N2 - Introduction: Childhood obesity is a risk factor for adult morbidity and mortality, independent of body mass index (BMI) in adulthood, family history of cardiovascular disease or cancer, and smoking. The present study was designed with the objectives to study contributing factors of childhood obesity and its metabolic consequences. Material and methods: Forty-nine obese and 13 normal children in the age range of 5-12 years were recruited. Subjects with hypothyroidism, Cushing's syndrome and any other disease contributing to endogenous obesity were excluded. Weight and height were recorded and BMI was calculated (weight in kg divided by square of height in meters). Children with weight above 90th percentile for age and sex and BMI > 28.5 or >95th percentile for that age were defined as obese. After an overnight fast (10-12 h) blood was drawn for the determination of plasma glucose, serum insulin, lipid profile and free fatty acids. Observations: The calorie intake in obese children was significantly higher than controls and fatty meal contributed significantly to high calorie intake. Obese children indulged less in outdoor activities than controls. Liver enzymes were significantly higher in the study group. The levels of hepatic enzymes were raised above normal in 26 (53.06%) children. Total cholesterol and LDL cholesterol were higher in the study group, but only the LDL values reached statistical significance. Fasting plasma glucose in the study and control groups were 75.25 + 13.57 and 66.07 + 9.52 mg/dL respectively and it was significantly higher in the study group ($p = 0.009$). Fasting insulin and fasting free fatty acid levels in study group were 31.66 + 17.58 $\mu\text{U/mL}$ and 379.35 + 148.00 $\mu\text{mol/L}$ and in control group were 8.6 + 4.98 $\mu\text{U/mL}$ and 263.84 + 71.00 $\mu\text{mol/L}$ respectively hence both are significantly higher in the obese children. The mean insulin glucose ratio in the study group was 0.41 + 11.20. Sixteen (32.65%) children had values of more than 0.4, suggesting insulin resistance but none of the control group had insulin glucose ratio above this level. Insulin free fatty acid ratio was also higher in the study group 8.58 + 6.34 than control group 3.10 + 1.19. The mean HOMA-R in the study group and control group were 6.08

+ 3.83 and 1.37 + 0.73 respectively indicating significant insulin resistance in the obese children. Conclusion: The environment influence like increased calorie intake and decreased physical activity are major determinants of childhood obesity. The biochemical consequences of childhood obesity are hyperinsulinemia, increased LDL, FFA levels and increased hepatic transaminases. The triglycerides, HDL, fasting hyperglycemia and hypertension do not seem to have association with metabolic syndrome in children as seen in adults. Therefore it is proposed that the diagnostic parameters of metabolic syndrome should be redefined in children with population-based values of these new biochemical parameters. 2007 Diabetes India

N2 - Objectives: To assess the applicability of a test to measure the physical activity of Indian school children in the school environment. Subjects and Method: 2,008 school children aged between 9 and 12 years were included. The test used to measure physical efficiency included four items: standing long jump, cricket ball throw, 60 yard run (54.86 metres) and chin-ups. All children completed the four components of the test. Results: The majority of children in the three age groups studied managed to reach the standard norm values for the standing long jump (77%), 60 yard run (90%) and the chin-up tests (86%). However, only just over half (51%) of the children managed to qualify in the cricket ball throw test. Conclusion: The majority of the school children achieved the standard norms of the physical activity test which was practical to use in the school environment

N2 - Respondent error, low resolution, and study participant burden are known limitations of diary timelines used in exposure studies such as the National Human Exposure Assessment Survey (NHEXAS). Recent advances in global positioning system (GPS) technology have produced tracking devices sufficiently portable, functional and affordable to utilize in exposure assessment science. In this study, a differentially corrected GPS (dGPS) tracking device was compared to the NHEXAS diary timeline. The study also explored how GPS can be used to evaluate and improve such diary timelines by determining which location categories and which respondents are least likely to record "correct" time-location responses. A total of 31 children ages 3-5 years old wore a dGPS device for all waking hours on a weekend day while their parents completed the NHEXAS diary timeline to document the child's time-location pattern. Parents misclassified child time-location approximately 48% of the time using the NHEXAS timeline in comparison to dGPS. Overall concordance between methods was marginal ($=0.33-0.35$). The dGPS device found that on average, children spent 76% of the 24-h study period in the home. The diary underestimated time the child spent in the home by 17%, while overestimating time spent inside other locations, outside at home, outside in other locations, and time spent in transit. Diary data for time spent outside at home and time in transit had the lowest response concordance with dGPS. The diaries of stay-at-home mothers and mothers working unskilled labor jobs had lower concordance with dGPS than did those of the other participants. The ability of dGPS tracking to collect continuous rather than categorical (ordinal) data was also demonstrated. It is concluded that automated GPS tracking measurements can improve the quality and collection efficiency of time-location data in exposure assessment studies, albeit for small cohorts. 2007 Nature Publishing Group All rights reserved

N2 - Several studies have investigated the health of children attending schools located near busy roads. In this study, we have measured personal exposure to traffic-related pollutants in children to validate exposure classification based on school location. Personal exposure to PM_{2.5}, soot, NO_x and NO₂ was measured during four 48-h periods. The study involved 54 children attending four different schools, two of which were located within 100 m of a major road (one ring road and one freeway) and the other two were located at a background location in the city of Utrecht, The Netherlands. Outdoor monitoring was conducted at all school sites, during the personal measurements. A questionnaire was administered on time activity patterns and indoor sources at home. The outdoor concentration of soot was 74% higher at the freeway school compared to its matched background school. Personal exposure to soot was 30% higher. For NO_x the outdoor concentration was 52% higher at the freeway school compared to its background school. The personal concentration of NO_x was 37% higher for children attending the freeway school. Differences were smaller and insignificant for PM_{2.5} and NO₂. No elevated personal exposure to air pollutants was found for the children attending the school near the ring road. We conclude that the school's proximity to a freeway can be used as a valid estimate of exposure in epidemiological studies on the effects of the traffic-related air pollutants soot and NO_x in children. 2007 Elsevier Ltd. N2 - The purpose of the present study was to examine the association between fundamental motor skill development and various types of outside-school physical activity. Outside-school physical activity of 133 elementary schoolchildren was measured using a modified observational method validated by O'Hara et al. (18) and Caltrac accelerometers (Hemokinetics, Madison, Wisconsin). Developmental level of overhand throwing and jumping was assessed using total-body developmental sequences. The results revealed that developmental levels of both overhand throwing and jumping were significantly correlated with the skill-specific physical activity ($r = .44$ and $.55$ for overhand throwing and jumping, respectively). Caltrac score was not significantly related to jumping and overhand throwing skills. Skill-specific physical activities accounted for 20% of the variance (adjusted R^2) in overhand throwing and 17% of the variance in jumping performance. Findings supported the hypothesis that developmental level of fundamental motor skills would be related with skill-specific outside-school physical activity but not with general level of physical activity of elementary schoolchildren. 2006 Human Kinetics, Inc

N2 - Policy approaches towards risk in relation to young people's leisure activities are characterized by uncertainty. While some organizations have sought to emphasize the need to reduce or even eliminate the risk of 'unintentional injuries' in outdoor play, others highlight the dangers in excessively restricting young people's access to the outside world. Drawing on semi-structured interviews with families in the South Wales area, this

paper argues that while parents are not in the grips of 'paranoia' (Furedi 2001) they are wrestling with competing sets of social expectations, as well as their own rational and emotive judgements. Young people tended to respond to their parents' concerns by demonstrating their street-wisdom, claiming sanctuary behind the notion of 'accident' and asserting their moral right to access the outside world

N2 - Subjects working in or living near informal gold mining and processing in southern Peru were studied to determine mercury exposures from two tasks: amalgamation and amalgam smelting. The authors collected 17 airborne and 41 urinary mercury levels. The mean urinary levels were 728 (range: 321-1,662) and 113 (45-197) mug/L for working in smelters and living near smelters, respectively. A third group working in amalgamation had a mean 18 mug/L (range 8-37). People living in the mining town but with no mining activities had 8 mug/L (5-10), while a control group outside the town had 4 mug/L (2-6). Mean airborne mercury exposure was 2,423 mug/m³ (range 530-4,430) during smelting, 30.5 mug/m³ (12-55) during amalgamation, and 12 mug/m³ (3-23) in the mining town. Smelters are highly contaminated with mercury, as are the people living around smelters

N2 - Background. The purpose of this study was to investigate the frequency and course of tick-borne encephalitis (TBE) in children and young adults (ages 1-15 years) in southwestern Germany. Patients and methods. Clinical and epidemiological data from children were recorded by means of a questionnaire by Departments of Paediatrics in Baden-Wurttemberg and Southern Hessen. Results. Between 1994 and 2003 a total of 124 children with TBE were recorded. Seventy-seven children (62%) had noticed a tick bite, and the first symptoms occurred an average of 7 days later. The disease had a biphasic course in 89 (72%) of the 124 children. TBE presented as meningitis in 80 children (64%), as meningoencephalitis in 43 (35%), and as encephalomyelitis in 1 child (1%). The most frequent neurological symptoms of meningoencephalitis were impaired consciousness (35%), ataxia (4%), and paresis of the extremities (2.4%) and cranial nerves (2.4%). Laboratory investigations revealed leukocytosis in the peripheral blood in 102 of the 124 patients (82%), elevation of the sedimentation rate in 102 (82%), and increased C-reactive protein in 92 (74%). Conclusion. Even though the course of TBE is less dramatic, and its prognosis better, in children than in adults, there is just

as much reason to protect children against TBE by active immunisation as there is to immunise adults in any area where any cases of TBE are known. The beginning of a vaccination course should be linked to the frequency of exposure through outdoor activities in areas where there is a risk of TBE. 2006 Springer Medizin Verlag

N2 - The incidence of skin cancer has been increasing steadily, and a direct correlation with sun exposure has long been recognised. Primary prevention actions, mainly directed at children, are important to promote behavioural changes regarding sun exposure. A questionnaire-based enquiry, followed by a sensitisation action, with distribution of didactic material, was carried out in several private and public schools, in June 2003. A significant number of children reported the existence of only a few trees at their schools' playground and the practice of outdoor gymnastics during risky hours. Although they admitted to usually applying sunscreens when

going to the beach, this was not a normal practice when going to school on sunny days. A history of sunburn was reported by 53% of the children. We found some changes in behaviour after the summer holidays following the sensitisation action, which emphasizes the importance of this type of campaigns

N2 - Data was analyzed from the nationally representative Canadian Community Health Survey. A total of 17,549 adolescents reported whether they had "migraine headaches" (response rate 99.9%) and in what exercise activities they participated. Those with migraine reported more daily activity than migraine-free peers when corrected for age and sex. They were as likely to play contact sports but were more involved in other noncompetitive activities, such as walking ($P < 0.001$), gardening and yard work ($P = 0.008$), jogging and

running ($P = 0.002$), and fishing ($P = 0.03$). Canadian adolescents with migraine are therefore overall more active than their peers without migraine. 2006 Elsevier Inc. All rights reserved

N2 - In the last decade, several bodies (American Academy of Pediatrics 1,2, American College of Emergency Physicians 3, United States Department of Health and Human Services 4, Royal College of Paediatrics and Child Health 5,6) have published guidelines for management of acute pain, including procedural pain. 3 In 2003, the Royal Australasian College of Physicians recognized the need for a local document to: * Raise awareness that the treatment of pain is essential and should be a priority. * Invite paediatricians and other child health professionals to reflect on their own attitudes, beliefs and practices. * Make recommendations relevant to clinical settings in Australia and New Zealand which can then be a resource for individuals and institutions developing local protocols. * Bridge the gap between research and clinical practice. Significant advances have been made in the field of pain management in recent years. The essential question is no longer whether children feel pain but how best to treat and prevent it.⁷ However, despite the established efficacy of pain management techniques, multiple studies and reviews show that pain and distress is poorly managed and that children, in particular, continue to suffer unnecessarily.^{8,10} The values and attitudes of society, family members and health care professionals, together with health care practices within an organizational system, all present obstacles to optimal pain control.^{8,11-13} Preventing pain is not only humane, it can also reduce the risk of subsequent morbidity¹⁴ including delayed healing.¹⁵ One of the consequences of untreated pain is that children of all ages become sensitized to pain.^{16,17} This is because pain may activate the physical, biochemical and cellular processes that change the future response to pain. This central plasticity or sensitization may cause previously non-painful stimuli to be painful

or may enhance the response to painful stimuli.¹⁸ As health care providers, we have a clinical, moral and ethical obligation to minimize pain and suffering in children. There are a number of ways to achieve this, with regard to procedures: * Adopt a child-centred approach (listening to the needs of the child and family) rather than a procedure-focused 'get-it-over-with' approach.¹⁹ * Make the child and their family active participants and members of the team, rather than passive recipients.¹⁹ * Use parents for positive assistance, not negative restraint.²⁰ * Ensure that all procedures undertaken are necessary that is, the benefit outweighs any negative impact caused by the procedure. * Ensure that all procedures are carried out in order to maximize safety for the child. * Perform procedures in a child friendly environment, away from the bed.²¹ * Use pain assessment routinely.⁵ * Use the least invasive equipment where possible. * Ensure that the person performing the procedure has appropriate technical expertise, or is closely supervised by someone who does.¹ * Use appropriate combinations of non-pharmacological and pharmacological interventions to manage pain and anxiety.²² Sedation alone does not provide pain relief. * Optimize waiting time: too little time increases distress but too much time increases anticipatory anxiety. Time required for preparation is child-specific.^{1,19} * Ensure that the development of anticipatory anxiety is prevented as far as possible by maximizing the intervention to alleviate pain and distress for the first procedure (e.g., general anaesthetic for bone marrow aspirate).²¹ The guideline statement associated with this executive summary is an evidence-based approach to procedural pain management, outside of the operating theatre and neonatal intensive care unit environments, for all children. The document integrates both non-pharmacological and pharmacological approaches to common childhood procedures. In addition, specific information is available on pain assessment, pre-procedure preparation, resources required for procedural pain management, special situations unique to the care of children, a consumer's perspective, and details of common techniques, including non-pharmacological techniques. 2006 Blackwell Publishing Ltd

N2 - These bioethical reflections review the comparative arguments surrounding specific responsibilities raised by prenatal diagnosis: i) in the face of a risk pregnancy, attested by precise medical documentation, should recourse to prenatal diagnosis figure as a moral obligation or, conversely, is unconditional acceptance of the child incompatible with all prior "quality control"? (parental responsibility) ii) if so, does the final decision rest with the parents, and is a completely neutral attitude by the doctor justified even when the foetus has a complaint for which adequate forms of treatment are available? (medical and professional responsibility) iii) is it right to promote health campaigns introducing compulsory screening for risk categories with the prospect of automatically selecting out foetuses bearing genetic anomalies? (social responsibility). After analysis and discussion of the conflicting arguments over responsible management of prenatal diagnosis, there is a review of the stages through which the diagnostic process passes when a couple go for prenatal diagnosis under the shadow of a risk pregnancy. The aim is to assess the role that may be played by specific ethically-oriented support within the counselling process. For such support to be properly framed, the following suggestions are made: i) Helping towards an aware decision: the consultant should help the couple take a sufficient distance from the outside world and face up to the situation in personal terms. They must be able to decide by criteria they see as their own, worked out as a couple and not absorbed from outside (which mostly means ratified by hearsay). As part of helping the couple to an authentic decision, one notes the concern not to reduce prenatal diagnosis to an automatic stage in a medical routine. Being referred for diagnosis by one's G.P. does not dispense with the need for the parents involved in the first person to size up the position for themselves, ii) Helping to pinpoint the responsibilities that can in all conscience be shouldered: amid the ambivalence that most couples experience, it is important that some outsider should let them know the difficulties that await them, but also the resources they can draw on. Though it is up to the couple to decide whether to terminate or go on with the pregnancy, the process of talking, confiding, reflecting and judging nonetheless gives its own weight of humanity to the decision that will come of it. At the same time it creates the right space in which to identify the real responsibility that one can in all conscience take upon oneself; iii) Creating the conditions for authentic ethical discernment: prenatal diagnosis puts the couple in a paradoxical situation precisely because every pregnancy lives in the hope of a child as its achievement and outcome; the handicap that one learns of through prenatal diagnosis just when the investment is at its ideal height may prove to be something truly intolerable. There are two particular ways of imaging the "blow" of a positive outcome which strongly condition the ethical discernment or even make it impossible: seeing it as an "error"; seeing it as a "horror". The real alternative to these lies in configuring limitation and impairment as an integral part of our human condition, through which discerning attitude one can come to identify with the handicapped child and recognise the right it has to lead "its own" life

N2 - Background: The objective of this study was to evaluate a competitive voucher program intended to make sexual and reproductive health care (SRHC) accessible to adolescents from disadvantaged areas of Managua. Methods: A quasi-experimental intervention study was performed in which 28,711 vouchers that gave free access to SRHC in 20 health centers, were distributed to adolescents. To evaluate the impact, community sampling took place in markets, neighborhoods, and outside schools where self-administered questionnaires were distributed. The study comprised a random sample of 3,009 female adolescents, ages 12 to 20 years old, 904 voucher receivers and 2,105 nonreceivers. Their use of SRHC, and knowledge and use of contraceptives and condoms were measured. Results: Voucher receivers had a significantly higher use of SRHC compared with nonreceivers, 34% versus 19% (adjusted odds ratio, 3.1; 95% confidence interval, 2.5-3.8). The highest influence was seen among respondents at schools, where use was 24% relative to 6% in nonreceivers (adjusted odds ratio, 5.9; 95% confidence interval, 3.7-9.5). Voucher receivers answered significantly more questions correctly that were related to knowledge of contraceptives and sexually transmitted infections than nonreceivers. At schools, sexually active voucher receivers had a significantly higher use of modern contraceptives than nonreceivers, 48% versus 33% (adjusted odds ratio, 2.3; 95% confidence interval, 1.2-4.4); and in neighborhoods, condom use during last sexual contact was significantly greater among voucher receivers than nonreceivers (adjusted odds ratio, 2.5; 95% confidence interval, 1.4-4.5). Conclusion: The voucher program succeeded in increasing access to SRHC for poor and underserved girls. The needs of adolescents were met with a relatively simple intervention through existing health facilities. Many adolescents appeared willing to protect themselves against the risks of sexual intercourse. This suggest that access to SRHC can play an important role in changing youth behavior and increase the use of contraceptives and condoms. 2006 Society for Adolescent Medicine. All rights reserved

N2 - Aim: To explore how children's self-consciousness would change after outward bound training in order to provide a theoretical reference for effectively optimized children's self-consciousness. Methods: In June 2002, 78 children aged 8-16 years from the primary or middle schools in Xi'an city were randomized into experimental group (outward bound training group) and control group (without training group) for randomized control observation. Before outward-bound training, children in the control group were measured with the Piers-Harris children's self-concept (PHCSS). After training, children in the experimental group were measured, the experiment content was part of field programs (hiking, camping, fieldwork, outdoors survival) and ground programs (stop bridge, top tightwire, buttocking, one wood bridge, game of across river, debutton hand in hand, blind man phalanx, electrical net, etc.), and it cost 48 hours. Results: (1) Comparison of the total score between the control group and experimental group: The average total score of PHCSS in the experimental group was 61.05, increased by 2.70 as compared with that in the control group (58.70). The lowest and highest total scores in the experimental group were 11 and 1 point higher than those in the control group respectively. The total score of self-consciousness level was above 58 points in 60% and 71% of the children in the control group and experimental group respectively. (2) Comparison of the scores of the corresponding dimensions of self-consciousness between the experimental group and control group: The least scores of all six dimensions in the experimental group were increased as compared with those in the control group, which were more obvious in

the dimensions of behavior, gregariousness and anxiety (13.39+1.84, 12.10+2.92; 10.08+1.48, 9.23+2.03; 11.37+2.07, 9.75+2.49). Conclusion: Outward bound training plays an improvement role in enhancing children's self-consciousness, especially the children with low self-consciousness. Outward bound training affects the six dimensions of children's self-consciousness more or less, which is especially significantly embodied the dimensions of anxiety, gregariousness and behavior

N2 - Objectives. - The objectives of this study were to identify the number and types of recreational injuries sustained by visitors to Mount Rainier National Park and Olympic National Park in Washington State and to compare the nature of injuries sustained by children compared with adults. Methods. - We retrospectively reviewed case incident reports obtained by rangers in Mount Rainier National Park and Olympic National Park between 1997 and 2001. Data collected included victim age, gender, date of injury, activity preinjury, type of injury, and mechanism of injury. Results. - There were 535 cases of recreational wilderness injuries (including 19 total deaths), yielding a rate of 22.4 injuries per million visits. The mean age of injury victims was 34 years. Males were more likely to sustain injury than were females (59% vs 41%). Most injuries occurred during summer months between noon and 6:00 PM, and 90% occurred during daylight hours. The most common preinjury activities included hiking (55%), winter sports (15%), and mountaineering (12%), and the most common types of injuries included sprains, strains and soft tissue injuries (28%), fractures or dislocations (26%), and lacerations (15%). A total of 121 (23%) of the injuries occurred in children (<18 years of age). There were 19 deaths in the 2 national parks (18 men, 1 woman); all victims were adults. Hiking (58%) and mountaineering (26%) were the most common activities at the time of death. Mechanism of death included falls (37%), medical (eg, myocardial infarction) (21%), drowning (5%), and suicide (5%). Conclusions. - The most common type of injury was soft tissue injury, and injuries occurred most commonly while hiking, during daylight hours, and in the summer. Preinjury activities and types of injuries were different in children compared with adults. Knowledge of how and when injuries occur in national parks can assist in determining what resources are needed to help provide a safer environment for park visitors. This study may also aid prevention strategies in the national parks, guide training of rangers, aid in the preparation of first aid kits, and further the education of people who participate in wilderness activities

N2 - Background: As the most common cause of severe diarrhea among children, rotavirus has a significant economic impact. Previous studies focused on the direct medical costs of rotavirus infections; however, nonmedical costs account for the majority of the financial burden from this disease. Herein, we report the results from the largest prospective study in the United States determining the nonmedical costs of severe rotavirus infections. Methods: Prospective, active, gastroenteritis case surveillance was conducted between November 1997 and December 1999 at 3 pediatric medical centers. Rotavirus infection was identified for 548 children admitted between 2 weeks and 5 years of age. Detailed information about nonmedical costs during the prehospitalization, hospitalization and posthospitalization periods was obtained through interviews. Results: The average nonmedical cost per case of rotavirus disease was \$448.77, including \$359.04 for missed work, \$56.66 for transportation, \$11.90 for oral rehydration solutions, \$9.59 for diapers, \$6.83 for child care changes, \$3.82 for special foods and \$0.93 for formula changes. More than one-half of these expenses (53%) occurred outside the hospitalization period, and 80% of the cost was attributable to missed work. Conclusions: With an estimated 50,000 hospitalizations attributable to rotavirus each year in the United States, the nonmedical costs of severe rotavirus infections may exceed \$22 million annually. Previous cost effectiveness analyses of rotavirus vaccines substantially underestimated this burden, suggesting that the nonmedical costs associated with mild to moderate rotavirus disease have been similarly underestimated. These findings are needed to assess accurately the cost effectiveness of future rotavirus immunization strategies. Copyright 2005 by Lippincott Williams & Wilkins

N2 - Extreme measures, such as ketogenic diets and surgery, have been tried to deal quickly with obesity, but recidivism is high. There are no quick preventions or cures. The answer-permanent behavior change-is amazingly simple in description but formidable in implementation. Obesity prevention will require radical lifestyle change across the lifespan. Such change takes time, discipline, perseverance, and daily effort. And if it is not viewed as permanent, the efforts will be in vain. So what do we know, and what can we do? We know that overweight adolescents are at high risk of becoming obese adults. We know that this is a problem that may begin in utero, and insulin resistance and oxidative endothelial cell damage are basic to the disease. We know that obesity is a disease of all ages and all nationalities, not just those with thrifty genes. The morbidity and mortality associated with this pandemic and their concomitant costs are monumental, with the potential of bankrupting the health care delivery and Social Security disability systems if the situation is not curbed. Human suffering associated with obesity further feeds the epidemic through depression, resulting lack of motivation to change, increased emotional eating and social isolation, and decreased physical activity. Hopelessness prevails among health care professionals trying to care for these patients. Their lament: "Nothing works." And indeed, there is little evidence thus far for success, at least not in the long term. There is an extreme paucity of evidence-based study, but the few trials reporting success, albeit short term, are multidisciplinary, involving psychological, dietary, and exercise components. We at the University of Tennessee Health Science Center are encouraged by our experience to date using our "Guidelines for Rearing Healthy Children," and we are now collecting data as to its effectiveness, both short term and with the intention of longitudinal follow-up. The American Academy of Pediatric policy statement on prevention of childhood overweight and obesity focuses on health supervision and advocacy in bringing about desperately needed societal changes. This statement calls for individualization of the plan for each child within the broader context of societal reforms related to issues ranging from vending machines to safe playgrounds to sound public health policies. Also suggested are advocacy efforts to obtain reimbursement for delivery of preventive medical care and education and funding for further research. The power of health care professionals to impact the lives of their patients cannot be overstated. When careful compassionate words create an informed, positive environment, this voice is heard above the media din, and the self-fulfilling prophecy of hope can begin its mission. We must be optimistic enough to believe in the ability of people to change and heal. Despite occasional steps backward, meaningful and permanent lifestyle changes can be effected. If we do not believe this to be so, neither will our patients

N2 - Background: At present, most general hospitals in China treat patients with neurosis and mental diseases merely by means of clinical psychological consultation, which cannot meet the requirements of social service for metal disorders. Is it feasible to establish open psychology wards? Objective: To investigate the feasibility of establishing open psychology ward in general hospitals for patients with neurosis and mental diseases. Design: Case analysis based on patients. Setting: Department of Psychology of Guangdong Medical College Affiliated Hospital. Participants: Totally 900 patients with various types of neurosis were admitted to the Department of Psychology of Guangdong Medical College Affiliated Hospital between July 2000 and March 2003. There were 688 patients with different kinds of psychoneurosis and 112 cases of mental diseases. Of them, there were 523 men and 377 women aged from 11 to 80 years with the mean age of (42+8) years and hospitalization duration of(17.0+6.5) days. Methods: Open management consisting of open ward, supporting system, humanized restriction, collective physical exercise and psychological support was adopted. Symptom checklist (SCL-90) was used by trained psychological doctors to assess the therapeutic effects in the 900 patients with neurosis and mental diseases after two-month rehabilitation. Meanwhile, 169 patients with depression were examined with Hamilton rating scale for depression(HAMD) at 2,4,8-weeks of treatment. Main outcome measures: 1 The results of HAMD in the 169 depressive patients after treatment; 2 The therapeutic effect in the 900 patients. Results: Open psychology ward could provide an environment for patients to live and make free contact with the outside world. Of the 900 patients with various neurosis and metal diseases, 531 (59.0%) had recovery to normal, 264(29.4%) had obvious improvement, 81(9.0%) had improvement, and 24 (2.6%) had no therapeutic effect, with the total effective rate of 97.4%. None of the patients had any accident. HAMD score of the 169 patients with depression was (32.3+3.6) before treatment, was obviously lower at 2,4 and 8 weeks of treatment [(17.4+4.2), (11.5+4.8) and(5.8+3.6),respectively]($P < 0.01$). Conclusion: The therapeutic effect of the open psychology ward in the general hospital on various neuropathies and mental diseases was 97.4% in the 900 cases, with no accident occurring during hospitalization. Depression of the 169 patients was obviously improved, indicating that it is feasible to establish open psychology ward in general hospitals

N2 - Aim: The reinforcement method of psychological behavior therapy combined with the interests actuating in the treatment of amblyopia of children, and to observe its effects. Methods: 1 172 amblyopic children (287 eyes) who were diagnosed in Outpatient Ophthalmology Clinic of Kaifeng Children's Hospital between January 2000 and June 2003 were selected, based on the awareness of patients and parents. They were randomly divided into two groups: Control group with 87 cases (141 eyes) and psychotherapy group with 85 cases (146 eyes). 2 The commonly used complex treatment (wearing glasses + covering + red light scintillation and meticulous exercises training, once for 15 minutes in each day) were applied in control group; The reinforcement therapy of psychotherapy and interest actuating were add to psychotherapy group on the base of the commonly used complex treatment. The different grade prizes or outside activities were awarded to children in time to irritate children's synergic motivation and enhance their acclimatization. 3 The sight changes of the children in the two groups were observed, and review and eyesight examination were conducted once every 4 months respectively and the effects were compared. Inefficiency was retrogress, immovability or increase of 0.1 of sight; Utility was increase of 0.2 or over 0.2 of sight; Significant utility was that the sight increased to > 0.9 (The effective rate=significant utility + cases of utility/the total cases of the group). 4 The difference of enumeration data was detected by chi² check. Results: 172 children patients (287 eyes) with amblyopia were all involved in the result analysis. The effective rate of intervention: It bacame higher as the prolongation of intervention time in the two groups. At the intervention for 3 months, it was similar in control group and psychotherapy group (46.1%, 49.3%, P > 0.05); But at the intervention for 6, 9 and 12 months, it was significantly higher in psychotherapy group than that in control group (71.3%, 78.8%, 83.5%; 55.3%, 59.6%, 64.5%,

