.1 years). After-school care was associated with maternal education, race, and family income but not with child gender, family marital status, neighborhood safety, or parenting style. When maternal education, race, and family income were controlled, attending a formal after-school program was associated with better academic achievement and social adjustment in comparison to other types of after-school care. Children's activities and experiences also varied in different after-school settings. Children in formal programs spent more time in academic activities and enrichment lessons and less time watching TV and playing outside unsupervised than other children. They also spent more time doing activities with peers and adults and less time with siblings than did other children. The time that children spent in these activities was correlated with their academic and conduct grades, peer relations, and emotional adjustment

N2 - Kenya experienced a severe drought and temporary food shortage during a study on mild malnutrition. Effects of the temporary food shortage on energy intake, weight, and behaviors were evaluated in schoolchildren and in toddlers and their mothers. Schoolchildren were seriously affected, showing significant declines in their energy intake, age-corrected weight, activity on the playground, and classroom attention. Toddlers appear to have been somewhat protected since their energy intake, weight, and play and language behaviors were stable. Maternal caregiving of toddlers declined for the group as a whole, but individually those mothers who maintained family food levels delegated responsibility for toddlers to other caregivers. While the food shortage affected poorer families more than those of higher SES, declines in the behaviors of schoolchildren occurred regardless of SES and previous level of nutrition, suggesting that food shortages can have behavioral consequences for schoolchildren in all communities

N2 - This study was conducted in Switzerland between May and October 1989 to assess possible decrements in lung function occurring as a result of 10 minute exposure to ambient air containing different ozone concentrations. Once a month, 128 children in two different areas of Southern Switzerland (Chiasso and Aurigeno) had a pulmonary function test before and after a standardized 10 minute exercise (pulse rate, 170/min) on a cycle ergometer, outdoors. Ozone concentrations were similar in both areas, ranging from 40 to 157 micrograms/m³ (1/2h means) during the exercise tests. The two communities differed with respect to long-term average pollution levels. The mean NO₂ concentration over the six months study period was 70 micrograms/m³ in Chiasso and 18 micrograms/m³ in rural Aurigeno. Of the eligible children 85% participated and attended 4-6 tests. Parents completed a standardized questionnaire on family background, home characteristics and the child's early and present illness history. A total of 500 acceptable pairs of spiromograms and corresponding ozone concentrations (average 3.8 per child) were available for analysis. Regressions of each individual's pre-post differences of FVC, FEV₁ and peak flow on ozone concentrations measured during the outdoor exercise indicated that elevated ozone levels significantly reduced peak flow values. Adjustments for temperature and relative humidity increased the magnitude of the peak flow slopes. The average adjusted regression coefficient for delta-peak flow on ozone was -2.28 mL/s/micrograms/m³ (95% CI, -0.57 -3.99). It is noteworthy that the observed relationships occurred at ozone concentrations below 160 micrograms/m³ and after an exercise duration of only 10 minutes

N2 - OBJECTIVES: The aim of the study was to define the phenotype in three families with mild haemophilia A and to determine restriction fragment length polymorphisms (RFLP), which could support a hypothesis of a common progenitor of the families. DESIGN: Family survey. SETTING: Index cases were identified in and outside hospital and a family survey for symptoms and signs of bleeding in family members and sampling for coagulation and RFLP studies were mostly carried out in the field. SUBJECT: Family members with and without symptoms of bleeding were selected for investigation and normal spouses and unrelated individuals were investigated for control. INTERVENTIONS: Medical advice regarding affected family members were given to the families and their physicians. MAIN OUTCOME MEASURES: Bleeding time, factor VIII activity, quantification of factor VIII:Ag, von Willebrand factor (vWF) Ag and vWF ristocetin assay. Typing of RFLP polymorphisms for genetic homogeneity. RESULTS: Bleeding manifestations are present in both sexes in the three families although more frequent and more severe in the males. The level of factor VIII activity is between 10 and 20% in most affected males whereas 35-60% is found approximately in 2/3 of female carriers and in 1/3 of them factor VIII activity is within the normal range. It is suggested that screening for this mild haemophilia A gene by a molecular genetic method would be of clinical value now, its mutation having been detected.

CONCLUSIONS: Transmission of mild haemophilia A through six to seven generations is demonstrated by the study. The mild haemophilia A type described is the most prevalent of haemophilia A types in Iceland (population 260,000, 1992). The founder effect was confirmed by studies of RFLP polymorphisms

N2 - Two young boys were struck by lightning during summer outdoor activities. One of them died. A literature review reveals that the most commonly reported locations of childhood lightning injuries are on the playing field, at the swimming pool, and in tents. Knowledge of measures to lower the risks of lightning strikes as well as the use of new lightning detection technology should help to reduce the numbers of these tragic events in the future. N2 - To examine injuries related to playground equipment, children's vehicles, roller skates, and skateboards, 1991 data on emergency room patients younger than 25 years in the Consumer Product Safety Commission's 91 surveillance hospitals were used. Head injury was the primary diagnosis for an estimated 58,480 patients, exceeding the total number of head injuries to bicyclists younger than 25 years. The head injury rate decreased with age. The large number and high rate of head injuries in children involved in a variety of recreational activities suggests the value of multipurpose helmets

N2 - In 1991 it was discovered, that a large number of sporting grounds and playgrounds in Germany were covered with a waste slag material from a former copper smelter located at Marsberg, Germany. This material was found to contain high levels of PCDD/F ranging up to 100,000 TE/kg. The objective of the present study was to assess whether subjects sporting on such grounds had elevated levels of PCDD/F in blood. PCDD/F in blood fat was used as an indicator of the PCDD/F body burden. Additionally, six children and seven residents of a contaminated sporting and playground were examined. Generally, the levels of PCDD/F in blood fat were in the range of background levels in all subjects. Taking into account the effect of age, slightly elevated blood levels of PCDD/F were detected in children. The results show that the bioavailability of PCDD/F in the slag material is very low. However, from the preventive point of view children who might ingest slag material by hand-to-mouth-activities, should not play on such contaminated playgrounds

N2 - We investigated whether an exercise challenge protocol is suitable for measuring bronchial responsiveness in epidemiological studies of asthma in children, and determined its comparability with histamine challenge. The exercise challenge was 6 minutes of outdoor, free-range running at 85-90% of maximum heart rate, measured by heart rate monitor. Nose clips were worn. Distance run was measured to estimate oxygen consumption. Water content of the inspired air was $< 10 \text{ mg H}_2\text{O.l}^{-1}$. Histamine challenge was by the rapid method. We used questionnaires to measure respiratory symptoms and skin prick tests to measure atopy. A total of 96 children aged 8-11 years were studied. Bronchial hyperresponsiveness (BHR) to exercise challenge was defined as a fall in forced expiratory volume in one second (FEV1) of 13% or greater. Eleven children had a positive response to exercise challenge and 11 to histamine challenge but 12 responded to one challenge and not to the other. The correlation coefficient between the two tests was 0.65 ($p = 0.0001$). Exercise challenge thus proved to be a practical epidemiological tool for objective measurements of bronchial responsiveness in children. In this sample, some children responded to one challenge and not to the other which suggests that the two challenges identify different abnormalities of the airways

N2 - Current guidelines for heparin therapy in pediatric patients have been extrapolated from trials in adult patients without rigorous evaluation of efficacy and safety. We prospectively monitored consecutive pediatric patients receiving systemic doses of heparin over 10 mo at one institution using a predetermined nomogram to monitor maintenance therapy. Sixty-five consecutive children; 38 males and 27 females, received systemic doses of heparin. Thirty children had deep venous thrombosis and/or pulmonary embolism; 11 had arterial thrombi, most frequently after diagnostic angiography; and the remaining 24 received heparin prophylactically, for congenital heart disease. Twenty-nine (45%) of the 65 patients were less than 1 y of age and 22 (34%) were 10 y or older. Congenital heart disease was the predominant diagnosis under 1 y and deep venous thrombosis in older children. After a bolus dose of 50 U/kg, 39% of children (n = 30) achieved a minimal level activated partial thromboplastin time (APTT). Sixty-eight percent of children achieved a minimal level APTT by 24 h and 81% by 48 h. For all 65 children, APTT values were within the therapeutic range 43% of the time. APTT values outside the therapeutic range were twice as likely to be low as high. The average amount of heparin required to maintain therapeutic APTT values for children was 22 U/kg/h: 28 U/kg/h for infants < 1 y and 20 U/kg/h for the rest. Bleeding was rare (2%) and mild. Documented recurrent thrombotic disease was more common (7%) with associated morbidity.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - OBJECTIVE: To apply a measure of exposure to injury risk for schoolchildren aged 11-14 across a population and to examine how risk factors vary with sex, age, and affluence. DESIGN: Self completion questionnaire survey administered in schools in May 1990. SETTING: 24 schools in Newcastle upon Tyne. SUBJECTS: 5334 pupils aged 11-14, of whom 4637 (87%) completed the questionnaire. RESULTS: Boys were exposed to greater risk than girls in journeys to places to play outdoors; they took longer trips and were more likely to ride bicycles (relative risk 5.30 (95% confidence interval 4.23 to 6.64)) and less likely to travel by public transport or car. Younger pupils (aged 11-12) were less exposed to traffic during journeys to and from school: their journeys were shorter, they were less likely to walk (trip to school, relative risk 0.88 (0.83 to 0.94)), and they were more likely to travel by car (trip to school, relative risk 1.33 (1.13 to 1.56)) or school bus (1.33 (1.10 to 1.62)). Poorer children were exposed to greater risk than affluent children (from families that owned a car and a telephone): they were less likely to travel to school by car (relative risk 0.26 (0.20 to 0.33)) or to be accompanied by an adult (0.39 (0.32 to 0.48)). CONCLUSION: Injury risk data can provide useful information on child injury prevention and can be used to identify priorities and target resources for injury prevention on a citywide scale or for an individual school

N2 - A large scale study of human exposure to nitrogen dioxide (NO₂) was conducted in the Los Angeles Basin, the only metropolitan area in the United States that exceeds the NO₂ NAAQS. Data are available for a population representative sample of 482 households and 682 individuals. Personal exposures, as well as indoor and outdoor home levels, were monitored using passive time-integrating filter badges. Monitoring extended over a one-year period (May 1987 to May 1988), with each individual providing two consecutive days of data. Information was also collected on activity patterns, household and personal characteristics, and spatial and temporal variables. This paper describes the study design, summarizes the sample characteristics and representativeness, and presents the distribution of personal, indoor, and outdoor NO₂ concentrations recorded by the monitors. Over the entire sample, median personal and outdoor levels were 35 ppb; median indoor levels were 24 ppb. Personal exposures for those in homes with gas ranges with pilot lights average 10 ppb greater than those with electric ranges, and 4 ppb greater than those with gas ranges without pilot lights. Forty percent of the variation in indoor concentrations is explained by outdoor levels; 59 percent of the variation in personal exposures is explained by indoor levels; and 48 percent of the variation in personal exposures is explained by outdoor levels

N2 - OBJECTIVE: Because an increasing proportion of US children spends time in day care center environments, a national estimate of injury risks in day care centers is needed. METHODS: We interviewed directors of 1797 day care centers from every state and the District of Columbia from October to December 1990 and analyzed medically attended injuries and center characteristics reported by the directors. RESULTS: The centers were attended by 138,404 children. In the 2 months before the center directors were interviewed, 556 children sustained injuries requiring medical attention while attending the centers. The injury rate was 1.5 injuries per 100,000 child hours in day care. The most common injuries were cuts or lacerations (31%), bumps or bruises (15%), fractures (10%), and dental injuries (8%). Most injuries (51%) occurred on the playground. Many injuries (18%), and more than half of fractures and concussions (53%) were due to falls from climbing equipment. CONCLUSIONS: Day care center injury rates estimated by this study were relatively low. Many injuries that occur in this setting are probably minor. However, lowering the height of playground equipment and providing more resilient playground surfaces could further reduce injury risks in day care centers.

N2 - A nine-home pilot study was conducted to evaluate monitoring methods in the field that may be used to assess the potential exposures of children aged 6 months to 5 years to pesticides found in the home environment. Several methods, some of which were newly developed in this study, were tested for measuring pesticide residues in indoor air, carpet dust, outdoor soil, and on the children's hands. Information was also collected on household characteristics, pesticides used and stored at the residence, and children's activities. Pesticides were detected at all nine study homes. With the exception of one home, at least one pesticide was detected in all matrices sampled at each house. Of the 30 target pesticides, 23 were detected during the study. The most frequently detected pesticides were chlordane, chlorpyrifos, dieldrin, heptachlor, and pentachlorophenol. The greatest number of pesticides and highest concentrations were found in carpet dust. The results of these investigations will be discussed in terms of performance of the methods and the distribution of pesticides across the various media sampled

N2 - Varicella-zoster virus (VZV) is a highly contagious infectious agent that causes outbreaks in institutional settings. Transmission of VZV is felt to occur following direct contact with an infected individual and by aerosol spread. To document the aerosolization of VZV, a polymerase chain reaction (PCR) assay was used to detect VZV DNA in air samples obtained from hospital rooms of patients with active VZV infection. VZV DNA was detected in 64 (82%) of 78 air samples from rooms housing patients with active varicella and 9(70%) of 13 samples from rooms of patients with herpes zoster. VZV was detected 1.2-5.5 m from patients' beds and for 1-6 days following onset of rash. On some occasions, VZV DNA could be detected outside the hospital isolation rooms housing patients. This PCR-based method allows the detection and semiquantitation of VZV aerosolization and can be a useful tool for monitoring efforts to control VZV aerosols in the environment

N2 - Communities surrounding the Rocky Mountain Arsenal (RMA), a Superfund site in Colorado, were studied in order to determine whether exposures to arsenic were greater among persons who resided there than among residents of a comparison area. A census was conducted in areas adjacent to the RMA and in a comparison area 12-15 miles distant. From a stratified random sample, 469 persons were interviewed and urine samples obtained. Arsenic was detected in urine from 43 (9.2%) of the 469 persons sampled at a detection limit of 10 ppb. Trace levels of arsenic (detectable, but non-quantifiable) were found in 184 (39.2%) of those persons sampled. Neither the frequency of detection, the arithmetic mean nor the geometric mean values for urine arsenic was found to be statistically different when persons living near the site were compared to persons from the more distant comparison area. Therefore, the data were pooled across the study areas to evaluate risk factors for exposure to arsenic in this population-based sample. Multivariate logistic regression analyses were conducted to evaluate the risk of arsenic exposure associated with variables included in the interviews while controlling for confounding. Pathways for exposure to arsenic were evaluated through analysis of residence history, occupation, hobbies, dietary habits, water supply, housing and activity patterns. Children of Hispanic origin or non-white race, children who drank less than three glasses of water daily, and children who spent more time outdoors had an increased risk of having $>$ or $=$ 10 ppb of arsenic in their urine. Among adults, younger persons, especially those less than 40 years of age, persons of Hispanic origin or nonwhite race, and those employed in occupations where arsenic is likely to be found had an increased risk of having $>$ or $=$ 10 ppb of urine arsenic. Consumption of red wine or fish during the week prior to sampling was associated with trace levels of arsenic in urine

N2 - Between 1984, and 1992, we observed 8 patients with an obstructed St. Jude Medical (SJM) valve. Of these, 1 had an obstructed SJM valve in the aortic position, 3 in the mitral position, and 4 in the tricuspid position. Diagnosis of obstruction of the SJM valve was made by cineradiography combined with echocardiography in all 8 patients. Restriction or absence of movement of the leaflet of the SJM valve was observed by cineradiography in all of the 8 patients. Normal range of leaflet mobility of the SJM valve was measured by conventional cineradiography in 70 patients with a normal SJM valve, and the results were compared with the leaflet mobility obtained from the 8 patients with an obstructed SJM valve. In this study, leaflet function in the obstructed SJM valve was strikingly abnormal, with both opening and closing angles, and leaflet motion clearly outside the normal range. Of the 8 patients, 4 underwent urgent prosthetic valve replacements after cineradiography and echocardiography were carried out. Thrombolysis using urokinase was performed in 4 patients, and this treatment was successful in 1 patient. Efficacy of thrombolytic therapy was evaluated by repeat cineradiography. Three of the 4 patients who received thrombolysis showed no significant improvement of leaflet mobility after at least 72 hours of thrombolytic therapy, and finally required surgical correction for the obstructed SJM valve. We believe that cineradiography combined with echocardiography is the optimal method for the diagnosis of obstruction of the SJM valve, and to follow the effect of thrombolytic therapy on prosthetic valve function.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - Epidemiological studies indicate a world-wide and significant increase in atopic diseases over the past decades, which has adopted alarming dimensions within the industrialized world. However, allergic asthma and pollinosis, in particular, are on the increase in Third world countries, in parallel to the industrialization and westernization of their life-style. Since both antigen exposure and the presence of additional realization factors are required for the manifestation of atopic diseases, this increase in prevalence is not surprising. In addition to increased indoor and outdoor pollution, changes in the way of living--causing increased allergen exposure--certainly play an important role as cofactor in the increased incidence of allergies. Accurate diagnostic procedures permit a better understanding of the realization factors for allergic diseases in epidemiological studies and identification of the causative agent in the individual so that effective therapeutic and prophylactic steps can be taken. Despite improved in vivo and in vitro test methods, the case history is still of paramount importance in reaching a diagnosis; the potential hazards of skin and provocation testing, as well as the high costs and limitations of in vitro methods prohibit "blind allergy screening". N2 - In Djohong in the wet season the prevalence of malaria is 17.5% for Plasmodium falciparum and 1.1% for Plasmodium malariae. In children 2 to 9 years of age the plasmodic index is 38.6% (mesoendemicity) for the children of the peasants and 9.4% for those belonging to other socioeconomical groups. In infants less than 12 months old, the plasmodic index is 9.3%, this relatively high rate corresponding to the high transmission period of the rainy season. Anopheles gambiae is the mosquito species most often found in the area (2/3 of the mosquitoes caught in the houses). The breeding sites in the surrounding of the houses are rainwater holes linked to human activity. At a larger distance from the houses, in the valley, the breeding sites are water holes borrowed for the retting of cassava tubercle or natural rock pools found in the basaltic shores of the Mbere river. The trophic activity of Anopheles gambiae and Anopheles funestus is high between 0 and 4 hours a.m. In

October the mean number of anopheline mosquitoes bites per night per inhabitant is 33 inside the houses and 7 outside