$\chi^2=7.83, 12.43, 13.56, P < 0.01$). Conclusion: The reinforcement method of psychological behavior therapy which is suitable for the psychological character of children combined with the interests actuating can effectively enhance more effectively the therapeutic efficacy of the sight level of amblyopia children patients

N2 - Recess offers primary-school-age children the opportunity to engage in physical activity, though few studies have detailed the physical activity levels of children in this environment. The physical activity levels of 270 children ages 6-11 years from 18 schools were monitored on 1 school day using heart rate telemetry. Data revealed that boys engaged in higher levels of moderate-tovigorous and vigorous physical activity (MVPA) than did girls during recess (26 and 20 min, respectively). These results suggest that recess can make a worthwhile contribution to the recommended 60 min of MVPA per day. 2005 Human Kinetics, Inc

N2 - Background: Chronic urticaria (CU) is an autoimmune process in some patients. An association between CU and autoimmune thyroid disease has also previously been proposed. Our group has identified functionally significant histamine-releasing autoantibodies in one subset of CU patients (subset 1), predicted by positive autologous intradermal serum tests and positive histamine release from donor basophil leucocytes in vitro. Sera from a second subset of patients (subset 2), all of whom had positive autologous intradermal serum tests, failed to release histamine from donor basophils. A final disease subset (subset 3) has no identifiable skin reactivity (negative autologous serum skin test) or in vitro histamine releasing activity. Objectives: In order to examine further the possible relationships between thyroid autoimmunity, thyroid dysfunction and CU, we have examined thyroid autoantibodies and thyroid-stimulating hormone (TSH) levels (an indirect measure of thyroid dysfunction) in the three CU subsets. Patients/methods: We studied 182 patients (69% female), of whom 90 had a positive autologous intradermal serum test. Results: Eighteen skin test-positive and four skin test-negative patients had thyroid microsomal antibodies (TMA). TSH outside the normal range was found in 13 skin test-positive and one skin test-negative patient. These findings represent clustering of TMA positivity [risk ratio (RR) 4.06, 95% confidence interval (CI) 1.56-10.6] and of abnormal thyroid function (RR 15.5, CI 2.07-11.6) among the skin test-positive patients. However, in the overall study group an elevated TSH was present in seven patients (3.8%, CI 1.6-7.8) comparable to the 5% expected prevalence in the community. Thyroglobulin antibodies (TGA) were present in two of 182 patients. Conclusions: There were significant differences between skin test-positive and skin test-negative patients with regard to autoimmune thyroid disease. Evidence for

autoimmune thyroid disease and abnormal thyroid function was largely found among the skin test-positive patients, supporting the theory of an autoimmune aetiology in this group. 2005 British Association of Dermatologists

N2 - Objective: To test a collaborative-care, cognitive-behavioral therapy (CBT) program adjunctive to selective serotonin reuptake inhibitor (SSRI) treatment in HMO pediatric primary care. Method: A randomized effectiveness trial comparing a treatment-as-usual (TAU) control condition consisting primarily of SSRI medication delivered outside the experimental protocol (n = 75) versus TAU SSRI plus brief CBT (n = 77). Participants were identified by a recent dispense of SSRI medication followed by telephone screening. Adolescents with a diagnosis of major depressive disorder (n = 152) were enrolled. The CBT program employed cognitive restructuring and/or behavioral activation training. Therapists consulted with prescribing pediatricians to improve medication adherence. Results: Through 1-year follow-up, the authors found CBT advantages on the Short Form-12 Mental Component Scale (p = .04), reductions in TAU outpatient visits (p = .02), and days' supply of all medications (p = .01). No effects were detected for major depressive disorder episodes; a nonsignificant trend favoring CBT was detected on the Center for Epidemiology Depression Scale (p = .07). Conclusions: The authors detected a weak CBT effect, possibly rendered less significant by the small sample and likely attenuated by the unexpected reduction in SSRI pharmacotherapy in the CBT condition. Small, incremental improvements over monotherapy, such as observed in this study, most likely represent the new norm in adolescent depression treatment research. 2005 by the American Academy of Child and Adolescent Psychiatry

N2 - Objective. To explain the increase in the number of deaths due to sudden infant death syndrome (SIDS) that occurred while the infant was in a playpen or on a playpen mat placed outside of the pen. 13 deaths were reported in the period I September 1996-31 August 2004, in contrast to 0 deaths in the years 1984/'96. Design. Descriptive. Method. Data on the 13 infants that were reported to the National Study Group on SIDS were analysed and the presence of risk factors for SIDS was assessed. Results. Of the 13 infants, 9 were male and 4 were female. 12 were aged less than 12 months and I was aged 13 months. Known risk factors for SIDS were often present and frequently occurred in combinations: male sex (n = 9), higher birth order (n = 9), age 1-8 months (n = 12), parental smoking (n = 6), primary prone sleeping position (n = 4), secondary prone (n = 6, often the first time), face down (n = 9), no adult present (n = 13). Conclusion. There was no clear explanation for the observed increase in SIDS that occurred in a playpen or on a playpen mat placed outside of the pen

N2 - It has been shown that acute exposures to particulate matter (PM) may exacerbate asthma in children. However, most epidemiological studies have relied on time-integrated PM measurements taken at a centrally located stationary monitoring sites. In this article, we characterized children's short-term personal exposures to PM_{2.5} (PM with aerodynamic diameters <2.5 µm) and separated them into ambient and nonambient components. The personal DataRAM without a size-selective inlet was used to estimate real-time PM_{2.5} concentrations on 20 asthmatic children, inside and outside of their residences, and at a central site. The personal and indoor pDRs were operated passively, while the home outdoor and central site instruments were operated actively. The subjects received 29.2% of their exposures at school, even though they only spent 16.4% of their time there. More precise personal clouds were estimated for the home-indoor and home-outdoor microenvironments where PM concentrations were measured. The personal cloud increased with increasing activity levels and was higher during outdoor activities than during indoor activities. We built models to predict personal PM exposures based on either microenvironmental or central-site PM_{2.5} measurements, and evaluated the modeled exposures against the actual personal measurements. A multiple regression model with central site PM concentration as the main predictor had a better prediction power ($R^2=0.41$) than a three- microenvironmental model ($R^2=0.11$). We further constructed a source-specific exposure model utilizing the time-space-activity information and the particle infiltration efficiencies (mean=0.72±0.15) calculated from a recursive mass balance model. It was estimated that the mean hourly personal exposures resulting from ambient, indoor-generated, and personal activity PM_{2.5} were 11.1, 5.5, and 10.0 µg/m³, respectively, when the modeling error was minimized. The high PM_{2.5} exposure to personal activities reported in our study is likely due to children's more active lifestyle as compared with older adult subjects in previous studies. 2005 Elsevier Ltd. N2 - Air pollution is a current and growing concern for Canadians, and there is evidence that ambient levels that meet current exposure standards may be associated with mortality and morbidity in Toronto, Canada. Evaluating exposure is an important step in understanding the relationship between particulate matter (PM) exposure and health outcomes. This report describes the PEARLS model (Particulate Exposure from Ambient to Regional Lung by Subgroup), which predicts exposure distributions for 11 age-gender population subgroups in Toronto to PM_{2.5} (PM with a median aerodynamic diameter of 2.5 µm or less) using Monte Carlo simulation techniques. The model uses physiological and activity pattern characteristics of each subgroup to determine region-specific lung exposure to PM_{2.5}, which is defined as the mass of PM_{2.5} deposited per unit time to each of five lung regions (two extrathoracic, bronchial, bronchiolar, and alveolar). The modeling results predict that children, toddlers, and infants have the broadest distributions of exposure, and the greatest chance of experiencing extreme exposures in the alveolar region of the lung. Importance analysis indicates that the most influential model variables are air exchange rate into indoor environments, time spent outdoors, and time spent at high activity levels. Additionally, a "critical point" was defined and introduced to the PEARLS to investigate the effects of possible threshold-pathogenic phenomena on subgroup exposure patterns. The analysis indicates that the subgroups initially predicted to be most highly exposed were likely to have the highest proportion of their population exposed above the critical point. Substantial exposures above the critical point were predicted in all subgroups for ambient concentrations of PM_{2.5} commonly observed in Toronto after continuous exposure of 24 hours or more. 2005 Society for Risk Analysis

N2 - Inclusion in activity at recess can have important implications for the health and for the physical, social, and cognitive development of children, according to play theorists (Pellegrini, 1995). This study examined whether children described their decisions (and those of fictitious others) to engage in recess activities in achievement terms consistent with expectancy-value theory (Eccles, Wigfield & Schiefele, 1998). Ten Grade 3 children with different patterns of recess engagement did confirm that attainment, interest, utility, and cost values were salient to decisions to participate. Children distinguished among value components, and confirmed that expectancies and values contributed to activity choices, providing support for the conceptualization of recess as an achievement setting in which expectancy-value theory applies. 2005 Human Kinetics Publishers, Inc

N2 - The purpose of this study was to compare daily, physical education, recess, and after school moderate to vigorous physical activity (MVPA) levels between children with and without autistic spectrum disorders (ASD). Children ages 5 to 12 years wore a uniaxial accelerometer for five days (four weekdays, one weekend day).

There were no differences between children with and without ASD at any physical activity setting. Both groups were more active during recess compared to after school, and children with ASD were similarly active in recess and physical education. Although many children with ASD acquired 60 min of physical education per day, this may decrease with age as opportunities for recess and physical education are eliminated. 2005 Human Kinetics Publishers, Inc

N2 - Objective. To determine the epidemiology of mild head injury by means of a study carried out among children treated in hospital emergency services. Material and methods. We evaluated 153 cases of pediatric head injury diagnosed in our institution. The data were analyzed using descriptive statistics. Results. The series consisted of 95 boys and 58 girls (94.1% were white). In 68.6% of cases, the mother worked outside the home. The socioeconomic conditions were poor in 6.5%. The most prevalent number of siblings per family was two. Injuries were more frequent between 11:00 and 13:00 hours (24.9%). A large majority of the injuries were produced outside the home (64.7%), with 19.6% occurring at the school playground, while 35.3% occurred at home. Frontal region injury accounted for 26.1% of the cases and 52.9% were treated by medical procedures and/or minor surgery. Conclusions. Mild head injuries were most prevalent among children under 5 years of age and occurred more frequently in boys (62.1%) than in girls; 32.7% of the children had had a previous head injury, while 19.7% had had more than one. The accidents occurred more frequently outdoors, mainly at the school playground and parks. The frontal region was that most often involved. The children received medical attention within 2 hours in 68% of cases. Neuroimaging was not necessary in our series

N2 - Purpose: To define a comprehensive, long-term, child- and family-centred rehabilitation programme for patients following TBI. Methods: Patients are treated by three integrated multi-disciplinary teams, according to stage of recovery. The programme offers a continuous follow-up, from the acute phase until the patient reaches the age of 18. In addition to teams' own neurologists, team members may consult specialists such as neurosurgeons, ophthalmologists and psychiatrists on demand at any stage of the rehabilitation. The hospital team: In the acute phase post-injury, focus is put on informative and emotional support of the family and early multi-sensory therapy to achieve initial consciousness. Sub-acutely the rehabilitation is intensified, still located in the in-patient ward. When medical stability is reached, the patient is transferred to day-care therapy. Assessment weeks are held regularly, during which progress is evaluated by all therapists. Standardized instruments are used for evaluation. These instruments offer the teams a reliable baseline status, help form adequate therapy programmes and offer the possibility to evaluate progress over time. Feedback and recommendations are given to family and social network on a continuous basis. The school rehabilitation team: After the day therapy programme the patient is offered continued physical rehabilitation as well as cognitive and social therapy in a school-like environment, outside the hospital. The school rehabilitation team stays in close contact with patient's home school or a more appropriate school alternative. The outreach service: This team

offers an outpatient rehabilitation programme for patients following mild TBI, suffering mainly from cognitive impairments. The team provides psychological and cognitive screenings in order to give adequate advice to home and school. The team activates networks and local resources close to the patient's home. Conclusions: The rehabilitation programme at Astrid Lindgren Children's Hospital improves the patients' chances to: (1) leave the hospital at an earlier stage of recovery, (2) return to their home school and succeed academically and socially and (3) minimize secondary consequences, physical as well as social. The programme offers the patients' families continuous support throughout childhood and adolescence

N2 - Scientific interest in indoor pollution has been increasing since the second half of the 1980s. Growing scientific evidence has shown that because people generally spend the majority of their time indoors, indoor pollution plays a significant role in affecting health and is thus an important health issue. Indoor environments include dwellings, workplaces, schools and day care centres, bars, discotheques and vehicles. Common indoor pollutants are environmental tobacco smoke, particulate matter, nitrogen dioxide, carbon monoxide, volatile organic compounds and biological allergens. In developing countries, relevant sources of indoor pollution include biomass and coal burning for cooking and heating. Concentrations of these pollutants can be many times higher indoors than outdoors. Indoor air pollution may increase the risk of irritation phenomena, allergic

sensitisation, acute and chronic respiratory disorders and lung function impairment. Recent conservative estimates have shown that 1.5-2 million deaths per year worldwide could be attributed to indoor air pollution. Approximately 1 million of these deaths occur in children aged under 5 years due to acute respiratory infections, and significant proportions of deaths occur due to chronic obstructive pulmonary disease and lung cancer in women. Today, indoor air pollution ranks tenth among preventable risk factors contributing to the global burden of disease. Further research is necessary to better evaluate the respiratory health effects of indoor pollution and to implement protective programmes for public health

N2 - Rubber tiles are popular in playgrounds as protective surfacing to reduce the incidence of head injuries caused by children falling from equipment. However, Taiwan has not yet established a test code for assessment of the shock-absorption properties of such surfacing. For this study, an experimental model was established to evaluate the behavior of various rubber tiles. A hemispherical headform was dropped from a set height to strike the center of the specimen tile. The peak acceleration and Head Injury Criterion (HIC) were measured to assess the impact absorption of and critical height for a given rubber tile. The results show that utilization of the HIC index provides a more conservative assessment of the shock absorption and, ultimately, protection from head injuries than peak acceleration. The maximum critical heights of the rubber tiles used in this study for tile thicknesses of 45, 60 and 80 mm were 1.6, 2.0 and 2.2 m, respectively. Two-part rubber tiles with a base

structure consisting of a box-like core offer superior protection from head injuries relative to analogous cylindrical, square pillar and solid structures. The maximum differences in peak-acceleration and HIC values comparing the box-like core and solid structures at a thickness of 45 mm were 21% and 44%, respectively. The results of this study suggest a minimum of rubber thickness of 60 mm, based on probable maximum fall heights of more than 1.6 m. Moreover, incorporation of an appropriate cushioning structure in the base of the rubber tile could further improve protection

N2 - Introduction. Mexico has a long migration tradition: thousands of Mexican farm laborers and, more recently, industrial and service workers, constitute an essential sector of the US economy. The effects of this geographical movement on the physical and mental health of adults who participate in this process and the changes it produces in the familial and community sphere have been widely documented. Little is known, however, about the impact of these social processes on the mental health of members of the following generations, i.e., the offspring of international migrants who remain in their communities of origin. Various

international studies report that the psychosocial malaise that this process causes in children and teenagers is reflected in behavioral problems during childhood and identity conflicts and constant mood changes during adolescence, which may or may not turn into symptoms of various psychological disorders such as depressive symptomatology. In Mexico, authors such as Lopez and Moctezuma have pointed out that there is a culture of migration in the communities of origin of these children and teenagers which makes them view migration as "something natural", since this process has been part of the family history of their inhabitants for several generations. In Mexico, the adolescence of the children of migrants takes place in social contexts where the father's physical absence as a result of international migration is expected. Studies have also shown that migrants' wives may display high rates of depressive symptomatology associated with the numerous responsibilities and new tasks they perform as a result of their husbands' absence. All these circumstances may make these teenagers more vulnerable. It is therefore important to determine whether the father's physical absence due to international migration is in any way linked to the presence of possible depressive symptomatology in these teenagers.

Method: The aim of this study was to report the psychometric characteristics of a sample of rural adolescents from communities with a strong migratory tradition from the State of Zacatecas on the Radloff Center for Epidemiological Studies Depression Scale (1977) and to provide new analytical tools to determine the effects of international migration on their mental health. The CES-D was applied to a sample of 310 adolescents from primary schools, during school hours, with the consent of the school authorities. It formed part of a questionnaire students could answer on their own, including an assessment of self-esteem and suicidal ideation. Its general objective was to study psychological malaise and well-being through everyday Stressors and compensators associated with the father's physical absence due to international migration. Schools were selected through intentional, non-probabilistic sampling to ensure that semi-urban and rural schools were equally represented. Students were assured that the information provided would be confidential. The data were statistically analyzed using SPSS, version 10.

Results: The age range of the sample was 11 to 14 years (mean=11.51, s=.72), 51% of the participants were male and 34.2% were the children of migrant fathers. In addition to studying, 37.7% contributed to the family income. The group mean of depressive symptomatology was 19.3 (s=7.6) and no differences were observed between males and females or between the children of migrant fathers and non-migrant fathers. The scale had a .76 Alpha Cronbach, which increases to .84 without the positive affect items that had a low correlation with the total scale. Although factor analysis yielded four factors, the configuration of the latter failed to confirm the factorial structure reported by Radloff. A total of 15.8% of the sample was located above the cut-off point (the mean plus a standard deviation =27). Being the child of an emigrant was not linked to greater depressive symptomatology, although having to work outside the home was: a higher proportion of adolescents who, in addition to studying, engaged in economic activities to contribute to the family income, had greater depressive symptomatology. At the end, an analysis was carried out of the Pearson correlation between the overall CES-D score and Coopersmith self-esteem scale, yielding a negative significant correlation ($r=-0.341$, $p<0.01$), meaning that the higher the level of depression, the lower a person's self-esteem. Analysis of depressive symptomatology with suicidal ideation showed a positive, significant correlation through the Pearson coefficient ($r=.501$, $p<0.001$): the greater the symptomatology, the greater the presence of suicidal ideation.

Discussion: Results confirm that the CES-D is a valid, reliable scale for measuring depressive symptomatology in this population. Further research, however, is required on the behavior of items concerning the positive affect factor, since its low correlation with the total scale and its lack of correlation with negative affect, psychosomatic complaints and interpersonal relations factors indicate that, as suggested by Iwata and collaborators (1998), these items are not measuring depressive symptomatology in this population. Two results call for further comment: 1. In this study, it was not the offspring of migrant fathers who obtained high scores in depressive symptomatology, but rather 2. teenagers who studied and worked who obtained scores of "possible cases" of depression. These results can be analyzed from various angles and as a consequence of the interaction of various factors: 1. Although paternal absence due to international migration has been cited as a predictive factor of emotional malaise, particularly among young teenagers, the culture of migration present in these communities may restrict its negative influence by regarding it as "normal"; 2. it is possible that certain characteristics of the mothers of these teenagers may act as a resilience factor to paternal absence and 3) regardless of whether or not teenagers lived with their fathers, there are certain structural situations that directly influence their emotional malaise, such as the conditions of everyday poverty in which they are raised and the lack of real opportunities for development (such as employment, agricultural training, and middle school education), which affect all the population sectors of these rural communities. It is essential to determine the specific importance of each of the various situations outlined here and their interaction in order to obtain the elements that will enable health professionals to deal with the emotional malaise detected in these adolescents as well as providing a satisfactory response to the structural conditions in which they are raised.

Otherwise, "going North" will continue to be their preferred life choice and Mexico will continue to lose a key element of its productive development: its youth population

N2 - The purpose of this study was to determine the performance of a sample of Icelandic students, aged 6 to 12 years, with various impairments, on the School Function Assessment (SFA). The SFA was administered to 75 Icelandic students with identified special needs, 35 with physical impairments and 40 with cognitive/behavioral impairments. Both diagnostic groups demonstrated most participation in mealtime/snack time but had low scores on the school playground. Differences were found between the two study groups on all three parts of the instrument, with higher performance and participation scores for the students with cognitive/behavioral impairments. The findings raise the awareness of some of the challenges encountered by Icelandic students with special needs and indicate the importance of adapting Icelandic school settings to promote social participation of all students. 2004 Taylor & Francis

N2 - In industrialised countries, lung cancer is the most common form of cancer among males and it is growing among females. For both sexes, rates reflect smoking behaviours. The pattern appears to be different in Asia, particularly in China, where lung cancer rates in men reflect high smoking rates but high rates among non-smoking women appear to be related to other factors. The incidence of lung cancer is low in most African countries, but it is increasing. In addition to tobacco smoking, a number of etiological factors have been identified for lung cancer: indoor exposure to environmental tobacco smoke, cooking oil vapour, coal burning, or radon, outdoor air pollution and occupational exposure to asbestos and other carcinogens. Recent studies have shown that dietary factors may be important, with high consumption of vegetables and fruits being protective while preserved food and fatty food are harmful, and certain infections such as Mycobacterium tuberculosis, human papilloma virus and Microsporium canis are associated with a high risk of lung cancer. Among non-smokers, the probable role of genetic predisposition in lung cancer by increasing the individual's susceptibility to environmental carcinogens is currently being studied actively. As the single most important cause for lung cancer is tobacco smoke and, with increased sales, a major epidemic is predicted for both Asia and Africa, all health care professionals, government health authorities and national and international health organisations must join in a concerted effort against tobacco

N2 - Will is an Amish school-aged boy with Duchenne muscular dystrophy. After reading about attention-deficit hyperactivity disorder (ADHD) in the local newspaper, his mother asked Will's pediatrician, "Do you

think my son has this (condition)?" She noted that Will fidgets in different settings and has difficulty focusing on his work when in school. She also reported that his teacher in the Amish school does not want him in her classroom because he is disruptive and noncompliant. The teacher tried incentives to encourage Will to complete his schoolwork but without success. Subsequently, his teacher prevented Will from participating in recess activities; at other times, she sent him home as punishment for noncompliance in the classroom. During the past week, Will did not attend school while his teacher sent assignments home with his sister. Will's mother reported that he seemed to be happy with a normal appetite and sleep pattern. She was not aware of any behavior problems with other children. Will's father, who also attended the pediatric appointment, added that he did not feel that the teacher was patient with Will. He stated that Will has friends, but may have a difficult time keeping up with them due to his physical weakness secondary to muscular dystrophy. He also believed that due to motor limitations, writing was difficult for Will. The parents did not provide consequences for Will's insistence on not attending school nor did they positively reward him for school attendance. When at home, Will did his work and kept to himself. Will was quiet and motionless in his seat. He stated that he liked school and playing with friends and that the schoolwork was not too difficult. Copyright 2004 by Lippincott Williams & Wilkins, Inc

N2 - This paper presents a series of 12 cases of chronic tinnitus patients who participated in 4 weeks of auditory discrimination training either close to or far removed from the tinnitus frequency. The training was based on the assumption that tinnitus is related to a shift of the representation of the tinnitus frequency in auditory cortex outside of the normal tonotopic map and that training close to but not removed from the tinnitus frequency should result in a reduction in the severity of the tinnitus. Tinnitus severity was measured 4 times per day during the entire treatment and other tinnitus-related variables were assessed 1 week before and 1 month posttreatment. The comparison of the training close to as compared to remote from the tinnitus frequency did not yield a statistically significant difference. However, a post hoc analysis revealed that patients who engaged in regular training as compared to those who practiced irregularly were significantly more successful in reducing tinnitus severity independent of the trained frequencies. Treatment success was best predicted by days of training and general activity levels. The data suggest that auditory discrimination training shows a dose response effect irrespective of training location and that treatment success is also related to psychological variables. For more substantial changes in multiple variables an extended training period with additional consideration of emotional variables would be necessary. In addition, controls for nonspecific training effects need to be implemented

N2 - A pedometer is a practical, inexpensive tool used to measure physical activity. Bassett et al. (1996) found that interinstrument consistency of the Yamax Digi-Walker was higher than four other pedometers when measuring distance walked in adults. The purpose of this study was to investigate the interinstrument consistency of the Yamax pedometer in children. Seventy-one children in Grades 3 to 5 wore one Digi-Walker on each hip during school hours for 1 week. Time and counts data were recorded separately for (a) regular classroom, (b) recess, and (c) physical education class times. Interinstrument reliability for total counts was estimated using one-way analysis of variance intraclass coefficients, adjusted for a single pedometer. Intraclass correlation coefficients were .96 for the whole week, .94 for classroom time, .98 for recess time, and .92 for physical education time. For applied use and research with children, the Yamax Digi-Walker provides a reliable estimate of physical activity

N2 - Children's daily physical activity patterns are influenced by many factors outside of their immediate control (e.g., school, parents' availability, time allowed outdoors). Because all children do not have an equal opportunity to participate in physical activity, investigating the relationship of psychosocial variables and actual voluntary activity has been problematic. Therefore, the purpose of this study was to determine the relationships among psychosocial correlates and physical activity levels when children have an equal and optimal opportunity

to be active. Participants were 25 children (ages 10-12) who participated in a summer fitness camp. The structured and repeated nature of the camp provided a unique opportunity to study variability in children's activity patterns over an extended period of time. Participants completed Harter's Perceived Athletic Competence Scale, the Children's Attraction to Physical Activity Scale, and the Children and Youth Physical Self-Perception Profile during the first 2 weeks of the camp. They wore an accelerometry-based activity monitor for 3 subsequent weeks. Physical activity was evaluated by computing T scores for their activity levels for distinct time periods and then averaging these T scores across the 3 weeks. Correlations between the activity levels and the Perceived Athletic Competence Scale were high for all 3 weeks (mean $r = .72$); however, correlations were consistently weak with the other correlate measures. The average pairwise correlation for the physical activity scores across the 3 weeks of the camp was high ($r = .72$), indicating that some children seek out ways to be active whereas others consistently choose to be less active. The consistently strong correlations with the Perceived Athletic Competence construct suggest that this may be an important mediator of children's physical activity behavior

N2 - There is epidemiological and preliminary clinical evidence that exposure to moisture and mold growth is associated with wheezing and asthma in children. Lung function and challenge tests may find obstructive changes in the airways before clinically evident symptoms. The aim of the study was to evaluate lung function and bronchial reactivity in school children in a follow-up setting, and relate them to changes in mold exposure over a 3-year observation period. We performed flow-volume spirometry and an exercise challenge test by outdoor free running 3 years apart to the same 139 students from moisture-problem and control schools. The subjects were classified into four exposure groups: exposure continued, eased, started, and no exposure. There were no significant differences in spirometry or in the exercise challenge test among the children in the four different exposure groups. However, there was a trend that, on average, bronchial reactivity increased when exposure started, and decreased when exposure eased. Spirometry and exercise challenge offer no benefits over symptoms in the follow-up of symptomatic children exposed to moisture and/or molds

N2 - This study focused on the physical activities of 228 children over 3 years. Children were divided into control (n = 112) and intervention (n = 116) groups. Parents of intervention-group children received information and concrete suggestions on how, when, and where to encourage their child's physical activity. Children in the

intervention group spent more time playing outdoors ($p = .041$) than did children in the control group, and play in the high-activity category increased with age ($p < .001$), whereas no change occurred in the control group. Our study showed that children's physical activity could be increased via family-based intervention

N2 - The sources of sporadic *Salmonella enterica* serotype Enteritidis (SE) infections in the United States are unclear. To determine risk factors for sporadic SE infection, we conducted a population-based case-control study in 5 Foodborne Disease Active Surveillance Network surveillance areas. During the 12-month study, 396 cases of SE infection were ascertained. Among the 182 case patients and 345 controls, SE infection was univariately associated with international travel (matched odds ratio [MOR], 61; 95% confidence interval [CI], 8-447), eating undercooked eggs (MOR, 2.2; 95% CI, 1-5), and eating chicken prepared outside of the home (MOR, 2.2; 95% CI, 1.3-3.4). Multivariate analysis revealed that eating chicken outside of the home remained the only significant risk factor for illness (MOR, 2.0; 95% CI, 1.1-3.6). Chicken consumption has not previously been identified in the United States as a risk factor for SE infection. Measures to prevent SE infections include educating consumers and food handlers about food safety and interventions to decrease contamination of eggs and poultry