N2 - To demonstrate the prevalence of Toxocara eggs in sandpits in Tokushima Prefecture, Japan, sand samples were examined. Of 46 sandpits surveyed, 29 sandpits (63.3%) had Toxocara eggs. Sandpits in public parks and playgrounds in residential areas were more contaminated (87.5%) with the eggs than those in kindergartens, schools, and children's centers (36.4%). To examine the seasonal change in the contamination, sand samples obtained from five sandpits were examined monthly from May 1990 to April 1991. Toxocara eggs were found in the majority of sandpits (3/5-5/5) in the spring, early summer, and autumn. In the summer and winter, the

rates of sandpits contaminated were lower (2/5-3/5) than in other seasons. Egg counts became smaller in the summer and winter, especially in summer. The ratio of *T. canis* to *T. cati* eggs recovered was 2:3. Fecal examination of 144 puppies revealed that 98 (68.0%) were positive for *T. canis* eggs. These findings show that *Toxocara* eggs, a possible causative agent of visceral larva migrans, commonly present in sandpits of the urban area. To prevent the contamination of sandpits with these eggs, control measures are needed

N2 - During summer 1991, we collected indoor, outdoor, and personal ozone concentration data as well as time-activity data in State College, Pennsylvania. These concentrations were measured for 23 children and their homes using passive ozone samplers. Outdoor concentrations were also measured at a stationary ambient monitoring site. Results from this pilot study demonstrate that fixed-site ambient measurements may not adequately represent individual exposures. Outdoor ozone concentrations showed substantial spatial variation between rural and residential regions. Ignoring this spatial variation by using fixed-site measurements to estimate personal exposures can result in an error as high as 127%. In addition, evidence from our pilot study indicates that ozone concentrations of a single indoor microenvironment may not represent those of other indoor microenvironments. Personal exposures were significantly correlated with both indoor ($r = 0.55$) and outdoor ($r = 0.41$) concentrations measured at home sites. Multiple regression analyses identified indoor ozone concentrations as the most important predictors of personal exposures. However, models based on time-weighted indoor and outdoor concentrations explained only 40% of the variability in personal exposures. When the model included observations for only those participants who spent the majority of their day in or near their

homes, an R2 of 0.76 resulted when estimates were regressed on measured personal exposures. It is evident that contributions from diverse indoor and outdoor microenvironments must be considered to estimate personal ozone exposures accurately

CY - GERMANY

N2 - In 1991 "Kieselrot", a material with extremely high PCDD/PCDF-contamination up to about 200,000 ng TEQ/kg was detected on many leisure centres and sports fields in Germany. The contaminated grounds were closed, and covered up. The following examinations to prepare the planned decontamination are described here. The need for decontamination of those "Kieselrot"-areas is discussed with special reference to its relevance on

behalf of environmental toxicology and preventive medicine. Risk estimates, based on mathematical models had shown a considerable health and cancer risk for the users of such play- and sports grounds. However, recent studies conducted with sportsmen, groundsmen, and residents after many years of contact with "Kieselrot"-covered grounds did not reveal any additional PCDD/PCDF blood fat burden. But raised TEQ-levels and a typical congeneric pattern pointing to a "Kieselrot"-load could be seen in some of the examined children. Following these results it was concluded that children play grounds contaminated with "Kieselrot" should remain closed and should be decontaminated, whereas sports fields could be used again. Another possibility could be the adaption of the decontamination concepts and methods to the proven low bioavailability of PCDD/PCDF from "Kieselrot"

N2 - In a prospective study it was found that cerebral palsy constituted 0.29% of total paediatric outdoor cases during the study period of 1988-1990. Seventy-five children suffering from cerebral palsy were studied at SN Children Hospital, Allahabad. Male to female ratio was 1:2. There were 42.8% cases who belonged to the age between one and 2 years. Hypertonic cases were predominant over hypotonic cases (3:1). Hemiplegia was commonest (68%) while triplegia was least common (2.7%). There were 24.5% cases who were mentally retarded. Hypertonic cases improved more frequently than hypotonic cases. An early management by paediatric physiotherapy may play an important role in the treatment of cerebral palsy

N2 - Endurance training was conducted on a group of 41 East Indian boys aged 10-14 years and was compared with 25 untrained boys of the same age. A continuous slow-running method was adopted for 12 weeks. The intensity of the training was 80-85% of maximum heart rate and frequency was 3 days per week. The boys were trained for a 1500-m event and therefore they covered three to five times their racing distance. For psychological reasons the training was carried out in a playground. The investigations included different physical and motor fitness tests: measurement of flexibility, agility, speed, leg muscle strength etc. Their performance times were also recorded before and after training. From statistical analysis we concluded that this particular type of training programme did not produce any detrimental effects on 10-14-year-old boys. On the other hand, this type of training did have some influence on improving physiological parameters in this age group of boys when compared with untrained boys of the same age

N2 - The distribution of individual lifetime exposures to radon was estimated using data from studies on radon concentrations, mobility, and time-activity patterns in the state of California. The distributions of radon concentrations in various geographic regions were obtained from the results of year-long radon measurements of 310 residences. The mobility patterns were acquired through a survey of the moving histories of the members of 507 households. The indoor and outdoor time-activity data were collected for 1,780 individuals in 1,596 households. Based on these data, a computer simulation technique was used to estimate the distribution of radon exposures with a parametric (lognormal model) and a nonparametric approach (bootstrap method). The estimated average lifetime exposure for radon was 2,448 Bq.m-3.yr for the lognormal model and 2,487 Bq.m-3.yr for the bootstrap method. The standard deviation was 1,130 and 1,145 Bq.m-3.yr respectively. Assuming no move over the lifetime, the estimated average lifetime exposure to radon was 2,052 Bq.m-3.yr for the lognormal model and 2,078 Bq.m-3.yr for the bootstrap method, while the standard deviation increased to 1,378 Bq.m-3.yr for the lognormal model and 1,514 Bq.m-3.yr for the bootstrap method

N2 - Repeated measurements of nitrogen dioxide were obtained from 1988 to 1991 in the homes of 1,205 infants living in Albuquerque, NM. Passive diffusion samplers were used to obtain a series of two-week integrated measurements from the home of each infant for use in a cohort study of the relation of residential exposure to nitrogen dioxide and respiratory illnesses. Information on stove use and time spent inside the residence was collected at two-week and two-month intervals, respectively. During the winter, in the bedrooms of homes with gas cooking stoves, mean nitrogen dioxide concentrations were 21 parts per billion (ppb); mean concentrations in the living room and kitchen were 29 ppb and 34 ppb, respectively. In homes with electric cooking stoves, the mean bedroom concentration was 7 ppb during the winter. Lower indoor concentrations were observed during the summer in homes with both gas and electric stoves. On average, infants spent approximately 12.3 hours per day in their bedrooms, 7.3 hours in the living rooms, 35 minutes in the kitchens, and 3.8 hours out of their homes. (As a condition of participation, none of the infants spent more than 20 hours per week in day care outside of their homes). The mean time infants spent in the kitchen during cooking was approximately nine minutes per day. We tested whether exposures of infants living in homes with gas stoves could be reasonably estimated by measurements in the bedroom in comparison with time-weighted average concentrations based on time-activity data and simultaneous nitrogen dioxide measurements in the kitchen, living room, and bedroom. In 1,937 two-week intervals from 587 infants, 90% of time-weighted exposure (on the three-level classification used in this study) estimates were in agreement with estimates based on bedroom concentrations alone. The agreement of the time-weighted nitrogen dioxide exposure estimates with the bedroom concentrations is attributed to limited amounts of cooking stove use (the mean was 29 minutes per

day), small room-to-room differences in nitrogen dioxide concentrations (the mean kitchen-bedroom difference was 12 ppb), and the relatively large proportion of time that infants spent in their bedrooms

N2 - Posttraumatic stress disorder is a form of anxiety disorder which is poorly known in children and manifests as a series of symptoms occurring after an extraordinary event outside the range of usual human experiences and responsible for a feeling of terror. Virtually pathognomonic symptoms include re-experiencing the event through play and ceaselessly repeated behaviors (re-enactments), cognitive distortions when relating the facts (chronological errors, belief in omens), changes in attitudes towards others and life in general, and neurovegetative hyperactivity (hypervigilance, startle responses, difficulties controlling impulses). Although adequate follow-up data are lacking, the disorder can probably become chronic in children, as in adults. This nosographic entity raises the theoretical issue of the roles of life events and individual vulnerability. A number of factors may either "predispose" or "protect" the child: degree and duration of exposure to the trauma, nature of the event, preexistence of psychiatric disorders, level of cognitive development, sex, degree of social support, and containing or noncontaining attitude of the family. Treatments advocated in adults (pharmacotherapy, cognitive and behavioral therapies, group therapy) remain to be used and evaluated in children. [References: 23]

N2 - This study investigated the mediational role of affect in the influence of perceived success, causal attributions, and friendship provisions on choice and future expectancies for success and enjoyment, using a multi-sample structural equation modeling approach. Subjects were 422 seventh- and eighth-grade students participating in physical education classes. Higher levels of perceived success, personally controllable attributions, companionship, and esteem support were found to positively influence levels of affect experienced, which in turn enhanced future expectancies for success and enjoyment in physical education and choices to participate in physical activity outside of school. Furthermore, participation experience outside of school influenced adolescents' perceptions within the physical education setting and their consequent affect and motivation

N2 - Twenty-two potential correlates of children's physical activity were examined. Two hundred and one Mexican-American and 146 Anglo-American families with 4-year-old children were studied. Children's physical activity was directly observed in the evening at home on 4 visits for 1 hr each time. Anglo-American children and male children were found to be more active. Demographic variables explained 11% of the variance in children's physical activity. After adjusting for demographics, 3 children's variables and 6 social-family variables did not account for significantly more variance. Five environmental variables accounted for 11% additional variance. Variables observed concurrently with physical activity, such as time spent outdoors and prompts to be active, were highly associated with children's physical activity

N2 - BACKGROUND: There is some controversy as to the fitness levels of U.S. school-age youth. Some experts claim that U.S. youth are fit. Others feel that there has been a decline, despite a recent adult fitness boom. **METHODS:** The purpose of this article is to examine the research conducted on the cardiovascular endurance and body composition levels of U.S. youth. Research studies noting the activity patterns of youth outside and during physical education are presented. The frequency and duration of physical education requirements are also reviewed. The effects of these patterns and requirements on cardiovascular endurance and body composition are presented. **RESULTS:** U.S. youth do not engage in physical activity, within our outside physical education, sufficient to develop cardiovascular endurance. Our youth are, therefore, at risk of developing a myriad of diseases associated with sedentary lifestyles. **CONCLUSIONS:** Exercise is known to have a prophylactic effect on disease, death, and disability. Young people must be instructed and encouraged to be involved in lifetime fitness activities if we are going to control health care costs, reduce disease incidence, and improve the overall quality of life of our citizens. N2 - In a retrospective survey of patients with fractures and dislocations attending the Accident department of a District General hospital, comparison was made between patients with fractures and dislocations in the hand and fractures and dislocations of other sites. Patients with hand injuries accounted for 28% of the total patients seen. They were more likely than other fracture patients to be male and between the ages of 10 and 40 years. Almost a quarter of hand injuries attended on Monday. Leisure activities outside the home formed the commonest aetiological factor. Only 66% of patients with hand injuries attended the Accident department within 24 hours of injury. The little finger was the commonest site of injury. This survey emphasizes the differences between hand injuries and injuries of other sites, identifies the risk factors for hand injuries and has implications for the management of hand injuries in a District General Hospital

N2 - Since reduced physical activity might be a risk factor for body weight gain, we studied the relationship between physical activity and body composition in 43 Pima Indian children (22 male/21 female, mean +/- s.d.: 9.9 +/- 1.1 years) and 42 Caucasian children (21 male/21 female, 9.7 +/- 1.2 years). A list of usual sport leisure activities was established (e.g. bicycling, swimming, basketball) and the subjects were asked how much time they had devoted to each activity over the past week and the last year. Data on time spent playing outside (excluding sport leisure activities for the estimation of physical activity) and watching television/videos were also collected. Pima Indians were taller (143 +/- 9 vs. 137 +/- 8 cm, $P < 0.001$), heavier (48.6 +/- 15.8 vs. 32.9 +/- 7.8 kg, $P < 0.0001$) and fatter (39 +/- 16 vs. 24 +/- 7% fat, $P < 0.001$) than Caucasians. Pima Indian girls showed significantly lower past year and past week sport leisure activity than Caucasian girls ($P < 0.01$) and spent significantly more time watching television/videos ($P < 0.05$). Pima boys also showed significantly lower past week sport leisure activity than Caucasian boys ($P < 0.05$). In Pima Indian boys, past year sport leisure activity correlated negatively ($P < 0.05$) with body mass index ($r = -0.49$) and percentage body fat ($r = -0.56$). However, such correlations were not found in Pima Indian girls, possibly due their very low levels of activity. (ABSTRACT TRUNCATED AT 250 WORDS)

N2 - Hypoglycaemia is the most frequent acute complication of insulin-dependent diabetes mellitus. The clinical symptoms of insulin-induced hypoglycaemia can be grouped into those attributable to the sympathetic and adrenergic responses, e.g. tremor, pallor, palpitation, sweating, mydriasis ('hypoglycaemia awareness'), and those attributable to brain dysfunction, ranging from headache to convulsions and coma. Hypoglycaemia in diabetic children can occur at any time of the day, but nocturnal hypoglycaemia is a particular fear and worry. The frequency of mild hypoglycaemia is almost impossible to ascertain and the incidence of severe hypoglycaemia varies between 0.07 and 3.6 episodes per patient-year, though most authors report a range of 0.1-0.2 episode per patient-year. The most frequent causes of hypoglycaemia in diabetic children are deviations from treatment routine such as strenuous exercise, omission of snacks or skipped meals, and gross deviations from the prescribed times of insulin injections and recommended doses of insulin. Other predisposing factors include intensified insulin treatment, improved glycaemic control, young age, longer duration of diabetes and defective counterregulation. The available paediatric studies do not seem to support the suggestion that human insulin impairs the perception of hypoglycaemic symptoms ('hypoglycaemia unawareness') and increases the frequency of hypoglycaemic episodes, but further conclusive studies are needed. Prolonged and recurrent severe hypoglycaemia, particularly in younger children, can cause permanent neuropsychological dysfunction (e.g. learning disabilities) and permanent electroencephalographic abnormalities. Mild hypoglycaemia has also been documented to affect cognitive function, and the performance of neuropsychological tasks can remain decreased for some time (up to several hours) after full clinical recovery from hypoglycaemia. An impending hypoglycaemic attack can usually be averted by the ingestion of 20 g of rapidly absorbed carbohydrate. A severe episode can be effectively treated outside hospital with subcutaneous or intramuscular glucagon (0.5-1.0 mg) or in the hospital by an intravenous bolus of 0.2-0.5 g/kg glucose followed by a continuous glucose infusion. Patient and parent education and vigilant application of diabetes self-care principles are perhaps the most effective means of prevention, but in very young children a less strict metabolic control (higher glycosylated haemoglobin levels) may be necessary. N2 - An epidemiologic survey was conducted of the 818 households in a community consisting of aggregated dwelling units in Tokyo, Japan, in order to assess the relationship between housing environment and psychological or physical health status of the female residents. Psychological health status was assessed by the 28-item General Health Questionnaire in Japanese translation. Main housing factors such as internal density (person-to-room ratio) and floor level (vertical location) of the dwelling unit did not have significant effects on the psychological health status of the sample of Japanese women, but the internal density generally did not exceed 1.5 persons per room. However, physical health status might be associated with floor level: women living at the highest levels complained of more symptoms than did those at lower floor levels, when the type of dwelling unit (i.e., high-rise, low or medium height building) was not taken into account. Poor psychological health status was found among women who were dissatisfied with the plan of their house or with the room arrangement, were anxious about earthquake or other accidents, perceived the house as inadequate for the children, were annoyed by indoor noise, and complained of outdoor noise

N2 - In order to assess the health effect of environmental exposure to arsenic, the urinary arsenic concentrations were determined in 25 children aged 2-5 yr in the De Huet quarter in Doetinchem, an area with an increased amount of naturally occurring arsenic in the upper soil, and in 25 children from the other quarters of Doetinchem. With a questionnaire information was obtained regarding playing outdoors and eating fish (also a source of arsenic intake). There were no statistically significant differences in urinary arsenic concentrations between the subgroups of children

N2 - To examine patterns of seeking care for gravely ill infants and children, we studied all deaths in children under 5 in 10,000 households in Indramayu, West Java, Indonesia, between July 1, 1991, and Dec 31, 1992. 141 deaths were identified (mortality rate 80.7 per 1000), of which 139 were due to causes other than trauma. No treatment of any kind was sought outside the home for 30 (22%) of the children who died from natural causes, and for 59 (42%) others only a traditional healer or other source of non-western medical advice was consulted. Whether or not a mother sought western medical care was strongly associated with the age of the child, the duration of the terminal illness, the previous attendance of the mother at a community-based maternal-and-child-health facility, and the mother's response to a prospectively asked question about what care should be sought for a hypothetical 1-month-old baby with signs of severe pneumonia. Household income, maternal age, and education, and distance between home and government health post were not associated with whether or not western medical care was sought

N2 - We report the case of a 5-year-old girl with severe developmental disabilities, skeletal anomalies, hypotonia, rectal atresia, malrotation of the intestine, horseshoe kidney, vesicoureteric reflux, and minor facial anomalies. Conventional cytogenetic techniques suggested that she had a mosaic 46,XX/47,XX,+i(8p) constitution, and the identity of the isochromosome was confirmed by in situ hybridization and chromosome painting. Polymorphic DNA markers are consistent with the i(8p) having arisen as the result of a segregation error and centromere misdivision at the second maternal meiotic division. The i(8p) was seen in 17/25 (68%) lymphocytes at the age of one month but had declined to 31/100 (31%) cells by the age of 5 years. At this time the i(8p) was seen in 30/68 (44%) cultured skin fibroblasts. The proposita had an approximately twofold increase in red cell glutathione reductase activity but a normal level of tissue-plasminogen activator. These enzyme results are consistent with the known localisation of the glutathione reductase gene on the short arm of chromosome 8 but suggest that the tissue-plasminogen activator gene may map outside this region. N2 - Social and medical consequences of 278 children and 264 adults injured in bicycle accidents and seen in two hospitals in Helsinki in 1985-86 were analyzed. Information was collected from patient records, by means of a special questionnaire and by telephone interview. A child outpatient required 1.7 and a child inpatient 3.0 physician visits on an average, while adults required 2.2 and 4.9 visits, respectively. The average duration of hospital stay was 8 days for hospitalized adults and 6 days for children. Rehabilitative care outside the hospital was received by 6% of the adult outpatients and 25% of the inpatients, but none of the injured children. The mean duration of work disability was 82 days among inpatients, 11 days among outpatients, 127 days among the inpatients injured in motor vehicle collisions and 65 days among inpatients injured in other bicycle accidents. Of inpatients 32% and of outpatients 5% reported persistent (> 6 months) disability. Persistent disability was recorded in 11% of children, in 47% of adults and in 67% of elderly inpatients. Most serious consequences were

due to intracranial injuries in motor vehicle-bicycle collisions. Of the hospitalized bicyclists 4% suffered from severe cognitive and behavioural changes or sense impairment and of adult inpatients 3% suffered from permanent work disability. The average costs of health and social services were about FIM 1000 per adult outpatient and FIM 13000 per adult inpatient. In prevention high priority should be given to motor vehicle collisions, head injuries and injuries among the elderly bicyclists

N2 - INTRODUCTION: The main objective was to determine the risk factors involved in unintentional injuries in children under 10 years old occurring at home. MATERIAL AND METHODS: A Case Control study was conducted in the emergency room of three pediatrics hospitals in Mexico City. The sample size was 160 cases and 320 controls. RESULTS: Boys were more affected than girls (OR) 1.7, C.I. (95%) 1.2-2.5. The age group more affected was two-three years old (OR) 1.6, C.I.1.1-2.2. When children play outside home (roof, stairs,

patio) the risk was OR 2.48, C.I. 1.63-3.76. If mother is not encharged of children care (OR) 2.9, C.I. 1.8-4.8. The age > 40 years old of the person encharged of children care (OR) 2.2, C.I. 1.4-3.5. CONCLUSIONS: The results showed us how necessary is to develop injury prevention programs especially to implement passive measures, with target populations people encharged of children care

N2 - In study 1, 8- and 11-year-old girls and boys (N = 110) were interviewed individually and asked about why children in general, and themselves in particular, fight with fellow pupils in the playground. A substantial proportion of children (51 per cent) reported having had at least one aggressive fight during the previous year. The most common reasons for children resorting to fighting were retaliations to teasing, retaliations to unprovoked assaults, disagreements over aspects of the game that was being played, because another child was disliked, and to settle dominance disputes. In study 2, a direct observational methodology was employed to examine how often children of these ages engage in aggressive fighting, how long fights last, and their proximate causes. Among the younger pupils, a large proportion of fights (43.3 per cent) had no obvious immediate cause to an adult observer, but others were caused when a playful assault received an aggressive retaliation (15.4 per cent), and by disputes over space in the playground (13.5 per cent). Among the 11-year-old pupils, a smaller percentage of fights (14.8 per cent) had no obvious immediate cause. The two most common causes of fighting at this age were aggressive retaliations to teasing (25.9 per cent) and aggressive retaliations to accidental injury/hurt (18.5 per cent). In study 3, in situ interviews were combined with direct playground

observations in order to reveal participants' views (or onlookers' views if participants were not available to be interviewed) about the causes of fights. Again, the most common causes of fighting were disputes over some aspect of the game being played (33.3 per cent), aggressive retaliations to teasing (25.0 per cent), disagreements over possession of toys/equipment (14.6 per cent), and aggressive retaliations to accidental injury/hurt (14.6 per cent). Age and sex differences are reported in some measures across all three studies. The results are discussed in terms of their implications for interventions aimed at improving children's experiences of life on the school playground

N2 - Blindness due to trachoma is a serious public health issue world wide. The currently recommended treatment of active trachoma with repeated doses of tetracycline eye ointment has many disadvantages. The new azalide antibiotic azithromycin is effective as a single oral dose in the chemotherapy of genital Chlamydia trachomatis infections, and we have assessed its efficacy for trachoma treatment. We carried out a randomised single-blind comparison of azithromycin (a single oral dose of 20 mg/kg) with conventional treatment (6 weeks of topical tetracycline plus erythromycin for severe cases) in two villages with endemic trachoma in The Gambia. The patients were followed up for 26 weeks from the start of treatment by an observer unaware of treatment allocation. By 6 months' follow-up, trachoma had resolved in 76 (78%) of 97 subjects who received azithromycin compared with 70 (72%) of 97 who were treated conventionally (95% CI for difference -6% to 18%). Compliance with both treatments was good, but that for conventional treatment could probably not be achieved outside the research setting. There were no significant differences in treatment effect, baseline characteristics, or re-emergent disease between the treatment groups. Azithromycin was well tolerated. As a systemic treatment effective in a single dose it has important potential for trachoma control

N2 - **PURPOSE:** To discuss the factors that might explain the rate of myopic progression and the degree of myopia after a 3-year follow-up among schoolchildren with myopia. **METHODS:** Myopic progression among 238 schoolchildren was followed up in a randomized clinical trial of myopia treatment. The associations between the explanatory factors and myopic progression and the final value of the spherical equivalent after the follow-up were studied by analysis of variance and regression analysis. **RESULTS:** Myopia progressed faster among girls than boys. According to the regression models for the boys, 25% of the variation of myopic progression and 57% of the final spherical equivalent could be explained by initial spherical equivalent, age at receiving first spectacles, time spent on sports and outdoor activities, and on reading and close work. Among the girls, 30% of myopic progression could be explained by age at receiving first spectacles, time spent on reading and close work, and reading distance. Similarly, 49% of the final spherical equivalent could be explained by age at receiving first spectacles, initial spherical equivalent, time spent on reading and close work, and reading distance. The rest of the variations could not be explained by the variables measured in this study.

CONCLUSIONS: The factors with the most significant relationships to myopic progression were sex, age of onset, and degree of myopia at the beginning of the follow-up. Myopic progression and final myopia were related to time spent on reading and close work and to reading distance but not, however, to accommodation stimulus

N2 - The level of physical activity of 3- and 4-year-old children was assessed in alternative physical locations by month and time of day and by age, gender, and ethnicity. Physical activity was assessed by observation with the Children's Activity Rating Scale (CARS) for up to 12 hours from 7:00 am to 7:00 pm. A sample of 191 three- and four-year-old children was observed for up to four times in the course of a year. The sample was tri-ethnic. Boys were significantly more active than girls. Activity was consistently higher outside than inside. There were significant differences in the amount of time children in this age group spent inside versus outside by time of year; the activity levels of boys and girls differed by time of year, particularly when outside. A model including gender, month, and location terms accounted for 75% of the variance in physical activity. These data further documented gender differences in physical activity among very young children using measures not subject to self-report biases but did not explain or clarify the gender differences. The substantial differences by physical location and time of year deserve future attention, but more refined methods will be needed to balance data by location and important seasonal times. An inference from these results is that activity levels among young children may be increased by encouraging them to spend more time outdoors

N2 - Aspartylglucosaminuria is a lysosomal storage disorder inherited as an autosomal recessive trait.

Progressive mental retardation is the main symptom, and the lifespan of the patient is abnormally short. The adaptive skills and maladaptive behaviour of 110 patients aged from 7 to 56 years were analysed using the Portage scale and the AAMD Adaptive Behaviour Scale Part two. The sample was divided into four groups; school-aged, young adults, adults and middle-aged. All patients needed help in the household and transactions outside the home. The school-aged turned out to be superior and middle-aged inferior to other groups concerning adaptive skills. The school-aged and young adults were quite independent in dressing, toileting, bathing and walking alone near the home. Out-of-home replacement became necessary in the majority in adulthood. Twenty-eight patients (25%) were regarded as having behavioural disturbances and the amount of personal disturbances increased significantly with age

N2 - The increasing number of children attending child day care has led to a corresponding concern for their safety in the absence of parental care. Previous studies have documented that the majority of injuries occurring in child day care involve falls, and that the most common consumer product associated with such falls is playground equipment. This study describes New Zealand children less than 5 years of age admitted to hospital between 1979 and 1988 for injuries associated with playground equipment located at home or a child care facility. There were 528 hospitalized home injuries involving playground equipment, and 145 such day care injuries. Fractures were the most common injury, and the head was the most commonly involved body region. Lower limb injuries were the most severe. Among the differences between home and day care injuries were the type of equipment involved. Swings were disproportionately associated with head injuries

N2 - Polycyclic aromatic hydrocarbons (PAH) have become an ubiquitous upper soil component in consequence of industrialisation involving a multitude of combustion processes. Meaningful contaminations can be found on child playgrounds, for example. These may enter into the organism of small children playing there, as children are capable of unintentionally swallowing minute quantities of foreign matter - be that as it may, we cannot exclude such a possibility. Suitable rules are mandatory in particular to prevent such occurrences in an area that is susceptible to them, as preventive health care should always be the order of the day. In the following

article we report on the present scientific-toxicological state of the art, on update data on environmental pollution and reasons for a quantitative risk assessment for different paths of pollution. [References: 104]

N2 - Ciliary beating frequency, one component of mucociliary function, was measured outside of the sinus in vitro with a photoelectric method in 150 patients with chronic sinusitis and in 26 control subjects. In the mucosal samples of 35 patients (23%), no ciliary activity was seen. Ciliary beating frequency in maxillary sinus mucosa of the rest of the 115 patients (77%) was, as an average, 16.6 +/- 3.0 Hz (range, 10.9 to 23.3 Hz) and it was 15.9 +/- 2.6 Hz (range, 13.2 to 22.8 Hz) for the control patients. No differences in ciliary beating frequency

were found according to quality of sinus secretion, prevalent respiratory allergy, or mucosal thickness. However, in sinuses with purulent secretion, ciliary beating frequency was slightly better ($P < .05$) than in "empty" sinuses. The study suggests that in many cases of chronic sinusitis, the sinus mucosa still has a capacity to recure

N2 - The Childhood Injury Prevention Program of the Boston Department of Health and Hospitals conducted a survey of injury risk in Boston's playgrounds. A standardized checklist was used to assess a 25% sample of public playgrounds for hazards. Climbers accounted for 34% of the hazards observed and had the greatest proportion of significant hazards. The surfacing material in 100% of the playgrounds observed was unsafe. Urban children risk exposure to hazardous playground equipment frequently situated above unsafe surfacing material

N2 - A study of injuries among 0-15 year old children attending primary care clinics in a low social class and a middle class neighbourhood was carried out during a period of one year. Data were collected in a structured form by the physicians while the patient was in the clinic. The rate of injuries was 121.3/1000 children per year in the clinic from the lower social class neighbourhood and 70.7/1000 children per year in the clinic from the middle class neighbourhood. Injuries in playgrounds, and on pavements and streets occurred in higher proportions in the low social class than in the middle class neighbourhood clinics. The most frequent causes of injuries were falls and being struck and injured by cutting/piercing instruments; these caused mostly contusions and lacerations. The clinic was the first place of treatment in 65% of the cases in the middle class area and in 45% in the lower social class area; 28% and 10% respectively were referred to the hospital for additional treatment. Data from primary care clinics should be considered when estimating the incidence of injuries in the community, in planning intervention programmes, and future research

 N2 - **BACKGROUND:** Intercellular adhesion molecule-1 (ICAM-1) is expressed on follicular dendritic cells (FDC), and the ICAM-1/LFA-1 pathway is essential for affinity selection of activated B-cells in germinal centers (GC). The expression of ICAM-1 has been studied by immunostaining methods in GC, but not in neoplastic follicles (NF). **METHODS:** The authors studied the expression of ICAM-1 by the avidin-biotin-peroxidase complex (ABC) method with frozen sections in GC of reactive nodes (n = 22) and NF of follicular lymphomas (n = 19), in comparison with FDC staining. **RESULTS:** GC stained uniformly for ICAM-1, with staining intensity varying little from node to node, and follicular borders were well demarcated from the surroundings. Endothelial cells within GC did not stain whereas those outside stained strongly. In contrast, NF stained variably from tumor to tumor, and in any given tumor. Characteristically, follicular borders were not demarcated, and stained areas were difficult to define due to the lack of demarcation, with the exception of large cell type with diffuse areas (n = 2). Endothelium of intrafollicular vessels stained prominently (12 of 19), and appeared to contribute to the staining intensity of the follicles. FDC staining revealed a meshwork pattern in GC which was similar to that of ICAM-1. The FDC mesh-work pattern was present in 15 tumors. The pattern was remarkably uniform with sharply defined borders, which contrasted starkly to the variable staining and lack of follicular borders in the ICAM-1 stain of the same tumors. **CONCLUSIONS:** The staining pattern of follicles for ICAM-1 was similar to that for FDC in reactive nodes, but distinct from the latter in follicular lymphomas. An appropriate expression of ICAM-1 appears to be essential for normal GC, as the alteration of the expression coincides with the malignant transformation of GC. The altered expression of ICAM-1 may be useful in distinguishing NF from reactive GC

N2 - In this within-subjects design field experiment children's behaviour in the playground was charted as a function of gender and time in the classroom immediately preceding playtime. Playground behaviour was also related to post-recess classroom behaviour. Twenty-three 9-year-old children were observed for 14 weeks. Classroom behaviour (i.e., task relevant behaviour on standardised seat work immediately before and after playtime) and playground behaviour (i.e., social and non-social exercise and sedentary behaviour) were observed. Time in classroom before playtime was manipulated so that there was a shorter and a longer confinement period. Results indicated that children were less attentive to seat work as a function of time and that longer confinement resulted in more exercise for boys and more social sedentary behaviour for girls. Social behaviour at playtime and post-playtime attention to seat work were significantly related. Results are discussed in terms of Novelty Theory

N2 - Lead poisoning in childhood is an important public health problem, and thus, it is important to determine how children are exposed to lead. In 1987, the authors conducted an exposure assessment and blood lead screening for children aged 6-71 months living in Leadville, Colorado. High levels of lead had been found in the soil as a result of both past mining and smelting activities and natural mineralization. Blood was collected from each child for lead analysis, and behavioral characteristics were identified through an interview with a parent or guardian. Three sources of exposure to lead were associated with blood lead levels: lead in a core sample taken from the backyard of the family's home, lead brought home on the clothes of a miner, and lead from soldering in the home. Two pathways of exposure were associated with blood lead levels: the child swallowing things other than food, and taking food or a bottle outside to play. Multivariate regression using these variables found effect modification by age. For children aged 6-36 months, only sources of exposure were independent predictors of blood lead levels, while in children aged 37-71 months, a pathway of exposure in addition to sources of exposure independently predicted blood lead levels

N2 - The potential effects of elevated ozone concentrations in The Netherlands were evaluated by the measurement of peak expiratory flow (PEF) of exercising children. Peak expiratory flow was measured with mini-Wright peak flow meters, both before and after out-door sports training. The relationship between PEF and ozone was investigated with individual regression analysis. The difference of PEF after and before training (delta PEF) and the PEF after training were used as dependent variables. The ozone concentration during the training and the 1-h maximum ozone concentration of the same and the previous day were used as independent variables. The highest observed 1-h maximum ozone concentration was 236 micrograms/m³. delta PEF was unrelated to the ambient ozone concentration during training. Peak flow measured after the training was positively correlated with ambient temperature. The high correlation between ozone and temperature prevented the evaluation of effects of the maximum ozone concentration of the same day on PEF after training. A small negative association of borderline statistical significance between PEF after training and previous-day maximum ozone was observed

N2 - Immunohistochemical (antibodies against laminin) and histochemical methods (Ulex europaeus lectin, 5'-nucleotidase activity) were used to describe the vascular pattern of human intervertebral discs and the surrounding tissue at different ages. Blood and lymph vessels were found in the connective tissue outside the annulus in all age groups. In the annulus blood vessels and lymphatics were detected up to 20 years of age, in the cartilage end-plate blood vessels appeared up to 7 years of age (cartilage canals). In the nucleus pulposus neither blood nor lymph vessels could be seen at any age. The occurrence of blood and lymph vessels in growing intervertebral discs help us to understand childhood discitis without simultaneous affection of the vertebral body

N2 - Data from the 1989 National Health Interview Survey concerning migraine occurrence and impairment were analyzed to assess the impact of migraine on the US population. About four of every one hundred persons in the United States were found to have migraine, accounting for nearly 10 million individuals. Migraine was most prevalent in those aged 25 to 44 years and was about 2.5 times more frequent in females than males. Migraine was most common in whites (85%) and those with low household income. In women, migraine prevalence increased with the level of education. About 10% of migrainous children missed at least one day of school over a two-week period due to migraine; nearly 1% missed four days. Migraineurs were bedridden for about three million days per month and had an estimated 74.2 million days per year of restricted activity due to migraine. The potential cost of lost productivity was estimated at \$1.4 billion per year for the estimated 6,196,378 migraineurs who worked outside the home. It is difficult to derive similar estimates for costs of lost productivity in housewives; however, housewives experienced an estimated 38 million days per year of restricted activity. Eighty-five percent of females and 77% of males reported a physician visit at some point for their migraine. Migraine is a relatively common disease whose social and financial impact has been poorly understood

N2 - During the past 10 years, epidemics of black spots on the scalps of schoolchildren have caused considerable concern in at least 4 communities in the Rocky Mountain states. We describe the clinical presentation of "black spots" in a group of Wyoming elementary school students and the epidemiologic investigation that revealed the cause. Our study included a questionnaire survey of students' parents, examination of students at the affected school and at two other schools, observation of playground activity patterns, and laboratory analysis of specimens taken from affected children and from the school environment. The black material in the scalp spots was chemically identical to flakes of black material found on the playground and tar from the school roof. We concluded that the spots were caused by flakes of windblown tar from the school roof. Previous outbreaks of black spots may have had a similar cause

N2 - In this study, 33% of the variance in the 10-year trend of forced expiratory volume in 1 second (FEV1), used as an index of pulmonary health, was explained by differences in family characteristics at the start of the study. Balanced family coping, a family emphasis on personal growth, and compliance with treatment for 91 children with cystic fibrosis were assessed at the start of the study and the FEV1 was observed at every clinic visit over the next 10 years. When both parents' coping emphasized family integration, support for self, and medical consultation, the FEV1 trend was better. Compliance with daily chest physical therapy and with quarterly clinic visits was associated with a better FEV1 trend. Poorer FEV1 trend was associated with active social involvement of family members. Older patients and patients whose parents worked more hours outside

the home had lower compliance. These findings support the importance of encouraging families to balance their resources between the child's health needs and family needs