N2 - This study compared physical education and recess physical activity levels of elementary school age students with mild mental retardation (MR) and students without disabilities who possessed either high or low cardiorespiratory fitness. For this study, the System for Observing Fitness Instructional Time (SOFIT), a measure of physical activity, was validated for students with mild MR. A significant difference for moderate to vigorous physical activity was obtained between settings. Findings suggest that students with MR and those without disabilities were more active during recess than during physical education. Students with mild MR and those with low cardiorespiratory fitness performed similarly in both the physical education and recess settings

N2 - Objective: Protocols for monitoring patients with differentiated thyroid cancer (DTC) include measurement of serum Tg and, for most patients, whole-body scan (WBS) with low radioiodine activities ('diagnostic' WBS). Recently, recombinant human thyroid-stimulating hormone (rhTSH) has become available to provide the TSH stimulation necessary for these procedures, whilst avoiding thyroid hormone withdrawal and hypothyroid complications. In addition, the inclusion of diagnostic WBS in DTC follow-up has recently become controversial. We have assessed the compliance with withdrawal-aided monitoring and the informative value of diagnostic WBS in consecutive tertiary referral center patients. Design: Forty-eight patients received rhTSH (0.9 mg) in two consecutive daily injections, with radioiodine administration 24 h, diagnostic WBS 48 h, and serum Tg testing prior to and 72 h later. Methods: Compliance with withdrawal-aided monitoring was assessed with a questionnaire provided by the referring physician, patient record analysis, and patient interview. The informative value of diagnostic WBS was assessed by comparing findings against serum Tg measurements in light of physical and other radiological examinations. Results: Forty of the forty-eight patients were female, the mean age was 43.9 years and the median follow-up from diagnosis was 4.5 years (range 1-19 years). Twenty-seven (56%) patients were compliant and 12 (25%) were non-compliant; compliance was not known in nine. Of 17 patients with clinically suspicious or significant findings on any available modality, four had uptake outside the thyroid bed on WBS but stimulated Tg <2.5 ng/ml on immunometric assay, while five had a negative WBS with serum Tg >2.5 ng/ml. Conclusions: Thyroid hormone withdrawal substantially impairs, and rhTSH administration substantially promotes, compliance with DTC monitoring. rhTSH-aided WBS is informative and should be included in the follow-up of unselected patients with DTC. 2004 Society of the European Journal of Endocrinology

N2 - This study examined the association between self-reported physical activity and a number of potential correlates in a sample of 256 Grade 6 children. Physical activity was assessed in both summer and winter, and children and parents completed questionnaires assessing potential correlates of physical activity. Analyses revealed that gender, time spent playing outside, self-efficacy in overcoming barriers, and number of items of exercise equipment at home were variables associated with physical activity in both seasons. School location was a variable associated with physical activity only in the summer, whereas private-lesson attendance, sports-club attendance, and best friend's physical activity were variables associated with physical activity only in winter. Variance explained in physical activity were 42% and 51% in winter and summer, respectively

 N2 - Otitis media with effusion (OME) is a common and important condition that may result in developmental delay in children, and significant health care resources are devoted to its management. Newer techniques including polymerase chain reaction are implicating organisms not previously considered important in etiology. The role of gastroesophageal reflux as a cause of OME is likely to receive greater research attention. Regarding prevention, more is being learned about potentially modifiable risk factors such as environmental smoke, care outside the home, and breast feeding. Although immunization may play a role in the future, existing evidence suggests that the general population of children should not be immunized in order to prevent OME. Several major studies have recently added to the understanding of epidemiology and management. Large trials in the United States, the Netherlands, and the UK suggest that OME is not an appropriate condition to include in a screening program. In addition, the advantages of early treatment with ventilation tubes over watchful waiting in terms of language development tend to be modest and diminish by about 18 months. Treatment with hearing aids should be further evaluated. The search for effective medical management continues, and better ways are being identified of targeting interventions to those children with OME who are most likely to benefit. N2 - The aim of this research is to learn the percentage of teenagers aged among 12 to 16, that regularly do some kind of physical activity and sedentary, to learn the percentage of smokers and to establish a connection between the smoking habit and the different types of physical exercise (individual, collective, aerobic and anaerobic), as well as other variables such as sex, age, smoking habits within the families... 367 teenagers aged among 12 to 16, belonging to the three current educative models (Public, Semi-Public and Private) have been questioned in this research. The measures and assistance to obtain the result were an epidemiologic inquiry about tobacco consumption and dependence, together with the sport activity practised by teenagers. As most interesting data we may say that the 61,9% of the inquired teenagers have never tried tobacco (65,4% of the boys and 57,6% of the girls); the 18% declared to have smoked at least once (5,6% of the boys and the 4,1% of the girls), a 4,9% consider themselves as ex-smokers; and 15,1% smoke regularly, the 6,8% only at weekends and the 8,2% everyday (7,1% of the boys and 9,4% of the girls). The average age to start smoking in this survey

has been 12, 2 years old +1, 84. 31, 5% of the students do physical activity only in their P.E. classes, whereas 68, 1% usually practice a sport outside their school (44,1% are even federacy). We find a statistical relationship between smoking and practice a sport ($p < 0, 01$) and within those who do sport smoke less those who are federacy ($p < 0, 01$). It is not of significance smoking with the kind of energetic system used (aerobic, anaerobic or mixed), neither with the type of sport (individual or collective), but it is connected with the fact of sharing a house with smokers ($p < 0, 01$). Therefore we can affirm that the students asked are active and little smoker. We can say that physical activity has a great influence on teenager's attitude towards tobacco, and to great extend it prevents from taking to smoking and even more among the federacy group. The smoking habit in the teenager family is directly connected to the acquisition of the smoking habit by the teenager

N2 - Objectives: Evaluation of sequence evolution as well as structural defects and mutations of the human immunodeficiency virus-type 1 (HIV-1) nef gene in relation to disease progression in infected children. Design: We examined a large number of nef alleles sequentially derived from perinatally HIV-1-infected children with different rates of disease progression: six non-progressors (NPs), four rapid progressors (RPs), and three slow progressors (SPs). Methods: Nef alleles (182 total) were isolated from patients' peripheral blood mononuclear cells (PBMCs), sequenced and analysed for their evolutionary pattern, frequency of mutations and occurrence of amino acid variations associated with different stages of disease. Results: The evolution rate of the nef gene apparently correlated with CD4+ decline in all progression groups. Evidence for rapid viral turnover and positive selection for changes were found only in two SPs and two RPs respectively. In NPs, a higher proportion of disrupted sequences and mutations at various functional motifs were observed. Furthermore, NP-derived Nef proteins were often changed at residues localized in the folded core domain at cytotoxic T lymphocytes (CTL) epitopes (E₁₀₅, K₁₀₆, E₁₁₀, Y₁₃₂, K₁₆₄, and R₂₀₀), while other residues outside the core domain are more often changed in RPs (A₄₃) and SPs (N₁₇₃ and Y₂₁₄). Conclusions: Our results suggest a link between nef gene functions and the progression rate in HIV-1-infected children. Moreover, non-progressor-associated variations in the core domain of Nef, together with the genetic analysis, suggest that nef gene evolution is shaped by an effective immune system in these patients. 2003 Lippincott Williams & Wilkins

N2 - Background: Marathon runners and elite swimmers showed increased inflammatory cells in the airways at baseline. Although airway neutrophils increase further after a marathon race, the airway response to swimming is unknown. The aim of this study was to assess the effects of swimming on airway cells. To avoid the concomitant effects of chronic exposure to chlorine, the study was conducted in seven nonasthmatic swimmers [mean age (SD): 23.3 + 7.7 yr, training: 32 + 15 km.wk⁻¹] habitually training in an outdoor pool (OP), i.e., a low-chlorine environment. Methods: Spirometry, exhaled nitric oxide (NO), induced sputum, and peripheral blood samples were obtained at baseline, after a 5-km trial in OP, and after a 5-km race in the sea (S), i.e., hypertonic airway exposure. Results: Airway neutrophil differential counts at baseline were higher in swimmers than in sedentary controls (N = 10), but cell counts, neutrophil elastase, and eosinophil cationic protein were unaffected by 5-km swimming. After swimming, L-selectin expression on airway cells decreased, suggesting exercise-induced cell mobilization into the airways and/or direct effects of hyperventilation on airway cells. After S, airway eosinophil differential counts increased slightly. Exhaled NO concentration was 19 + 6 ppb at baseline, 8 + 4 ppb after OP, and 21 + 7 ppb after S (P < 0.005 for OP vs baseline and S). Conclusions: In swimmers not chronically exposed to high chlorine concentrations, data obtained at baseline

suggest a direct relationship between airway neutrophilia and endurance training. The low L-selectin expression by airway cells postexercise suggests hyperventilation-induced cell recruitment or modulation of cell function. Hypertonic exposure of airways during exercise may slightly increase airway eosinophils and exhaled NO. Overall, 5-km swimming exerted smaller effects on airway cells than running a marathon

N2 - The objective was to test a method of assessing sun exposure for use in stratifying adolescent girls according to potential for vitamin D₃ synthesis in the skin. Thirty-five girls wore polysulphone ultraviolet (UV) dosimeters and kept diaries of their activities on August 17, 2000. Minutes spent outdoors during each hour of the day were tabulated and adjusted for the fractional strength of ultraviolet B (UVB) radiation relative to peak hour. Total adjusted minutes outdoors were compared with UV dosimeter readings. A

series of ampules containing 7-dehydrocholesterol were exposed on a flat plane to further investigate the potential for skin synthesis of previtamin D₃ with a given sun exposure. The correlation between measured UVB exposure and self-reported minutes outdoors adjusted for the time of day was $r = 0.64$. In vitro previtamin D₃ synthesis at midday was reduced by 50% on a cloudy day compared with a sunny day. 2003 Elsevier Inc. All rights reserved

N2 - Fifth-grade students' physical activity levels were examined via heart rate telemetry and pedometry during school fitness and recess breaks. Twenty-seven students with a mean age of 11.03 (+.32) years participated in morning recess (MR), lunch recess (LR), and fitness breaks (FB) for three days. Structured FB's consisted of students engaging in locomotor and nonlocomotor activities within an obstacle course framework, while recess breaks followed a traditional model. Results from repeated measures ANOVAs indicated students engaged in significantly more physical activity during FB than MR and LR. Fitness breaks provided a viable method for increasing children's school time activity levels

N2 - The present study illustrates the use of brief functional analysis probe conditions to verify the results of a descriptive assessment. An initial descriptive assessment of the disruptive behaviour of an 8-year-old student with severe developmental disabilities showed that levels of disruptive behaviour (screaming and throwing equipment) were higher in some lessons than others and suggested that the behaviour might be maintained by escape from task demands. An intervention in which work demands were alternated with 5-minute periods of free activity reduced levels of screaming to under 50%, and of throwing to under 25%, of baseline levels. Brief experimental variations of demand level in some lessons confirmed that levels of disruption were generally higher under high demand conditions. We conclude that brief probes provide a method by which experimental analyses can be conducted in the client's natural environment, reducing the problem of non-occurrence of the target behaviour that can pose problems for analogue assessments and facilitating ongoing assessment during initial intervention. We note also, however, that the consequent reduction in control over establishing operations may reduce the precision of the analysis and that ethical considerations limit the range of behaviours for which the method is appropriate

N2 - A field study was performed to assess the internal exposure of 149 five- to seven-year old children to traffic-related pollutants. The study was carried out in areas with high and low traffic density located in Western Germany (Essen/Ruhr, Borken, Northrhine-Westphalia) and Eastern Germany (Halle/Saale, Osterburg, Saxony-Anhalt). The benzene, toluene, o-,m-,p-xylene (BTX) concentrations in blood and the platinum excretion in urine served as markers for a traffic-related exposure. The parents were asked to answer a questionnaire, which asked for such information as traffic density in the vicinity of the dwelling, redecoration activities inside the rooms, exposure to solvent containing household products, passive smoking, etc. The results of this study show, that emissions from traffic have a significant influence on the internal BTX burden of children. The internal benzene exposure is mainly a result of the benzene concentration in outdoor air, which as a result of the absence of indoor sources is reflected in indoor air. Regarding toluene and xylene indoor air concentrations were generally higher than those outdoors indicating that several relevant indoor sources exist. The urinary platinum (Pt) excretion of the children from both high traffic areas (Essen/Ruhr, Halle/Saale) tended to higher values when compared with the Pt excretion of those children from the low-traffic areas. However, this differences were statistically not significant. The results of this study do not definitively prove whether emissions from automobile catalysts are responsible for the slightly higher Pt exposure of these children

N2 - At a central elementary school in the capital of Upper Austria children aged 7-10 years underwent repeated respiratory health checkups (questionnaires, diaries, spirometry). Between March and May 2001 the

daily means of the signals of a diffusion charging sensor, measuring the "active surface" of suspended particles, and a photoelectric aerosol sensor, measuring the particle-bound polycyclic aromatic hydrocarbons, were related to spirometric results of the total 164 children examined and to the daily symptom scores of a susceptible subgroup. Significant reductions of forced vital capacity ($p=0.006$) and forced expiratory volume in the first second ($p=0.001$) and significant increases of wheezing ($p=0.001$), shortness of breath ($p=0.041$), cough in the evening ($p=0.031$) and at night ($p=0.018$) were found with increase of "active surface" of suspended particles measured at the adjacent outdoor monitoring station, but not with the increase of particle-bound polycyclic aromatic hydrocarbons. Monitoring "active surface" of particles with diameters of about 10nm-1µm by means of a diffusion charging sensor might provide additional information in surveillance of particulate matter for prevention of acute effects on respiratory health. 2003 Elsevier Science Ltd. N2 - One of the most challenging aspects of therapy for school-age children who stutter is generalizing the skills learned in the therapy room to other settings such as the classroom, lunchroom, playground, or home. An additional challenge is seen in maintaining gains over the long term. This article reviews common roadblocks to generalization and maintenance, including the goals of therapy, the nature of the treatment strategies that require generalization, the scheduling and implementation of generalization activities within the overall therapy process, and the child's understanding of the treatment goals. Specific strategies for overcoming these roadblocks include: desensitizing children to both stuttering and treatment strategies designed to improve fluency, using hierarchies as a way of structuring treatment and moving children toward success in their daily activities, integrating the child's real world and clinical settings, and using structured practice activities to help children solidify all of the lessons they learn in treatment. This article highlights the importance of taking a broad-based view of stuttering to help children improve their overall communication across a variety of settings and over time

N2 - Objective: To determine in complete unilateral cleft lip and palate (UCLP) subjects the characteristics (location, shape) of the cleft-side lateral incisor. The presence of a supernumerary tooth at the cleft side and the prevalence of hypodontia outside the cleft area were evaluated. A comparison was made of the shape of the cleft side lateral incisor to its contralateral incisor. Setting: Hospital for Rehabilitation of Craniofacial Anomalies (HRCA), Sao Paulo, Brazil. Patients: Orthopantomograms of 203 subjects with UCLP and without syndromes were chronologically selected from the HRCA data bank, within an age range of 5 to 10 years. Outcome Measure: Orthopantomograms were analyzed by the same observer according to established criteria. Results: There were no statistically significant differences between sexes for any of the criteria studied. The cleft-side lateral incisor was present in 50.2%, and it was more commonly located at the distal side (76.5%). The congenital absence of the cleft-side lateral incisor was observed in 49.8% of the sample, and its antimere was congenitally missing in 10.9%, this difference being statistically significant. The most commonly missing tooth outside the cleft area was the maxillary second premolar. Conclusions: The high prevalence of hypodontia of the

permanent lateral incisor in the cleft side showed that the cleft could play an important role in this absence. There were different patterns for the presence of the cleft-side lateral incisor

N2 - The number of children in the United States who are bilingual or multilingual is both significant and increasing. Pediatricians, physician assistants, and nurse practitioners need to understand the processes of language development in bilingual children in order to support the families of bilingual children, provide accurate educational information, and prevent potential of misdiagnoses in these children as having such conditions as mental retardation, learning disabilities, or speech-language disorders. Evaluation of a child's development begins with a careful review of home, social, educational environments, and medical history. Gathering an accurate history may require the use of resources such as an interpreter, social worker, education consultant, psychologist, or speech-language pathologist. Pediatricians, physician assistants, and nurse

practitioners can have a positive impact on the educational and health care environment of these children by using this information, assessing the development of these children, and by sharing their knowledge with others who play a role in the lives of these children. Bilingualism/multilingualism does not lead to ongoing language delays. Bilingualism/multilingualism can play a positive role in a child's emotional development. In families that place a high value on tradition, speaking the language of parents and grandparents offers a way for the child to better understand the family's heritage even though it is not the dominant language of the child's environment outside the home. Speaking the language of a surrounding culture also provides insights into that culture. Bilingualism is an important resource; it has the potential to increase employment and offer other opportunities in the child's future especially in this rapidly globalizing world

N2 - The human immunodeficiency virus type 1 (HIV-1) nef gene is a crucial determinant in AIDS disease progression. Although several in vitro activities have been attributed to the Nef protein, identifying the one critical for in vivo pathogenicity remains elusive. In this study, we examined a large number of nef alleles derived at various time points from 13 perinatally infected children showing different progression rates: six nonprogressors (NPs), three slow progressors (SPs), and four rapid progressors (RPs). The patient-derived nef alleles were analyzed for their steady-state expression of a Nef protein, for their relative ability to downregulate cell surface expression of CD4 and major histocompatibility complex class I (MHC-I) and for their capacity to bind the clathrin adaptor AP-1 complex. We found that NP-derived nef alleles, compared to nef alleles isolated from SPs and RPs, had reduced CD4 and MHC-I downregulation activities. In contrast, SP- and RP-derived nef alleles did not differ and efficiently downregulated both CD4 and MHC-I. AP-1 binding was a conserved function of primary nef alleles not correlated with clinical progression. Defective Nef proteins from NPs, rather than sharing common specific changes in their sequences, accumulated various amino acid substitutions, mainly located outside the conserved domains previously associated with Nef biological properties. Our data indicate that Nef-mediated downregulation of cell surface CD4 and MHC-I significantly contributes to the expression of the pathogenic potential of HIV-1

N2 - Problem. The increased incidence of childhood thyroid cancer in areas heavily contaminated by the accident at Chernobyl is now well established. Initial studies outside the former USSR showed no evidence of changes in this incidence. France received much less fallout than did the former USSR, but deposition was highly heterogeneous in eastern France, particularly in the region of Franche-Comte. Under the auspices of the Union regionale des medecins liberaux de Franche-Comte (regional association of private practitioners), the general practitioners of this area decided to assess the health consequences in children living in Franche-Comte at the time of the accident of Chernobyl. Method. Incident cases from 1980 through 1998 among children younger than 15 years were collected from general practitioners, specialists, and hospital staff physicians in the Franche-Comte and surrounding regions. A Poisson test was used to analyse temporal heterogeneity (including a 4-year latency period) and spatial heterogeneity (between the 4 administrative areas composing the area) separately. Results. During the 19-year study period, 8 cases of childhood thyroid cancer were identified. The sex ratio was 1.67, and 7 of the cases were diagnosed in children in the 10-14 age group. The standardized incidence rate was 0.15/100,000. The incidence rate increased from 0.13/100,000 (95% CI: 0.03-0.37) in 1980-1989 to 0.26/100,000 (95% CI: 0.08-0.60) in 1990-1998. No variations were significant, however, either in space ($p = 0.44$) or time ($p = 0.48$). Conclusions. Although this study did not observe a significant increase in the incidence of childhood thyroid cancer after Chernobyl, it highlights two needs: first, for the assessment of the consequences of the accident at Chernobyl in France among a wider population, and second, for an extension of the follow-up period. This study also illustrates the role that private practice physicians can play in the field of public health

N2 - Objective To perform a pilot study that evaluates the nutritional and dietary habits of primary school children in a socioeconomically disadvantaged area prior to and following a healthy eating intervention programme. Design A quantitative study whereby the food intakes of 20 boys and 20 girls aged 8 to 9 years old were recorded for five days prior to, and for five days after the intervention. Discussions with the children to ascertain their attitudes towards healthy foods were carried out and parental support was encouraged. Setting A primary school in a socioeconomically disadvantaged area in the city of Limerick, Republic of Ireland. Method Food intake data was collected using food diaries and analysed using the computer package Diet 5 for Windows. Paired t-tests were performed to assess any significant changes in the dietary intakes. Results Following intervention, there were significant increases in the consumption of energy ($P < 0.001$), protein ($P < 0.001$), fat ($P < 0.01$), and calcium ($P < 0.0001$). Whilst most of the nutrients were consumed in appropriate amounts, the percentage energy from fat was higher than recommendations, whilst iron intakes were below recommendations. Conclusion Although, the changes in food consumption were positive, future interventions should emphasise the need to monitor fat intakes, improve iron status and encourage discussion outside the classroom environment. Similar interventions based on this pilot study could also be used with respect to other areas of health promotion, for example, activity, anti-smoking and so on

N2 - Current national demographic data based on the National Health Survey states that 20.6 million or approximately 25 per 100 children in the United States are injured each year. There are about 56,000 nonfatal injury episodes in children each day that require medical attention. Eight common recreational activities: baseball/softball, basketball, bicycling, football, playgrounds, roller sports, soccer, and trampolines, led to most injuries in children ages 5 to 14 years old. These injuries accounted for more than 2 million medically treated musculoskeletal injuries costing over \$33 billion. Caring for children with orthopaedic injuries requires an awareness of their unique mechanism of injury, associated injuries, and healing and remodeling rates. The focus of this chapter is to review the past year's literature with a discussion of prevention, epidemiology, evaluation, treatment, and complications of pediatric orthopaedic injuries. 2002 Lippincott Williams & Wilkins, Inc

N2 - Status epilepticus is a medical emergency, if not treated in time and effectively may cause significant mortality and morbidity. Medical therapy has been the mainstay of treatment but in refractory status surgical resection, multiple subpial transection, electroconvulsive therapy, caudate stimulation and acupuncture play important role. The present operational definition for adults and older children considers status as > 5 minutes of continuous seizure or two or more discrete seizures without regaining of full consciousness. Status epilepticus accounts for 1-8% of all hospital admissions for epilepsy. Physiological changes in generalised convulsive status epilepticus include transient or early (0-30 minutes) and late (after 30 minutes) changes. Temporal changes occur as tonic-clonic status epilepticus progresses. Management can be considered in two ways - out hospital management and inpatient management. Benzodiazepine is considered 1st line of treatment outside hospital. Emergency/inpatient management includes basic life support (0-10 minutes) and pharmacological management (10-60 minutes). Drugs used in pharmacological management are lorazepam, midazolam, propofol, phenobarbital, phenytoin, fosphenytoin, IV valproate, rectal diazepam, etc. The classical definition of refractory status epilepticus includes seizure that has not responded to sequential treatment of lorazepam, phenytoin or phenobarbitone or seizure continuing >60-90 in spite of adequate treatment

N2 - Environmental factors are usually considered as risk factors for increase of asthma prevalence. They may act isolately but are frequently associated. They act either directly by inducing asthma or more likely by increasing allergenic sensitization. Geographic situation is a well known risk factor. Important differences are noted between countries. The western lifestyle is evocated, including type of alimentation, small size of siblings, increased allergen exposure in houses. Intrauterine environment may play a role, particularly tobacco smoke during pregnancy and its respiratory effects on infant. Maternal allergenic exposure during pregnancy is an important factor because of maternofetal immunologic interactions. Outdoor pollution acts by enhancing bronchial responsiveness, allergenic sensitization and worsening respiratory diseases. Its effect is probably less important in infants and small children who are living indoor most of the time. Infections seems to have a complex action. Some virus, including respiratory syncytial virus, act to induce asthma or sensitization. Other type of infections (viral ou microbial) have a protector effect. Exposure to tobacco smoke, particularly maternal smoking, is identified in all studies, as one of the most important factors to be considered in childhood asthma. Exposure to allergen increases the risk of sensitization. Its direct responsibility to induce asthma is not established. Some of recent studies are suggesting the concept of a protective effect of early exposure. As far as preventive intervention is concerned, the recognition of these factors is important to limit the prevalence of childhood asthma. 2002 Editions scientifiques et medicales Elsevier SAS

N2 - Aggressive behavior in childhood has become a socially relevant problem demanding special attention from researchers, as a sharp increase has been reported in the aggressive and antisocial behavior of children and adolescents. Especially disturbing is the high participation of underage individuals in crimes such as robbery, drug trafficking and homicide, while numerous studies have shown that aggressive behavior evolves into more severe antisocial behaviors in adolescence and young adulthood. Research studies conducted on childhood aggressiveness has shown that these behaviors tend to become habits across time, and furthermore to progress into more complex and serious behaviors such as delinquency. For example, a high correlation has been reported between childhood aggressive behavior and antisocial behavior in adolescence and early adulthood. In an effort to prevent and stop the evolution of childhood aggressive behavior, efforts have been made to identify and describe those factors associated with the emergence of these behaviors in the developmental stages that comprise childhood and adolescence. Some researchers have coined terms such as risk and protective factors, reporting that it is highly probable that an individual might develop problem behaviors as the number of risk factors increases and exceeds the number of protective factors. It has been suggested that risk factors may be classified into four large groups: 1) the child's characteristics, 2) the parent's characteristics, 3) the contextual factors, and 4) the parent-child interaction. In a similar fashion, the protective factors that seem to ameliorate the occurrence of antisocial behaviors are classified into 5 main types: 1) parent-child support relations, 2) positive disciplinary styles, 3) monitoring and supervisory skills, 4) child centered families, and 5) parents seeking information and support. Based on the identification of risk and protective factors associated to antisocial behavior in children, other indicators that explain the progression and generalization of these behaviors across settings have been reported though they are less reliable. In particular, it has been reported that aggressive

behavior develops within the family unit, however, it has been also reported that as the child comes into contact with other settings and agents, his aggressive behavior generalizes. The generalization of aggressive behaviors in other settings seems appears to be the antecedent of its progression to antisocial behavior through developmental stages ending in adulthood. It has been reported that before this behavior progresses toward a more severe type, antisocial behavior generalizes across settings and agents. Furthermore, lack of control of the new agents promotes the increase and maintenance of antisocial behavior. Based on the results of numerous studies conducted in other countries that have identified and described those factors associated to aggressiveness in children, and the relative absence of longitudinal research studies in Mexico that might shed reliable information on this topic, it is necessary to conduct research for identifying the existing relationships between those factors described in the bibliography and the development, evolution and maintenance of antisocial behavior in Mexican children. With these considerations in mind, the purpose of the present study is to identify and describe those factors that are associated with the occurrence and maintenance of aggressive behaviors in a sample of school Mexican children, as well as to attempt to describe the process of generalization of these behaviors to other settings, specially the school environment (the classroom and the playground). A group of 345 children from seven public grammar schools in Mexico City were studied through a three year longitudinal cohort design. The sample was divided into two main groups: those whose reported level of occurrence of aggressive behaviors fell below the 25th percentile (non-aggressive) and those whose level of reported aggressive behaviors was above the 75th percentile (aggressive), based on the use of an Aggressive Behavior Checklist. The primary data for this study was gathered by using a direct observation system to record and classify parent child interactions in the home setting, teacher-child interactions in the classroom, as well as child-peer interaction in the playground. Additional data was gathered through the application of a series of psychological assessment instruments that measured childrearing processes such as: parental stress, disciplinary styles and family social environment as well as the child's anger control, peer preference, and types of friends maintained by the child. Results seem to identify those risk factors associated to the children's aggressive behavior, as well as those risk factors that are predictive of the aggressive behavior of the parents such as the use of an explosive irritable disciplinary style. Additional protective factors associated to reduced rates of aggressive behaviors by the child were also identified, as well as factors that seem to promote the generalization of childhood aggressive behaviors to other settings. In other words, the data shows that certain risk factors are related to the child's or parent's characteristics, while others are related to the type and quality of the parent-child interaction. The most important child characteristics were inadaptability, high levels of physical anger and disobedience, all of which predicted higher rates of aggressive behaviors in those children. In relation to parental characteristics, results seem to indicate that when parents perceive themselves as barely competent in childrearing, there are more probabilities of showing higher rates of aggressive behavior in their interactions with their offsprings. In a similar fashion, higher rates of aggressive behavior in the parents seem to be associated to their perception of their restricted parental role. The type of parent-child interaction which has been emphasized by other researchers, appears in the results of this study to confirm the findings that lack of childrearing skills is a risk factor significantly associated with the child's aggressive behavior. In particular, the use of unspecified instructional commands by the parents, an explosive irritable disciplinary style, as well as higher rate of their aggressive behavior, are reliable predictors of the child's aggressive behaviors. In a similar fashion, results appear to indicate that within family interactions, the parents' aggressive behavior predicts their child's aggressive behavior in concordance with Patterson's Coercion Theory, which states that coercive parent-child interactions increase the overall level of aggressive behavior in those families. Other risk factors were identified as a product of the analysis of the longitudinal data. They were those that reliably predict the parents' aggressive behavior, and which can also be classified into three general categories: child's characteristics, parental characteristics, and parent-child interaction. In terms of the child's characteristics, data shows that child's aggression and disobedience at home promote parental aggressive behavior. The parents' perception of certain child characteristics (problems in adaptability, demandness, distractibility and hyperactivity) is a risk factor that predicts parental aggressive behavior towards the child. Another risk factor were the parents vague and nonspecific instructions to the child with no opportunity for his compliance. Both risk factors reliably predict parental aggressiveness. Parental perception of his highly restricted parenting role is also reliably associated with higher levels of parental aggressive behavior. One of the identified risk factors in this study refers to parental disciplinary styles, specifically of an explosive irritable type. Results indicate that when a child is perceived by the parent as distracted, hyperactive, demanding, humorless, with adaptability problems, and non reinforcing for the parent, there is a significant increase of the probability that the parent will use an explosive irritable disciplinary style which, in turn, will be significantly associated with the child's aggressive behavior. Parental characteristics are also predictive of the parent's explosive irritable disciplinary style, in particular low childrearing competency, social isolation, reduced parental bonding family health problems,

perceived parental role restriction, depression, and low levels of spousal support. The findings also identified those factors associated with reduced levels of childhood aggression which seem to protect them against other child behavior problems. These factors include certain family characteristics and parental disciplinary styles that are reliably associated with reduced levels of childhood aggression, specifically, family environment with adequate levels of organization, goal orientation, religiousness and cohesiveness linked to a consistent and flexible disciplinary style not affected by emotional states. Appropriate levels of supervision of the child's activities outside the home setting favor the child's social and family development. The identification of these risk and protective factors points towards the relevance and need of developing specific interventions geared not only at the reduction of risk factors, but also towards the development of intervention strategies that promote the development of familial protective factors such as parent training in skills such as: childrearing, communication, supervision, social interaction, planned activities and incidental teaching. Additionally child-focused interventions in social skills, anger management and problem solving skills are also required along with setting-based intervention packages such as classroom and playground behavior management

N2 - This study examined the relationship between components of Eccles' (Eccles et al., 1983) expectancy-value model and perceptions of physical competence of children with and without learning disabilities (LD) across three physical activity contexts (physical education class, outdoor school recess, and at home).