N2 - OBJECTIVE: To compare between eras the early care of extremely low birthweight (birthweight < 1000 g) infants born in non-level-III centres, that is, centres without a neonatal intensive care nursery, in Victoria, to identify changes associated with the improved quality of survival over time. DESIGN AND SETTING: The early care and outcome for infants of birthweight 500 to 999 g born in a non-level-III centre in Victoria were compared between two distinct eras, 1979-1980 and 1985-1987. PATIENTS AND OUTCOMES: Mortality data to two years of age were available for all infants liveborn in non-level-III centres in the two eras (1979-1980, n = 106; 1985-1987, n = 129). In 1979-1980, 47 of 52 infants transferred to a level-III centre were transported by the Newborn Emergency Transport Service (NETS); in 1985-1987, all 49 infants transferred were transported by NETS. Data concerning the immediate care after birth and during transport to a level-III centre were available for all infants transferred by NETS. All survivors were assessed for sensorineural impairments and disabilities at two years of age, corrected for prematurity. RESULTS: In both eras, 18 children born outside and transferred to a level-III centre survived to two years of age. Survivors in both eras had almost identical mean birthweights and gestational ages. There were trends for more survivors to be referred by paediatricians--1979-1980, 61%; 1985-1987, 83%; odds ratio (OR), 2.94; 95% confidence interval (CI), 0.7-12.4--and for quicker referral times to NETS in 1985-1987 (1979-1980, median 34.5 minutes after birth; 1985-1987, median 21.5 minutes after birth; z = 1.91, P = 0.056). It was possible only during 1985-1987 to monitor transcutaneous PO₂ during transport. Durations of transport were similar in both eras. However, only in 1985-1987 was it possible in survivors to reduce significantly the inspired oxygen concentration during transport (median reductions in inspired oxygen, 1979-1980 3.5%; 1985-1987 20%; P = 0.028). Neurological impairment rates were substantially lower in survivors transported in the latter era (1979-1980 72% impaired; 1985-1987 22% impaired; OR 0.14, 95% CI 0.04-0.52). Of the neurological impairments, fewer had severe developmental delay alone (1979-1980 22%; 1985-1987 0%; OR 0.09, 95% CI 0.018-0.46), and the rate of blindness was lower, but the latter difference was not quite statistically significant (1979-1980 28%; 1985-1987 6%; OR 0.21, 95% CI 0.037-1.19). Over all, neurological disabilities were significantly reduced in the latter era (z = 2.93, P < 0.005). CONCLUSIONS: More active management of extremely low birthweight infants before transfer to a level-III centre, including prompt referral and transcutaneous PO₂ monitoring during transport, may be important in improving the sensorineural outcome of survivors

N2 - This study investigated sleeping habits, difficulties in being able to fall asleep and their connections to self-reported health conditions, as well as other selected health behaviours and use of leisure time, among 11-16 year old Europeans from 11 countries. The study was part of a larger, comparative, WHO coordinated project on the health and life-style of school children (Health Behaviour of School Age Children--A WHO Cross-National Survey, The HBSC Study). In most of the countries, research data were collected from samples representative of the whole country. Using a standardized survey questionnaire, the data were collected anonymously in schools. Altogether 40,202 students responded to the survey. Sleeping habits and an inability to fall asleep varied significantly between countries as well as between age groups but only slightly between the sexes. Finnish school children experienced the most difficulty in being able to fall asleep. After the Israeli youth, the Finnish school children had the shortest night's sleep. At least a fifth of Finnish and Norwegian school children also reported that they felt tired almost every morning, the corresponding figure being smaller in other countries. A frequent use of psychoactive substances (alcohol and tobacco), lack of physical activity, excessive watching of TV/videos together with numerous evenings spent outside the home were all connected with going to bed late as well as with frequent difficulty in not being able to fall asleep. The results of the study offer an important challenge to health promotion and health education. Much more attention must be paid to this essential and exciting health habit!

N2 - Tennessee State medical examiner reports of firearm fatalities classified as accidents involving victims aged 19 year or less from 1961 through 1988, were reviewed to evaluate circumstantial and contributing factors. A total of 225 were analyzed. The peak age for victims was 17 years, and there were more than five times more male than female victims. In Shelby County (Memphis), the racial distribution of fatalities was approximately that of the general population. Playing with a gun was the most frequent circumstance. The person responsible for pulling the trigger was equally likely to be a friend, a family member, or the victim. Head or neck were injured in most cases. The urban mortality rate was nearly twice that of the rural rate. More than half of the deaths in urban counties occurred indoors and involved handguns, whereas in rural counties only a third were due to handguns and the location was more often outdoors. Deaths in rural counties showed a seasonal variation that corresponded with the hunting season; by contrast, a peak in early summer was noted in the urban deaths. Defective guns or guns unsafe in design caused several deaths. (Semiautomatic pistols, which can be fired after unloading the ammunition magazine, are conspicuous examples of guns unsafe in design.) An important observation of this study is that medical examiners vary considerably in their classification of accidental manner, particularly when children are involved. Furthermore, medical examiner reports need to include much more information than is currently recorded if they are to be useful in guiding public policy to reduce firearm injuries

N2 - Although the rate of injuries in soccer is high, this sport puts children only at moderate risk of getting injured. In younger children this risk is very low but the number and severity of injuries increases with puberty. The most common cause for injuries is a collision with another player, the most common injury is distortion of the talocrural joint. Playing soccer indoors is more dangerous than playing outdoors. The danger of accidents and injuries can be reduced by preventive measures, such as weight categories in children leagues

N2 - Because medical illness is associated with malnutrition, it might contribute to the poor outcomes seen in malnourished children. This study explored relations between frequency of mild illness and development in 133 mild-to-moderately malnourished school-age Kenyan children. Morbidity information was collected for one year. Concurrent assessments of cognitive status and playground behaviors were obtained. Nutritional and environmental variables were also assessed. Girls with more reported days of mild illness performed less well on developmental measures than did their healthier female peers. They were less cognitively advanced, and, on the playground, girls with more mild illness were less active, happy, and social. Furthermore, relations between frequency of mild illness and playground behaviors (but not cognitive score) in the girls remained statistically significant when other variables, such as socioeconomic status, parental literacy, food intake, and anthropometry, were considered. For the boys, frequency of mild illness was not related to cognition or play behaviors

N2 - This article reviews the available evidence of mortality from acute respiratory infections (ARI) among children aged under 5 years in contemporary developing countries and compares the findings with European populations before 1965. In European populations before 1965, the level of mortality was found to be a determinant of the proportion of deaths due to ARI. There were marked differences according to regional patterns of mortality. Deaths from ARI played a smaller role after 1950, when the use of antibiotics became generalized. In developing countries, the role of ARI mortality seems to be similar to the European experience. The age pattern is very marked. In absolute values, ARI mortality is highest in the neonatal period and decreases with age. In relative values, ARI mortality is highest in the postneonatal period. ARI, mainly pneumonia, accounts for about 18% of underlying causes of death in developing countries. Pneumonia and other ARI are frequent complications of measles and pertussis; ARI is also commonly found after other infections and in association with severe malnutrition. Virtually no data are available in developing countries to provide final estimates of the role of ARI in mortality of children aged under 5 years. However, the WHO figure of 1 out of 3 deaths due to--or associated with--ARI may be close to the real range of the ARI-proportional mortality in children of developing countries. Results are discussed in light of the definitions of ARI used in various studies, the difficulties in ascertaining and coding multiple causes of death and the quality of data from some sources

N2 - The prevalence of hepatitis B markers was determined in a representative sample of the general population of Catalonia (Spain). HBsAg was found in 0.5% of children (less than 15 years of age) and in 1.7% of adults (more than 15 years of age), and anti HBs in 1.6% and 18%, respectively. Age-specific prevalence for both markers showed a low risk for hepatitis B before puberty, and a progressive rise since adolescence, suggesting that perinatal transmission and horizontal transmission in children are relatively uncommon in Spain. Prevalence of hepatitis B markers was significantly higher among subjects with low education level, residing in an urban area and born outside Catalonia, but in the stratified analysis, a statistical significant difference was only maintained in the prevalence of HBV markers between those who live in urban and rural areas, and between those who were born outside Catalonia and in Catalonia. These data may be used as a basis for a strategy of hepatitis B prevention in Spain which include universal vaccination of adolescents, passive-active immunization of newborns to HBsAg positive mothers and vaccination of susceptible adults subjects from high-risk groups

N2 - We investigated activity patterns of 17 elementary school students aged 10-12, and 19 high school students aged 13-17, in suburban Los Angeles during the oxidant pollution season. Individuals' relationships between ventilation rate (VR) and heart rate (HR) were "calibrated" in supervised outdoor walking/jogging. Log VR was consistently proportional to HR; although "calibrations" were limited by a restricted range of exercise, and possibly by artifact due to mouthpiece breathing, which may cause overestimation of VR at rest. Each subject then recorded activities in diaries, and recorded HR once per minute by wearing Heart Watches, over 3 days (Saturday-Monday). For each activity the subject estimated a breathing rate--slow (like slow walking), medium (like fast walking), or fast (like running). VR ranges for each breathing rate and activity type were estimated from HR recordings. High-school students' diaries showed their aggregate distribution of waking hours as 68% slow inside, 8% slow outside, 10% medium inside, 9% medium outside, 1.5% fast inside, 1.5% fast outside. Elementary students' distribution was 47% slow inside, 15% slow outside, 20% medium inside, 12% medium outside, 2.5% fast inside, 3.5% fast outside. Sleep occupied 38% of high-school students' and 40% of elementary students' time; HR were generally lower in sleep than in slow waking activity. High school students' mean VR estimates were 13 L/min for slow breathing, 18 for medium, and 23 for fast; elementary students' were 14 slow, 18 medium, and 19 fast. VR distributions were approximately lognormal. Maximum estimated VR were approximately 70 L/min in elementary and approximately 100 L/min in high school students. Compared to adults studied similarly, students reported more medium or fast breathing, and had equal or higher VR estimates during slow and medium breathing despite their smaller size. These results suggest that, relative to body size, young people inhale larger doses of outdoor air pollutants than adults

N2 - 123 survivors of severely head injured patients presenting with coma grade III show a decreasing mean duration of coma with increasing age. The numbers and frequency of good recovery decrease, whereas poor recovery increases with age. Increase of the duration of coma grade III produces an increase of the mean latency and time of recovery and of the frequency of poor recovery, regardless of the age of the patients. Increasing age does not increase the mean latency and time of recovery systematically. The important conclusion of this analysis is, that the clinical feature of coma grade III, corresponding to GCS score of 4 and RLS of 6 and 7, indicates a different kind of brain damage at various age groups. It represents a lesser degree of brain damage for younger patients under 20, than for those over 20. In our opinion our observations do not demonstrate a better capacity of recovery of the young patients: but the young patients show a more severe clinical picture than the older patients do, if only the clinical syndrome of coma grade III with extensor rigidity, is considered as a yardstick for comparison

N2 - Bronchial hyperreactivity (BHR) can be proved by various methods. 21 children, 14 asthmatics and 7 healthy subjects were submitted to inhalative methacholine challenge as well as to 'free running' as a form of exercise challenge in a randomized sequence. For the methacholine inhalation a standardized procedure was followed and the provocative concentration defined (PC20) at which a decrease of more than 20% in FEV1 was found. There is no real standardisation for 'free running' (concerning temperature and humidity of the inspired air; individual level of exercise) but subjects had to run for 6 minutes while the heart rate should have been between 170 and 180 beats/minute. This increase in pulse rate relates to a submaximal work at which 60-85% of maximal O2 uptake are obtained. A decrease of 15% from basic value of FEV1 was defined as a positive result. By the use of methacholine inhalations we found 16 children (14 diseased, 2 controls) to be hyperreactive, whereas only 3 of them showed a positive result after 'free running'. We conclude, that firstly, methacholine provocations and exercise challenges assess different kinds of bronchial reactivity, secondly, 'free running' as a form of exercise is very difficult to standardize and therefore prone to errors and thirdly, 'free running' is not sensitive enough to assess BHR in children with mild asthma bronchiale if used as the only form of challenge.

Problems concerning measurement of BHR are discussed

N2 - Sick leave among the children in 24 day nurseries in Copenhagen was registered during a period of one year. The physical, environmental and hygienic conditions of the institutions were assessed by means of interviews and inspection, supplemented by information from the local authorities. Sick leave constitutes 7.5% of the days during which the institutions were open and the average number of sick days per child varied from 14.6 to 24.4. Comparisons with similar investigations are inclusive on account of variations in the methods of registration and age distributions. It was characteristic of the institutions investigated that these included a number of old institutions in flats, many in streets with considerable traffic and where the conditions of ventilation and space do not conform with present-day standards. In some of the institutions, the hygiene is unsatisfactory, particularly where ventilation, outdoor activities and hand-washing are concerned. A statistically significant connection was found between amount of traffic at the institution, the hygiene and playroom area per child, on one hand, and absence due to sickness, on the other, as assessed by a statistical model for sick leave for child in a given institution. In order to prevent sickness, it is concluded that efforts to improve hygiene and space are desirable and, similarly, further research concerning the effects of atmospheric pollution is relevant

N2 - To explore relations among parents' self-reported disciplinary styles, preschoolers' playground behavioral orientations, and peer status, 106 mothers and fathers of preschool-age children (age range = 40-71 months) participated in home disciplinary style interviews. Observations of their children's playground behavior in preschool settings and measures of sociometric status were also obtained. Results indicated that children of more inductive mothers and fathers (i.e., less power assertive) exhibited fewer disruptive playground behaviors. In addition, daughters and older preschoolers of inductive mothers exhibited more prosocial behavior. Children of inductive mothers were also more preferred by peers. Few significant relations were found between paternal discipline and child behavior/peer status. Age-related patterns of behavior also indicated that older preschoolers who engaged in more prosocial and less antisocial and disruptive playground behavior were more preferred by peers. In addition, child behaviors were found to mediate maternal discipline and peer status

N2 - In 86 asthmatics (age 8-16 years), divided into several groups, the protective effects of pharmacological and non-pharmacological agents on the exercise-induced airway obstruction (e.i.a.o.) by 5 minutes free running were studied. There were studied the preventive inhalations of bronchodilators, i.e. fenoterol (0.2 mg), ipratropium-bromide (0.06 mg) and both combined of 0.15 mg of fenoterol and 0.06 mg of ipratropium-bromide on the exercise-induced airway obstruction. The protective effects of breathing through nose as well as the effect of the temperature in the surrounding environment on the e.i.a.o. were studied too. The exercise-induced airway obstruction was assessed on the basis of parameters measured from maximum expiratory flow-volume curves. Maximum expiratory flow at 25% of vital capacity was most sensitive in the assessment of e.i.a.o. The studied bronchodilators protected all patients against e.i.a.o. The textile face mask (surgical mask) put on the nose and mouth during 5 min. free running outdoors and in a closed room protected some asthmatics completely against e.i.a.o. or reduced substantially e.i.a.o. in others. The nose breathing had a similar effect on e.i.a.o. as the textile face mask. The surrounding temperature of air was not decisive in the induction of post-exercise airway obstruction. Non-pharmacological agents ought to be thus more included among the therapeutical means in pediatric and adolescent asthmatics

N2 - Three supervisors of integrated preschools were trained in a collaborative team approach to encourage resource and classroom teachers to develop strategies that promote peer interaction of all children, including children with disabilities. The focus of classroom teachers' behaviors and the interactive play of children with disabilities were measured daily in both a training (indoor play period) and a generalization (outdoor play period) setting. In a multiple baseline design, supervisors were individually trained in a collaborative team approach using a manual, modeling, and role playing; then they implemented the approach with classroom and resource teachers. We found that after supervisor training, classroom teachers increased their behaviors directed towards children with disabilities and decreased their behaviors directed towards nondisabled children.

Moreover, we found a doubling of the interactive play of children with disabilities and, for two of the three classes, an increase in the interactive play of comparison children, randomly selected by the classroom teachers. Changes in both teachers' and children's behaviors were also found in the generalization setting. The implications of the results for interventions in community settings are discussed

N2 - Among school-aged children, unintentional injuries are the leading cause of morbidity and mortality. We began this prospective study in a sample of nine schools within the Boulder Valley School District (Colorado) during the 1988-1989 school year in an effort to explore the etiology of school-related injuries and to provide information relevant to their prevention. During the study period, 509 injuries were reported among a population of 5,518 students, yielding an incidence of 9.22 per 100 students. Boys were nearly one and one-half times more likely to have sustained a school-related injury than girls (risk ratio (RR) = 1.41; 95% confidence intervals [CIs] 1.18, 1.68). We found a significant difference among injury rates by school level (P less than .001). Middle/junior high students had the highest rate, followed closely by elementary students and distantly by high school students. Sports activities accounted for the largest percentage of school injuries (53%), and the percentage of sports-related injuries increased with increasing grade level. Analysis of injury rates by school location revealed that high school students were most frequently injured in the gym (1.52 per 100), middle/junior high students on the athletic field (4.26 per 100), and elementary students on the playground (6.12 per 100). Using injury location as the focal point, we examined relationships among the variables sport/activity, body site, and nature of injury. We found that a large percentage of injuries sustained on the athletic field or in the gym were similar and affected similar body sites, whereas playground injuries differed in their nature and in body site affected.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - The levels of lead in settled dust samples collected near small streets, playgrounds, gas stations and main streets in the Tripoli area have been determined by atomic absorption spectrophotometry. The overall mean values observed were 417, 533, 553 and 797 micrograms g⁻¹ dry wt for the above locations respectively. The overall mean concentration for main streets was significantly higher (P less than 0.05) than for other sites. The data were also compared with those reported in the literature for other cities

N2 - Periodic activity during light sleep is well recognised in many physiological systems, particularly respiration. In damaged brains this activity can become exaggerated. It involves the autonomic nervous system, the muscles, the cerebrospinal fluid (CSF) pressure, the cerebral blood flow and the electroencephalogram (EEG). It is related to the level of arousal. The EEGs of 52 subjects were studied. In stage 0-1 sleep, periods of alpha activity alternated with periods of theta activity related to the level of arousal. The intervals between the

alpha onsets were measured and the data pooled. There was a dominant interval of about 16 sec. It is suggested that this is a physiological cerebral rhythm involving the cortex and the brain-stem activating mechanisms, responsive to outside stimuli but essentially endogenous. It is related to the controls of the autonomic, motor, and some cerebral auto-regulatory mechanisms. It may be severely disturbed in brain damage

N2 - Habitual physical activity in children is related to physical fitness and appears to mediate cardiovascular disease (CVD) risk factors. We studied the physical activity patterns and associated variables of a large bi-ethnic cohort of 4-year-old children from low to middle socioeconomic families. Trained observers coded the behavior of 351 children (150 Anglo-American, 201 Mexican-American; 182 boys, 169 girls) during two 60-minute home visits and two unstructured recesses lasting up to 30 minutes each at 63 different preschools. Findings indicated that although children were much less active at home, there were low but significant correlations between their activity patterns at home and during recess ($r = .13$). Children who had activity-promoting toys at home also tended to have them available during preschool recess ($r = .20$). Ethnic differences were evident for both activity and environmental variables. Mexican-American children were less active than

Anglo children at home (p less than .002) and during recess (p less than .03), thus adding to the adult literature that has found Mexican-Americans to be less active than Anglos, and supporting to the notion that physical activity life-style habits may be established in early childhood. In both settings, Mexican-American children spent more time in presence of adults (home, p less than .04; recess, p less than .03) and had access to fewer active toys (home, p less than .001; recess, p less than .05). Gender differences were also evident for both activity and environmental variables.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - STUDY OBJECTIVE: To determine injury and illness patterns and occurrence rates during wilderness recreation. DESIGN: Prospective injury and illness surveillance study. SETTING: Wilderness areas throughout the Western hemisphere. TYPE OF PARTICIPANTS: All students and instructors on National Outdoor Leadership School courses over a five-year period. MAIN RESULTS: A single fatality occurred, resulting in a

death rate of 0.28 per 100,000 person-days of exposure. Injuries occurred at a rate of 2.3 per 1,000 person-days of exposure. Sprains and strains and soft tissue injuries accounted for 80% of the injuries. The illness rate was 1.5 per 1,000 person-days of exposure. Sixty percent of illnesses were due to nonspecific viral illnesses or diarrhea; hygiene appeared to have a significant impact on the incidence of these illnesses. Thirty-nine percent of the injuries and illnesses required evacuation (1.5 per 1,000 person-days of exposure). CONCLUSION: The injury and illness patterns indicate that wilderness medical efforts should concentrate on wilderness hygiene and management of musculoskeletal injuries and soft tissue wounds. The data also indicate that wilderness activities can be conducted relatively safely, but the decision to participate should be individualized, with an understanding of risks versus benefits

N2 - In a clinical study, 25 accidents involving injuries by a fall with a skateboard were investigated and classified in respect of epidemiology, accident mechanism and injury patterns in the facial region. Accident victims are predominantly boys between 7 and 9 years of age. A multiple trauma involving the teeth and the dental system in general and the soft parts of the face is defined as a characteristic orfacial injury pattern in skateboard accidents. The high proportion of damage to the front teeth poses problems of functional and aesthetic rehabilitation necessitating long-term treatment courses in children and adolescents. Effective prevention of facial injuries may be possible by evolving better facial protection systems and by creating areas of playgrounds where skateboarders can practise safely

N2 - Three studies of calibration are reported. Calibration refers to the accuracy with which one can predict one's own performance. In the first study child chess players, non-chess playing parents, and statistics students were asked to predict chances of winning chess games against hypothetical opponents. These subjective probabilities were compared to the actual probabilities, based on the Elo rating system. Better players' predictions were better calibrated. Confidence and ratings are negatively correlated, indicating that with lower ratings, players re overconfident. Skilled child players' predictions were better calibrated than any of the adults'. In the second study subjects were asked to estimate chances of winning in conjunctive situations, e.g., winning all the rounds in a tournament. Again, better child players were more accurate in their predictions and more accurate than adults. In the third study, child players were asked to predict their chances of winning in a non-chess domain after hearing a hypothetical win/loss history. Higher-rated players' predictions were again better calibrated, even though the domain was outside their expertise. The motivational and cognitive implications of calibration are discussed

N2 - Occurrences of spontaneous pointing in 20-, 30-, 40-, and 50-mo.-old children were observed during the children's indoor or outdoor free-play periods. Observers recorded the sex of the pointer, the behavioral pattern observed, the reason for the point, the response of the adult, and the distance of the child from the adult at the time of a point. Analysis indicated a significant dip in the rate of pointing among the 30-mo.-olds while the 20- and 50-mo.-olds were observed to point most often. With the exception of the 30-mo.-olds, pointing was significantly more likely to be observed in boys. For all age groups, the point was used primarily to name. After 20 months adults were significantly less likely to respond to the point, and when they did respond they were more likely to name or demonstrate irrespective of the apparent reason for the child's point. Finally, the probability of adults' response appeared to be unrelated to the distance from the child to the adult, and further, the likelihood of an adult's response appeared to exert little influence on the rate of pointing. The results suggest that pointing may be an expressive act that can be used as a communicative gesture, but there was little evidence that any of these age groups were using the point as a ritualized gesture, that is, as an action conventionalized within the context of social interaction

N2 - Decreasing chronic joint pain is a major goal in the management of juvenile rheumatoid arthritis. Cognitive-behavioral self-regulatory techniques were taught to children with juvenile rheumatoid arthritis to reduce musculoskeletal pain intensity and to facilitate better adaptive functioning. Subjects were 13 children between the ages of 4.5 and 16.9 years who had pauciarticular or systemic onset juvenile rheumatoid arthritis. Baseline data included an initial comprehensive assessment of pain, disease activity, and level of functional disability, as well as pain intensity ratings gathered over a 4-week period. Subjects were seen for eight individual sessions in which self-regulatory techniques (progressive muscle relaxation, guided imagery, meditative breathing) were taught, and parents were seen for two sessions in which key aspects of behavioral pain management techniques were reviewed. Results indicated that these techniques led to substantial reduction of pain intensity, which generalized to outside the clinic setting. Six- and 12-month follow-up data showed consistent decreases in pain as well as improved adaptive functioning. The data suggest that cognitive-behavioral interventions for pain are an effective adjunct to standard pharmacologic interventions for pain in patients with juvenile rheumatoid arthritis

N2 - In this study, 11 prepubertal hyperactive boys with tic disorder received placebo and three doses of methylphenidate (0.1, 0.3, and 0.5 mg/kg) for 2 weeks each, under double-blind conditions. Each boy was observed for approximately 20 hours in the school setting (classroom seatwork activities, lunchroom, and playground). Results showed that methylphenidate effectively suppressed hyperactive/disruptive behaviors in the classroom and physical aggression in the lunchroom and on the playground. Methylphenidate also reduced the occurrence of vocal tics in the classroom and the lunchroom. None of the motor tic measures revealed drug effects, but the lowest mean rate of motor tics occurred on the 0.3 mg/kg dose. On an operationally defined minimal effective dose, only one boy experienced motor tic exacerbation

N2 - In 115 asymptomatic asthmatic children and adolescents (age 6-18 years) there was studied the magnitude of airway obstruction, induced by various physical efforts and assessed from the recording of maximum expiratory flow-volume curves and in some patients by "specific" airway conductance measurement in a body plethysmograph. The effects of 5 minutes free running outdoors, 5 minutes of exercise on a bicycle ergometer (2 watts/kg of body weight), routine swimming training in swimming pool and of forced expiration maneuver on the magnitude of airway obstruction were assessed. The most frequent and largest degree of airway obstruction was observed after 5 min. free running outdoors (heart rate after running 160-200/min). The obstruction was revealed in 80-100% asthmatics in various groups. The chosen lung function parameters showed exercise-induced airway obstruction in the same patients in various proportions as well as the magnitude of the obstruction. Following free running outdoors the values of maximum expiratory flow at 25% of vital capacity and "specific" airway conductance were most reduced. Spontaneous retreat of obstruction was observed in the course of 2 hours. The physical exercise on a bicycle ergometer was a small stimulus in inducing of airway obstruction. The swimming in a pool did not provoke any obstruction. In 10% of our asthmatics airway obstruction was observed following forced expiration maneuver. Airway obstruction induced by 5 minutes free running outdoors and assessed best by flow-volume curves appeared as a suitable test in the assessment of airway hyperresponsiveness

N2 - To determine the prevalence of safety hazards and current injury prevention practices in child care settings, we administered a structured telephone interview to a geographically stratified, randomly selected sample of licensed child care facilities. Representatives of 130 child care facilities responded to questions about current injury prevention practices. Specific hazards assessed were related to burns, falls, poisoning, playgrounds, and emergency telephone numbers. Results indicated that 26.8% of providers who knew the temperature of their tap water stated that it was over 130 degrees F.; 14.1% had space heaters accessible to children; 30.3% of those with stairs accessible to children lacked safety gates; 61.4% of those with playgrounds did not have an impact-absorbing surface under playground equipment; 16.9% of respondents had an unexpired bottle of syrup of ipecac; 55.8% demonstrated that a poison control center telephone number was available to them; and 80% of providers could demonstrate the availability of the telephone number of the local ambulance. We conclude that potential and remedial injury hazards exist in some licensed child care centers and that providers of child care within licensed facilities are a promising target for childhood injury prevention interventions

N2 - This study was designed to determine the incidence and prevalence of Lyme disease in a section of Chappaqua, NY, a residential community in which Lyme disease is epidemic, and to identify risk factors for this disease. On the basis of clinical history and baseline serologic testing, the overall prevalence of Lyme disease for 114 persons entering the study was 8.8%. The incidence during the 5-month study period of May through September 1989 was 2.6%; all three incident cases had erythema migrans (EM). Hours outdoors per week in play or exercise correlated with the occurrence of Lyme disease

N2 - Although more than 2 million US children are in self-care after school, little is known of the extent to which self-care may adversely affect developmental processes, such as the development of self-esteem. To test the hypothesis that lower self-esteem is associated with being in self-care, 297 subjects in fourth and sixth grades from three ethnically diverse schools in northern California were enrolled in a cross-sectional study during November 1987. Sixty percent of subjects were in adult in-home care, 13% in adult out-of-home care, 19% in self-care, and 8.0% in older sibling care. No significant differences in self-competence scores, as measured by the Harter Self-perception Profile for Children, were observed for children in self-care compared with the three other care groups. However, children who were cared for by older siblings unexpectedly exhibited lower self-competence scores for five of the six self-competence domains, with three domains showing significance at P less than .05. Children in self-care were significantly more isolated socially than children in adult care, reporting fewer opportunities to play outside or have friends visit at their homes. The results indicate that children in sibling care may be at potentially greater risk for negative effects on self-esteem and social development. Children in self-care may also experience more social isolation after school than children in other forms of afterschool care

N2 - Obese boys [n = 10, aged 10-11 y, average percent body fat (%BF) 32.4] were given a regimented training program (4 wk, 5 1-h sessions, 45 min cycling/wk at 50-60% of predetermined VO₂max) to investigate whether they modify their energy expenditure by reducing or augmenting their spontaneous physical activities. No change was observed in mean weight (52.7 vs 52.9 kg), %BF based on 2H- and 18O-dilution and densitometry (32.4 vs 31.7), sleeping metabolic rate (5.83 vs 5.68 MJ/24 h), and spontaneous activity by heart rate recording (percent time of light intensity: 85.3 vs 83.6; medium: 11.2 vs 12.4; and heavy: 3.5 vs 3.9) and activity questionnaires (861 vs 821 min physical activity/wk). There was a 12% increase in average daily metabolic rate by doubly labeled water, half of which can be explained by the energy cost of training and the rest by an increase in energy expenditure outside the training hour. In conclusion, training leads to an appreciable augmentation in the overall energy expenditure of obese children, even with a lack of change in spontaneous physical activity

N2 - The leveling of oxygen uptake at high work loads has been utilized to define maximal VO₂ during progressive exercise testing. Exercise studies in children have indicated, however, that a VO₂ plateau can commonly be demonstrated in less than one half of subjects. To examine the potential contributions of subject effort, aerobic fitness, and nonaerobic performance to this variability, 15 children ages 7 to 10 years performed progressive treadmill walking to exhaustion with a ramp protocol. The VO₂ plateau was defined as a change in VO₂ during the final minute of exercise less than 2 SD below the mean of increases between the previous 4 to 5 submaximal minutes. Five subjects (33.3 percent) demonstrated a plateau. No significant differences in mean peak VO₂, heart rate, or respiratory exchange ratio were observed between plateau and nonplateau groups. Testing results of speed (50-yard sprint) and leg power (vertical jump) were also similar. These findings suggest that following: (1) subject effort, aerobic fitness, and nonaerobic factors do not explain the presence or absence of a VO₂ plateau during exercise testing of children; and (2) a VO₂ plateau should not be used as a requirement for defining VO₂max during treadmill testing in this age group

N2 - Thirty-seven patients with idiopathic hypopituitarism, of whom 12 had multiple pituitary hormone deficiencies (MPHD) and 25 isolated growth hormone deficiency (IGHD), were evaluated by magnetic resonance imaging (MRI). Twenty-two of the 37 showed congenital anterior pituitary hypoplasia, stalk agenesis and ectopic posterior pituitary gland at the infundibular recess (group A), while the remaining 15 presented isolated anterior pituitary hypoplasia (group B). Perinatal histories obtained from all patients demonstrated that 18/22 children of group A (81.81%) had histories of adverse perinatal events, with breech presentation in 15 (68.18%). Twelve of 12 children of group A born by breech delivery developed MPHD; 3 born by cesarean section for breech presentation had only IGHD. Patients of group B had also a high incidence of perinatal insults (12/15, 80%), but breech delivery was markedly less frequent (13.33 vs. 68.18% of group A) and responsible for only IGHD. Group B had also higher percentages of maternal spontaneous abortion and low birth weight. Our study suggests that several factors may play a role in the development of growth hormone deficiency. Some patients had severe perinatal insults apparently leading to hypopituitarism. We were able to define by MRI a group of patients with congenital abnormalities, such as anterior pituitary hypoplasia, stalk agenesis and posterior pituitary ectopia, among whom breech presentation was very common. In this group, breech delivery was always followed by MPHD while cesarean or normal delivery in such patients was followed by IGHD only

N2 - We determined the cumulative exposure of 3 body sites to ultraviolet radiation from sunlight for 126 children observed from 1-3 d during a variety of common recreational activities at a girl scout camp, baseball camp and community baseball field. Median arm exposure to children playing baseball at a camp ranged from 27.6% to 33.2% of the possible ambient exposure. These exposures are similar to adult exposures reported for comparable activities. Median exposure to the arm at the girl scout camp during mixed activities ranged from 9.0% to 26.5% of possible ambient exposure. At the girl scout camp, exposure both within and between activity groups varied substantially and were more variable than the baseball players' exposure. Arm exposure was greater than cheek and forehead exposure for all subject groups, with an arm-to-cheek exposure ratio ranging from 1.7 to 2.3. For organized sports, such as baseball, it may be possible to assign a single exposure estimate for use in epidemiologic studies or risk estimates. However, for less uniform outdoor activities, wide variability in exposure makes it more difficult to predict an individual's exposure

N2 - "Spontaneous," i.e., self-promoted, feeding without the promotion of offering of energy-dense food (eating incentives), was maintained for 7 months in a randomized, controlled, prospective, semiblind investigation in 88

2-year-old diarrheic children. This behavior was associated with 30% lower energy intake throughout the investigation period while normal growth and blood assessments were maintained and intestinal functions improved. The dependence of a child's energy intake on maternal administrative behavior at each meal was proposed. The energy content of each meal was thus investigated in relation to a preprandial request for food, glycemia, and acceptance of nonstarchy vegetables (NSV). A sample of 210 meals eaten by 10 children with chronic nonspecific diarrhea in the second year of life before mothers were instructed in spontaneous feeding was compared with 210 meals after 1.5 months of spontaneous feeding. Compliance, food weight, preprandial glycemia, and outdoor activities were reported by the mothers in 7-day diaries. Requests for food by the child before the meal was seen and acceptance of more than two-thirds of the prescribed amount of NSV were associated with significantly lower preprandial glycemia and lower energy intake in the investigation of all meals before and after instructions were given. Feeding children on demand and habitual NSV administration may safely educate children to avoid overeating after weaning

N2 - The preresection and postresection intraoperative electrocorticograms of 76 consecutive patients undergoing resective surgery for intractable epilepsy were analyzed to see if location, configuration, and discharge rate of epileptiform activity correlated with type and location of pathology of the resected specimens and outcome in regard to seizure control. The location of the predominant spike focus did not correlate with either type of location of pathology or with seizure outcome from temporal lobe surgery (n = 58). The presence of spontaneous or activated spikes outside the resected area did not correlate with outcome from any surgery type. Positive spikes recorded from the amygdala and anterior hippocampus (n = 37) were not associated with type or location of pathology, but bursts of fast repetitive spikes on these needle recordings tended to associate with mesiotemporal pathology (p = less than 0.02) and with mesial temporal sclerosis (p = less than 0.04). A preresection spike discharge rate of 1 per 4 minutes or less was associated with a poor outcome in 5 of 6 patients (p = 0.03), whereas a rate of 18 or more per minute was associated with a good outcome in 15 of 18 patients (p less than 0.06). Persistence of 50% or more of the preresection epileptiform activity in the postresection electrocorticogram after temporal lobectomy correlated with poor outcome in 80% (p = less than 0.03), although the absolute amount of epileptiform activity remaining in the postresection electrocorticogram did not correlate with outcome. Further studies are needed to define the role of intraoperative electrocorticograms in resective epilepsy surgery

N2 - Comparisons were made between children and teachers in two schools, one a mainstream school with an integrated resource unit for children with mild learning difficulties, the other a special school. Seventeen children with mild learning difficulties from the special school and ten children with mild learning difficulties from the mainstream school, matched with ten mainstream children for age and sex, took part in the study. Observations were made on children in the playground and their social proximity and positive and negative behaviours were categorised. Self-reports on teasing, bullying and friendships were also collected from children in the mainstream school. Teachers from both schools completed a questionnaire on their attitudes to integration. There was no difference in amount of social contact children with mild learning difficulties had in the mainstream and special school nor were there significant differences in total positive and negative behaviours. Mainstream children, however, played significantly less frequently with children with mild learning difficulties and this was more marked in the older than the younger children. Self-reports from children in the integrated school indicated that the children with mild learning difficulties were teased/bullied more and made fewer friends than the mainstream children. Teachers in the mainstream were more positive and teachers in the special school were more negative towards integration. The special school teachers' expectations fitted more with the findings of the study than did those of the mainstream teachers

N2 - The evidence is provided of a close relationship between the features of women's reproductive behaviour, their health status and the health of their children: the lack of rational planning child-birth results in increasing maternal and infant mortality rates, prematurity, birth of unwanted children. The use of abortions as one of the basic means of birth control produces a negative effect, i.e. they are a frequent cause of sterility, gynaecological diseases, complicated future pregnancies and deliveries. There is a description of the priority tasks and conditions for the effective introduction of family planning into the everyday life--the necessity of taking into account sociopsychological, regional aspects of birth control within a family, demographic situation at the local level; identification of women populations which are in need of family planning activities

N2 - Serial EEGs have been carried out during the acute phase of haemorrhagic shock and encephalopathy syndrome (HS&E) in 22 infants and children aged 3 months to 14 years. Most patients presented with fits and coma and all had shock with bleeding and disseminated intravascular coagulation (DIC). The initial EEG showed prolonged runs of often rhythmic discharges which fluctuated in amount and amplitude with varying distribution and morphology ("electrical storms"). Over a period of days the "electrical storms" gradually

decreased leaving only low amplitude EEG activities or evolving to electrocerebral silence (7 cases). Fifteen patients died and all five children with multifocal "electrical storms" who survived showed gross neurological handicap. The rather distinctive EEG pattern is unusual in the context of an acute encephalopathy outside the neonatal period although similar "electrical storms" may be seen in a less extreme form in infants and children with other conditions associated with DIC. This EEG pattern presumably reflects changes in the cerebral microcirculation which in HS&E are usually relentlessly progressive and associated with devastating cortical damage