Participants, 60 children with and without LD between 10 and 13 years, completed the Modified Pictorial Scale of Perceived Physical Competence (Ulrich & Collier, 1990) and an expectancy-value questionnaire measuring perceived importance, usefulness, enjoyment, and gender orientation of selected motor skills. Gender differences in perceptions of physical competence were found in recess and home settings. No significant group differences were observed in perceptions of physical competence. Expectancy-value subscales contributed differently to understanding competence judgments of boys and girls across context. Results are discussed with implications for improving self-concept and expectancy-value among girls toward sport and physical activity

N2 - Background: Brodifacoum is the major rodenticide used in the United States today. It is similar to warfarin but has more potent and prolonged effects. Large overdoses and chronic intoxication have been associated with significant coagulopathies and death. Currently, the management of acute unintentional ingestions by young children is controversial. Methods: American Association of Poison Control Centers (AAPCC) data from 1993 to 1996 were retrospectively searched for acute, unintentional brodifacoum exposures without coingestions followed-up to a known outcome in children aged 6 years and younger. The cases were analyzed by management site, symptoms, therapy, and outcome. Cases coded as having clinical or laboratory evidence of coagulopathy were further evaluated for severity. Results: Our study reviewed 10,762 cases that involved single, acute, unintentional ingestions of brodifacoum. All of the patients were followed-up to a known outcome as defined by AAPCC data collection standards. In this cohort, there were no deaths or major effects reported. Although 67 patients reported evidence of coagulopathy, no major effects or deaths were reported. Minor and moderate effects were reported in 38 and 54 children, respectively. Management occurred outside of a healthcare facility in 5404 (50.2 %) cases. Approximately half of all the children received some form of gastrointestinal decontamination. Decontamination had no effect on the distribution of outcomes. Adverse effects from decontamination therapy were reported in 42 patients. Conclusion: Acute pediatric ingestions of brodifacoum rarely caused clinical effects and were not associated with life-threatening symptoms or death in young children. It seems reasonable that acute unintentional ingestions of small quantities of brodifacoum by young children can be adequately managed with home observation and parent education

N2 - Multidrug resistance implicates decreased sensitivity of cancer cells to various, unrelated drugs. The "classical" mechanism of resistance is the upregulation of PGP (permeability glycoprotein), product of the MDR1 gene, which plays a physiological role in ATP-dependent transport of various substances outside the cell. The scope of this study is the analysis of PGP expression in childhood acute leukemias and its correlation with in vitro drug resistance profile. Forty-five children were enrolled in the study. PGP expression was determined as a percentage of blast cells by flow cytometry and drug resistance profile by means of the MTT assay. Cytotoxicity was measured as the concentration of drug that is lethal to 50% of cells. Median expression of PGP was: 0.24% for ALL de novo patients; 1.89% for relapsed ALL ($p=0,002$) and 12.60% in AML de novo ($p<0.001$). The highest individual PGP expression was observed in relapsed AML child (70.5%). The value of PGP expression showed a strong correlation ($p<0.01$) with resistance to idarubicin, mitoxantrone, etoposide, prednisolone, dexamethasone and type of leukemia. A weaker correlation ($p<0.05$) was observed for daunorubicin, doxorubicin, mercaptopurine, cladribine, fludarabine, 4-HOO-cyclophosphamide and 4-HOO-ifosfamide. No correlation was found between PGP expression and combined resistance profile for prednisolone, vincristine and L-asparaginase expressed by PVA score. These results might confirm that PGP

expression in childhood acute leukemias is related not only to resistance to anthracyclines, epipodophillotoxines and vinca alkaloids, but also to glucocorticoids, antimetabolites and alkylating agents. This is especially seen in AML and relapsed ALL

N2 - Study Objective: To investigate the knowledge, attitude, and behavior of secondary (high) school students concerning HIV/AIDS as a way of assessing the need for inclusion of reproductive health education in the school curriculum. Design: A questionnaire was constructed to expose depth of knowledge and attitude of respondents concerning HIV/AIDS. Setting: This was a workshop venue, a civic center, outside a school compound. Participants: Three hundred and sixty students were randomly selected from 5 secondary (high) schools in Enugu, Nigeria. Intervention: The questionnaire was administered just before the commencement of a workshop. Main Outcome Measure: All the students responded to the questionnaire but none responded to all the questions. Results: The students had a defective knowledge of the disease. They were aware and afraid of the disease as being deadly but not sure of the cause, nature, or modes of transmission and prevention, except

that illicit sexual activity should be avoided. Their attitude and behavior were consequently defective. Their main source of information was the media. Conclusion: There is need to provide students with correct, detailed, and broad-based information on reproductive health as part of the school curriculum to help them acquire adequate knowledge and develop appropriate attitude and behavior towards HIV/AIDS and other STDs

N2 - The t(2;14)(p13;q32.3) involving the BCL11A and IGH genes is a rare but recurrent chromosomal aberration in B-cell malignancies. Hitherto, juxtaposition of BCL11A and IGH has only been described in B-cell chronic lymphocytic leukemia (B-CLL) and immunocytoma. As subgroups of B-CLL can be distinguished by the pattern of somatic mutation of immunoglobulin variable (V) genes we investigated four lymphomas with IGH/BCL11A involvement for IGH hypermutation. Clonal V_H gene rearrangements were amplified; in all four cases, sequencing of the amplicates revealed the rearranged V_H genes to lack somatic mutations. These results suggest that t(2;14)(p13;q32.3) is associated with a subset of B-CLL/immunocytoma characterized by non-mutated IG genes deriving from pre-germinal center B cells. As the translocations in both informative cases are targeted to the switch regions of the IGG2 gene, which is mainly used in T cell-independent immune responses, these translocations presumably occurred in activated B cells in the course of T cell-independent immune responses outside the germinal center

N2 - The energy expenditure of 47 children aged 5-7 years was assessed before and after a school playground was painted with fluorescent markings. Physical activity was measured using heart rate monitors and energy expenditure calculated for 3 playtimes per child before and after the playground was painted. Total energy expenditure and the rate of energy expenditure increased significantly, as did the duration of play. The effect of painting the playground on total energy expenditure was analysed using an ANCOVA to control for play duration and body mass. Results revealed a 35% increase in total energy expenditure ($P < .01$) and a 6% increase in the rate of energy expenditure ($P < .01$). The significant interaction between time (before and after) and group (experimental and control) ($P < .02$) demonstrated that the intervention programme significantly increased heart rates. These results suggest that playground markings and duration of play can have a significant and positive influence on young children's energy expenditure

N2 - The therapeutic experience inside the institution disposing of a day-care hospital and a night hospital, leads us to conclude that there is no possible therapeutic act without moments of crisis, both inside the institutional dynamic as in the child's itinerary. The institutional device proposes a complex figuration whose aim is to avoid the relation of the emprise and to favor the quest towards the incertitude: the maintenance of the

main consultant outside the institution; inscription of the children in the heterogeneous age groups; favoring fictional affiliation; children's circulation from one place to another, permitting a confrontation with reality and the process of the constructive bereavement; unequal therapeutic periods (full time or part time) that incite the therapeutic staff to a constant investment; externalized classes that help avoiding creation of the culture of exclusion. The therapeutic action includes a series of punctuations that will mark the time of the child's cure. Thus, the child itinerary is permeated with transitional periods, sources of anxiety during which the child will mobilize as soon as he encounters a therapeutic frame that favors the activity of the representation. The child will thus narcissizes himself by discovering that he can survive the changes and benefit from them. The institutional crises appears thus as a paradigm of child's cure even if the institutional actors are always taken by surprise by this phenomenon while dreaming of a solidarity therapeutic community. 2002 Editions scientifiques et mdicales Elsevier SAS

N2 - Underdiagnosis of asthma is frequent in children and may be improved by the development of school-based health programs. Material and methods. - We developed an educational program in 11-year-old schoolchildren who participated in a screening test for exercise-induced asthma (EIA). All children were given an asthma questionnaire before and after two educational sessions. Results. - Mean score for asthma knowledge quiz increased from 63 to 85 % ($p < 0.001$). Thirty-six children (3.7 %) were initially considered as asthmatic and showed better responses than non-asthmatic children. Peak expiratory flow (PEF) was measured before and after an outside running exercise. A fall in PEF of at least 15 % was considered an abnormal result. Seventy-eight children (8 %) had a decrease in PEF, including 65 children initially not recognized as asthmatic. For these latter, a medical evaluation was recommended to parents. Only 28 of these children gave informations on follow-up: 19 had lung function tests, two received a treatment without preliminary function test, and seven had neither lung function test nor treatment. Among the children who realized lung function tests, five had criteria for airway obstruction at baseline, and ten had significant bronchial hyperreactivity. Conclusions. - However, a new screening test revealed that only a small minority of children initially not recognized as asthmatic but having decreased their PEF, were consequently considered as asthmatic by their practitioner, even in case of positive lung function test. 2002 Editions scientifiques et medicales Elsevier SAS

N2 - In recent years there has been a considerable increase in understanding of changes in mortality in Russia and some other former Soviet republics. However, the situation in the republics of the Caucasus remains poorly understood. Information on Georgia is especially fragmentary as a fifth of the country remains outside government control, there has been large scale migration since 1991, and the introduction of fees for vital registration has compromised the quality of official statistics. The aim of the study is to produce plausible estimates for life expectancy in Georgia for the period 1990-1998 and thus to assess whether Georgia has undergone changes similar to other former Soviet republics in the post-independence period. Four models were used to construct life tables. Model 1 used officially published statistics on deaths and population. Model 2 applied new estimates of population derived from household surveys to the observed deaths. Model 3 adjusted model 2 for under-registration at extremes of life, with parameter estimates derived from a survey of infant mortality and comparison of observed rates with Coale-Demeny standard life tables. Model 4 arose following inspection of death rates by cause that revealed implausible discontinuities in cancer mortality rates and involved applying the estimates of under-registration that this finding implied to model 3. The four models produce quite different estimates of life expectancy, differing by 7.8 y for men and 6.8 y for women by 1998. In any of the models, however, Georgia does not appear to have experienced the marked deterioration in life expectancy seen in Russia following the transition to independence. Importantly, Georgia had also not experienced a marked improvement in life expectancy during the 1985 Soviet anti-alcohol campaign, again unlike other Soviet republics. Official statistics substantially over-estimate life expectancy at birth in Georgia. Despite undergoing a civil war, life expectancy in Georgia has been less affected by the transition than has Russia and the overall trends in mortality since the mid 1980s suggest that this may be because alcohol has played a smaller role in these changes than it did in Russia

N2 - Background - Our previous publications on the epidemiology of blastomycosis suggested that the etiologic organism, Blastomyces dermatitidis, may be acquired at home, however this view was challenged in an editorial. Methods - 1) Field study of 2 properties that preliminarily suggested disease acquisition in the home. Owner interviews, site visits and environmental cultures using our in-vitro technique were used. 2) An address registry of human and dog blastomycosis cases was constructed from extensions of our previously published case series. 3) Literature review. Results - 1) Blastomycosis occurred in a dog (December, 1998) and then a cat confined to its home (September, 1999), from a household in urban Manitowoc County, WI; and additionally in a houseconfined cat (July, 1998) at a home in Milwaukee, WI. Interviews implicated the basement and the attic or basement, respectively, as the most likely source of infection at these homes. Environmental cultures were negative for Blastomyces.² Of the 229 domiciles in the registry, a minimum of 27 (12%) were associated with more than one blastomycosis case, 10 sites with more than two and 7 with more than three. In 4 domiciles, repeat cases occurred in different families. Most cases were separated by 1 year or more (range: 3 weeks to 7 years).³ Recent case series reveal a minority of outdoor activities and occupations among humans with blastomycosis. The organism has been isolated from an inhabited yard and from a house being razed. Conclusions - There appears to be growing evidence that blastomycosis may be acquired at home, and that B. dermatitidis may be relatively persistent on certain properties

N2 - A 21 month young boy who shows autistic disorders, and who will reveal oneself tetrasomy 15q carrier, is observed with an ethological method in the day-care he frequented during 10 months. After a first three months in which autistic behaviours and an extreme retreat, this child enrich progressively his gestual expressions' repertoire and shows less indifferent to his environment. Moreover he increases his moving area, investing gradually day-care's playgrounds and putting up with the other children and adults easier. So he reveals potential evolutions in spite of extremely serious developmental disorders. 2001 Editions scientifiques et medicales Elsevier SAS

N2 - Background. Intensive care medicine productivity has not been quantified in Spain. The aims of this study were 2-fold: a) to evaluate the productivity of staff physicians (in-door), and b) to evaluate the productivity of the intensive care unit (ICU) (out-door). Material and methods. In-door productivity was analyzed in the ICU of a center with 260 beds. To evaluate in-door productivity the daily activities performed by the staff physicians were chronologically described and analyzed: planning of daily activity, contact with external departments, consultation with patients, special techniques and inter-consulting, informing families, transfers out of the ICU, clinical documentation and clinical sessions, duty shifts and other activities. To analyze out-door productivity, a univariate identification was carried out of the number of consultations per department which were adjusted for calendar (working days of weekends and public holidays) and timetable (morning, afternoon or night nursing shifts), type of consultation, care of post-critical patients and transfers. Results. The results for in-door and out-door productivity showed that the two ICUs studied were a source of advantage, generating value among the community. The results also indicate that intensive care medicine fits within the strategic concept of essential competition. Conclusions. ICUs are ideal for meeting the social and economic needs of the community by attending critically-ill patients within a hospital

N2 - This paper focuses the problem of psychomotor evaluation in children and adolescents in the presence of significant disorders in comparison with a norm. Knowing the child history and its events, the characteristics of parental patterns and the peculiarity of relation allows the understanding of reasons and pathogenetic dynamics which caused and support child's disorder or pathology. Therapy must be carried out with a constant confrontation between the therapeutic process inside the setting and the child's behaviour modifications in the outside family and social environment, as well as pointing to know the way patterns react to modifications;

these factors have inevitable repercussions on setting, requiring possible adjustments. So it is indispensable to regard the evaluation as a non-static intervention to be done only before the beginning of the therapy, and as a task to be frequently accomplished in a dynamic way, with the primary purpose to take into account the child's family and social world, the area in which improvements are expected and the proper adjustments relevant to the figures the child refers to in his development

N2 - Background: Sleeping sickness, caused by two trypanosome subspecies, *Trypanosoma brucei gambiense* and *Trypanosoma brucei rhodesiense*, is a parasitic disease transmitted by the tsetse fly in sub-Saharan Africa. We report on a recent outbreak of *T b rhodesiense* sleeping sickness outside the established south-east Ugandan focus, in Soroti District where the disease had previously been absent. Soroti District has been the subject of large-scale livestock restocking activities and, because domestic cattle are important reservoirs of *T b rhodesiense*, we investigated the role of cattle in the origins of the outbreak. Methods: We identified the origins of cattle entering the outbreak area in the 4 years preceding the outbreak. A matched case-control study was conducted to assess whether the distance of villages from the main market involved with restocking was a risk factor for sleeping sickness. We investigated the spatial clustering of sleeping sickness cases at the start of the outbreak. Findings: Over 50% (1510 of 2796) of cattle traded at the market were reported to have originated from endemic sleeping sickness areas. The case-control study revealed that distance to the cattle market was a highly significant risk factor for sleeping sickness ($p < 0.001$) and that there was a significant clustering of cases (27 of 28) close to the market at the start of the outbreak ($p < 0.001$). As the outbreak progressed, the average distance of cases moved away from the cattle market (0.014 km per day, 95% CI 0.008-0.020 km per day, $p < 0.001$). Interpretations: The results are consistent with the disease being introduced by cattle infected with *T b rhodesiense* imported to the market from the endemic sleeping sickness focus. The subsequent spread of the disease away from the market suggests that sleeping sickness is becoming established in this new focus. Public health measures directed at controlling the infection in the animal reservoir should be considered to prevent the spread of sleeping sickness

N2 - The purpose was to examine the reference groups used by children with and without learning disabilities (LD), ages 10-13 years, when judging perceived physical competence in three contexts (in physical education class, during outdoor school recess, and at home). Participants, 30 students with LD and 30 without LD, completed the athletic competence subscale from the Self-Perception Profile for Learning Disabled Students (SPPLD; Renick & Harter, 1988) and two social comparison questionnaires in each activity context. Differences in the percentage of students citing the various reference groups across context was not statistically significant. Observations of responses indicate participants relied primarily on classmates, self-comparison, and family members to judge their physical competence. These results suggest that, while students with and without LD tend to compare themselves with their general education classmates, their reliance on eight different social comparison groups from which to judge physical competence varies with context

N2 - We hold nutritional counselling to be a prescription resulting from a customised nutritional advice. In the case of child obesity, the patient is not to be considered a miniature adult to whom one can prescribe a reduced food diet. Moreover, there are many solutions, not just one to the problem of obesity, just as there are many different cases of obesity. Therefore, different strategies are to be conducted, according to the etiological nature

of the obesity, its intensity and chronicity, depending also upon both the gender and the age of the child, the psychological problems and the family set-up, etc. We recommend that the preliminary dietary investigation be accompanied by a study on the patient's physical activities. Weekdays and week-end food behaviour during meals (at home and/or at school lunch-room) is to be observed, just as the patient's food intake outside of meals, the quantity, the family dietary behaviour such as cultural and cooking styles, etc., and the food choices of the other members are also to be taken into consideration when investigating obesity. Indeed, the prescription will be drawn up during the following clinical visits according to the above-cited specific parameters of the child and the dietary guideline. It is therefore necessary to have a perfect understanding of a child's dietary needs according to age. With additional advice on increasing the patient's physical activity and on fighting against sedentariness, the prescription will be made out based on positive instructions neither negating any food, nor listing authorised or forbidden food items. The identification of errors made in the earlier consultations will help in drawing up the prescription, so as to recommend a decrease of fat intake and an increase of carbohydrates, however checking that there be no increase in the total food energy balance. In practice, we can formulate a customised one-day dietary instruction with the help of the child: a diet that will comprise those food items that the child likes which also correspond to the desired criteria. The guidelines that concern both parents and children deserve a special attention. Snacking in-between-meals can play an important role in the total food balance. In a child, the disorders are seldom a form of bulimia, but are more often the result of snacking "in hiding", especially in the case of harsh and stringent restrictions during the meals or at afternoon snack, such that they entail a vicious circle of "restriction-desinhibition". Therefore, parents' attention ought to focus on meals taken at home, by varying the food in order to compensate the imbalanced generated by outdoor food intake. The first aim is to stabilise the weight of the obese child: to grow up without gaining weight results to be thinner. If the child cannot discipline himself/herself to the instructions, or if the weight goals are not be reached, the study of the psychological elements that determine the weight gain and that of the conflictual situations should be placed at the core of the therapy. At times, a study of the child's psychology has to be initiated and undertaken

N2 - A complex mixture of air pollutants is present in the ambient air in urban areas. People, animals, and vegetation are chronically and sequentially exposed to outdoor pollutants. The objective of this first of 2 studies is to evaluate by light and electron microscopy the lungs of Mexico City dogs and compare the results to those of 3 less polluted cities in Mexico. One hundred fifty-two clinically healthy stray mongrel dogs (91 males/61

females), including 43 dogs from 3 less polluted cities, and 109 from southwest and northeast metropolitan Mexico City (SWMMC, NEMMC) were studied. Lungs of dogs living in Mexico City and Cuernavaca exhibited patchy chronic mononuclear cell infiltrates along with macrophages loaded with particulate matter (PM) surrounding the bronchiolar walls and extending into adjacent vascular structures; bronchiolar epithelial and smooth muscle hyperplasia, peribronchiolar fibrosis, microthrombi, and capillary and venule polymorphonuclear leukocytes (PMN) margination. Ultrafine PM was seen in alveolar type I and II cells, endothelial cells, interstitial macrophages (M), and intravascular M-like cells. Bronchoalveolar lavage showed significant numbers of alveolar macrophages undergoing proliferation. Exposure to complex mixtures of pollutants-predominantly particulate matter and ozone-is causing lung structural changes induced by the sustained inflammatory process and resulting in airway and vascular remodeling and altered repair. Cytokines released from both, circulating inflammatory and resident lung cells in response to endothelial and epithelial injury may be playing a role in the pathology described here. Deep concern exists for the potential of an increasing rise in lung diseases in child populations exposed to Mexico City's environment

N2 - Objective: We investigated the effect of Psychological Job Demands (PJD) on the occurrence of the clinical symptoms of common cold. Methods: Subjects, participating in a large prospective cohort study on psychological determinants of fatigue at work, were asked to fill in a questionnaire on the occurrence of common cold during the previous four months. High PJD were considered as a potential risk factor. Other factors such as age, gender, and having young children were considered as potential confounders. Results: In logistic regression analysis, the adjusted odds ratio (OR) for having a recent cold in subjects reporting high PJD vs. those reporting low PJD was 1.20 (95% confidence interval (CI), 1.08-1.33). A higher risk emerged among those with young children (OR, 1.70; 95% CI, 1.47-1.96), those having a history of asthma (OR, 1.69; 95% CI, 1.28-2.22), or being under the age of 40 (OR, 1.28; 95% CI, 1.14-1.43) and among smokers (OR, 1.23; 95% CI, 1.09-1.38). Conclusion: The results support an association between PJD and common cold. In spite of the almost inevitable shortcoming of a large cohort study using questionnaires, this study gave us the opportunity to study the relationship between common cold and work-related factors in a nonexperimental setting with participants observed in a natural environment with all the normal everyday hassles. 2001 Elsevier Science Inc. N2 - The purpose was to develop a valid protocol for use by physical educators in assessing whether children suspected of having developmental coordination disorder (DCD) meet the American Psychiatric Association (1994) diagnostic criterion of interference in activities of daily living when interference is defined as culturally subaverage engagement in activities of daily living in physical play (ADL-PP) on the playground. Participants were 136 children (75 girls, 61 boys) from Grades 1 to 4 at three elementary schools in Canada. Data were collected two ways: (a) three administrations of an ADL-PP self-report of activities done during recess and (b) observation of children's ADL-PP during two recess periods. Examination of reactivity, accuracy, content relevance, and content representativeness of the ADL-PP report form indicated protocol validity. An example illustrating the use of the ADL-PP self-report protocol to identify interference is described

N2 - A dynamic multi-compartment computer model has been developed to describe the physical processes determining indoor pollutant concentrations as a function of outdoor concentrations, indoor emission rates and building characteristics. The model has been parameterised for typical UK homes and workplaces and linked to a time-activity model to calculate exposures for a representative homemaker, schoolchild and office worker, with respect to NO₂. The estimates of population exposures, for selected urban and rural sites, are

expressed in terms of annual means and frequency of hours in which air quality standards are exceeded. The annual mean exposures are estimated to fall within the range of 5-21ppb for homes with no source, and 21-27ppb for homes with gas cooking, varying across sites and population groups. The contribution of outdoor exposure to annual mean NO₂ exposure varied from 5 to 24%, that of indoor penetration of outdoor air from 17 to 86% and that of gas cooking from 0 to 78%. The frequency of exposure to 1h mean concentrations above 150ppb was very low, except for people cooking with gas. Copyright (C) 2000 Elsevier Science B.V

N2 - Sexually Transmitted Diseases (STDs) in children may be transmitted by sexual abuse, by accidental contact or perinatally. But sexual abuse is one of the most important concerns related to STDs in children. Transmission of STD pathogens occurs in 2% to 10% of abuse children and it is presumed that when penetration occurs, the risk is higher. Search in the literature of Bangladesh suggest that occurrence of STDs in children is rare. The reported cases of sexually abused children who presented to the Skin and VD outdoors of 2 Medical College hospitals in Bangladesh with Sexually Transmitted Diseases. One male of 13 years and four female

children of 5, 7, 9 and 13 years age respectively attended the Skin and VD outdoors of Sylhet MAG Osmani Medical and Bangladesh Medical College Hospitals during 1996 with the complaints of urethral / genital discharge, ulcers and multiple swellings in the genitalia along with their guardians. After proper clinical examinations, urethral / genital smear test were done where available for gonococcus, trichomonas and candida and sera were tested by RPR / TPHA for confirmation of syphilis. All the children gave the history of exposures with adult persons. Specific treatments were given and prompt improvement were noted after a week. Age range of children varies from 5 years to 13 years. Two female children and one male child were diagnosed as gonococcal urethritis and two female children were diagnosed as syphilis. It is revealed from histories that infected adults transmit these disease through sexual abuse. Children's STDs parallel those in adults. As more adults are infected in our country due to various factors, the likelihood of children contracting STD increases although few cases are included in our study. STDs in children are hard to imagine, since children are rarely sexually active, but they do occur due to sexual abuse. So, evaluation for sexual abuse should be done in all cases of child STDs. Prevention and treatment of adults are the most important steps to prevent these infections in children

N2 - Objective: To determine problems associated with electric-powered indoor/outdoor wheelchairs (EPIOCs) and benefits perceived by their users. Design: Hospital-based cohort study of all patients referred over a 19-month period. Setting: Regional Wheelchair Service for North West London serving nine district wheelchair services. Subjects: Of the 174 subjects referred, 10 withdrew their application or were found to be unsuitable at screening, 164 were assessed and 124 were prescribed chairs. One hundred and thirteen subjects were interviewed by telephone four months after provision of the chair. Main measures: Demographic and diagnostic data; current chair usage; self-reported accidents and component faults were compared with those recorded in the unit records; new activities embarked on since delivery; and benefits reported for main carers. Results: Seventeen 'mishaps' were reported by 15 users including tipping from chairs (6) and falls during transfers (3). Three probably reflected mechanical failure. Component failure was found in 39% of EPIOCs, mostly affecting control boxes (22), frames (10) and footrests (10). New activities were undertaken by 56 (50%) users, usually shopping and visits to friends/family. Eighty-five per cent of users felt that the chairs made life easier for their informal carers through increased independence, reducing transfer and reduced need for 'pushing'. Conclusions: The component failures and self-reported accidents (some potentially dangerous) have implications for the NHS, manufacturers, prescribers and users. EPIOCs enhance the independence of severely physically disabled individuals in the community and assist carers by lessening dependence and enhancing social interactions. This study demonstrated the need for follow-up of EPIOC users and chairs