N2 - The present report discusses the standard limit reference values for metal content of playgrounds, set by the authorities in North-Rhine-Westphalia, Berlin, Hamburg and Bremen. Taking the metals arsenic, lead and cadmium as an example, the causative role of region specific conditions for establishing the limit values for protective measures are described. Essentially, two factors influence the decision: 1. the background concentrations of metals in sand and soils differ between the various states; 2. there is a lack of a uniform concept for the quantitative evaluation of oral intake as a main route of ingestion of metals endangering the health of children on child playgrounds. Due to insufficient data, arbitrary assumptions in respect of intake, relevant age group or playing-time on playgrounds are made. From a toxicological point of view the standard limit values, exceed the span of toxicological tolerance, in an attempt to combine pragmatic and toxicological considerations. However, only few of these values agree with the basic principles of preventive care

N2 - Respiratory symptoms, atopy, and bronchial reactivity were measured in primary school children living in Lake Munmorah (LM), a coastal town near two power stations, and in Nelson Bay (NB), a coastal town free from any possible major sources of outdoor air pollution. A prevalence survey and longitudinal follow-up study were performed 1 year apart. In both studies, the prevalence of ever wheezed, current wheezing, breathlessness, wheezing with exercise, diagnosed asthma, and use of drugs for asthma at LM were all approximately double the prevalence at NB (all P values less than 0.01). The prevalence of bronchial reactivity was significantly greater at LM than NB (P less than 0.01) at the first but not the second survey. By contrast, no significant differences were found between the two areas for skin test atopy or for parental history of allergic disease. Multivariate analysis supported the conclusion from the univariate analysis that there was more wheezing at LM compared to NB at both studies, when adjusted for atopy, smoking in the home, age, and sex. As expected, a positive skin test reaction to house dust mite was the predominant explanatory variable. Asthma was more common in the community near power stations (LM) than in the NB area. The absence of significant differences in skin test atopy and parental history of allergic disease argued against major genetic differences between the

two groups. By contrast, the more common reporting of siblings' chest disease and asthma in Lake Munmorah supported an environmental cause

N2 - Injuries at school were studied for one school year in 57 primary and three secondary schools (13,733 students, aged 7-19 years) at Umea in northern Sweden. The injury rate was 22/1000 student years. There was a wide variation in injury rate between different schools. The boy/girl ratio was 1.1/1. Physical education was the dominating activity at the time of injury for the older students and play in the school yard for the younger. The majority of the students had a minor injury, but 17% had a fracture. The injured students did not seem to have more somatic, psychological or social problems than students in general. Fewer competitive sports and ball games and more adult supervision and organized activities during breaks are suggestions to reduce injuries at school. A hospital-based injury registration system is well fitted for serving as a base for analysing school injuries

N2 - During a 12-month period ending on November 30, 1988, data were collected on 4623 pediatric patients visiting a pediatric emergency department with trauma (excluding burns). Sixty-one percent were male.

Common causes of the trauma included suspected child abuse (4%), organized sports (6%), nonorganized sports (4%), pedestrian motor vehicle accidents (MVs) (3%), bicycle MVs (2%), and automobile MVs (3%).

However, most of the incidents had none of the identified associated activities surrounding the trauma (60%).

Incidents took place at home (41%), on the street (11%), at school (10%), and at a playground or park (10%).

Injuries involved the external body (59%), extremity (26%), head or neck (13%), face (4%), chest (1%), and abdomen (2%) and were more common during the summer. Injury severity scores had a mean of 1.8 and were grouped as: less than 3 (80%), 3-6 (19%), and greater than 6 (1.6%). Factors associated with higher trauma

severity included MVAs, water-related injuries, sports, streets, schools, parks, playgrounds, skateboards, skates, and alcohol

N2 - As noted in a parent newsletter, the inclusion of children and young adults with disabilities with other students in our schools will result in "an ever widening circle of people who believe that disabilities are a part of life, that people with disabilities are a part of [our] natural environment who should not be isolated, and that people with disabilities can have a positive effect on non-disabled people and the general community". All students can benefit from regular class activities even though the individual goals for some may be quite different. Such efforts are not always easy to implement, and depend on adequate support for both students and school personnel--but the benefits for all students are substantial. As one regular education teacher noted: "Above all, we want our kids to show concern for others, now and in their future days. Typical kids in integrated classrooms benefit because these goals are as much a part of their daily classroom experience as the 'academics'. In reality, I believe the academics are enhanced because of these goals." And this teacher observed: "I believe that all kids have a right to be in inclusive classrooms--to be educated with their peers. When everybody in a class is considered equal, some very great things will happen."

N2 - The aim of this study was to determine the incidence rate and to determine the etiology and the severity of accidents caused by playground equipment during the period 1.1.1989-31.12.1989 and to compare the results with the study made by Christensen et al (1-3). The number of children aged below 15 years was 42,635. A total of 270 playground accidents were registered, which resulted in an incidence rate of 6.3 per 1,000 children per year. This is a reduction from 9.3 per 1,000 children per year in 1981. The incidence rates between boys and girls were 7.0 and 5.6 per 1,000 children per year, as compared with respectively. The sex ratio for the population studied was 1.31 to 1 as compared with 1.44 to 1 in 1981. The sex ratio in the background population was 1.05 both in 1981 and 1989. The greatest number of accidents were seen in spring, especially in April and May. Swings, climbing frames, slides, playhouses and playcastles were responsible for 80% of the accidents. The etiologies were fall accidents in 211 cases, being caught between two objects in 17 cases, being hit by an object in 21 cases and different causes in 21 cases. The underlying surfaces were sufficiently soft in 24% of the cases. The severity of the injury was classified according to the Abbreviated Injury Scale and was found to be: no lesions 1.1%, minor lesions 70%, moderate lesions 25.1% and severe lesions 3.7%. A total of 17 patients were admitted and of these 13 patients had fractures. The possibilities of reducing the number of injuries resulting from playground equipment are discussed

N2 - Questionnaires were sent concerning all of the patients aged 0-15 years who were admitted to the Ringkøbing County Hospitals during the period 1.1.1982 to 31.8.1989 with head injuries. The object of the questionnaires was to elucidate the circumstances of the accident which resulted in hospitalization.

Questionnaires concerning 988 patients (67.5%) were returned. Definite accumulation of the accidents was observed during the period 12.00-18.00 with 55.2% of all the accidents. The majority of the accidents (72.3%) occurred out-of-doors and the majority of these on transport areas. Bicycle accidents were most common, most frequently in children over the age of four years. Where younger children were concerned, accidents in the home were commonest. Accidents in playgrounds and during sports constituted only 13% of the total material. A relatively great proportion of the children (42.9%) were under supervision, usually from their own family, when the accident occurred. On the basis of this investigation, the authors recommend that possible prophylactic measures in the County of Ringkøbing should be directed towards bicycle accidents among the older children and accidents in the homes where smaller children are concerned

N2 - Two aspects of hand-washing were explored in this study. Mothers and children from 80 families in Zimbabwe were asked to wash their hands in the traditional manner in sterile water. Mothers were asked to answer a socio-economic questionnaire. By using the questionnaire and observations in conjunction with the microbiological data from hand-washing, factors were identified which contributed to high counts on the hands. These were: high relative humidity, living on a commercial farm, and having an infant in the family. Mothers and children 1-5 years of age had higher counts than children of 6-12 years. People recently involved in outdoor physical activities such as farming had higher counts than those involved in other activities. The traditional hand-washing method was also compared with two other hand-washing methods: hand-washing using soap and hand-washing using a container known as the mukombe. Hand-washing with soap was the most effective method closely followed by hand-washing using the mukombe. The least effective method was traditional hand-washing

N2 - The widespread public concern in Britain over childhood injuries arising from playground accidents is examined using a new national data base on leisure accidents managed by the Department of Trade and Industry. Popular beliefs about the level of risk, the nature and cause of injury, and remedial measures are found to be unsupported by the analysis. Playground risks are comparatively low; accident causes are diverse and most involve long bone injuries and not head injuries as has been widely reported; and the cost of some popular risk reduction measures would seem to be incommensurate with the reasonably-anticipated risk reduction which they might afford. It is suggested that for those who wish to reduce risk further, consideration should be given to increasing public awareness of the many causes of risk, of the opportunities which the individual has to control risk, and of the inevitability of residual risk

N2 - All sports injuries, and this is certainly true of dentally related sports injuries, occur for predictable reasons. In some instances, these predictors have been well studied and are recognized by participants as well as coaches, dentists, and other responsible parties. In other instances, there is much to be learned about these predictors. There is no question that predictors have direct influence upon the incidence and prevalence data for dental injuries related to each sport. Because of the variability of these predictors from one sport to another, from one sports participant to another, from one age group to another, and even from one playground, field, or court to another, the importance and validity and usefulness of much of the data available currently is debatable. The importance of sports dentistry is not based solely on the urgency afforded by a given number of injuries among a specified number of participants over a certain amount of time. It is the predictable nature of these injuries and the need for the profession to take responsible action in their prevention and treatment that provides the strongest imperative for a sports dentistry movement. N2 - Sixteen patients suffering from acute *Plasmodium falciparum* malaria were studied. All were residents of an area of unstable malaria-transmission in Eastern Sudan. Blood-samples were drawn at diagnosis, and 7 and 30 days later. Blood-samples from thirteen donors, drawn outside the malaria transmission season 5 months prior to the attack, were included in the study. Lymphoproliferative responsiveness to purified soluble malarial antigens and to the unrelated antigen PPD was lost during the acute phase of the disease in most donors, but was regained during convalescence, except in four donors recrudescing or reinfected by day 30. In contrast to the suppression of antigenic responses, cellular responses to phytohaemagglutinin (PHA) remained virtually unaffected. All donors showed elevated plasma-levels of soluble IL-2 receptor during the acute phase of the disease which normalized during convalescence. Five donors examined by fluorescence-activated cell sorting (FACS) showed no increase in surface expression of IL-2 receptor on peripheral lymphocytes. The data indicate that acute *P. falciparum* malaria causes a depletion of antigen-reactive T-cells from the peripheral circulation, probably due to homing of this cell-population to lymphoid tissues. It was also found that acute-phase plasma was suppressive to PPD-induced proliferative responses, indicating an additional suppressive mechanism operating *in vivo*

N2 - The extent of infection among 722 residents of an enzootic focus of Crimean-Congo hemorrhagic fever (CCHF) virus in rural northern Senegal and putative modes of transmission were studied by a cross-sectional seroprevalence survey done from February through May 1989. Anti-CCHF virus IgG was found in 13.1% of 283 persons who completed a standard questionnaire and provided blood samples. Seropositivity rates were similar between sexes and increased significantly with age among nomadic persons. Behavior patterns providing exposure to multifactorial risk factors were gender-based. Male risk factors, primarily associated with herding activities, included sleeping outside during seasonal migrations (also a risk factor for nomadic women), bite by a tick (adult male *Hyalomma truncatum*), tick bite during the cool dry season, and contact with sick animals. Human infection of CCHF occurred more frequently or with less mortality in the region studied than has been found elsewhere in Africa; however, the rate of seroconversion-associated illness is undetermined. *Hyalomma* ticks appear to be the primary transmission mode

N2 - Schools are uniquely situated to provide information relevant to the assessment and treatment of Attention Deficit-Hyperactivity Disorder (ADHD) across a variety of tasks, settings, and observers. The importance of the school setting to the assessment and treatment of ADHD has resulted in the development of numerous measures appropriate for such assessment, but few guidelines for their use. The purpose of this article is to describe school-based assessment procedures and their relationship to ADHD. These procedures include teacher rating measures, direct observations in classrooms and on playgrounds, peer rating and sociometric measures, and permanent product measures such as academic performance. It is recommended that school-based assessment of ADHD involve the concurrent use of multiple measures to assess adequately the wide variety of symptoms associated with this disorder. It is further recommended that assessment serve the purpose of determining treatment efficacy to avoid unwarranted preoccupation with diagnostic issues that are as yet unresolved. The components of a comprehensive school-based assessment of ADHD are described, and their relationship to school-based treatment is discussed. [References: 94]

N2 - Ventilatory function was measured twice daily on 46 healthy children aged 8-14 years on at least 7 days for each child during a 4-week period at a northwestern New Jersey residential summer camp in 1988. The highest 1-hr O₃ concentration was 150 ppb, while the highest 12-hr H⁺ concentration (as H₂SO₄) was 18.6 micrograms/m³. The highest temperature-humidity index was 81 degrees F. The regressions of FVC, FEV₁, FEF₂₅₋₇₅, and PEF_R on O₃ in the hour preceding the afternoon function measurements yielded slopes essentially the same as those measured on other children at the same camp in 1984. Regressions of the changes in function between the late morning and late afternoon function measurements on average O₃ concentration between them produced significant, but somewhat smaller effects, while regressions of morning function on O₃ during the previous day indicated small but still significant effects. There were no significant correlations with other measured environmental variables including H⁺. Based on the results of this study and similar previous studies, we conclude that O₃ exposures in ambient air produce greater lung function deficits in active young people in natural settings than does pure O₃ in controlled chamber exposure studies because of: (1) longer exposures; (2) potentiation by other factors in the ambient exposures; (3) the persistence of effects from prior day's exposures; and (4) the persistence of a transient response associated with the daily peak of exposure. It follows that projections of likely effects in the real world from controlled chamber exposure studies should either have a large margin of safety, or the judgment of the extent of effects likely to occur among populations should be based directly on the effects observed in field studies

N2 - BACKGROUND: With 1.9 million US children cared for in organized group child care, the safety of these children is a public health concern. In the absence of federal policy, each state has developed its own day care safety regulations. METHODS: After creating a set of 36 criteria from three sets of national guidelines, we assessed the safety regulations of 45 states. With a mailed survey of state day care regulatory personnel, we examined the processes of formulating and implementing safety policy in 47 states. RESULTS: For 24 of the 36 items, more than half the states' regulations were below the criteria or failed to mention the topic. Most notable is the inattention to playground safety, choking hazards, and firearms. CONCLUSION: The uneven quality of regulations may be a reflection of a regulatory process that is fragmented, with many different groups sharing authority and with limited involvement of injury prevention specialists

N2 - The chest wall of neonates and infants is compliant and thus the outward recoil of the chest wall and the inward recoil of the lungs theoretically balance at a low lung volume (FRC) incompatible with gas exchange. The neonates and infants, however, have a number of mechanisms that actively maintain a high FRC: (1) Laryngeal breaking during expiration. (2) Short expiratory time relative to long time expiratory time constant. (3) Sustained inspiratory muscle tone during expiratory phase. When lung recoil is increased as in many disease states, the third mechanism fails due to muscle fatigue. The increased lung recoil pulls in the chest wall and a catastrophic decrease in FRC occurs. The measurement of respiration from the outside through chest wall movement is especially important in infants and young children for these reasons. The other reason is that the breathing pattern remains unaltered, unlike measurement via the airway such as by mask and pneumotachometer

N2 - An important question in the attempt to generalize laboratory findings on attention deficit-hyperactivity disorder (ADHD) children to clinical issues concerning their assessment, diagnosis, outcome, and treatment response is the ecological validity of the commonly used tasks and analogue behavioral observation procedures. This paper examines the concept of ecological validity and issues inherent in its evaluation. The evidence from a variety of sources is then reviewed on the relationship between laboratory methods of assessing inattention, impulsivity, and overactivity and measures of these same constructs in natural settings. Additional findings pertaining to this issue from a recent study of 140 ADHD and normal children and 159 ADHD and normal adolescents using a multimethod battery of tests are also reported. In general, the ecological validity of most methods is of a low to moderate degree, with some traditional laboratory tasks proving unsatisfactory. A few tasks demonstrated acceptable degrees of ecological validity but even these require improvement. It is concluded that future advances in ecological validity are likely to come from: (a) a greater reliance on assessments of the target behaviors in natural settings and (b) combining several of the more promising tasks and analogue methods into a battery that is taken over longer time intervals than has been customary and averaged across repeated administrations. N2 - This study examined the relationship between deaf preschoolers' language abilities and their play behavior. Twenty-nine deaf children aged three to five years were observed during outdoor free play throughout the school year. Their language abilities varied widely and did not correlate with age. On the basis of two language tests, they were divided into three language ability groups--high, middle, and low. Language ability was found to be related to several aspects of play and social interaction. The children with high language ability were more likely than the other children to play with two partners at the same time (i.e., engage in triadic interaction), to interact with teachers, to prefer to play with children of similar language ability, to use language, and to receive language from their partners. Most of these effects seemed to be due solely to differences between the children with high language ability and those in the other two groups. Children in the low and middle language ability groups behaved similarly. Language ability was not related to any other aspect of peer relations. Thus, the impact of language ability seems limited. These results, in conjunction with past research, suggest that, for the most part, deaf preschoolers' language and social skills develop independently from each other

N2 - An observational study was conducted to examine injury-risk situations as they occurred during playground recess periods. A process analysis approach was used to describe antecedent conditions, response, consequence, and reaction depicted in the video scenes. Results indicate that boys were more involved than girls, playground equipment was frequently used improperly, aggressive behaviors were sometimes a factor, situations occurred more frequently with nonteacher than teacher monitors, and children infrequently took action to stop the situations. Other children were more likely to react to the target child than the monitor.

Direction is provided for child and monitor safety promotion programs

N2 - The situation of children and adolescents in families with an alcohol problem has been neglected in the mental health field. A role model is therapeutically beneficial, because "role" is a metaphor which implies that change can take place within a short period of time. These roles can be considered generalizations on various functions which present a bind to the alcoholism system for the children. Behavior which conforms to these roles impairs the formation of personal identity, individuation from the family of origin, and the development of stable relationships outside of the nuclear family. Therapy should aim at activating resources, rather than focussing on deficits

N2 - STUDY OBJECTIVES: (1) To determine those diseases that most often mimic Kawasaki disease (KD) in the United States. (2) To examine the physical findings and laboratory studies that influenced experienced clinicians to exclude the diagnosis of KD. (3) To compare epidemiologic features of patients with KD and patients referred for evaluation of possible KD in whom alternative diagnoses were established. DESIGN: Case comparison study. SETTING: Seven pediatric tertiary care centers. PATIENTS: Consecutive sample of 280 patients with KD and 42 comparison patients examined within the first 14 days after onset of fever.