N2 - Many of the risk factors previously identified for disorders such as Alzheimer's disease, periventricular leukomalacia, multiple sclerosis, stroke, cerebral palsy, mental retardation, and acquired learning and attention disorders ultimately may be shown to damage the central and peripheral nervous systems through activation of inflammatory mediators. The challenge to epidemiologists in the future is to expand use of epidemiologic methods to explore how immune-mediated insults produce CNS disorders in human populations. Studies of the association of use of nonsteroidal anti-inflammatory drugs with risk of Alzheimer's disease and those of the association of immune parameters with risk of cerebral palsy are excellent examples of how epidemiology can contribute to our understanding of the causes of neurologic and/or neurodevelopmental disorders. Many of the immune parameters of interest have short half-lives and are difficult to measure outside of the laboratory setting. Questions also remain as to the proper timing of measurements in relation to the initial insult and, in some cases, which tissue is the most appropriate to sample. These measurement issues will need to be resolved before use of immune biomarkers in epidemiologic studies of the etiologies of neurologic disorders can be fully realized. Epidemiologists are most likely to help identify ways to prevent neurologic disorders if they are knowledgeable about the molecular biology of inflammation, modulators of CNS vulnerability, and genetic polymorphisms that influence both inflammation and CNS vulnerability and are prepared to become adept at biomarker epidemiology. This does not necessarily compel them to gain extensive knowledge of neurobiology. Rather, neuroepidemiology in the 21st century will require increased collaboration between epidemiologists, neurologists, and neurobiologists

N2 - Skin cancer incidence in the United States has increased. Exposure to ultraviolet radiation (UVR) is a major risk factor for skin cancer. Every year, millions of children with their families visit outdoor leisure facilities such as zoos where overexposure to UVR may occur. This study was conducted to assess the proportion of U.S. zoos that provided sun safety activities during the summer of 1998 and their willingness to incorporate skin cancer prevention strategies at their facility in the future. A 56 item self-administered questionnaire was mailed to 140 zoos accredited by the American Zoo and Aquarium Association. A follow-up telephone survey was also conducted with 33 mail non-respondents. The response rate was 97% (N = 136). Results revealed that in the summer of 1998, only 5% of zoos provided sun safety recommendations to visitors and 25% of zoos provided recommendations to their employees. The recommendations made most often to visitors and employees were to use sunscreen and wear protective clothing. Eighty-five percent of zoos indicated interest in providing sun safety activities at their facilities in the future. The next step will be to design environmentally appropriate sun safety programs for zoos and to encourage zoos to implement these programs

CY - Netherlands

N2 - Objectives: To develop a 'methodology assessment' to evaluate the strengths and the weaknesses of two different epidemiological approaches and to identify the best suited monitoring strategy to measure the effects of 'normal levels' of nitrogen dioxide exposure on the health of an urban population. Methodology: all exposures to nitrogen dioxide were determined with passive samplers, each sampler consisting of 3 measuring Palmes tubes. In the first study the nitrogen dioxide exposure was assessed in 23 school children (11 asthmatic and 12 non asthmatic). Children wore samplers for a week and parallel measurements were made in their kitchens, in bedrooms and outside their homes. The second study consisted in a case-control study where the relative risk of hospital admission was calculated considering nitrogen dioxide levels in a city of northern Italy. 110 asthmatic patients were compared to a control group of 5322 people. Results: Personal sampler measurements highlighted significant differences in exposure when nitrogen dioxide atmospheric levels were compared in asthmatic and healthy children ($p < 0.05$). No other parameters were significant in the two groups. A significant action of atmospheric nitrogen dioxide on hospital admission was demonstrated ($p < 0.01$). Conclusions: Although a cause-

effect relation as such cannot be identified, the studies show a relation between the exposure to nitrogen dioxide and the presence of adverse effects on people's health. However the 'disadvantage' is for subjects with asthmatic pathologies, compared to the others. To manage this problem most effectively, a combined approach with the activation of specific personal monitoring campaigns of the subjects with verified risk seems necessary. This requires 'reading' the data resulting from most extensive and up to date information systems, capable of a thorough control both of the living environment and of the clinical outcome of the whole population

N2 - Prevalence: Whatever method is used (observation, interviews, questionnaire, laboratory tests), it is difficult to collect epidemiological data on doping. Particularly difficult problems are related to the definitions of sports players and the drugs involved as well as the often illicit nature of drug use. Results: The prevalence of doping in children and adolescents participating in sports is estimated at 3% to 5% with higher percentages in

boys, older adolescents and those playing at a competition level. Use of anabolic steroids, as early as 8 years of age, has increased since 1990, especially in girls. All studies have emphasized how easy it is for adolescents to procure any prohibited drug. In adults participating in amateur sports, the prevalence of doping would be 5% to 15%. All sports are involved with higher prevalence in men, age ranges 20-25 years and 35-39 years, and competitive level players. The main drugs used are stimulants, narcotics, corticosteroids and anabolic steroids. Combination of at least 2 drugs is frequent with an increase of mean daily dose over the last 15 years. According to users, the drugs are obtained with a medical prescription, on the underground market, or from other participants. Few data are available on doping outside sports activities. In the French department Meurthe-et-Moselle, 15% of the inhabitants use drugs to improve their occupational performance. Conclusions: Doping is more widespread than would be expected from antidoping control data. Other studies are needed to acquire more precise epidemiological data

N2 - Background: Viral infections are a serious threat to the immunocompromised child. While effective treatment is available for varicella zoster, herpes simplex and cytomegalovirus, measles remains a major obstacle with a high mortality. Diagnosis is often hampered by atypical clinical features. Patients: We report on 2 cases of clinically unrecognized measles in children with acute myeloid leukemia (AML) and interstitial pneumonitis. Case 1 is a 3-year-old girl admitted with high fever, lymphadenopathy, hepatosplenomegaly, and leukocytosis. A diagnosis of AML was made and induction therapy initiated. Throughout treatment, the child remained febrile with temperatures above 39 degreeC. A rash was noted on both legs. Virus serology was nonspecific. Cough and tachypnea developed with interstitial infiltrations on X-ray. An open lung biopsy was diagnostic. The child died due to respiratory failure despite intensive therapy. Case 2 is a 7-year-old girl referred for treatment of AML in relapse. On admission, conjunctivitis was noted. Antibiotic therapy had been initiated for high-grade fever at an outside hospital. Reinduction chemotherapy was begun. On the 3rd hospital day a rapidly progressing pneumonitis, and on the 6th day a total-body erythema developed. The child died in spite of mechanical ventilation on day 13. On autopsy, giant-cell pneumonia was evident. Conclusion: With the currently low uptake of active immunization against measles in Germany, measles and its complications remain a continuing problem in immunocompromised children. Physicians should be aware of the atypical presenting features of measles in the oncology patient

N2 - The horse has been used as a therapeutic medium since the time of the ancient Greeks and Xenophon is quoted as saying that 'the best thing for the inside of a man is the outside of the horse' (Longden 1998, p44). Man has been using horses for more than 3,500 years as draught horses or for riding; therefore, the man-horse relationship may be perceived 'as a close psychophysical attachment' (Schulz 1997, p65). The horse and its environment has been and continues to be used as a therapeutic tool for people with a wide range of needs and abilities, as is evidenced in the literature. This paper identifies some of the benefits and limitations of therapeutic horse riding and its relationship with occupational therapy, through a review of the literature and the use of case summaries from the author's personal experience

N2 - The aim of study was to assess the uptake of polycyclic aromatic hydrocarbons (PAH) by children living in a city and its effect on 1-hydroxypyrene (1-OHP) excretion. Two groups of children (n=11 and 13; 3-6 years old) were chosen: (1) a group from a kindergarten situated near a road with a high traffic density ('polluted' area); (2) a group from a kindergarten situated in a green zone ('non polluted' area). Food consumption was recorded in all children and PAH uptake from foodstuffs was estimated. Ambient air samples were collected on the playground and indoor of kindergartens during 3 days in summer 1997. Soil samples were collected on the playground. Urine samples were collected in the morning and in the evening. Mean outdoor total PAH concentration (sum of 12 individual PAH) in 'polluted' area was 12 times higher than that in 'non polluted' area (22.9 vs. 1.9 ng/m³). However, indoor concentrations were similar (3.0 vs. 2.1 ng/m³). The same trend was observed for pyrene concentrations. The contribution to the total pyrene absorbed dose from food consumption (estimated daily absorbed dose of 167 and 186 ng, respectively, in 'polluted' and 'non polluted' area) was much more important than that from inhalation (8.4 and 5.4 ng, respectively) in both areas. The estimated daily absorbed doses of pyrene from the soil were 0.061 and 0.104 ng in 'polluted' and 'non polluted' kindergarten, respectively, which correspond to 0.032 and 0.059% of the total absorbed dose. Higher urinary concentrations of 1-OHP were found in children from 'polluted' kindergarten. In conclusion, the food seems to be a main source of the total pyrene and total PAH uptake in small children, even under a relative high PAH air exposure in the city. Pyrene concentration in soil had a negligible contribution to the total pyrene absorbed dose. Usefulness of the urinary 1-OHP as an indicator of the environmental exposure to PAH needs further research. Copyright (C) 2000 Elsevier Science B.V

N2 - Gene defects in lipoprotein metabolism usually cause conspicuous alterations in plasma lipoprotein profile and, often, more or less severe clinical problems. Increased or decreased lipid parameters therefore represent starting points for detection of these gene defects, but also provide important information to select target proteins whose activity is limited or destroyed. An increase of a single lipid parameter facilitates the search for the target protein, which can be identified afterwards by an activity assay. Employing this strategy we were able to identify lipoprotein lipase (LPL) deficiency in a 6 week old patient with grossly increased plasma triglyceride concentrations. In another instance, an increased level of HDL cholesterol in patient M.Y. led to the identification of cholesteryl ester transfer protein (CETP) deficiency. In patient M.H. displaying mixed hyperlipidemia a variety of target proteins were possible. Careful clinical examinations and performance of activity measurements of several enzymes were necessary to detect lysosomal acid Lipase (LAL) deficiency. Delineation of the molecular defect is facilitated by the knowledge of described mutations which can often be rapidly identified using PCR and subsequent restriction analysis. In this way we were able to identify a nonsense mutation in the LPL gene of patient M.K. as well as a splice site defect in the LAL gene of patient M.H. In the

case of absence of known mutations, we recommend cDNA analysis using PCR and subsequent sequence analysis. Using this technology patient M.Y. could be identified as heterozygous carrier of a nonsense mutation within the CETP gene. Defective transcription may be caused by destroyed gene structure, splice site mutations, or mutations altering expression of the corresponding gene. Amplification and sequence analysis of genomic DNA fragments allow identification of mutations within intron-exon boundaries or gene promoter regions. The gene structure can be examined via amplification employing long range PCR with subsequent restriction analysis. The identification of mutations outside the coding region of a structural gene may be complicated, since they may be able to prevent transcription although being located more than 100 kB from the corresponding gene

N2 - Continuous subdural electrocorticographic (ECoG) monitoring was performed to test the hypothesis that human temporal lobe epileptogenicity, during long-term monitoring following antiepileptic drug (AED) withdrawal, regardless of the specific AED regimen, is dependent upon ECoG ictal onset and interhemispheric spread of epileptic activity. In 121 patients, ECoG parameters were analyzed for association with seizure frequency, a clinical measure of epileptogenicity. Significantly associated with increased seizure frequency

were: ictal medial temporal lobe onset, absence of ictal frontal lobe desynchronization and short interhemispheric propagation time (IHPT). Seizure frequency during long-term ECoG monitoring was not predictive of post-operative seizure outcome. It is concluded that, following AED withdrawal, regardless of the specific AED regimen, increased seizure frequency is associated with medial temporal lobe ictal onset, short IHPT and absence of frontal lobe desynchronization. The results confirm the hypothesis that human temporal lobe epileptogenicity, after withdrawal, is dependent upon ECoG ictal onset and interhemispheric spread of epileptic activity. Future development of procedures which promote ECoG factors associated with increased seizure frequency following AED withdrawal might decrease duration of invasive long-term monitoring and improve efficiency for the pre-surgical selection of temporal lobectomy candidates. Intervention producing ictal frontal lobe desynchronization and increased IHPT might inhibit temporal lobe epileptogenicity and should be evaluated for therapeutic efficacy outside of the long-term monitoring context. N2 - Background and Aims. The lifestyle of children in developed societies is susceptible to rapid changes and these may affect the nutritional status of children. Reduced physical activity and changes in diet have been proposed as contributing factors to the growth in childhood overweight and obesity. The aim of this study was to assess trends in the food-related behaviour and markers of activity/inactivity in French 9-11-year-old children. Methods. Three successive surveys (1993, 1995, 1997) were carried out in samples of 1000 French children, aged 9-11 years. Sociodemographic, anthropometric and food-related parameters were obtained for each child, using standardized questionnaire administered by trained interviewers. Results. Previous-day reports of food intake by the child revealed a strong persistence of the traditional French meal structure. Breakfast was eaten by 97% of children. Over the three surveys, an increasing percentage of reported breakfasts contained at least one dairy food, one cereal food, and one fruit or juice (from 11% to 17%). Almost all children had lunch, which occurred at the school cafeteria for one-third of the subjects. The afternoon snack, a traditional meal for French children, was consumed by 86-88% of the samples. Almost all children had dinner (99%), most often at home and in the company of all family members (73-87%). Lunches and dinners were composed of several courses presented in succession, as is usual in France. The foods most preferred by the children were often rich in sugar and/or fat (fried potatoes, ice cream, nut spread, chocolate, cake, etc.). The children could list 'healthy foods' competently. They also demonstrated knowledge of terms used in nutrition (e.g. calories, fats) and were aware of possible links between intake of certain substances and disease. In families of higher socio-economic strata (income, education of parents) more time was devoted to sports by the children. Over the three surveys, linear trends indicated more exercise time per week and less television viewing. A high risk of obesity was likely in very sedentary children whose proportion (33%) was stable over the 1993-1997 period. Conclusions. In general the traditional French pattern of eating persisted among these children. Although there were signs of movement towards a more complete breakfast, less television and more exercise in active children, a substantial proportion of children engaged in no sports activity outside school hours. Maintaining appropriate weight is therefore difficult in view of the plentiful supply of food available to children. Inactive children are at high risk of obesity and should be encouraged to adopt a more active lifestyle

N2 - Objective: The purpose of this study was to evaluate the antiemetic effect of prophylactic dimenhydrinate application prior to Faden operation and to compare the incidence of PONV between bimedial Faden operation (BMF) and horizontal recess-resect procedure (R and R). Methods: Ninety-nine children (4-10 years) scheduled for BMF were included in this prospective double-blind study. Midazolam (0.5 mg/kg body weight, BW) was administered orally for premedication 30 min before induction of anesthesia. Additionally, children weighing >

23 kg received either dimenhydrinate suppositories or placebo. The placebo group was compared with 148 children who underwent R and R surgery without antiemetic prophylaxis during the same period. Anesthesia was induced with thiopentone (5-10 mg/kg BW) and vecuronium (0.1 mg/kg BW) bromide and maintained with halothane (1-2 vol%) in N₂O/O₂ (65/35 vol%). Age, height, weight, and incidence of oculocardiac reflex were documented. PONV was classified into 'no vomiting', 'vomiting without therapy', and 'vomiting requiring rescue medication'. In the latter case dimenhydrinate was given again. The chi-square test was used for statistical analysis. Results: Forty-eight patients received placebo, while 51 received dimenhydrinate. No differences between any groups were observed concerning age, height, weight, and incidence of oculocardiac reflex. Compared to R and R surgery, PONV requiring rescue medication occurred significantly more frequently after BMF (45% vs 23% after R and R). PONV after BMF was significantly less severe in the dimenhydrinate group than in the placebo group. The total incidence of PONV after BMF, however, was not significantly reduced. Conclusion: The high incidence of PONV after BMF can be explained by the greater invasiveness of BMF than R and R surgery. PONV requiring antiemetic rescue medication can be reduced by preoperative administration of dimenhydrinate suppositories

N2 - Objectives - To assess the diagnostic process of retinoblastoma in a developing country. Study design - Prospective survey of 95 consecutive parents of patients with retinoblastoma. Results - Fifty six parents

consulted initially with a paediatrician. Their children tended to be younger, with a significantly higher frequency of advanced disease. Only half of the patients who consulted with a paediatrician were appropriately referred to an ophthalmologist; the paediatrician underestimated the complaints in the remainder. Children taken to an ophthalmologist were older and had less advanced disease. In about three quarters of these children, a diagnosis of retinoblastoma was suspected by the ophthalmologist on the first visit. Parents of patients with more advanced disease consulted significantly later. Poor parental education correlated significantly with late consultation. Lack of health insurance and living outside Buenos Aires City correlated significantly with an increased risk of extraocular disease. Conclusions - Paediatricians are the first health professional seen by most children with retinoblastoma. However, the diagnosis is not readily established. There is also a delay in consultation by parents, which is significantly longer in cases with advanced extraocular disease.

Socioeconomic factors and access to health care might play a role in delayed diagnosis

N2 - Each year approximately 211,000 U.S. children receive emergency department care for injuries sustained on playground equipment, making the use of this equipment the leading cause of injuries to children in school and child care environments. In response to the problem, the National Program for Playground Safety (NPPS) at the University of Northern Iowa (UNI) developed a national action plan that focuses on four areas of playground injury prevention: supervision, age-appropriateness of equipment, suitable fall surfaces, and equipment maintenance. During 1998-1999, NPPS surveyed a sample of the nation's child care, elementary school, and park playgrounds. This report summarizes the survey results, which indicate that playground injuries could be reduced by measures such as resilient surfacing below equipment, better equipment maintenance, improved supervision, and use of age-appropriate equipment

N2 - The incidence rate per 100,000 population by gender and age group was calculated for the 24 Maryland jurisdictions using 1,392 cases reported to the Lyme Disease Registry during 1993 to 1996. The overall incidence rate for the state was 7.0 cases per 100,000 inhabitants. Males (incidence rate = 7.7) were 1.2 times more affected than females (incidence rate = 6.2) ($p < 0.001$). The bimodal overall age distribution shows a peak in the 10 to 19 age category (incidence rate = 8.5) and in the 50 to 59 age group (incidence rate = 8.9), and in the 20 to 29 age group (incidence rate = 3.9). The incidence rate by jurisdiction ranged from 0.7 in Allegany County from Western Maryland to 88.3 in Kent County on the Upper Eastern Shore. Results from this study show that counties from the Upper Eastern Shore region had the highest specific incidence rate by age group/gender/jurisdiction while counties from Western Maryland had the lowest specific incidence rates and have not reported Lyme disease patients younger than 10 or older than 59 years of age. This difference might be explained primarily by the kind of outdoor activities in which the different age groups are involved and the relative abundance of *Ixodes scapularis* infected with the etiologic agent of Lyme disease, *Borrelia burgdorferi*, in these two regions

N2 - Background: Cisapride is a gastrointestinal prokinetic agent that is used worldwide in the treatment of gastrointestinal motility-related disorders in premature infants, full-term infants, and children. Efficacy data suggest that it is the most effective commercially available prokinetic drug. Methods: Because of recent concerns about safety, a critical and in- depth analysis of all reported adverse events was performed and resulted in the conclusions and recommendations that follow. Results: Cisapride should only be administered to patients in whom the use of prokinetics is justified according to current medical knowledge. If cisapride is given to pediatric patients who can be considered healthy except for their gastrointestinal motility disorder, and the maximum dose does not exceed 0.8 mg/kg per day in 3 to 4 administrations of 0.2 mg/kg (not exceeding 40 mg/d), no special safety procedures regarding potential cardiac adverse events are recommended. However, if cisapride is prescribed for patients who are known to be or are suspected of being at increased risk for drug-associated increases in QTc interval, certain precautions are advisable. Such patients include those:(1) with a previous history of cardiac dysrhythmias, (2) receiving drugs known to inhibit the metabolism of cisapride and/or adversely affect ventricular repolarisation, (3) with immaturity and/or disease causing reduced cytochrome P450 3A4 activity, or (4) with electrolyte disturbances. In such patients, ECG monitoring to quantitate the QTc interval should be used before initiation of therapy and after 3 days of treatment to ascertain

whether a cisapride-induced cardiac adverse effect is present. Conclusions: With rare exceptions, the total daily dose of cisapride should not exceed 0.8 mg/kg divided into 3 or 4 approximately equally spaced doses. If higher doses than this are given, the precautions above are advisable. In any patient in whom a prolonged QTc interval is found, the dose of cisapride should be reduced or the drug discontinued until the ECG normalizes. If the QTc interval returns to normal after withdrawal of cisapride, and the administration of cisapride is considered to be justified because of its efficacy and absence of alternative treatment options, cisapride can be restarted at half dose with control of the QTc interval. Unfortunately, at present, normal ranges of QTc interval in children are unknown. However, a critical analysis of the literature suggests that a duration of less than 450 milliseconds can be considered to be within the normal range and greater than 470 milliseconds as outside it. N2 - The purpose of this study was to examine patterns of physical activity (PA) during a single weekend to ascertain possible relationships between PA and anthropometry, fundamental motor skills, and CHD risk factors among 105 normal male and female children, aged 3-4 years. The children played, when awake, on the average for 14 hr, 16 min indoors and for 5 hr, 12 min outdoors of which low activity playing accounted about 4 hr. Notable gender differences were observed in the intensity of PA but not in fundamental motor skills and CHD risk factors. The results suggest that physical activity is weakly related to fundamental motor skills and CHD risk factors at an early age. The association between PA and body size was modified by gender ($p = .024$): The girls who played indoors a lot were heavier than the others, and the boys who played much more outdoors were heavier in relation to other boys. The associations between PA and motor skills as well as PA and CHD risk factors were also highly gender-dependent: The boys benefited from interacting with parents, while the girls benefited from independence. The most influential factors seemed to be the amount of playing outdoors, the amount of high level play activities, as well as interaction with parents

N2 - This paper presents findings from a self-completion questionnaire survey of primary schools in Wales conducted in the spring of 1998. The survey provides data on the organisation and provision of health education teaching, the implementation of health related policies, the involvement of outside agencies and professionals in the planning and delivery of health promotion, and the extent to which respondents perceive their schools to fulfil the role of a 'health promoting school'. The results from the responding 450 schools (80% response rate) show a continued commitment and expansion of health promotion activity since an earlier survey in 1993. Notable improvements include an increase in the number of schools reporting policies relating to bullying, sex education, and adult smoking on school premises. Fifteen per cent of respondents considered their school to be health promoting and it was encouraging to find that some health promoting practices were reported more often by these schools than others. However, the results also suggest that the concept of a 'health promoting' school may not yet be completely understood. It is recommended that greater attention in all schools should be given to: written health policies for both pupils and staff, in particular those regarding nutrition; the amount of in-service training devoted to health education topics; and further integration of community resources into school health promotion programmes

N2 - In children the major cause for surgical admissions to hospital are accidents and their long term sequels. In order to get epidemiological insides on the etiology, injury patterns, required surgical interventions, duration of hospital stay, convalescence, and return times to school, we analysed 1053 cases presenting at the Department of Trauma, University Hospital Freiburg, during a period of four years. Twohunderdnintysix (28.1%) admittances were due to traffic accidents, 276 (26.2%) to playground accidents, 225 (21.4%) to domestic accidents and 179 (17.0%) were associated to sport activities. Over all every 4(th) child (in case of traffic accidents every 2(nd)) suffered two or more injuries. The severity of injury was classified according to the Hannover Polytrauma Severity Score. Fractures comprising 42.8% of the treated injuries, were the main reason for surgical interventions. Sixtyseven (6.4%) of the 1053 cases represented abdominal trauma, being the 4(th) cause for treatment. Of these, 46 had blunt abdominal trauma without defined organic leasions. Fourteen had isolated organic leasions, and in 7 multiple organ injuries. The spleen was the most exposed and dangered organ and was involved in 9 cases, followed by kidney and liver trauma. In 53 cases the injuries could be treated conservatively, 14 children had to undergo laparotomy, 82.1% of the treated children recovered completely. The average time until full recovering was 85.5 days and correlated with the severity of the abdominal trauma

N2 - The nutritional status of Brazilians has improved over the last three decades. Still, little is known about the role played by nutritional assistance programs that public institutions and philanthropic organizations provide for low-income preschool children, who face greater nutritional risk. Therefore, we carried out a quasi-experimental study to evaluate the nutritional impact of the municipal preschool nutritional assistance program in the city of Sorocaba, Sao Paulo, Brazil. Over the course of a year, we performed quarterly measurements of weight and height on 444 children, whose ages ranged from 3 months to 6 years. In this population, 164 children were assisted by the preschool nutritional program (intervention group), and 280 children were not (nonintervention group). The children in the nonintervention group were identified by a special census for that purpose; they did not attend the preschool but lived nearby. After obtaining informed consent and carrying out a pretest, professionals and university students interviewed the mothers of the participating children, following standard techniques and conditions. Anthropometric measurements were done by teams of two interviewers, one of whom was a permanent member of the team, using equipment calibrated by the appropriate regional technical organization. The correspondence between the first measurement and subsequent measurements was evaluated by stratifying the population into three groups by z scores for weight-for-age and for weight-for-height, using U.S. National Center for Health Statistics reference curves. The z score groupings were established at the beginning of the study for three different age groups: younger than 24 months, 24-36 months, and older than 36 months. The two study groups (intervention and nonintervention) were similar sociodemographically, with the following exceptions: maternal employment (more of the mothers of children in the intervention group had jobs outside the home); age (children in the intervention group were significantly older); nutritional status (it was worse in the intervention group); and prevalence of hospital admittance (it was higher in the intervention group). After just the first three months of the study, 32% of the children in the intervention group had moved to a higher nutritional stratum, whereas only 13% of children in the nonintervention group had shown improved nutritional status. The difference in favor of the intervention group increased with the length of the intervention and was higher among older children. These results show that the preschool nutritional assistance program helped to improve the assisted children's nutritional status

N2 - Background: The amount of allergen necessary to sensitise genetically 'at risk' children is unclear. The relation between allergen exposure and asthma is also uncertain. Methods: To ensure a wide range of allergen exposures the data from case-control studies of asthma in children aged 12-14 years attending three schools in Los Alamos, New Mexico and Central Virginia were combined. Skin prick tests to indoor and outdoor allergens and bronchial hyperreactivity to histamine were assessed in children with and without symptoms of asthma. The concentration of mite, cat, and cockroach allergens in dust from the children's homes was used as a marker of exposure. Results: Three hundred and thirty two children (157 with asthmatic symptoms and 175 controls) were investigated. One hundred and eighty three were classified as atopic on the basis of allergen skin prick tests and 68 as asthmatic (symptoms plus bronchial responsiveness). The prevalence and degree of sensitisation to mite and cockroach, but not cat, was strongly associated in atopic children with increasing domestic concentrations of these allergens. Asthma was strongly associated with sensitisation to indoor allergens ($p < 10^{-6}$) and weakly to outdoor allergens ($p = 0.026$). There was an association between current asthma and the concentration of mite allergen amongst atopic children ($p = 0.008$) but not amongst those who were specifically mite sensitised ($p = 0.16$). Conclusions: The domestic reservoir concentration of mite and cockroach, but not cat, allergen was closely related to the prevalence of sensitisation in atopic children. However, the prevalence of current asthma had a limited relationship to these allergen measurements, suggesting that other factors play a major part in determining which allergic individuals develop asthma

N2 - For a quarter of a century Austrian environmental protection agencies took serious efforts to improve urban air quality. During the 1980s Austria achieved the highest SO₂ reduction among the signatory states of the Helsinki Protocol. Suspended particulates were reduced simultaneously.

NO₂ reduction was less, because reduction of emissions from industry, power plants and motor vehicles was counterbalanced by traffic increase. During the period of highest improvement of air quality in the 3(rd)-largest city of Austria 85% of pupils in compulsory schools (n = 15,045) have been examined by physicians and their lung function results were related to the air quality of their school district. Negative correlations of all lung function parameters were found with SO₂, especially of PEF, but also FEV₁ and FVC. Outdoor NO₂ and passive smoking both showed negative correlations with end- expiratory flow rates. A mixed longitudinal study on 3,451 children over 5 years confirmed cross-sectional results and demonstrated normalization of end-expiratory flow rates in districts where not only SO₂ and TSP but also NO₂ decreased. The cohort born 1979 had experienced the highest reduction of ambient air pollutants in elementary school and was reexamined at age 18 by the same methods. Social class and passive smoking did not show negative effects on lung function up to age 18, however, active smoking impaired growth of MEF₂₅. Higher growth of FVC was found where SO₂ decrease in winter half-years of elementary school exceeded 40 µg/m³ and higher growth of MEF₂₅ and MMEF up to age 18 was found where NO₂ decreased. Part of the improvement of MEF₂₅ could be due to the reduction of fine particulates. A matter of concern is the increase of motor traffic and Diesel engines (which destroy improvements from introduction of catalysts for cars) and continuing chronic effects of NO₂ and fine particulates on lung function growth in the area of small airways

N2 - Background. Although solar radiation is well established as a risk factor for melanoma, it is less clear how the pattern and timing of exposure to ultraviolet (UV) radiation might be important. The particular objective of this study was to evaluate the association of melanoma risk with various measures of intermittent and chronic exposures to UV radiation, and to assess how these exposures interact with other risk factors such as skin type. Methods. Data were analysed from a large case-control study (583 cases, 608 controls) of malignant melanoma, carried out in southern Ontario, Canada. Results. Significant risk increases were identified with several measures of intermittent exposure, including beach vacations in adolescence and in the past 5 years, previous sunburn, and use of sunbeds and sunlamps. Chronic exposure, indicated by days of outdoor activity during adolescence and by occupation in recent adult life, was associated with significantly reduced risk. Subgroup analyses showed: no major risk differences by body site of melanoma: stronger association of lentigo maligna melanoma with intermittent exposure; more pronounced effects of beach vacations and sunburn in younger subjects; and consistently higher risks for intermittent exposures among subjects with skin more susceptible to burning. Conclusions. The data lend limited support to the hypothesis of increased risk associated with

intermittent UV exposure. The findings suggest that future studies should take age at diagnosis, host susceptibility and histological subtype into account

N2 - The effects of a classroom-based, short-term Interpersonal Cognitive Problem-Solving programme for 7- and 8-year-old children were assessed immediately after a 4-week intervention programme and again after a 4-week follow-up period. A previous study implementing such a short-term programme relied on sociometric testing to measure the social effectiveness of the training and failed to find any changes in social status. The present study incorporated playground observations and found behavioural improvements immediately after training and after the follow-up period for the experimental group. However, confirming the previous study, no significant differences in sociometric status were found. The results highlight the limitations of sociometry as a measure of the effectiveness of a programme of training in Interpersonal Cognitive Problem-solving

N2 - Purpose: Nonoperative management of blunt hepatic injury (BHI) has become widely accepted in hemodynamically stable children without ongoing transfusion requirements. However, late hemorrhage, especially after discharge from the hospital can be devastating. The authors report the occurrence of serious late hemorrhage and the sentinel signs and symptoms in children at risk for this complication. Methods: Nonoperative management of hemodynamically stable children included computed tomography (CT) evaluation on admission and hospitalization with bed rest for 7 days, regardless of injury grade. Activity was restricted for 3 months after discharge. Hepatic injuries were classified according to grade, amount of hemoperitoneum, and periportal hypoattenuation. Results: Over 5 years, nonoperative management was successful in 74 of 75 children. One child returned to the hospital 3 days after discharge with recurrent hemorrhage necessitating surgical control. Review of the CT findings demonstrated that he was the only child with severe liver injury in all four classifications. A second child, initially treated at an outside hospital, presented 10 days after injury with ongoing bleeding and died despite surgical intervention. Only the two children with delayed bleeding had persistent right abdominal and shoulder discomfort in the week after BHI. Conclusions: Our findings support nonoperative management of BHI. However, late hemorrhage heralded by persistence of right abdominal and shoulder pain may occur in children with severe hepatic trauma and high injury severity scores in multiple classifications

N2 - Limited data are available on exercise capacity after surgery in young heart transplant recipients. To examine this question we assessed cardiorespiratory responses to exercise in young heart transplant recipients and healthy controls. We then sought a relation between the patients's exercise performance and three clinical post-transplant factors (time since transplantation, rejections per year and immunosuppressive drugs). Fourteen

consecutive heart transplant recipients (6 girls and 8 boys, mean age 9.4 ± 0.8 years, range 5-15 years) and 14 healthy matched controls underwent a Bruce treadmill test to determine duration of test, resting and maximum heart rate, maximum systolic blood pressure, peak oxygen consumption ($\text{VO}_{2\text{peak}}$), cardiac output and oxyhemoglobin saturation. Duration of test and heart rate increase were then compared with time since transplantation, rejections per year and immunosuppressive drugs received. Patients completed a questionnaire about their physical activity in and out of school and the reasons for eventual prohibition. Transplant recipients had tachycardia at rest (126 ± 4 b/min; $p < 0.001$). During exercise they had significantly reduced tolerance (9.3 ± 0.4 min; $p < 0.001$), maximum heart rate (169 ± 5 b/min; $p < 0.05$) and cardiac output (5.65 ± 0.6 l/min; $p < 0.05$), and a heart rate increase from rest to peak exercise lower than controls ($p < 0.001$), but a similar $\text{VO}_{2\text{peak}}$. Heart rate increase correlated significantly with post-transplant time ($r = 0.55$; $p < 0.05$), rejections per year ($r = -0.63$; $p < 0.05$) and number of immunosuppressive drugs ($r = -0.60$; $p < 0.05$). Cardiorespiratory functional assessment shows that young heart transplant recipients have significantly reduced exercise capacity. Heart rate increase depends on immunosuppressive drugs, numbers of rejections and time since transplant. After surgery few of these children do physical activity outside school, possibly owing to overprotective parents and teachers and to a lack of suitable supervised facilities

N2 - Epidemiological studies performed on children and young adults indicate that the prevalence of asthma has increased over the past decades in a number of countries. Since genetic determinants alone are unlikely to explain these findings, environmental factors are expected to have an important impact on the prevalence of this disease. Environmental pollution, among many other factors, may play a role in the initiation and manifestation of asthma. However, there is little epidemiological evidence for a causal association between the classical major outdoor air pollutants, such as SO₂ or particulate matter, and asthma. Evidence for an association between air pollution from motor vehicles and asthma is still controversial. Thus the indoor environment and other environmental determinants - including lifestyle factors - are likely to be more important as causes of asthma. Epidemiological studies are able to evaluate the effects of environmental factors on the health of human populations in their usual environments. In addition, they can measure associations between long-term environmental exposures and health outcomes. By using refined techniques for exposure and disease assessment, as well as time and cost-effective study designs, environmental epidemiology will increase the knowledge about the role of pollution as a possible cause of asthma. N2 - To stress a point made earlier, whether backyard or Little League, the tone of the youth sports experience is greatly influenced by the player and team selection process. All possible steps should therefore be taken to ensure that the draft is held on high moral ground, and that the adult participants, even on the Major Little League level, behave cooperatively rather than competitively. If it is the community's hope that Little League will 'build character, and not characters,' it must embrace Shields and Bredemeier's work and flood the Draft Room with the four virtues of compassion, fairness, sportspersonship, and integrity. In one attempt to achieve fairness and balance, some leagues enter player evaluations into a data base and allow a properly programmed computer to project equal teams. It might be best, however, to borrow a page from backyard baseball, and make team selection a more cooperative venture. Wolff has proposed such a draft model. He recommends that each child's name be placed on a big blackboard at the beginning of the draft. All assembled give their assessment of each child's baseball ability, and a consensus skill-level number (one through five) is entered next to each player's name. If there are 72 names, and the league wishes to form six teams of 12 players each, dividing up the rated players so that the skill levels balance would assure everyone (coaches, parents, the league, and by extension, the community) that the teams were of relatively equal strength. No coach at this point would know to which team he or she was being assigned, so there would be no motive for 'stacking' a given team. Each team would be designated by a letter of the alphabet, and the six letters would be thrown into a hat. The six coaches would then blindly pick a team from the hat. If a coach desired that his or her child play on his or her team, fair adjustments (trades) could be made subject to majority agreement. The three draft models can be summarized as follows: Draft Model 1 Public tryouts Previous year rating Coach makes selections Can be very competitive, lacking in 'character' Can result in very unequal teams Draft Model 2 Player evaluations placed into a data base Properly programmed computer projects equal teams Draft Model 3 All names placed on a blackboard Relative merits of players discussed Equal team drawn up and placed into a hat Adjustments can be made for coach's child If practical, this author suggests that coaches not pick a name for the team until the first team meeting or practice, when that task can be given to the children. In a symbolic way, this returns some of the sport to them while encouraging social interaction among new teammates, and helping the coach detect who the leaders are. Names of professional teams in the major sports, especially baseball, are to be avoided, as they fuel longstanding unconscious associations and fantasies, and may subtly tilt all participants toward the professional 'win at all costs' mentality. No one draft model is perfect for every town, and even the most ethical attempt to achieve balance among teams can be severely tested by parents who request that their athlete be placed on the same team as another child for social or car pool reasons. Such requests are not inviolate, however. For example, they do not usually dictate placement in school classes, and car pools are frequently disrupted when children, in individual sports such as Tae Kwan Do, reach different ability levels, and so attend practices at different times. Baseball is no longer the national pastime and, as we approach the millennium, American children have too many other attractive, competing interests and time demands to spontaneously organize a pick-up game. One coach shared with the author that his saddest moment in CAP League came when he arrived at 6 PM at a field that had been 'reserved' for his team, and found a group of boys who were playing a pick-up game. The coach's impulse was to set his boys free so that all could mingle and organize their own game. He bemoaned the fact that he had to ask the interlopers to leave so that his team could practice. Realistically, players live further from each other in the suburbs and it is hard to get a game together. It is frequently unsafe for children 8, 9, and 10 years of age to be at a playground or sandlot unsupervised by an adult. Certainly walking home at dusk, even in pairs, after a baseball game can be dangerous in many neighborhoods. Smith and Smoll and many others have therefore concluded that the real issue is not whether adult organized youth sports should exist, but rather how we can increase the likelihood that the outcome of participation will be favorable to our children. A favorable outcome hinges on the two main variables mentioned at the beginning of this article. Psychiatrists have the expertise to affect both of these variables positively and, in so doing, move one step closer to a youth sports system that is true to Carl Stotz's original vision, a gift, not a burden, to our children

N2 - This review examines whether there is a direct or indirect relation between damp or mould in the home and respiratory health. Home dampness is thought to have health consequences because it has the potential to increase the proliferation of house-dust mites and moulds, both of which are allergenic. The results from the many studies conducted to investigate whether damp and mould are associated with health outcomes are difficult to compare because the methods of measuring exposures and health outcomes have not been standardized. However, the studies that have been conducted in children are probably the most reliable because the confounding effects of active smoking or occupational exposures are absent, and because the presence of symptoms of cough and wheeze have been consistently investigated in many studies. The increased risk of children having these symptoms if the home has damp or mould is fairly small with an odds ratio that is generally in the range 1.5-3.5, these estimates being statistically significant when the sample size has been large enough. This range is consistent with the measured effects of other environmental exposures which are considered important to health, such as environmental tobacco smoke or outdoor air pollutants. The potential benefits of reducing mould in the home have not been investigated, and the few studies that have investigated health improvements as a result of increasing ventilation or reducing damp in order to reduce house-dust mite levels suggest that this intervention is expensive, requires a large commitment, and is unlikely to be successful in the long term. This implies that houses need to be specifically designed for primary prevention of respiratory problems associated with indoor allergen proliferation rather than using post hoc procedures to improve indoor climate and reduce allergen load as a secondary or tertiary preventive strategy

N2 - Objective: To map the frequency (prevalence) of torture victims among parents in asylum seeking Middle Eastern refugee families, to map the occurrence (prevalence) of experiences of war and other forms of organised violence among the children in these families, to map the occurrence (prevalence) of emotional symptoms and behavioural problems among the children, and to identify risk indicators and modifying factors for anxiety symptoms among the children. Design: Interview with parents using a structured interview questionnaire developed for this study. Validated through a blinded semi-structured interview conducted with approximately 1/3 of the families. Auspices: The study has been carried out by the Rehabilitation and Research Centre for Torture Victims (RCT) in cooperation with the Danish Red Cross. Material: Structured interviews with parents regarding 311 children aged 3-15 from 149 families, all registered as asylum seekers from the Middle East between February 1, 1992 and April 30, 1993. The response was 90.4%. Principal variables: background (past-past) - social and demographic data; trauma complex (past) - war-related life circumstances (conditions) and experiences of war and other forms of organised violence such as loss, separation, direct exposure to violence and witnessing acts of violence (specific events and changes of life conditions); present life context (past-present) - family circumstances upon arrival in Denmark; effect (present) - the child's current psychological state. Results: 28% of the parents (44% of the fathers and 13% of the mothers) had been tortured, to the effect that 51% of the children were part of a family including a survivor of torture. The most frequent specific types of violence-related events or circumstances were 'lived in a refugee camp outside the home country' (92%), 'lived under conditions of war' (89%) and 'been on the run with parents' (89%). Twenty percent of the children had lost one parent, and another 60% had been separated from one parent for more than a month. The highest prevalence of emotional symptoms were found within the anxiety dimension, as 67% of the children were

assessed as being clinically anxious. The most important risk indicators for anxiety were 'lived in a refugee camp outside the home country', 'part of a torture surviving family', 'lack of opportunities for play with other children', 'beaten/kicked by an official', and 'loss of father'. Current parental behaviour was also an important risk indicator for anxiety, if the mother or father hit or punished the child more than was the case prior to arrival in Denmark. The most important anxiety modifying factor was arrival in Denmark in the company of both parents. Conclusions: Asylum seeking refugee children from the Middle East have had many experiences of war and other forms of organised violence. The children frequently reacted with anxiety and with other symptoms of emotional instability. Prevalent anxiety symptoms correlated both with previous living conditions and present family situation. Living under prolonged conditions influenced by war and other forms of organised violence (prevalence) were found to a higher degree to be risk indicators for anxiety than were specific events or changes of life conditions (incidence)

N2 - The relationship between obesity and traumatic dental injuries was evaluated in a study population of 938 6- to 11-year-old schoolchildren from Rome, Italy, and it was suggested by the lifestyle and the physical activity of obese children, which, according to many authors, is different from the lifestyle of other children. The subjects were examined at school: presence and type of dental injury, overjet, incisor protrusion, upper lip incompetence and presence of obesity were recorded. Trauma predisposition was evaluated with a questionnaire

investigating the behaviour which may predispose to impacts. Six out of eight questions in this questionnaire concerned the children's lifestyle and the trauma predisposition score was therefore also considered an estimate of lifestyle and physical activity. The dental injury prevalence of the study population was 21.3% and obesity prevalence was 11.4%. Of the obese children 30.8% had dental injuries vs. only 20.0% of non-obese subjects ($P = 0.007$). Obese children had only enamel and enamel-dentine fractures and the main reported trauma cause was indoor play; conversely, lean children also had other types of injuries and the most frequently reported cause was outdoor play. The main predisposing factors significantly affecting the probability of dental injury, evaluated with multiple logistic regression, were upper lip uncoverage (OR: 1.23; $P = 0.02$), overjet larger than 3 mm (OR: 1.68; $P = 0.001$) and obesity (OR: 1.45; $P = 0.01$). Surprisingly, trauma predisposition was a protective factor (OR: 0.50; $P = 0.00001$). The results of this study were explained by the significant inverse correlation between obesity and trauma-predisposing behaviour, thus suggesting that subjects frequently playing sports and lively games were not only less obese but also more skillful and, for this reason, less prone to trauma when they fell or sustained impacts

N2 - OBJECTIVES: To review playground injury statistics over a five year period in order to develop an awareness of how and where children in the United States are being injured. METHODS: All data are based on the United States Consumer Product Safety Commission's National Electronic Injury Surveillance System (NEISS) for playground related injuries during 1990-4. The surveillance data includes injuries recorded in more than 90 hospital emergency departments located throughout the United States. RESULTS: Each year there are roughly 211,000 preschool or elementary school-children in the United States who receive emergency department care for injuries associated with playground equipment. On average, 17 of these cases result in death. 70% of all injuries occur on public playgrounds, with nearly one third classified as severe. Swings, climbers, and slides are the pieces of playground equipment associated with 88% of all NEISS reported injuries. Falls to the surface are responsible for 70%. CONCLUSIONS: NEISS playground injury statistics contribute to our understanding of playground injuries. By identifying where and how children are injured, suggestions can be made in an attempt to make playgrounds safer

N2 - This study investigates the relationship between behavioral and other modifiable factors and blood lead in children living in a lead-mining community and in a comparison group of children. Children six to 71 months of age were selected from a community that was heavily contaminated with lead-mining waste and from a comparison community. Participants were interviewed, and venous blood was collected for lead analysis. Environmental measurements of soil, dust, and paint were made. Study results indicate that average blood lead levels and environmental measurements were significantly higher in the mining community. Factors that were related to blood lead levels included income, education, home ownership, age of home, playing in grassy areas rather than dirt, putting nonfood items in mouth, bathing and washing practices, number of hours playing outside, taking nonfood items outside, swallowing nonfood items, and putting paint chips in mouth. These factors explained more of the variation in blood lead levels in the control group than in the mining group. Lead intervention strategies that consist only of education designed to modify behavior might be less effective in high-exposure areas such as those where lead-mining and smelting operations occur. Interventions that combine education with remedial activities are more effective in prevention of lead exposure

N2 - Researchers in this study have attempted to determine whether integrating generalization promoting strategies into intervention procedures would enhance the generalization and maintenance of social skills to peer

interactions in a preschool child with language delays. This intervention took place in the natural environment of the day care facility where the child was enrolled. A multiple baseline across behaviors design addressed social response behavior, approach behavior, and play organizers. The intervention utilized a prompting and social reinforcement procedure with minimal adaptations of the ongoing classroom activities to systematically improve the target child's peer interactions. Several generalization promoting strategies were also used. Improvements in all three types of behavior and generalization of treatment effects across persons, settings, and time were observed. These results lend support for the value of integrating several generalization promoting strategies pre-experimentally into the intervention instead of relying on post hoc evaluation of intervention

N2 - The Mash program has been activated in Nevers Hospital after scholar food intoxication. 110 children were concerned and 30 have been hospitalized. Scholar infirmary did not evaluate the food exposure as well. The select medical center has been installed with delay in school, where a large number of victims have been examined in second time. Emergency department was not saturated. A department with 40 beds was created with medical announcement. In France, declaration to health authorities is mandatory, epidemiological research begin as soon as possible. White Program test was a good exercise for medical personnel outside and inside the hospital

N2 - Due to concern regarding poor ambient air quality in the Fraser Valley, a series of exposure and health effects assessments were performed to evaluate the impact of summer photochemical air pollution. In 1992 and 1993, three groups of individuals were selected for personal monitoring of ozone exposure, based on prior expectations of their activity patterns. The first group spent a majority of the work day indoors or commuting, the second group spent more time outdoors and the third group spent the entire personal monitoring period outdoors. Time-activity data were collected for the first two groups and differences in personal ozone exposures were found to be associated with the fraction of time a person spent outdoors. Similarly, differences among groups in the mean ozone exposure were associated with time spent outdoors. These results and other exposure information were used to design a study of the health impacts of summer ambient air pollution that was conducted during the time period of the Pacific '93 held campaign. Aerosol acidity levels in the Fraser Valley were observed to be very low in 1992 so the health study focused on the effects of ozone exposure. The subjects were adult farm workers (26 male, 32 female; mean age 44.4, range 10-69) who spent the entire working day outdoors (a subset of group 3 above). Lung function measurements were made twice daily on each subject, once before and once after their work shift, from 23 June-26 August 1993. Ambient O₃ concentrations were measured continuously at several nearby locations. In a regression model including individual lung function level, date, temperature and daily maximum O₃, a statistically significant (p < 0.001) negative association was observed between ozone and lung function. This association between ozone and reduced lung function was still apparent the following day, suggesting a persistent ozone effect. These results indicate that exposure to ambient O₃ concentrations below either the U.S. NAAQS (120 ppb) or

the Canadian Air Quality Objective (82 ppb) may have an adverse effect on the lung function of people engaged in outdoor work for several hours a day

N2 - A study has been conducted on a sample of 1366 children attending compulsory school in order to examine the relationship between the time spent watching television and physical activity. A distinction has been made according to the time of the day when the children watch television: before going to school, back from school throughout the afternoon, and after dinner. As far as physical activity is concerned, the weekly frequency and the duration both of the organized physical activity and of the outdoor games have been considered separately. The practice of organized physical activity does not have a considerable influence on television viewing unlike the physical activity carried out by children after school. In the afternoon, when children dedicate themselves to outdoor games and sport activities, the time spent watching television is inversely proportional to the physical activity practiced 3 hours per week by the youngest children and 5.9 by the grown-ups, against 5.6 and 7 hours per week spent by those children who attend primary school and by the adolescents of secondary school: those who did not practice any physical activity (group A and D), those who practiced physical exercises less than an hour a day (group B and E) and more than an hour a day (group C and F). It has been noted that, considering the groups of those children who practiced physical activity for a longer period of time, the hours spent watching television were significantly lower as far as the children attending primary school are concerned (2.55+/1.19 vs 2.39+/1.12 vs 2.16+/1.14) ($p < 0.005$ A-C, $p < 0.05$ B-C) and those attending secondary schools (2.73+/1.15 vs 2.55+/1.03 vs 2.39+/1.02) ($p < 0.01$ D-F, $p < 0.05$ E-F). These data is mainly due to a variation in the number of hours spent watching television during the afternoon by children attending both primary (1.28+/0.87 vs 1.19+/0.86 vs 0.99+/0.81) ($p < 0.001$ A-C, $p < 0.05$ B-C) and secondary

schools (1.00±0.88 vs 0.89±0.84 vs 0.73±0.69) ($p<0.01$ D-F, $p<0.01$ E-F). The negative effects of a prolonged time spent watching television could be contrasted promoting any kind of physical activity and of outdoor games

N2 - Due to the scarcity of land in Hong Kong, most of the children playgrounds are being built on marginal lands which may be subjected to serious atmospheric emission. Hence, children playing in these playgrounds are exposed to a potential health risk. The aim of this study was to evaluate heavy metal pollution in children playgrounds using surface dusts and soils as indicators. Surface dust and soil samples were collected from seven selected playgrounds with different levels of traffic volume and urban development for the determination of total Cd, Cu, Pb and Zn concentrations. The mean Cd, Cu, Pb and Zn concentrations of surface dusts were 2.63, 201, 302 and 1517 mg kg⁻¹ respectively, whereas for soils they were 2.30, 28.4, 195 and 237 mg kg⁻¹. The results indicated elevated concentrations of Cd, Cu, Pb and Zn in both dust and soil samples especially for those samples collected from busy commercial and industrial areas i.e., Mei Foo, Tsim Sha Tsui and North Point. Surface dusts were enriched relative to soils in each metal, on average, by factors ranging from 1.1 to 7.1. The metal contents in dust and soil samples were significantly correlated with traffic volume. Significant correlations were also noted among all the metals studied indicating that Pb and Zn in the samples may be due to the same source i.e., automobile. The soil Pb and Zn contents of Mei Foo and North Point were higher than the investigation level of the Dutch Criteria for these two metals which indicated that further investigation is required to confirm their health hazard on children playing in these playgrounds

N2 - Objectives: To identify factors associated with the entrapment of children by clothing drawstrings and to explore intervention strategies that could be implemented through a voluntary standard to reduce or eliminate injuries. Design: Fifty eight cases reported to the US Consumer Product Safety Commission between January 1, 1985, and June 30, 1995, that involved the entrapment of children's clothing drawstrings in other products were reviewed. A computerized database was created for information about the victim, clothing, object in which the drawstring caught, and injury circumstances. Factors were analyzed by their contribution to preevent, event, and postevent phases, using a modified Haddon matrix. Results: Two primary and distinct hazard patterns were identified: (1) strangulation by hanging associated with the snagging of a hood or neck drawstring in a gap between segments of playground slides and (2) vehicular dragging associated with the snagging of a waist or bottom drawstring in a school bus handrail or door. Conclusions: Potential intervention strategies targeting clothing drawstrings include (1) remove drawstrings; (2) shorten drawstrings, sew them to the channel, and remove toggles and knots; and (3) design breakaway drawstrings. Based on available data, the only feasible intervention is removal of drawstrings. Improved supervision and increased awareness are in themselves infeasible interventions, but they can be interim or supplemental measures

N2 - Ozone constitutes a major outdoor air pollutant. Ambient air quality standards are frequently exceeded in large parts of Europe each summer. The pathophysiologic mechanism is related to local irritation of afferent nerve fibres in the airways as well as to inflammation of the upper and lower airways which is dominated by an influx of polymorph nuclear granulocytes. Decrements of lung function depend on the inhaled dose (concentration x time of exposure x minute ventilation) and tend to decrease after recurrent exposure. Due to physical activity pattern children are particularly susceptible to the effects of ozone. However, at current exposure levels respiratory symptoms are unlikely to occur. Data on long term effects such as morbidity or impaired growth of the respiratory tract of children are sparse. Hence, chronic adverse effects cannot be currently excluded

N2 - During a previous study on the Gram-negative anaerobic microflora in children we frequently isolated a non-pigmented Prevotella-like species with phenotypic characteristics not conforming to those of previously described species at the time. Among recently described Gram-negative anaerobic bacilli isolated from gingival crevices Porphyromonas catoniae (Bacteroides D26) most closely resembled our isolates biochemically which also typically produced a large amount of propionic acid. Sixty-three isolates originated from oral mucosal surfaces pooled to saliva and from the gingival crevices of 23 healthy children (mean age 32 months). In addition, one biochemically similar strain which was isolated from an abdominal abscess was included in the tests. The aim of the present study was to determine the cellular fatty acid (CFA) composition for the precise identification of our isolates, and further, to determine the enzyme profiles by API ZYM to emend the description of this species. CFA profiles agreed with the identification of Bacteroides D26 (*P. catoniae*), API ZYM patterns revealed positive reactions for beta-galactosidase, alpha-glucosidase (except for one isolate), N-acetyl-beta-glucosaminidase and alpha-fucosidase, and variable reactions for leucine arylamidase, trypsin, chymotrypsin and alpha-galactosidase. However, numerical analysis of the CFA data separated this species into at least three subgroups. Twenty-five oral isolates formed one subgroup which most closely resembled the type strain (ATCC 51270). The ubiquitous presence of *P. catoniae* in moderate numbers in the studied oral samples suggests that this anaerobic species belongs to the normal oral flora of children even at this young age; nevertheless, it may occasionally act as an opportunistic pathogen outside the oral cavity

N2 - To examine the possibility of interspecies transmission and genetic reassortment of influenza viruses on farms in Southern China, we surveyed 20 farm families living outside the city of Nanchang who raised pigs and ducks in their homes. Weekly interviews of family members and virus isolation studies of throat swabs and faecal samples, collected from September 1992 to September 1993, established the seasonal pattern of respiratory tract infections in these families and identified 11 influenza viruses (6 in humans and 5 in ducks). Most of the human isolates were type A of H3N2 subtype. Serologic studies of farm pigs indicated infection by

the same human viruses circulating in family members, but there was no evidence that either swine or avian viruses had been transmitted to pigs. Eight of 156 human serum samples inhibited the neuraminidase activity of two of the duck isolates, raising the possibility of interspecies transmission of these avian viruses. Genotype analysis of duck and human isolates provided no evidence for reassortment. Our findings support the concept that intermingling of humans, pigs and ducks on Chinese farms is favourable to the generation of new, potentially hazardous strains of influenza virus

N2 - Although gender-related issues are often cited as playing an important part in determining patterns of illicit drug use, little is known about the differences between male and female drug users outside treatment settings. In the present study, 558 heroin and cocaine users recruited from a range of community settings were interviewed by Privileged Access Interviewers. The women were found to be younger than the men. Differences existed in their drug use; women used smaller amounts, for a shorter duration, and were less likely to inject than

their male counterparts. No differences existed between treatment contact for the heroin users, but differences were found among the cocaine-using sample, with men being more likely to have contacted a treatment agency. Men were financing themselves through more criminal activities than women. Drug-using sexual partners were found to be an important influence over women's drug use, with most female injectors having been given their first injection by a male sexual partner. Structural differences in patterns of drug use found among female drug users and the influence of male sexual partners are likely to play an important role in determining appropriate treatment options for women drug users

N2 - Although several German schools have developed and tested concepts of a goal-directed health education, a stable and continuous implementation is missing. In this field free-practising physicians can support public health efforts. In the area Bruchsal/Ostringen it is demonstrated, that especially those primary care physicians, who work according to the 'Three-Level Concept of Free-Practising Physicians', can successfully use their geographical and social nearness to schools in their neighbourhood for a long-lasting implementation of recurring health-related activities. Within the years 1389 students in schools, further ca. 500 outside schools, were directly included in interactive learning in the framework of preventive measures, e.g. during school health days, 10 physicians (4 of them continuously) cooperated in these activities, which had been planned in close collaboration with teachers and parents, considering the different age groups. From the very beginning - although sometimes limited in scale - each activity was evaluated. Pupils in the age group 10-12 years generally showed the highest interest in health-related topics. Two years after specific school activities 28-40% of the student's family members reportedly cared more intensively for a health-related diet, 17-26% were physically more active. Promising are the results with respect to smoking: one fifth of the smoking students intended to quit as a consequence of the health activities in their schools