MEASUREMENTS AND MAIN RESULTS: (1) Infectious diseases, particularly measles and group A beta-hemolytic streptococcal infection, most closely mimicked KD and accounted for 35 (83%) of 42 patients in the comparison group. (2) The standard diagnostic clinical criteria for KD were fulfilled in 18 (46%) of 39 patients in whom other diagnoses were established. (3) Patients with KD were significantly less likely to have exudative conjunctivitis or pharyngitis, generalized adenopathy, and discrete intraoral lesions, and more likely to have a perineal distribution of their rash. The patients with KD were also more likely to have anemia and elevated erythrocyte sedimentation rate; leukocyte count less than $10 \times 10^3/\text{mm}^3$ and platelet count less than $200 \times 10^3/\text{mm}^3$ were significantly less prevalent in patients with KD. (4) Residence within 200 yards of a body of water was more common among KD patients. CONCLUSIONS: (1) Measles and streptococcal infection should be excluded in patients examined for possible KD. (2) Laboratory studies that may be useful in discriminating patients with KD from those with alternative diagnoses include hemoglobin concentration, erythrocyte

sedimentation rate, and serum alanine aminotransferase activity. (3) Residence near a body of water may be a risk factor for the development of KD

N2 - The arterial blood is often drawn during general anesthesia to measure many biochemical parameters, and, outside the operative period, those parameters are measured mainly in the venous blood. In this way, the A-V differences (the differences between the data from the arterial blood and those from the venous blood) will be found. However, there are few reports about the A-V difference in infants and children. The purpose of this investigation was to compare the arterial blood data with the venous data at the induction of general anesthesia (Enflurane-N2O-O2). In this report, Plasma total bilirubin concentration (by the Michaelson method), GOT activity, GPT activity (by the Karmen method), gamma-GTP activity (by the gamma-glutamyl CPA substrate method) and pseudocholinesterase activity (by the Shibata-Takahashi method) were measured with both the arterial (from the radial Artery) and the venous samples (from the saphena Magna), in 60 cases of infants and children who had no systemic disease. They were divided into three groups according to age. (Group I: three months old to one year old, Group II: one year old to three years old, and Group III: three years old to six years old.) Each group consisted of 20 patients. The difference and correlation coefficients between arterial and venous measurements were analysed with the paired t-test and correlation analysis $F_s = [r^2(n-2)/(1-r^2)]^{1/2}$. Additionally, the data was analysed with a one dimensional analysis for all Groups. In the results, the A-V difference was so small that the conclusion was reached that in these liver function tests there would be no problem in regarding arterial measurements as venous measurements

N2 - Third and fourth grade boys (n = 422) and girls (n = 390) in four Texas elementary schools reported their participation in moderate to vigorous physical activities (MVPAs) over a 3-day period. Students were surveyed during class on successive days. On a subsample (n = 44), the agreement between reported and observed physical activities during physical education or recess was 86.3%. Running, walking fast, games and sports, and bicycling accounted for 70% of Total MVPAs. Of Total MVPAs reported, 47.0% for boys and 44.6% for girls were 10 min or longer in duration (LMVPA). The average number of LMVPAs per day was 1.7 for both boys and girls. Students reported significantly more occurrences of LMVPAs out of school than during school. Significant interaction between grade and gender indicated that third grade boys reported more Total MVPAs and LMVPAs than third grade girls, but fourth grade boys reported fewer Total MVPAs and LMVPAs than fourth grade girls reported fewer Total MVPAs and LMVPAs than fourth grade girls. During the 3-day reporting period, 12.3% of boys and 13.3% of girls reported no LMVPAs, and 35.6% of boys and girls reported fewer than one LMVPAs per day. While the majority of children reported obtaining at least some activity daily, a substantial proportion of children in this sample reported fewer than one LMVPA daily, indicating that many children may not be obtaining adequate amounts of physical activity

N2 - In 1990, the State of North-Rhine-Westphalia established an ordinance on the quality of playground soil and sand. This ordinance includes guideline values for toxic metals (arsenic, lead, cadmium, chromium) in playground soil not covered by vegetation and quality standards for sand to be applied on playgrounds. Additionally guideline values were set for mercury, nickel and thallium. The guideline values include two categories: guideline value I represents the upper limits (95-percentiles) of the background levels of toxic metals generally found in upper soil layers in the State of North-Rhine-Westphalia. Guideline values II ("action levels") were selected on the basis of toxicological considerations. In cases where concentrations of metals above these guideline values are detected, immediate actions (urgent redevelopment measures) are required. Quality standards for playground sand were established to ensure that only noncontaminated sand is applied for playgrounds

N2 - During the sunny summers of 1989 and 1990 in Germany the outdoor ozone levels repeatedly exceeded the value of the air quality guidelines proposed by the World Health Organization. Both in multiple sites within industrial polluted and in supposedly clean outside areas the ozone concentrations exceeded the value of 180 micrograms/m³. The following paper is intended to contribute to an understanding of the health effects of ozone. It compiles data and views on the formation and analysis of ozone, on its distribution as ambient ground level pollutant, on respiratory and common symptoms in man and on the toxicokinetics, responses and pathogenesis in experimental animals. Studies on healthy exercising adult volunteers exposed to 240 micrograms/m³ ozone in purified lab air or in ambient air revealed a significant influence on connections between forced vital capacity, forced expiratory volume, flow rate and peak expiratory flow rate and the pollutant. Exposure to lower ozone levels induced the same effects, but they were of smaller magnitude. Children aged 8-15 years exercising under field conditions showed decrements in lung function even at ozone levels well below 200 micrograms/m³. Restitution of lung function needs periods of several days, although the induction of effects is a matter of hours. The relevance of the transient pulmonary responses is widely unclear. Among patients with chronic obstructive pulmonary disease or asthma, the functional responsiveness to ozone is not greater than among healthy subjects. Interindividual differences in responsiveness occur but are not predictable. Information on chronic effects is rather limited.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - Preparation of the New Zealand Playground Standard was seriously hampered by a lack of published information on the incidence, nature, and circumstances of playground equipment-related injuries. The present study was aimed at redressing this lack of information. Examination of all discharges from New Zealand public hospitals for 1984 identified 1125 children less than 15 years of age who had been admitted for the treatment of playground equipment-related injury. This gave an incidence rate of 137/100,000 children per year. The mean age was 7.2 years. The commonest injury was fracture of the upper limb (48%), followed by intracranial injury (26%). One-third occurred at school, climbing apparatus (40%) was most often involved, and the great majority involved falls (93%). With this study it has been possible for the first time in any country to report an incidence rate for all causes of playground equipment-related injuries resulting in hospitalization, based on data for an entire population. The findings support the emphasis placed on falls in the Standard

N2 - Unintentional injuries at school have been identified as a significant public health problem. A major barrier to the development of injury prevention policy has been the absence of national data on the circumstances of injuries to students which occur at school. This study sought to determine the incidence, nature, and circumstances of injuries which resulted in death or hospitalization. Fatalities were identified from national mortality data for 1977-86 inclusive. Coroners' files were then examined to obtain details of the circumstances of injury. Hospitalization cases were identified from the national hospital discharge summary for 1986. Fifteen fatalities were identified. The circumstances of the deaths were diverse with the most frequent event being a fall (n = 4). A total of 1013 first admissions to hospital were identified, giving an overall incidence rate of 152/100,000 students/year. Injury rates declined with increasing age, and males had higher rates than females for all ages. Fractures of the upper and lower limbs and intracranial injury represented more than three-quarters of all injury. The two leading causes of injury, falls, and incidents involving striking against or being struck by a person or object, represented 89% of all incidents. The use of playground equipment and involvement in sporting activity were two of the more common aspects of many injury events. The results suggest that prevention policy should place emphasis on those in their first 2 years of schooling, falls from playground equipment, provision of protective equipment for sporting activities, sporting activities designed to minimize physical contact, establishment of standardized injury referral procedures, first-aid training, and a standardized injury reporting system

N2 - The classroom and playground behaviors of students with disabilities, in an integrated classroom, are frequently cited as reasons for rejection of these students by their regular-class peers. We compared the classroom and playground behavior of 95 students with mild disabilities with that of 95 students without disabilities, age and sex matched, and enrolled in the same classes. The children, age 8-13 years, attended state government elementary schools. Behaviors were observed using a time-sampling method with nine categories of behavior in each setting. The behavior of both groups of students was in many ways similar, regardless of the presence of disabilities

N2 - Nurses are continually promoting health and healthy lifestyles. This contribution requires that nurses understand client values and priorities. Traditionally, women have had responsibility for their own and their families' health. Nurses must recognize and understand the complex influences shaping the value women place on health. The literature indicates that women want to participate actively in their own health care by assuming more responsibility for their health and well-being. This research evolved as a result of nursing student and faculty interactions with mothers of pre-school children enrolled in a Headstart program. During these experiences, observations related to the needs of the mothers included poor health practices (smoking, being overweight), lack of motivation, statements of feeling depressed, difficulty making decisions, feelings of being overwhelmed by parenting demands, powerlessness, and disenfranchisement. This descriptive, correlational study was designed to determine the value of health, incidence of depression, and characteristics of self-esteem among low-income mothers of pre-school children. This sample of convenience was comprised of 133 low-income mothers who responded to a mailed survey. Three instruments were used in the study: the Wallston and Wallston Health Values Scale, the Center for Epidemiologic Studies Depression Scale (CES-D), and the Rosenberg Self-Esteem Scale. Data were analyzed by collection of frequency of response, which was then converted to a percentage. To determine if differences existed in respect to demographic variables, ANOVA (self-esteem and depression) and Chi Square (health) measures were used. Participation in activities outside the home accounted for a significant difference in self-esteem. Mothers involved in activities reported higher self-esteem. The findings suggest that participation in activities may increase self-esteem and lower depression. Over three-quarters (85%) of mothers placed a high value on health. Based on their high valuing of health and the potential for increasing self-esteem through activity, it can be concluded that the women in this sample will benefit from planned health activities. It is also anticipated that, because of the strong relationship between self-esteem and depression, women who participate in these activities will demonstrate lower levels of depression

N2 - Abdominal migraine is a common childhood migraine equivalent, for which diagnostic criteria have not been defined. As in other children with migraine equivalents this leads to difficulties in diagnosis and determination of prevalence. By recording the fast wave activity (beta rhythm) in the visual evoked response (VER) to red and white flash, the pattern stimulation, 27 out of 28 children with clinically diagnosed abdominal migraine revealed significant differences compared with normal controls, outside the attack phase. Comparisons with children diagnosed as migraine with or without aura revealed, from the VER findings of higher amplitude fast wave activity and the presence of paroxysmal sharp wave activity, that abdominal migraine appears to be a specific form of childhood migraine. We found that both clinically and electrophysiologically, abdominal migraine changes with age; older children exhibiting a shorter duration of abdominal pain during attacks, and less evidence of sharp wave activity in the VER

N2 - An increase in energy intake often occurs at weaning. The increase may be due partly to prompting by the caregiver to accelerate the child's weight gain and partly motivated by the palatability of common weaning foods. Increased food intakes initiated during weaning and continued into the second year of life may be associated with chronic, nonspecific diarrhea in selected children. An educational project was designed to reduce intakes augmented by either cause. Reductions were achieved by the regulation of energy-dense foods in the child's diet and reliance on the child's appetite control to determine meal size. The educational intervention was applied prospectively under nonblinded, controlled conditions. Children, 1 to 2 years of age, with chronic nonspecific diarrhea were assigned randomly to either a treatment or control group. Compliance, food consumption, preprandial glycemia, and outdoor activities were reported by the children's mothers in four 7-day diaries; symptoms related to the children's clinical condition and anthropometric and biochemical indices of nutritional status were noted at the beginning and end of a 7-month period. Forty-four of 53 children in the experimental group maintained compliance, and 44 of 47 children in the control group completed the follow-up. Energy intake decreased significantly by almost one-third in the experimental group. Growth, skinfold thickness measurements, and outdoor activities were similar between experimental and control groups over the 7-month period. Diarrheal episodes occurred in 6, 1, and 2 children in the experimental group at 1.5, 3, and 7 months and in 22, 18, and 15 children in the control group, respectively (p less than 0.002).(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - An enzyme-linked immunosorbent assay with larval stage antigen was used to measure the concentration of antibodies to *Toxocara* sp in 2206 human sera. The results led to the determination of the specificity of our method, the experimental cutoff estimation and the *Toxocara* sp seroprevalence in different human populations. The prevalence of canine toxocariasis in pet dogs and the associated environmental contamination were studied through examination of 107 faecal and 20 sand-pits samples for *Toxocara* sp eggs. Our immunological studies and environmental research revealed the existence of toxocariasis as a zoonotic disease in Belgium. We compare here our results with those found in the world literature: in spite of some surprising results, the environmental factors are important for toxocaral infection. The urban residence, the restricted number of playgrounds for children and areas for dogs, the socioecological status are preponderant in the spread of infection

N2 - One of the least documented "known" effects of methylphenidate in hyperactive children is the suppression of peer aggression. In this study, 11 aggressive-hyperactive children received a low (0.3 mg/kg) and moderate (0.6 mg/kg) dose of methylphenidate and placebo for 2 weeks each under double-blind conditions. Children were observed in public school settings during classroom seatwork activities, lunch, and recess. Results showed that methylphenidate suppressed nonphysical aggression ($p = 0.06$) in the classroom, and a moderate dose decreased physical aggression (p less than 0.01) and verbal aggression ($p = 0.07$) on the playground. The effect on the rate of appropriate social interaction was variable. The majority of subjects exhibited either the same or higher levels of appropriate social interaction on the 0.6 mg/kg dose compared with placebo. In the classroom, both doses of methylphenidate also resulted in reduced levels of motor movement, off-task behavior, noncompliance, and disruptiveness. Teacher ratings of hyperactivity and conduct problem symptoms revealed drug effects, whereas parallel parent instruments did not

N2 - A total of 1,671 children aged 11, 13 and 15 years from a nationwide random sample of schools completed an anonymous questionnaire on their social backgrounds, social networks, health, life satisfaction, and health behaviour. The proportion practising outdoor activities at least three times a week was 57%; 37% did some physical exercise in their leisure time sufficient to make them breathless or sweat at least four times a week; 43% at least four hours a week. Two thirds were active members of a sports club. A minority of 8% did not carry out any physical exercise during their leisure time sufficient to make them breathless or sweat. Boys did more physical exercise than girls irrespective of the measurement of exercise. The most important motives for physical exercise were to improve health, to get in good shape, to have fun, and to make new friends. More than 90% of the children intended to do physical exercise at the age of 20. High intensity of physical activity was associated with high social class, strong social integration in the peer group, easy contact with parents and friends, physical exercise among parents and best friends, high degree of life satisfaction, and good health

N2 - Seventeen of 73 (23.3%) multiply transfused patients with thalassaemia major (age range, 1-39 years) tested positive for antibody to hepatitis C virus (anti-HCV). Eleven of the 24 patients regularly transfused in countries outside Britain were anti-HCV seropositive; only six of the 49 regularly transfused in Britain were seropositive. The incidence of anti-HBs and anti-HBc was similar to that of anti-HCV in both the British and foreign patients. The anti-HCV seropositive patients showed significantly higher plasma aspartate aminotransferase activities (AST), mean (SD) 10.2 (70.3) U/l, and serum ferritin concentrations, 4067 (2708) micrograms/l, than the anti-HCV seronegative patients (AST, 33.9 (15.6) U/l; serum ferritin 2051 (2092) U/l), respectively. Among the 36 patients who had earlier undergone liver biopsy 10 of 21 with histological features of chronic active hepatitis or cirrhosis, or both, were seropositive for anti-HCV whereas only one of 15 without histological evidence of chronic viral hepatitis was seropositive for anti-HCV. It is concluded that HCV is a major cause of chronic hepatitis in patients with thalassaemia major and is associated with raised AST activity and serum ferritin concentration compared with patients seronegative for anti-HCV

N2 - Childhood exposure to ultraviolet (UV) radiation in sunlight may be an important risk factor for later development of skin diseases. We quantified the UVB radiant exposure on the wrist and face of children performing mixed outdoor activities at a summer camp. Polysulfone film badges were attached directly to the skin for several hours and simultaneously were used to measure ambient UVB levels. The results for the ratio of site-specific exposure to ambient exposure indicate a high degree of intersubject variability, a parity of samples taken in right and left positions, and a significantly higher exposure on the wrist compared with the face. The technique was well accepted by the subjects but some badges could not be read because of loss or damage. Measurement of exposure ratios in additional settings as well as data on childhood activity patterns are needed for an overall assessment of childhood exposure

N2 - Correlations between ambient pollutants and health effects, such as observed in SIDS, may in reality be to a larger extent the result of indoor sources. These distinctions between indoor and outdoor sources, while important, do not detract from the overall conclusion that pollution affects the airway in children directly and indirectly. Much still needs to be learned about the permanence of these effects, the mechanism by which the effect is mediated, and the conditions under which some of these effects are maximal. Two approaches seem particularly suited to shed further light on these issues. First, identification of biological markers for exposure to pollutants will yield both more accurate measures of exposure to pollutants and information about health consequences. Second, newer modeling techniques promise to predict health outcomes under a variety of environmental conditions. Shumway et al., for instance, describe a promising model predicting an increase in

mortality due to ambient pollutants in the Los Angeles Basin with higher levels under extremes of temperature, especially during cold spells. Time series and factor analyses may further our knowledge as well. In the near future, large cohort studies should begin to reveal the cumulative effects of air pollution on the respiratory system, especially in relation to active smoking. Finally, studies in Black children are virtually unavailable. Given their high risk for respiratory illnesses, such studies are sorely needed. [References: 60]

N2 - A population survey of 1000 7 year old children found a significant excess of wheeze among children whose homes were reported to be mouldy (odds ratio 3.70, 95% confidence limits 2.22, 6.15). The airborne mould flora was quantified by repeated volumetric sampling during the winter in three rooms of the homes of 88 children. All of these had previously completed spirometric tests before and after a six minute free running exercise challenge. Total airborne mould counts varied from 0 to 41,000 colony forming units (CFU)/m³, but were generally in the range 50-1500 CFU/m³, much lower than the concentrations found outdoors in summer. The principal types of fungi identified are all known to be common out of doors, and most were found on at least one occasion in most of the homes. Median and geometric mean total mould counts were not related to reports of visible mould in the home, or to a history of wheeze in the index child. The heterogeneous group of non-sporing fungi (mycelia sterilia) were the only airborne fungi present at significantly higher concentrations in the homes of wheezy children (geometric mean 2.1 v 0.7 CFU/m³). A non-significant increase in total mould counts was observed in the homes of children with a 10% or greater decline in FEV1 after exercise (geometric mean 354 v 253 CFU/m³). Questionnaire reports of mould in the home may be a poor indicator of exposure to airborne spores. The total burden of inhaled mould spores from indoor sources is probably not an important

determinant of wheeze among children in the general population. Although the association with mycelia sterilia could be a chance finding, these non-sporing isolates may include a potent source of allergen