N2 - Regular physical activity is recommended for health maintenance in adolescence, but basic descriptive epidemiological data are lacking for this age group. The present study examined socioeconomic status (SES), ethnic, and sex differences in physical activity in a multiethnic sample of 1871 high school students in San Diego, California. Surveys were completed in required classes by a diverse sample of students from a low income school district and by Angle students from a nearby more affluent district. Boys reported more vigorous exercise outside of school and during school physical education, as well as more participation in sports teams, but girls reported taking more activity related lessons and classes. High-SES students had more frequent physical education classes, spent more time in vigorous exercise in those classes, and participated in more activity lessons outside of school. There were few ethnic differences on summary physical activity or physical education variables. There were no SES differences, but there were ethnic differences on 5 of 22 specific activities. Demographic differences in 25 psychological, social, and environmental variables that may influence physical activity were also examined. Differences between boys and girls were found on several variables, which may explain some of the boys' higher activity levels, Ethnic and/or SES differences were found in 10 of 25 potential correlates of physical activity. These data may be used to identify specific activities that may be preferred by subgroups of adolescents and specific mediating variables that can be targeted in physical activity promotion programs for adolescents

N2 - An activity deficit hypothesis was posited that children with movement difficulties are less physically active during recess than age- and gender-matched controls without movement difficulties. Criteria used in identifying children with movement difficulties were (a) a score of at least 4 on the Test of Motor Impairment, (b) regular physical education student, and (c) age 80 to 109 months. An observational study was conducted over a 2-month period in recess settings with 52 subjects. Findings revealed that during recess time, children with movement difficulties were vigorously active less often, played less often with large playground equipment, were not observable for significantly more time, and spent less time in positive social interactions with others of their own gender. Accordingly, it was concluded that the data support the activity deficit hypothesis

N2 - In patients with cystic fibrosis, infection with *Pseudomonas cepacia* is associated with poor outcomes. However; the epidemiology of *Burkholderia cepacia* is still unclear. The aim of this study was to investigate the epidemiology of *Burkholderia (Pseudomonas)* cepacia colonization among cystic fibrosis patients attending the Verona CF Centre, a large specialized unit to which patients from different parts of Italy are admitted. We used a genome finger-printing system to analyse the nucleotidic structure of *B. cepacia* isolates from 60 colonized cystic fibrosis patients. Forty-two different finger-printing patterns were identified. Thirty-two patients were colonized by individual *B. cepacia* strains (53.3%). The remaining 28 subjects were divided into 10 different subgroups, each exhibiting a distinct strain of *B. cepacia* (46.7%). Nevertheless, direct, person-to-person transmission was evident in only 10 cases (16.7%). The stability, up to 12 months, of the *B. cepacia* colonizing strain was documented in 36 individuals. Consistent with other reports, risk of *B. cepacia* transmission between cystic fibrosis patients through intimacy or nosocomial contact was found in our study. However, besides low contagiousness, our data suggest that the environmental reservoir of *B. cepacia* outside the hospital seems to play an important role in *B. cepacia* infection of our cystic fibrosis population

N2 - Residential exposure to elemental mercury typically involves small amounts (e.g., the approximately 0.3 mL in a thermometer). During August 1994, five children residing in a neighborhood in Palm Beach County, Florida, found 5 pints of elemental mercury in an abandoned van. During the ensuing 25 days, the children shared and played with the mercury outdoors, inside homes, and at local schools. On August 25, 1994, a parent notified local police and fire authorities that her children had brought mercury into the home. On the same day, 50 homes were immediately vacated and an assessment of environmental and health impacts was initiated by the State of Florida Department of Environmental Protection, the Health and Rehabilitative Services of the Palm Beach County Public Health Unit, and the U.S. Environmental Protection Agency. This report summarizes the investigation of this incident.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - In this article we report on the support facilities for child mental health after the earthquake in Kobe. We believe that the most important function is the ability to cope with the confused situation on-the-spot as there were no means of transport and facilities for medical treatment had been paralyzed. Establishing contact with people outside the stricken area is of great help immediately following a disaster. After the earthquake many children were psychologically confused and people were therefore concerned with mental health care, especially for their children. However, there were only a few cases of patients seeing their doctors in medical centers. They needed information booklets or case reports to refer to. Five months after the disaster symptoms such as acute uneasiness or terror seem to be few and severely ill patients have started to recover. There are few case reports on children who have had difficulties in adapting to educational organization such as day nurseries and elementary schools. However, recently there has been an increase in the number of bone fractures possibly due to decline in resistance. Means of dealing with child mental health are now being examined because some children are still suffering post-traumatic symptoms. In this report we analyze the rapid recognition of children's mental health problems at home, in the school and in society and examine the importance of close mother-child, family and relative relationships

N2 - Purpose. To study the development of grating acuity in children treated for dense congenital unilateral or bilateral cataract and to examine how variations in treatment affect grating acuity during early childhood.

Methods. The author's used optokinetic nystagmus (OKN), preferential looking (PL), or both to measure the grating acidity of children treated for congenital cataract in line eye (n = 63) or both eyes (n = 77) whenever possible from the time of treatment until 3 years of age. At each age, the authors compared patients' monocular acuity to that children with no history of eye disorders. Results. The OKN acuity of treated eyes did not improve with age and was abnormal by 12 months of age. In contrast, PL activity improved with age, and acuity of most treated eyes was not outside normal limits until 24 to 30 months of age. Nonetheless, at 12 months and at 3 years of age, PL acuity correlated significantly with age at treatment in children who had bilateral cataract. In children who had unilateral cataract, PL acuity correlated significantly with the number of hours per day the good eye had been patched since treatment. Children whose good eye was patched fewer than 3 hours per day did significantly worse than children treated at a comparable age for bilateral congenital cataract. However, children whose good eye was patched at least 3 hours per day had PL acidities similar to those of children treated at a comparable age for bilateral congenital cataract. Conclusions. Children treated for congenital cataract show deficits in grating acuity, with the deficit apparent earlier in OKN acuity than in PL acuity. At least by 1 year of age, visual development has begun to be influenced by the age at treatment and, in children treated for unilateral cataract, by patching of the good eye

N2 - Background: Exercise is one of the most common precipitants of acute asthma encountered in clinical practice. The development of airflow limitation that occurs several minutes after vigorous exercise, i.g. exercise-induced bronchoconstriction (EIB), has been shown to be closely correlated with the nonspecific bronchial hyperresponsiveness, which is the hallmark of bronchial asthma. All previous reports that assessed the correlation of EIB to nonspecific bronchial hyperresponsiveness have focused on airway sensitivity (PC_{20}) to inhaled bronchoconstrictor such as methacholine or histamine. However, maximal airway narrowing (MAN), reflecting the extent to which the airways can narrow, when being exposed to high dose of inhaled stimuli, has not been studied in relation to the degree of EIB. Methods: Fifty-six children with mild asthma (41 boys and 15 girls), aged 6 to 15 years (mean + SD, 9.9 + 2.5 years) completed this study. Subjects attended the laboratory on two consecutive days. Each subject performed the high-dose methacholine inhalation test at 4 p.m. on the first day. The dose-response curves were characterized by their position (PC_{20}) and MAN, which was defined as maximal response plateau (MRP: when two or three data points of the highest concentrations fell within a 5% response range) or the last of the data points (when a plateau could not be measured). On the next day, exercise challenge, free running outdoors for ten minutes, was performed at 9 a.m. FEV₁ was measured at graduated intervals, 3 to 10 minutes apart, until 60 minutes after exercise. Response (the maximal FEV₁ from the pre-exercise value) was classified arbitrarily into three groups; no response (-) EIB: FEV₁ < 10%, equivocal response (+)EIB: 10% < ~FEV₁ < 20%) and definite response (+) EIB: FEV₁ > 20%). Results. 1) When geometric mean PC_{20} of the three groups were compared, PC_{20} of (+)EIB group was significantly lower than that of (-)EIB group. 2) There was a close correlation between PC_{20} and the severity of EIB in the whole group ($r = -0.568$, $p < 0.01$). 3) Of the total 56 subjects, MRP could be measured in 36 subjects, and the MRP of these subjects correlated fairly with the severity of EIB ($r = 0.355$, $p < 0.05$) 4) The MAN of (+)EIB group was significantly higher than that of (-)EIB group ($p < 0.01$). 5) The MAN correlated well with the severity of EIB in the whole group ($r = 0.546$, $p < 0.01$). Conclusion: The degree of MAN as well as bronchial sensitivity (PC_{20}) to methacholine is correlated well with the severity of EIB. The results suggest that the two main components of airway hyperresponsiveness may be equally important determinants of exercise reactivity, although the mechanism may be different from each other. The present study also provides further evidence that EIB is a manifestation of the increased airway reactivity characteristic of bronchial asthma

N2 - Three data sets describe the pattern of gunshot injuries to children from 1960 to 1993: The Harlem Hospital pediatric trauma registry (HHPTR), the northern Manhattan injury surveillance system (NMISS) a population-based study, and the National Pediatric Trauma Registry (NPTR). A small case-control study compares the characteristics of injured children with a control group. Before 1970 gunshot injuries to Harlem children were rare. In 1971 an initial rise in pediatric gunshot admissions occurred, and by 1988 pediatric gunshot injuries at Harlem Hospital had peaked at 33. Population-based data through NMISS showed that the gunshot rate for Central Harlem children 10 to 16 years of age rose from 64.6 per 100,000 in 1986 to 267.6 per 100,000 in 1987, a 400% increase. The case fatality for children admitted to Harlem Hospital (1960 to 1993) was 3%, usually because of brain injury, but the majority of deaths occurred before hospitalization. During the same period, felony drug arrests in Harlem increased by 163%. The neighboring South Bronx experienced the same increase in gunshot wound admissions and felony arrests from 1986 to 1993. The NPTR showed a similar injury pattern for other communities in the United States. In a case-control analysis, Harlem adolescents who had sustained gunshot wounds were more likely to have dropped out of school, to have lived in a household without a biological parent, to have experienced parental death, and to have known of a relative or friend who had been shot than community adolescents treated for other medical or surgical problems. Since 1990, the Harlem Injury Prevention Program formed a coalition of school and community organizations joined by the District Attorney's Office in collaboration with the Tactical Narcotic Team (to eliminate drug selling from the schools and playgrounds), to provide safe, supervised activities for children. Data from 1990 to 1992 show a moderate decline in the incidence of gunshot wounds to children. Gun control legislation in conjunction with the community violence prevention activities are needed to curb the epidemic of gunshot injuries

N2 - Recent studies have reported that excessive TV viewing is associated with an increased probability of having cholesterol values of 200 mg/dl or higher. We have studied the relationship between excessive TV viewing and high levels of total and LDL-cholesterol. In addition, we have evaluated excessive TV viewing, lack of the practice of sports outside of school, and positive family history of hypercholesterolemia, heart attack, stroke, hypertension and diabetes mellitus as tests to detect children with hypercholesterolemia. For this purpose, 2224 children and adolescents between 6 and 18 years of age were studied. We have found that when compared to children who spent less than 14 hours per week watching TV, children aged 6 to 12 years and adolescent males aged 16 to 18 who spent more than 14 hours viewing the TV showed significantly higher mean levels of total cholesterol. Adolescent males from 16 to 18 years old also showed significantly higher levels of LDL-cholesterol. Excessive TV viewing was found to be strongly associated with the non-practice of sports outside of school. The percentage of subjects with a cholesterol value of 200 mg/dl or higher was found to be significantly higher in those children who watched TV for more than 14 hours a week ($p < 0.05$), did not practice sports ($p < 0.01$) and had a positive parental history ($p < 0.001$). A positive family history was found to be the strongest predictor of hypercholesterolemia. Excessive TV viewing, as well as the non-practice of sports, although associated with an increased risk of hypercholesterolemia, was not superior to family history as a test to detect children at risk

 N2 - The pharmacokinetic characteristics of ticarcillin and clavulanic acid were determined after the first dose (n = 22) and again under steady-state conditions (n = 16) in a group of infants and children. Study subjects ranged in age from 1 month to 9.3 years; all but 3 study patients were 6 months of age or older. Each patient received 50 mg of ticarcillin and 1.7 mg of clavulanic acid (30:1 ratio) per kg of body weight given intravenously every 4 hours. Elimination half-life, steady-state volume of distribution, and body clearance averaged 1.1 hours, 0.22 L/kg, and 2.7 mL/min/kg, respectively, for ticarcillin, and 0.9 hours, 0.4 L/kg, and 6.2 mL/min/kg, respectively, for clavulanic acid. A total of 71% of the ticarcillin and 50% of the clavulanic acid dose were excreted unchanged in the urine over the 4-hour sampling period. Corresponding renal clearances averaged 2.1 and 3.2 mL/min/kg for ticarcillin and clavulanic acid, respectively. No differences were observed between first dose and steady-state evaluations in the pharmacokinetic behavior of either agent. In contrast, the pharmacokinetic behavior of clavulanic acid was significantly different from that observed for ticarcillin. These pharmacokinetic data combined with known in vitro susceptibilities of important clinical pathogens support a dose of 80 mg of ticarcillin and 2.7 mg/kg clavulanic acid per kg body weight given as a fixed dose combination every 8 hours for the treatment of most systemic infections that occur outside the central nervous system

N2 - In both children and adults, it has been well established that the precise localization of a seizure focus allows for the best possible resection and outcome. Long-term invasive monitoring with DE has been the most widely used modality to evaluate patients with intractable seizures of temporal lobe origin. The study of epilepsy in children, however, requires assessment of the cause of the seizures with a resultant decision regarding the optimal modality of study for the particular problem. Complex partial seizures of medial temporal lobe origin without clear concordance, or lateralizing information are best studied using DE. With MR imaging anatomic localization, stereotactic insertion of DE can be performed accurately and relatively safely. The information obtained permits lateralization and focus localization if the lesion is within the medial structures. The ability of DE to study epilepsy outside of the medial temporal lobe, however, is suboptimal. Many centers have used surface electrodes to map temporal lobe foci successfully. SE and SGE have not been widely used in children. Subdural electrode arrays, however, are superior to DE in extratemporal epilepsy because the cortical surface contacts provide the best recordings of epileptiform activity from a wide range of extratemporal regions. The limitations of intraoperative ECoG in the awake child are well understood. It is rare that a child can undergo surgery under local anesthesia and cooperate to the extent necessary for definitive mapping of the seizure focus and eloquent areas. Thus, invasive long-term monitoring would seem ideal in the epileptic pediatric patient because it allows for a more relaxed pace in which to record events, and because of the indwelling nature of these electrodes, it is possible for the investigator to map eloquent areas of the brain before resection. This type of evaluation completely and accurately maps interictal and ictal activity, and through cortical stimulation or mapping of somatosensory areas by evoked potentials, eloquent areas of the brain, such as motor and speech regions, can be identified. This method is limited to older children because the young child often has inadequate cortical development to localize these areas definitively. One should note that in young children (under the age of 4 years), the absence of a response to standard cortical stimulation does not indicate nonfunctional cortex. Long-term intractable seizures and significant antiepileptic drug requirements may contribute to developmental and psychosocial deficiencies in the epileptic patient. Through early localization and surgical control of seizures, it is hoped that optimum development of behavior and intellect will not be impeded by repeated seizure activity or drug toxicity. Numerous reports have postulated that early surgical intervention that eliminates intractable seizures would result in an improvement in behavioral outcome. This hypothesis has been confirmed by others in patients who underwent not only resections for temporal lobe seizure foci, but also extratemporal resections. The authors, too, believe that through early evaluation, decisions regarding surgical intervention can be made for the relief of seizures. This early intervention may also alter the drug requirements and likely allow for a better developmental outcome in the pediatric epileptic population. To ensure optimal surgical resection, definitive localization through long-term invasive monitoring can be obtained in the young child with minimal morbidity. Noninvasive evaluation aids in the assessment of the proper monitoring modality for a particular patient. The authors have found these procedures to be useful and well tolerated modalities in the pediatric age group even in children as young as 1 year of age through days to weeks of recording time. Even with the

explosion of technology and functional neuroimaging, invasive monitoring can still aid in the selection of additional children as operative candidates for seizure surgery

N2 - Objective - To determine the incidence of acute symptomatic toxoplasma retinochoroiditis presenting to ophthalmologists for patients born in Britain and elsewhere. Design - Population based, cross sectional study.

Setting - 11 districts in south Greater London. Subjects-All patients ophthalmologists with symptoms toxoplasma retinochoroiditis in 1992-3. Main outcome measure - Intraocular inflammation in association with a retinochoroidal scar, active adjoining retinitis, and IgG serum antibodies to toxoplasma. Results - The estimated incidence of acute symptomatic retinochoroiditis for all people born in Britain was 0.4/100 000/year and for black people born in west Africa 57/100 000/year. If a mean of two symptomatic episodes per lifetime is assumed, 100 people born in Britain may be affected each year, about a fifth of the estimated 500-600 congenitally infected people born each year. Conclusions - A substantial proportion of people with acute symptomatic toxoplasma retinochoroiditis were born outside the country, and the number born in Britain was smaller than the number previously estimated to develop retinochoroidal lesions due to congenital toxoplasmosis. These findings suggest that prenatal screening for toxoplasmosis in Britain may be of limited benefit

N2 - Chagas' disease is caused by infection with the obligatory intracellular parasite Trypanosoma cruzi and affects several million people in Central and South America. The parasite can be transmitted not only by blood-sucking triatomine bugs but also by transfusion with infected blood. Therefore, serological screening of blood donors is important to prevent transmission of the parasite in endemic areas. Serological screening in blood banks can be now performed by using recombinant antigens and synthetic peptides in highly sensitive laboratory methods. In previous work we used recombinant DNA clones to study the reactivity of sera from Chagas' disease patients. We found that 51% of serum samples from symptomatic and only 25% of sera from

asymptomatic patients reacted with the SAPA clone (Shed Acute Phase Antigen), suggesting that reactivity might be related to active infection and symptoms. In this work we used sera from asymptomatic and symptomatic Chagas' disease patients to evaluate their reactivity against synthetic repeat peptides from clones 1, 2, 13, 30, 36 and SAPA. No differences in reactivity against the synthetic peptides were found when 74 symptomatic and 77 asymptomatic patients were compared. Therefore, the higher reactivity against SAPA recombinant DNA clone previously observed in symptomatic patients may be due to the recognition of epitopes located outside the repeated domain or the recognition of a repeated epitope which is not present or not represented on the SAPA repeat peptide

N2 - Flow cytometric analysis demonstrated that fresh human thymocytes contain only a low level of mature CD8⁺TCRalpha⁺ or CD8⁺ TCR⁺ cells and that they consist of ~70% double positive (DP) and ~10% double negative (DN) cells. These unfractionated thymocytes could be selectively expanded in vitro by stimulation with 12-o-tetradecanoylphorbol 13-acetate (TPA) and PHA in the presence of IL-2. The majority of the cells expanded from unfractionated thymocytes expressed CD3, TCRalpha and CD8 molecules after long-term culture (18 days). When highly purified DN thymocytes were expanded over a period of 18 days in the presence of DP cells, they also co-expressed CD3, TCRalpha and CD8 molecules on their surface. However, when purified DN thymocytes were expanded

alone, that is, in the absence of DP cells for 18 days, they expressed CD3-associated TCR, but not CD8 or TCRalphabeta. Despite the expression of measurable levels of IL-2 alpha and beta receptors, as well as a significant level of TCRalphabeta, purified DP cells failed to proliferate. These findings provide the first evidence, in humans, that the progression of precursor cells in the DN compartment to a later stage of differentiation can be induced outside the thymus and that DP cells can affect the development of TCR expression in proliferating DN thymocytes

N2 - The purpose of this study was to evaluate the clinical and neurophysiologic responses to oral prednisone therapy in a boy with enzymatically confirmed long-chain L-3-hydroxyacyl-CoA dehydrogenase deficiency in biopsied muscle and cultured skin fibroblasts. This boy presented with progressive limb girdle myopathy, recurrent myoglobinuria, peripheral sensorimotor axonopathy, and intraventricular conduction delays. Prior to prednisone therapy, at age 8 years, he exhibited marked distal weakness greater than proximal weakness with a waddling and high-steppage gait, Gowers' maneuver (10 s to rise from the floor), fatigue after 3-20 yards of walking and the ability to climb only 2 stairs. Serum levels of creatine kinase rose from 34 to 4,124 U/L following mild exertion. Nerve conduction studies revealed progressive axonopathy with secondary demyelination. Four weeks after initiation of oral prednisone (0.75 mg/kg/day) therapy, there was approximately a 100% increase in power and endurance. He was able to walk at least 100 yards before tiring, could rise from sitting on the floor in 3-4 s, and was able to climb 20 steps in 30 s. There was concurrent improvement in nerve conduction studies. Prednisone was gradually withdrawn over the next 4 months to 0.19 mg/kg/day; lower doses of 0.08 mg/kg/day resulted in a marked deterioration in power to the prior state. Although 0.19 mg/kg/day did not maintain the peak power achieved at 0.75 mg/kg/day, it provided adequate baseline power and endurance. It is concluded that there was a significant clinical and neurophysiologic response to prednisone at a dosage >0.16 mg/kg/day. Prednisone may stabilize muscle and neuronal plasma membranes, as well as the fatty acid oxidation enzyme complex in the mitochondrial membrane

N2 - The Preschool Play Scale (PPS) was used to rate the free play behaviors of 21 children with typical language development (control group) and 20 children with speech-language delays (study group) who were three and four years of age. Prior to being scored on the PPS, each child was individually observed for 30 minutes of outdoor free play and 30 minutes of indoor free play. After the observations, additional information for five categories on the PPS was obtained from a teacher observation check list to complete the scoring process. The following general research question was addressed: Will children who have speech-language delays and children with typical language development differ in play age and dimension scores on the PPS? Statistically significant differences were found in the play age, in all dimension scores, and for 14 of the 16 category scores. The control group consistently scored approximately one year higher than the children with speech-language delays. Some practical play intervention strategies were given for children with speech and language delays

N2 - Objective. To find the variation in the vaccinal coverage of two-year old children after incorporating the vaccination programme into the Health Centre's activities. Design. An analytical observation study of cases and check-ups. Setting. Primary Care. An urban Health Centre in Badajoz. Patients. Two random samples of 150 children. The Study Group (SG) was composed of children who began their vaccinations at the Health Centre after the incorporation of the vaccination programme. The Control Group (CG) was made up of children who were over 18 months old at the start of the vaccinal programme (October 1990) and therefore received their vaccinations outside the Health Centre. Measurements and main results. 84.8% of the CG children correctly completed the vaccination programme as against 98.7% of the SG ($p < 0.01$). 99.3% of the SG children had the triple viral vaccination as against 95.2% of the CG ($p < 0.05$). 99.3% of the SG completed three DTP-Polio vaccinations as against 93.1% CG ($p < 0.01$). And 98.7% SG had four DT-Polio as against 86.9% CG ($p < 0.01$). Conclusions. The level of vaccinal coverage of the under-two population improved after the vaccination programme was incorporated into the Health Centre's activities, data which supports the usefulness and appropriateness of such a programme

N2 - The knowledge of the skin surface pH-acid mantle is updated. The conviction that chronic alkalinization is damaging has been strengthened. Extensive skin surface pH data on the skin of non-white people are still missing. In the case of any measurement, the need for extensive infrastructural research and evaluation by non-parametric methods is emphasized. Infrastructural studies evaluate the range and change of the measured parameters for each test method according to sex, age and body area, as well as the sensitivity of the method to pharmacological influences. A detailed knowledge of the normal-representative range would make it possible to select those individuals whose measured parameter is outside the main 95% of the population; a detailed study of such individuals would be a very effective method of understanding the basic regulatory mechanism of the measured parameter

N2 - To the authors' knowledge, this is the largest study assembled of finger fractures in children. Distribution of fractures according to location within the hand (see Fig. 1), location within the phalanges themselves, and the percent of epiphyseal fractures as well as the age distribution of the patients are all similar to what has previously been presented in smaller studies. Previously unreported synchronous and double epiphyseal injuries were identified. For the most part, thanks to the remodeling capacity and rapid healing of children's bone, treatment is short and complications are few. Nevertheless, as in other locations, there is a limited capacity to remodel angular deformity and no capacity to remodel rotational deformity. The clinical information in our study conflicts somewhat with previously described anatomic information about the insertion of ligaments with respect to the growth plate. Bogumill and Hankin and Janda have suggested that the ligaments insert primarily on the epiphysis in the proximal phalanx, and on the epiphysis and metaphysis in the middle and distal phalanges. Taken by itself, this information would suggest that a Salter-Harris III mechanism would be relatively more common at the MP joint, and the Salter-Harris II and IV mechanism (where the proximal fragment includes bone both proximal and distal to the growth plate at the point where the ligament is attached) would be relatively more common at the more distal levels. In fact, the opposite was true. The Salter-Harris II mechanism made up an overwhelming majority of the percentage of injuries of the MP joint, whereas the Salter-Harris III mechanism predominated at the PIP joint and was relatively common at the DIP joint as well. This would seem to suggest that either the contribution of ligament insertion distal to the growth plate of the PIP and DIP joints is not functionally important or that other factors are involved in the injury mechanism at both levels and play a role in producing these injuries. Further study will be required, possibly involving experimental fracture production to help elucidate this issue. Finally, it is critical to recognize and properly treat the four major categories of injury that constitute a small percentage of the total but a large percentage of the complications. The condylar and subcondylar fractures must be identified by obtaining a true lateral film by whatever means necessary. If undisplaced, they need to be adequately immobilized, possibly including the entire arm of a small child, and if displaced, they almost always require internal fixation. Fracture-dislocations, which are even less common and more difficult to recognize, are usually due to a crushing or pincer-type mechanism and may present with excessive and prolonged swelling, or poor mobility. The radiograph demonstrates the presence of very subtle calcific densities that represent portions of the displaced epiphysis that are trapped either inside or outside the joint. This occurs at the PIP and DIP joint level, but it has not been reported at the MP joint level. At the MP joint, a spike of metaphyseal bone can impale flexor tendons when significant displacement occurs. Treating the fracture itself is seldom a problem. Finally, fractures in and around the growth plate of the distal phalanx on the average were responsible for the longest healing times within this series. When these injuries involve a displaced nail plate, they can usually be treated by replacement of the nail under the eponychial fold, thereby stabilizing the distal phalanx and preventing the need for a K-wire with additional complications

N2 - As part of an epidemiological study in Duisburg (FRG), exposure to benzene and toluene was investigated at 524 households in 1990. Both components were measured concurrently indoors (childs bedroom), and outdoors (window of childs bedroom) by passive sampling over 14 days. In addition, detailed information on the homes and ventilation habits was available by questionnaire. Furthermore, the seasonal variation of the components was measured at three stations in ambient air, both by passive and active sampling. For both components the average indoor concentration was 2-3 times the outdoor concentration, and seasonal differences in the absolute concentrations and the indoor/outdoors ratio could be identified. The average concentrations of benzene in the childrens bedrooms are 9,5 mug/m³, and 1.8 mug/m³ outside at the windows. The corresponding values for toluene are 19.89 mug/m³ and 4.7 mug/m³. The indoor/outdoor ratio during the winter season is 3:1 compared to 2:1 during mid-summer when windows are more frequently open. Automobile traffic has a direct impact on the concentration levels. The ambient concentrations of benzene and toluene on streets with high traffic load are twice as high as compared to courtyards. This difference is also seen in the indoor measurement, although not as pronounced. Indoor sources influencing the benzene and toluene concentrations were environmental tobacco smoke and redecoration. The use of lacquer has the strongest influence, followed by solvents and glues. Summing up, the most important contributions to indoor concentrations of benzene in childrens bedrooms as investigated in this study come from automobile traffic outdoors and redecoration indoors

N2 - In order to obtain epidemiological data regarding both modality and possible conditions favouring bone fractures in children, useful for preventive measures, we collected all cases of traumatic lesion in children under 12 years and 6 months of age, with the exclusion of road accidents. We interviewed 93% of the children's parents; each child was visited, during two distinct periods, in the pediatric department of a large hospital. The majority of accidents happened while children were playing games or practicing non competitive sporting activities (which are potentially not dangerous) explains the difficulty of making up preventive programs. In addition, the high number of fractures happened in presence of parents or teachers seems to put in discussion the preventive efficacy of protection-survey binomius. The frequent absence of parents or adult witnesses at the accident, especially for older children, make it necessary to favour the acquisition of self control in the school age. The variability of environmental factors is frequently dangerous for the child. In our study necessary structures of common use have contributed to determine the traumatic event, confirming the complexity of making different educative programs, aiming to reducing the prevalence of that group of domestic accidents in pediatric age