N2 - Examined demographic, environmental, and parent-child interactional correlates of physical activity in a group of 222 preschoolers. Activity levels were assessed with a system that quantified directly observed physical activity in the natural environment. Using regression-modeling procedures, results revealed a significant relationship between (a) child's relative weight, parental weight status, and percentage of time spent outdoors (environment) and (b) children's activity levels. Parental obesity was associated with lower levels of physical activity in children, childhood relative weight was associated with slightly higher levels of physical activity, and more outdoor activity was associated with higher activity levels. Parental participation in children's activities also significantly interacted with levels of parental obesity in predicting activity levels. Those children with a 50% risk for obesity (as defined by both, one, or neither parent being overweight) had small changes in activity across levels of parent-child interaction, whereas those at higher risk for obesity responded with increased activity as parent-child interactions increased. Results are discussed, and the implications of these findings for future intervention efforts are examined

N2 - We identified 684 playground hazards in 66 child care centers despite regulations mandating that the grounds be hazard-free. Of 21 centers with less than or equal to 5 hazards, 42.9 percent reported a playground-related injury in the previous year; of 25 centers with 6-11 hazards, 52.0 percent reported a playground-related injury; and of 20 centers with greater than or equal to 12 hazards, 60.0 percent reported a playground-related injury. Climbing equipment greater than or equal to 6 feet tall generally had inadequate impact-absorbing undersurfacing and had over twice the rate of fall injuries as climbing equipment less than 6 feet

N2 - Epidemiological studies-especially data from smog episodes-indicate that antropogenous outdoor air pollution exercises a deleterious effect on health and particularly on the respiratory organs. Controlled exposure test in animals and man confirm this. The main pollutants are SO₂, suspended dust particles (dust aerosols or solid atmospheric condensation nuclei) as well as NO₂ (NO_x) and O₃. The adverse influence of quite a number of meteorological factors such as low temperature and inversion cannot be denied. During smog conditions in January 1985 in the Federal Republic of Germany there was a highly significant negative correlation between atmospheric temperature and the rate of exacerbations of bronchitis. Indoor air pollution is gaining in importance. Airtight sealing of buildings associated with reduced indoor ventilation results in novel health upsets ("sick building syndrome"). Interiors are characterised by an accumulation of CO₂, CO, NO₂, dust aerosols and various organic substances such as benzene, benzopyrene, formaldehyde, nitrosamines etc. Cigarette smoke is a frequent cause of indoor air pollution. The possible unhealthy effects of passive smoking (mainly the inhalation of sidestream smoke) have been frequently studied. Infants of smoking parents are more often affected by respiratory diseases than non-exposed children. The same applies to schoolchildren: the incidence of bronchial signs and symptoms increases with increasing smoke consumptions of the parents. However, no definitely established effect on lung function has been seen in children, adults and asthmatics. The important question as to whether passive smoking increases lung cancer risk is still a subject of controversial discussion among experts. [References: 74]

N2 - In a national survey in the period May 1986-December 1987, *Aeromonas* was isolated from 277 out of 16,857 (1.6%) samples of watery, bloody or mucous stool, from patients with diarrhoea. There was a clear seasonal pattern (less than 1% in winter, up to 3% in summer). *A. caviae* was isolated most frequently (49%), followed by *A. sobria* (35%) and *A. hydrophila* (15%). Some non-identifiable strains were isolated as well. *Aeromonas* were isolated in particular from faeces of patients aged over 70 years (predominantly *A. sobria*) or under 5 years (predominantly *A. caviae*). In 67% *Aeromonas* was isolated as the only possible bacterial cause of diarrhoea, but in 33% other enteropathogenic bacteria were found as well (17% *Campylobacter*, 14% *Salmonella*, 2% *Shigella*). In addition, all *Aeromonas* isolates were collected which were obtained in normal diagnostic activities in the participating laboratories, among others from blood, from pus or wound fluid, from faecal samples which did not meet the above mentioned criteria. *A. caviae* was the dominant species in 'other' faeces and 'various' body sites but was not isolated from blood. The results of this study do not indicate that routine examinations for *Aeromonas* in faeces of patients with diarrhoea are necessary

N2 - The purpose of this study was to examine the effects of the interval training on metabolic parameters at maximal work and at the anaerobic threshold in 11 year olds. The subjects were five healthy male children. They trained outdoor for 50 min a day, five times a week for six weeks, using interval work at 25 and 50% above their anaerobic threshold. Before and after training program, they performed a progressive exercise test on a cycle ergometer. During the last 15 sec of each power output measurements were made of oxygen uptake (VO₂), carbon dioxide output (VCO₂), heart rate (HR), ventilation (VE), ventilatory equivalent for oxygen (VEO₂) and ventilatory equivalent for carbon dioxide VE_{CO2}). Following training, the group increased their anaerobic threshold (expressed as %VO₂max) significantly (P less than 0.05) during the progressive exercise test, by 22%. Also at the anaerobic threshold level, increases were observed following training in CO₂ output (VCO₂-AT) and respiratory exchange ratio (R). Oxygen uptake (VO₂, l.min⁻¹) was increased by 19%, but the difference was not significant (P greater than 0.05). Maximal ventilatory equivalent for (VE_{CO2}max) decreased significantly (P less than 0.05). Maximal heart rate was reduced significantly (P less than 0.05). We conclude that training led to an increase of both anaerobic and aerobic metabolism, at any submaximal work above the anaerobic threshold, for this specific age group

N2 - Thirty-six pediatric patients (ages 0.8-16.8 years) with recurrent intracranial ependymoma were treated for a total of 52 separate cases of relapse from 1970 to 1989. Therapy consisted of surgery in 33 cases and chemotherapy in 38 cases. Twelve patients received radiation at the time of first relapse, and five of these 12 who had initially been treated with surgery and chemotherapy alone were irradiated to full dose. The 2-year actuarial survival and progression-free survival (PFS) rates are 29% and 23%, respectively. Two-year survival after treatment of first relapse is 39%. Of the 52 cases, there have been 44 subsequent relapses (and one septic death), three of which have occurred in the five patients treated with definitive radiation. Twenty-seven relapses have occurred exclusively with local disease. Eight patients failed with disease outside as well as in the primary site. Survival was better for patients who had histologically benign lesions at relapse (53% versus 9%, P less than 0.02), and for patients in first versus subsequent relapse (p less than 0.005). Cisplatin and etoposide (VP-16) appeared to be the most active chemotherapeutic agents. The authors conclude that some patients with histologically benign ependymoma at first relapse may benefit from aggressive therapy, with occasional long-term, progression-free survival possible. Patients with malignant lesions, or patients who relapse a second time, are less likely to benefit from conventional therapy for a significant period of time

N2 - Observations that mucus transport rates (MTR) are depressed in anesthetized animals and humans have led to speculation that general anesthesia depresses ciliary activity or adversely alters the physical properties of the respiratory mucus (RM). We investigated the possibility that anesthesia changes the physical properties of RM in such a way as to depress ciliary transport. We collected 33 samples of RM from the endotracheal tubes (ETTs) of 25 people aged 1 to 79 years undergoing elective surgery who had no clinical evidence of lung disease. We measured the rigidity, viscoelasticity, spinnability, and the percentage of solid composition of these specimens as well as the transport of the collected RM across the mucus-depleted frog palate. These physical properties were not significantly different from RM collected from awake volunteers using the bronchoscopy brush collection technique. Differences in spinnability, transportability, and solid content of paired mucus samples from the inside and outside of the ETTs are suggestive of altered RM hydration, but this requires further study. The decrease in MTR during general anesthesia is probably due to mechanisms other than alterations in the physical properties of mucus

N2 - Investigated effects of aerobic exercise on a sample of 24 preschoolers. Thirty minutes of aerobic exercises were provided daily for a period of 8 weeks for a group of 12 children while the remaining 12 children engaged in freeplay on the school playground. The children were given pretests and posttests on the following measures: a submaximal exercise test on a pediatric bicycle (baseline and three workloads), an agility test, a health knowledge test, a self-esteem scale, and an observational measure of their gross-motor activity. Despite comparability on pretests, significant group X repeated measures effects suggested that the aerobic exercise group showed decreases in heart rate at all three workloads as well as increases in agility and self-esteem following the exercise program. These findings suggest that cardiovascular fitness, agility, and self-esteem can be facilitated in preschoolers by an aerobic exercise program

N2 - The feasibility of an intensified (i.e., all-day-for-2-weeks) integrated camping experience for children with and without severe disabilities was evaluated as was the impact of integrated programming on camp staff members' attitudes. Procedures employed for promoting social interactions included positive reinforcement and cooperative learning strategies. Task-analytic procedures were used to teach campers with severe disabilities a domestic skill and a life-long leisure activity. By the end of the 2 weeks, children with severe disabilities demonstrated substantially improved skills in targeted activities. Furthermore, campers without disabilities substantially increased their prosocial interaction bids, and ratings reflective of friendship increased significantly. Also, staff members' perceptions of operating an integrated camp versus a segregated one and their perceptions of the presence of participants with disabilities as facilitative of camp operations improved significantly

N2 - To delineate the propagation of electrical activation in the atrial septum, atrial epicardial and atrial septal maps were recorded intraoperatively using a 156-channel computerized mapping system in 12 patients during sinus rhythm (n = 10), supraventricular tachycardia associated with septal pathways in Wolff-Parkinson-White syndrome (n = 3), atrioventricular (AV) node reentrant tachycardia (n = 4), and atrial flutter (n = 5). The epicardial and septal data were recorded simultaneously from 156 atrial electrodes, digitized, analyzed, and displayed as isochronous maps on a two-dimensional diagram of the atria. During sinus rhythm, the activation wave fronts propagated most rapidly along the large muscle bundles of the atrial septum. During supraventricular tachycardia associated with Wolff-Parkinson-White syndrome, the earliest site of retrograde atrial activation usually corresponded to the position of atrial insertion of the septal pathways. However, the earliest site of activation during orthodromic supraventricular tachycardia was different from that during ventricular pacing in 1 patient with a posterior septal accessory pathway localized by the epicardial mapping study. The data document the rationale for dividing the ventricular end of the accessory pathways (ie, the endocardial technique) rather than the atrial end (ie, the epicardial technique) in patients with Wolff-Parkinson-White syndrome. During AV node reentrant tachycardia, atrial activation data suggested that atrial tissue lying outside the confines of the anatomical AV node is a necessary link in this common arrhythmia. Thus, these atrial septal maps explain why surgical dissection, or properly positioned small cryolesions placed in the region of the AV node, can ablate AV node reentrant tachycardia without altering normal AV node function. The maps recorded during atrial flutter suggest the importance of the atrial septum as one limb of a macroreentrant circuit responsible for the arrhythmia, and imply that atrial flutter is amenable to control by surgical techniques. These studies demonstrate the details of normal atrial septal activation, the importance of the atrial septum in a variety of different atrial arrhythmias, and the basis of and potential for surgical ablation of the most common types of supraventricular arrhythmias

N2 - We prospectively investigated the epidemiologic characteristics of all lacerations (N = 2834) repaired at the Children's Hospital of Philadelphia (Pa) during 1987 and identified common hazards and possible avenues of intervention. Two-year-old children incurred most injuries; males outnumbered females 2:1. Almost two thirds (61.8%) of all lacerations occurred from May through September, and 62.2% between 3 and 9 PM. Most injuries occurred indoors (47.0%), on the sidewalk or street (22.5%), or in the residential yard (13.0%). Injuries usually occurred during play (42.3%) or daily activity (32.1%); 1247 (44.0%) involved some sort of fall. Vectors most frequently causing injury were broken glass bottles (15.0%), wooden furniture (12.0%), and asphalt or concrete (11.0%). Broken glass bottles also most frequently inflicted injuries resulting in functional impairment (0.2%), hospitalization (0.9%), or both. Complications were seen in 8% of all lacerations. Our data confirm the importance of injury-prevention strategies aimed at reduction of discarded glass objects (ie, recycling legislation), improved furniture design, and improved municipal services (ie, street repair)

N2 - The present retrospective study was aimed to scrutinize constant traumatic sequelae in otorhinolaryngology on 586 traumatic reports, which have been documented by the Bohemian State Insurance starting from 1965 to 1985. Constant sequelae appeared to be subsequent both to individual damages of otorhinolaryngologic organs and multiple traumas, from them 59.4% affected the ear region. Most frequently were presented the partial hearing loss, deafness, and labyrinth lesions especially in multiple traumas. As to the nasal area, the amount of 22.7 per cent consisted of external nasal shape deformities with the disordered passage, and olfactory disorders in multiple traumas. The remaining 17.9% sequelae was concerned with the anatomical and functional lesions of other otorhinolaryngologic organs. To determine features and the extent of constant sequelae, most current diagnostical approaches and consiliary examinations were used. However, the objective assessment of olfactory disorders and tinnitus aurium is stated to be still diagnostically intricated. Both the simulation and aggravation were found out in 2.5% of insurers. Other relations were also studied, e.g.: insurer vice versa physician. In addition to other causes, the most frequent ones represented an underestimation of traumatic consequences all along with their erroneous treatment, low levelled outpatient care of ORL specialists as to the multiple trauma management outside ORL service. In many instances, the injured subjects were not appropriately recommended to provide them with simple and effective surgical treatment of yet manifested constant sequelae. The proper expertize activity was complicated with the defective trauma documentation, terminology variants and erroneous regulations dealing with the recompensation of injuries

N2 - The vitreous of 39 eyes with ocular toxoplasmosis was studied and photographed using an El Bayadi-Kajiura preset lens. In active cases of toxoplasmosis, the vitreous showed inflammatory opacities and gel shrinkage. In inactive cases, the vitreous was often liquefied. Compared with 39 normal eyes of age- and sex-matched controls, the prevalence of partial posterior vitreous detachment was significantly higher in toxoplasmosis (P less than .001). A higher prevalence of posterior vitreous detachment was found in eyes with the major chorioretinal lesion outside the temporal vascular arcade than in those with lesions inside the temporal vascular arcade (P less than .05). Our results indicated that various vitreous changes may cause posterior vitreous detachment and that location of the inflammatory focus may influence the vitreous condition

 N2 - To investigate sex differences in the professional achievements and personal life-styles of graduates, a questionnaire survey was conducted. The sample comprised surviving female medical graduates of the University of Melbourne and an equal number of male medical graduates who were matched by year of graduation. The final response rate was 70% (1764 subjects returned questionnaires) and was representative for both age and sex. This article describes the practice patterns and family lives of graduates. Considerable sex-related differences were found in the professional achievements and personal life-styles of the surveyed medical graduates. Women's professional careers tended to be more circumscribed than were those of male colleagues. Women were less involved in areas outside clinical practice such as teaching or lecturing, committees, medical administration, and research and its publication. Female doctors earned significantly (P less than 0.0001) less than did male doctors and were more likely to work as employees, locums or in sessional employment (P less than 0.0001). Women were more involved in all aspects of household activities, especially during midlife (40-60 years of age)--the peak career years for male doctors. The career underachievement of female doctors is likely to continue unless considerable changes are made to current postgraduate training schemes and career structures

N2 - The ability of school-based measures of child behavior to predict differentially the IOWA Conners teacher rating scale Inattention/Overactivity (IO) and Aggression (A) factors was evaluated in a sample of 71 school-aged boys. Multiple measures and multiple methods of assessment were utilized to provide a comprehensive assessment of social and academic behavior. These included direct observations of children in the classroom and on the playground, examination of the organization of children's desks, measures of academic performance, peer nominations of popularity and rejection, and sociometric ratings using the Pupil Evaluation Inventory. Despite moderately high correlations between the teacher rating factors ($r = .60$), considerable evidence was provided for differential validity on measures of academic performance, peer rating measures, and measures of disruptive or inappropriate classroom and playground behavior. These differences between IO and A factors indicated that the factors were logically independent in important ways, supporting prior work validating separate hyperactivity and aggression dimensions

N2 - From June 1987 through May 1988, we collected reports of injuries among 5300 children who attended 71 day-care centers in Atlanta, Ga. One hundred forty-three injuries severe enough for the child to require medical or dental care were reported, including 63 lacerations (44.1%), 23 fractures (16.1%), 5 crush injuries (3.5%), 4 dislocations (2.8%), 2 human bites (1.4%), and 2 concussions (1.4%). The head was the site of 98 (68.5%) injuries. Peak hours for injuries were 11 AM and 4 PM, the peak day was Monday, and the peak season was summer. After adjustment for hours and dates of attendance, the rate was 1.77 injuries per 100,000 child-hours in day care; among preschool-aged children, infants had the lowest rate (0.77) and 2-year-old children had the highest rate (2.26). Almost 47% of injuries occurred on the playground; falls were involved in 70% of such injuries. Because 33% of all injuries resulted from falls on the playground, impact-absorbing playground surfaces may be a possible intervention to reduce injuries

N2 - The present study evaluated alternative treatments for children (N = 112, ages 7-13) referred for severe antisocial behavior. Children were randomly assigned to one of three treatments: problem-solving skills training (PSST), problem-solving skills training with in vivo practice (PSST-P), which included therapeutically planned activities to extend training to settings outside of treatment, or client-centered relationship therapy (RT). PSST and PSST-P children showed significantly greater reductions in antisocial behavior and overall behavior problems, and greater increases in prosocial behavior than RT children. These effects were evident on measures obtained immediately after treatment and at a 1-year follow-up, and on measures of child performance at home and at school. PSST-P children showed greater changes than PSST children on measures of functioning at school at posttreatment, but these differences were no longer evident at follow-up. Children in both PSST conditions showed significant reductions in deviant behavior and improvements in prosocial behavior from pretreatment to follow-up, whereas RT children tended to remain at their pretreatment level of functioning. Notwithstanding the significant improvements, comparisons with nonclinic (normative) samples revealed that the majority of youth remained outside of the normal range of deviant behavior. Possible directions for improving treatment for antisocial youth are highlighted

N2 - A series of field studies involving repetitive functional measurements in relatively small populations of healthy children and adults engaged in normal outdoor activities has shown that significant decrements in respiratory function are associated with exposures to ozone (O₃) at concentrations below the national ambient air quality standard. The ability to detect such effects can be attributed, at least in part, to the study design criteria used, which emphasized maximization of signal-to-noise ratios. Locations were selected to ensure relatively high exposures to relatively uniformly distributed secondary pollutants, with minimal exposure to local sources of primary pollutants. Populations were selected that would be engaged in active recreation out of doors. Populations of healthy persons were used to minimize variability in baseline function. We found that the magnitude of the O₃-associated decrements in respiratory function was dependent on the variability in sensitivity to O₃ among the population, the minute ventilation during outdoor activity, and the duration of the outdoor exposure. We also concluded that the O₃-associated responses were potentiated by the presence of other air pollutants