N2 - Volatile organic compounds (VOC) are present in indoor air at concentrations generally higher than in outdoor air. In this study VOC concentrations in the air of two classrooms differing in insulation, and in the expired air of children in them, were investigated. Qualitative and quantitative determinations were done by gas chromatography-mass spectrometry techniques. Differences in the concentrations of VOC in indoor air and in the expired air of the children were linked to the endogeneous or exogeneous origin of the compounds, to the activities of the children and to the quality of indoor-outdoor air exchanges

N2 - Children up to five years of age, who are suffering from cerebral palsy, place great demands on mobility aids. This is especially so when they cannot move themselves forward by way of walking, need support for a sitting posture, cannot use their hands easily and have limited perceptions. They often have a wheelchair to be able to sit for a long time and move around indoors. Outdoors they are transported over greater distances by their parents in a push chair. A project has been set up at the Faculty of Industrial Design Engineering of the Delft University of Technology in order to develop a mobility aid, which creates new opportunities for independent activity and experiences with mobility. This paper deals the result of the first phase of this project: a programme of requirements with respect to the seating device of the mobility aid. The seat should be provided with adjustable elements in order to meet the need for support of each individual child

N2 - Analysis of data from a nationally representative sample of Hispanic youths age 12-17 and their parents was done to investigate the impact of a number of variables on youths' drug-using behavior. The significance of youth, household, and parental characteristics were tested using measures of youth drug use as dependent variables in regression models. Parents' attitudes and use of licit and illicit drugs were found to play an important role in their children's drug use behavior. The results also provide some support for the hypothesis that Hispanic children whose parents are more acculturated into American society are at higher risk of using drugs. Youths of Mexican origin, youths living outside large metropolitan areas, and females were found to be more likely to use drugs. The results provide supportive evidence that for drug prevention education programs to be effective with Hispanic youths, they must be family orientated

N2 - The Pocos de Caldas Plateau, Brazil, with 70 radioactive anomalies is used for cattle, pigs and poultry production and for raising crops like potatoes, corn, brown beans and carrots. Data on the radioactivity concentration of natural radionuclides in air, soil, animal products, vegetables, water, sediment, external dose rates, and outdoor and indoor radon were used together with socio-economical information to estimate the radiological exposure from these agricultural activities in this high natural radioactivity area for the local rural and remote populations. For the local population agricultural products from the plateau contribute only relatively little (ca. 0.14-0.24 mSv.y⁻¹) to the high radiation exposure (ca. 6-16 mSv.y⁻¹) from external exposure and inhalation of radon and thoron daughters. However, the agricultural products carry a significant annual collective dose (ca. 14 man.Sv.y⁻¹) to remote populations

N2 - Although the rate of injuries in soccer is high, this sport puts children only at moderate risk of getting injured. In younger children this risk is very low but the number and severity of injuries increases with puberty. The most common cause for injuries is a collision with another player, the most common injury is distortion of the talocrural joint. Playing soccer indoors is more dangerous than playing outdoors. The danger of accidents and injuries can be reduced by preventive measures, such as weight categories in children leagues

N2 - Indoor, outdoor, and personal acid aerosol monitoring was performed for 24 children living in Uniontown, PA, during summer 1990. These measurements were used to investigate the magnitude of personal acid aerosol exposures and its relationship to indoor and outdoor concentrations. Indoor, outdoor, and personal measurements were compared to outdoor measurements collected from a centrally located, stationary ambient monitoring site. Personal exposures reached a maximum of 300 nmol m⁻³ for both sulfate and aerosol strong acidity (12-h daytime measurements). Personal exposures were lower than corresponding outdoor levels and higher than indoor levels, with differences being greater for aerosol strong acidity. Air conditioning was found to be an important predictor of indoor sulfate and aerosol strong acidity, while ammonia was found to influence indoor and personal aerosol strong acidity concentrations. Time/activity weighted models of indoor and outdoor concentrations were used to predict personal sulfate and aerosol strong acidity exposures. These models predicted personal sulfate and aerosol strong acidity exposures substantially better than outdoor concentrations alone. The aerosol acidity model, however, was unable to explain all the variability in personal exposures. Research should be conducted to determine the effects of particle loss and ammonia neutralization around the human body

N2 - The present study examined the extent to which boys' and girls' preference for outdoor, vigorous activity changed as they became socialized to middle school. A sample of 133 boys and girls were studied for one year: those just beginning middle school (sixth graders) and those with one year experience (seventh grade). Measures of children's preference for the playground, the duration of their stay outdoors, and behaviors while outdoors were obtained through direct observational methods. Additionally, teachers' rated children's level of achievement, physical attractiveness, and facility in games. Children also rated each other in terms of dominance status. Results indicated that boys', compared to girls', preference to play outdoors existed only in sixth grade. Factor analyses indicated that three factors described these children: Teachers' Choice, Active Female Oriented, and Outdoor Male Oriented. All three factors varied as children progressed through middle school. Results are discussed in terms of life course developmental theory

N2 - To determine whether a population living on or adjacent to four sites of chromate production waste was measurably exposed to environmental chromium, spot samples of urine were collected along with wipe samples of household dust and lifestyle/activity interview data. Findings were compared to those from a control population in two communities with no significant chromium use or waste sites. Urine samples were collected and analyzed, employing measures to minimize background chromium contamination. The average Cr mass in dust was 3.7 times that in control houses. The mean creatinine-corrected urine Cr (Cr/c) level of the exposed subgroup residing in households in the 75th percentile of Cr mass in wipe samples was significantly greater than that of the control population. This subgroup was primarily located at a single exposure location. Using lifestyle/activity data, significantly elevated Cr/c urine levels were identified in other exposed subgroups defined by employment location and by outside play time. These data show an association between elevated exposure to chromium in household dust and elevated urine levels of chromium, consistent with residential exposure to chromate production waste. These data also suggest an association between chromium exposure and activities outside the home which are consistent with exposure to chromate production waste

N2 - Objective. - To determine the incidence of antibiotic-resistant pneumococcal disease and to compare the presentation and outcome of penicillin-resistant infections with penicillin-susceptible infections. Design. - Patient series. Setting. - General community hospital. Patients. - Eighty-three children with penicillin-resistant pneumococcal bacteremia or meningitis and 124 children with penicillin-susceptible pneumococcal bacteremia or meningitis. Selection Procedures. - Consecutive patients admitted between 1989 and 1991. Interventions. - None. Measurements and Results. - Forty percent of community-acquired isolates and 95% of hospital-acquired isolates were resistant to penicillin. Eighty-three (82%) of 101 penicillin-resistant infections were community acquired. Resistance to chloramphenicol, tetracycline, and erythromycin occurred in 9%, 12%, and 4% of all isolates, respectively. The proportion of penicillin-resistant pneumococci with cefotaxime minimum inhibitory concentrations greater than or equal to 0.5 µg/mL increased from 0% in a 1986 study to 21.5% in this study. The sites of infection, underlying diseases, and mortality of patients with penicillin-resistant infections outside the central nervous system did not differ significantly from those of penicillin-susceptible infections. Conclusions. - The resistance of *Streptococcus pneumoniae* to beta-lactam antibiotics has increased alarmingly in South Africa. Penicillin-resistant and penicillin-susceptible pneumococcal infections cause a similar spectrum of illness

N2 - The California Air Resources Board funded a statewide survey of activity patterns of Californians over 11 years of age in order to improve the accuracy of exposure assessments for air pollutants. Telephone interviews were conducted with 1762 respondents over the four seasons from fall 1987 through summer 1988. In addition to completing a 24-h recall diary of activities and locations, participants also responded to questions about their use of and proximity to potential pollutant sources. Results are presented regarding time spent by Californians in different activities and locations relevant to pollutant exposure, and their frequency of use of or proximity to pollutant sources including cigarettes, consumer products such as paints and deodorizers, combustion appliances and motor vehicles. The results show that Californians spend, on average, 87% of their time indoors, 7% in enclosed transit and 6% outdoors. At least 62% of the population over 11 years of age and 46% of nonsmokers are near others' tobacco smoke at some time during the day. Potential exposure to different pollutant sources appears to vary among different gender and age groups. For example, women are more likely to use or be near personal care products and household cleaning agents, while men are more likely to be exposed to environmental tobacco smoke, solvents and paints. Data from this study can be used to reduce significantly the uncertainty associated with risk assessments for many pollutants

N2 - The evaluation of postvaccine antibody responses can provide a reasonably convenient and useful adjunct to the evaluation of possible humoral immune dysfunction syndromes. In patients whose clinical history is suspicious for an antibody deficiency syndrome, such studies can document normal antibody responsiveness. On the other hand the wide age-dependent variation in antibody responses makes careful interpretation necessary in concluding that a patient falls outside the 'normal' pattern of antibody responsiveness. Finding a patient well below the mean values for age for multiple vaccines in concert with an appropriate clinical history would strongly suggest an abnormality of immune regulation. At this time the finding of abnormal antibody responses does not always imply that intervention with immunoglobulin therapy is indicated or that it would lead to improvement in clinical symptoms. It might help justify prophylactic antibiotic programs, however, similar to those used for recurrent otitis media. Interpretation of antibody responses in children younger than 2 years of age is probably hazardous since many patients may have relative retardation in their normal development of polysaccharide antibody responsiveness. Such patients usually develop a normal response as they grow older and do not need long term therapy. Until new technologies for measuring immune competence are developed, the above-mentioned measures of humoral immunity, when combined with clinical judgment, should be adequate to guide clinical decision-making in most cases

N2 - An important component of assessing the levels, the sources, and the health effects of children's exposure to air pollution is understanding how and where members of this sensitive population spend their time. There are, however, few data bases that allow the documentation of the day-to-day nature of children's activities. Of particular concern is whether the one-day snapshots provided by time activity diaries typically used in exposure studies represent the actual temporal and spatial extent of children's activities. As part of a community health study, longitudinal data on children's time activity patterns were recently collected. A respiratory health status and gender stratified sample of 90 children kept daily diaries over two-week periods during both the summer and the fall. This paper first presents baseline information of children's activity patterns: the sample distribution of time spent in each of five microenvironments (travel, outdoor, at school, at home, and inside other locations) and the daily temporal pattern of activities. The consistent patterns of children on school days suggest that for most days we can accurately predict children's locations by time of day. The second part of the analysis shows that there is both high child-to-child variation in the average time spent in each microenvironment, even after controlling for gender and respiratory health status, and strong temporal variability in activity patterns within a child over time, even after controlling for school days versus nonschool days

N2 - Fifty-four patients with a posteroseptal accessory connection and symptomatic tachycardias underwent catheter ablation of the anomalous pathway. Eight had the permanent form of reciprocating tachycardia (long RP' tachycardia) and 46 had a left posteroseptal preexcitation marked by a prominent R wave in lead VI. In 14 of 19 patients, ventriculoatrial conduction time during tachycardia lengthened in conjunction with functional left bundle branch block, this behaviour was significantly different from a series of patients with right posteroseptal preexcitation in which functional left bundle branch block lengthened the ventriculoatrial time in only one of 12 patients. A quadripolar electrode catheter was left within the proximal coronary sinus in order to locate the earliest atrial or ventricular activation site. The appropriate bipole was used as the radiographic and electrophysiological reference of the insertion of the accessory pathway. A catheter was then positioned on the

septal side of the right atrium, outside the coronary sinus, so that atrial activity during reciprocating tachycardia and ventricular activity during preexcitation were synchronous with or earlier than that recorded within the proximal coronary sinus. Accessory pathway potential was not recorded in any patient. Early ventricular potential occurring -1.5 ± 8 ms relative to delta wave onset was present at that site. In 38 patients, including 5 with permanent junctional tachycardia, high current (14mA) pacing yielded direct ventricular paced QRS complexes (no delay spike-QRS) with a morphology similar to left posteroseptal maximal preexcitation. Slight movements of catheter position yielded significantly different pace-maps. One to eight 160J cathodal shocks (510 ± 213 J cumulative per patient) were delivered at this site in 61 sessions. Following fulguration, tachycardia recurred without drugs in only one patient over a follow-up period of 20 ± 13 months. Asymptomatic intermittent preexcitation recurred in two patients. In all patients with long RP' tachycardia, the ablation procedure was successful without the need for drugs or permanent cardiac pacing. A long-term follow-up electrophysiological study in 18 patients demonstrated that conduction through the anomalous pathway was absent in 16 and deeply altered in the two patients with intermittent preexcitation; no tachycardia was inducible in any patient. In conclusion, catheter ablation of left posteroseptal accessory pathways is a feasible procedure using a right atrial approach outside the coronary sinus. This technique is also effective for the treatment of the permanent form of reciprocating tachycardia

N2 - Bronchial hyperreactivity demonstrated by means of a standardized exercise test in 30 asthmatic children was studied before and after one month of treatment with a pressurized aerosol providing 5 mg of sodium cromoglycate per spray. This study was carried out as a double-blind comparative trial against placebo, outside the period of allergenic provocation. Ventilatory parameters were measured before, and then 5, 15, and 30 minutes after a period of six to nine minutes on a moving walkway. The test session included three-minute incremental increases in gradient and speed. This exercise test was performed on day 1 without prior treatment; on day 2 and day 34 it was preceded by administration of two sprays of sodium cromoglycate, 15 minutes earlier. The baseline values of ventilatory parameters on days 1, 2, and 34, like their variations following exercise on day 1, were similar in the treated and the placebo group. On day 1, five minutes after the exercise test, the fall in the forced expiratory volume in one second (FEV₁) was greater than or equal to 20% in all cases and was accompanied by a highly significant decrease in the vital capacity (VC), the midexpiratory flow between 25% and 75% of VC (MEF(25%-75%)), the flow at 25% of VC (V25), the flow at 50% of VC (V50), the flow at 75% of VC (V75), and peak expiratory flow (PEF). On day 2, five minutes after the exercise test, 66.7% of the children in the placebo group versus 20% of the children in the treated group had a fall in the FEV₁ of greater than 20% (P = 0.01). Decreases in VC, V75, and PEF were significantly greater in the placebo group than in the treated group. After one month of treatment, the active and placebo groups were statistically different for all ventilatory parameters, with the most marked variations in the placebo group; five minutes after the exercise test, 64.3% of children in the placebo group had a fall in FEV₁ of greater than 20% versus 13.3% of children in the treated group (P = 0.007); VC was not changed after exercise in the active group. Compared with day 2, five minutes after exercise, MEF(25%-75%), V25, and V50 were highly significantly improved in absolute terms in the treated group only (P < 0.001). This statistically significant improvement in airway flow rates at the bronchiolar level shows that regular use of sodium cromoglycate reduces bronchial hyperreactivity

N2 - Dosimetry of inhaled substances is based on the air volumes breathed every day by people under exposure to gases and aerosols. In order to assess modern standards for average inspired air volumes according to age and gender, information was recorded on daily activities and breathing rates both indoors and outdoors, of specific categories of the population. Economic surveys recently published provided time budgets and activities of adults, teenagers and children. The data were matched with published data on physical activities and breathing parameters in order to calculate the daily inspired volumes of air. The results were given for adults (age > 17 years), neonates, and children 1, 5, 10 and 15 years old. The values obtained are close to those published by the International Commission for Radiological Protection and the reports of the United Nations Scientific Committee on the Effects of Atomic Radiation

N2 - The purpose of this study was to examine the effects of the interval training on metabolic parameters at maximal work and at the anaerobic threshold in 11 years olds. The subjects were five healthy male children. They trained outdoor for 50 min a day, five times a week for six weeks, using interval work at 25 and 50% above their anaerobic threshold. Before and after training program, they performed a progressive exercise test on a cycle ergometer. During the last 15 sec of each power output measurements were made of oxygen uptake (VO_{2}), carbon dioxide output (VCO_{2}), heart rate (HR), ventilation (V(E)), ventilatory equivalent for oxygen (V(E)O_{2}) and ventilatory equivalent for carbon dioxide (V(E)CO_{2}). Following training, the group increased their anaerobic threshold (expressed as $\% \text{VO}_{2\text{max}}$) significantly ($P < 0.05$) during the progressive exercise test, by 22%. Also at the anaerobic threshold level, increases were observed following training in CO_{2} output ($\text{VCO}_{2\text{-AT}}$) and respiratory exchange ratio (R). Oxygen uptake (VO_{2} , $1.\text{min}^{-1}$) was increased by 19%, but the difference was not significant ($P > 0.05$). Maximal ventilatory equivalent for ($\text{V(E)CO}_{2\text{max}}$) decreased significantly ($P < 0.05$). Maximal heart rate was reduced significantly ($P < 0.05$). We conclude that training led to an increase of both anaerobic and aerobic metabolism, at any submaximal work above the anaerobic threshold, for this specific age group

N2 - The effect on birth outcome of work requiring different degrees of physical exertion was examined among 15786 pregnant women who were followed through the Guatemalan Social Security Institute's Hospital. Work inside and outside the home was ascertained through a questionnaire administered to each woman before delivery. Odds ratios were adjusted for household income, maternal height and age, and birthweight of previous infant. Women with three or more children and no household help were at increased risk for small-for-gestational-age (SGA) births compared with women with family (odds ratio (OR) 1.79; 95% confidence interval (CI) 1.31, 2.47) or hired help (OR 2.0; 95% CI 1.16 to 3.33). Compared with office work, manual work increased the risk for an SGA (OR 1.32; 95% CI 1.12 to 1.56) and SGA/preterm birth (OR 2.56; 95% CI 1.10 to 5.96). Work in a standing compared with sitting position significantly increased the risk for a preterm birth (OR 1.56; 95% CI 1.04 to 2.60). There was a significant positive trend in frequency of SGA and SGA/preterm birth with an increase in the physical demands at work, as measured by an activity score. These data suggest that interventions to reduce physical exertion among pregnant women could improve birth outcome

N2 - A personal air quality model (PAQM) has been developed to estimate the effect of being indoors on total personal exposure to outdoor-generated air pollution. Designed to improve air toxics risk assessment, PAQM accounts for individual hourly activity patterns, indoor-outdoor differences, physical exercise level, and geographic location for up to 56 different population groups. Unique hourly activity profiles are specified for each population group; group members are assigned each hour to one of up to 10 different indoor and outdoor microenvironments. To illustrate PAQM use, we apply it to two example cases: a long-term example representative of situations where pollutant health impact is related to integrated exposure (as in the case of potentially carcinogenic air toxics) and a short-term example representative of situations where health impact is related to acute exposure to peak concentrations (as with ozone). Case study results illustrate that personal exposure, and thus health risk, attributable to outdoor-generated air pollution is sensitive to indoor-outdoor differences and population mobility. Where health impact is related to long-term integrated exposure (e.g., air toxics), exposure and subsequent risks are likely to be lower than that estimated by previous modeling techniques which do not account for such effects

N2 - Health and pollution control professionals and the general public need to develop a more complete understanding of the health effects of ozone (O_3) because: 1) we have been unable to significantly reduce ambient O_3 levels using current strategies and controls; 2) in areas occupied by more than half of the U.S. population, current peak ambient O_3 concentrations are sufficient to elicit measurable transient changes in lung function, respiratory symptoms, and airway inflammation in healthy people engaged in normal outdoor exercise and recreational activities; 3) the effects of O_3 on transient functional changes are sometimes greatly potentiated by the presence of other environmental variables; and 4) cumulative structural damage occurs in rats and monkeys exposed repetitively to O_3 at levels within currently occurring ambient peaks, and initial evidence from dosimetry models and interspecies comparisons indicate that humans are likely to be more sensitive to O_3 than rats. The extent and significance of these effects, and the multibillion dollar costs of ambient O_3 controls need to be considered in any future revisions of ambient standards and the Clean Air Act. The transient effects of O_3 are more closely related to cumulative daily exposure than to one hour peak concentrations, and future revisions of the ambient standard for O_3 should take this into account. The effects of long-term chronic exposure to O_3 remain poorly defined, but recent epidemiologic and animal inhalation studies suggest that current ambient levels are sufficient to cause premature aging of the lungs. More research is needed to determine the need for a standard with a seasonal or annual average concentration limit

N2 - This report presents key outcomes of joint growth and development studies conducted in children permanently living in areas adversely affected by pollutants in air. Further attention is focussed on the evaluation of effects of some so-called compensatory measures applied in Czechoslovakia, namely a 3-week outdoor schooling organized for these children in the relatively clean recreational areas. The beneficial health effects of year's season and specifically of the spontaneous, active and sufficiently long outdoor exercise are documented in graphs. As it is pointed out in this context, children in the place of their permanent residence tend to have relative little exercise outdoor, may run an increased risk of exposure to indoor pollutants, and may suffer from passive smoking effects if their parents cannot refrain from smoking habits at home

N2 - Autism is a developmental disorder characterized by a triad of behavioral impairments involving (1) reciprocal social relationships, (2) communicative intent, and (3) the ability to play, to invest play with imagination, and to develop interests outside of stereotypic preoccupations. Deficiencies in these essential human characteristics occur in all autistic children, 80% of whom are mentally retarded. They can be attributed to a deficiency in the capacity to direct attention to persons, things, and activities; hence, they could reflect an impairment in sensory processing. Two additional symptom clusters are found in autism. The disturbances of sensory modulation are characterized by under- and overreactivity to sensory stimuli. The overreactivity includes distraction by background stimuli, distress from stimulation, and, paradoxically, behavior that provides repetitive sensory input. The motility disturbances are stereotypic behaviors which mediate this self-stimulation. The disturbances of sensory modulation and motility are observed clinically primarily before 6 years of age. This paper documents these sensory and motor behaviors in young autistic children by quantitative evaluation of their parents' responses on a standardized developmental inventory and demonstrates that they are essential components of the autistic syndrome. Based on their presence, a neurophysiologic model of autism as a disorder of sensory processing and directed attention is elaborated. In this model, there is dysfunction of brainstem and related diencephalic systems and the cascading impact of such dysfunction on higher neural structures which elaborate, refine and modulate the activities of the lower centers. Autism results from dysfunction of this neuroanatomically distributed sensory processing system which mediates the direction of attention

N2 - We studied 19 Eskimo patients with alveolar hydatid disease from the north-western coast of Alaska for risk factors for infection with Echinococcus multilocularis. Each case-patient was matched by age and sex with 2 unrelated controls who had no clinical or serologic evidence of infection with E. multilocularis and who resided in three villages endemic for alveolar hydatid disease. Behaviors thought to increase exposure to E. multilocularis and the chronologic occurrence of these behaviors in the participant's life were assessed by a standardized questionnaire. Case-patients were more likely than controls to have owned dogs for their entire lives (odds ratio 6.00, $P < 0.05$), tethered their dogs near the house (odds ratio 8.50, $P < 0.05$), and lived in houses built directly on the tundra rather than on a gravel or a permanent foundation (odds ratio 11.00, $P < 0.01$). Case-patients were not more likely to have owned sled dogs, trapped or skinned foxes, or engaged in other outdoor activities away from home. These findings suggest that controlling the parasite in the domestic dog population, as well as controlling the dog population itself, are important aspects of preventing alveolar hydatid disease in the northwestern Native Alaskan population

N2 - This experiment was designed to assess the effects of integrating intellectually normal and trainable mentally retarded (TMR) children into a physical activity program. The following research hypotheses were tested: (1) TMR students integrated with intellectually normal pupils will show greater improvements in their motor performance than their nonintegrated mentally retarded peers; and (2) intellectually normal students integrated with TMR pupils will show no lesser improvements in their motor performance than their nonintegrated peers. Two age levels of TMR children were integrated with intellectually normal third and sixth grade children in a physical education instructional program over a period of five months. Motor performance test scores were secured at the beginning and end of the experiment. Similar data were obtained on control groups of TMR and intellectually normal children in nonintegrated instructional settings. One hundred and ten students in two experimental and four control groups completed the experiment. The intellectually normal-TMR student ratio in the integrated program was about four intellectually normal children to one TMR child. The instructional program (similar for all groups) emphasized fundamental motor patterns with attention also given to sport skills. Three motor tests, namely, the 20-yard dash, standing long jump, and softball throw were used in assessing motor performance of all children. It was found that under the conditions of this experiment the scores of the intellectually normal subjects were in no way impaired by the integrated program. Motorically, the TMR subjects participating in the integrated program showed significantly greater gains than those participating in the segregated program

N2 - Twenty-four-hour motor activity was assessed in a naturalistic setting in 12 hyperactive boys for four weeks (672 consecutive hours). Dextroamphetamine, 15 mg/day, or placebo was administered on alternate weeks, using a double-blind ABAB design. When the boys received dextroamphetamine, motor activity was significantly decreased for about eight hours after drug administration. This decrease was followed by a period of slight but significant increases in activity ('rebound'). Dextroamphetamine decreased activity most strikingly during structured classroom activity; during physical education, however, there was a significant drug-induced increase in motor activity

N2 - The vulnerability of children to arthropod bites, infestations, and parasites is well known. Unfortunately, the papules, urticaria, blisters, nodules, and hemorrhagic lesions produced by these conditions are frequently misdiagnosed. This difficulty in diagnosis exists because most lesions are not absolutely characteristic and physicians may not recognize the lesions caused by insects and parasites indigenous to areas outside of their practice region. The evaluation and diagnosis of any dermatologic problem requires utilization of historical clues in addition to direct observation. Information that is essential to elicit includes the seasonal incidence of the lesions, recent history of travel or migration, the playing habits of the child, exposure to pets, and the existing environment and living conditions. The grouping and distribution of lesions is also very important to consider. This article will discuss the dermatologic findings and treatment of the conditions caused by a number of the most common arthropods and helminths

N2 - During the period 1. VII. 1979-30. VI. 1980, 466 children aged 1-14 yr were registered in the Casualty Departments of the Municipal and County Hospitals in Aarhus with injuries resulting from use of playground equipment. In 329 cases (70.2%), falls were involved. In every case, the scene of the accident was visited. The height of the fall was measured and the underlying surface described. These two parameters were compared with the age and sex of the child and the severity of the injury as classified by the Abbreviated Injury Scale (AIS). The height of fall was shown to increase with increasing age ($p < 0.001$). In the ages 0-9 yr, sex had no influence on the fall height but in the age group 10-14 yr, greater fall heights were demonstrated in boys ($p = 0.013$). The fall heights for the individual types of playground equipment deviated statistically significantly from one another, the greatest fall heights being for climbing frames and the least from swings ($p < 0.001$). The severity of the injuries sustained increased with increasing fall heights ($p < 0.001$). In the majority of cases, the underlying surfaces were unsuitable. Surfaces with sufficient shock absorbing properties were found in only 22 cases (6.7%). The problems surrounding the underlying surface are reviewed. It is considered advisable that the maximal fall height for any playground equipment and the underlying surface should be adapted to one another. It should thus be impossible for a child falling accidentally from a form of playground equipment to reach deceleration levels which exceed 50 G at the impact with the underlying surface

N2 - In order to illustrate the frequency of accidents with playground equipment, children aged 0-14 years who sustained injuries while using such equipment during the period 1.VII.1979-30.VI.1980 were registered in the Municipal Hospital and the County Hospital in Aarhus. In addition, in-depth investigation of each accident was undertaken. A total of 466 children were registered and, as the number of children aged 0-14 years in the region served by the hospitals was 50,000, this corresponds to an incidence rate of 9.3/1000 children/year. A further 20% were treated by the general practitioners. The number of accidents was greatest in the age group 4-5 years. The sex ratio for the total material was 1.44 (boys/girls). The sex ratio was observed to increase with age. Accumulation of accidents was observed at midday and late in the afternoon. The number of accidents was greatest on week days and the number was halved at week-ends. The greatest number of accidents occurred in the months of May, August and September. One hundred and sixty-nine accidents occurred in private playgrounds, 146 in day-care institutions, 90 in school playgrounds and 55 in municipal playgrounds. Swings, climbing frames and slides were responsible for 64% of the accidents. The next most frequent were play houses and seesaws. Small children were most frequently injured on slides while older children were injured while playing on climbing frames. Girls dominated where play equipment with a swinging motion was concerned

N2 - The 30-year history of ergonomics as applied to adults' occupational activities is outlined. Plat applied ergonomic principles to school work and to children's activities outside school, with a view to their developing as physiologically as possible and to creating optimal conditions of perception, learning and assimilation of knowledge. Since 1976-1977, the concept of school ergonomics has been promoted officially in France by the Department of Biomedical Research at the National Institute of Pedagogic Research. This institute uses earlier work on the biological, psychological and sociological characteristics of pedology and stimulates new research. A report is presented of results so far obtained in regard to rational scientific organization of studies and anthropometric knowledge of the child. An analysis is made of the schoolchild's optimal work place, with reference to the screen terminals in computer-assisted teaching, and to optimal environmental factors

N2 - A cost/benefit analysis of both general and oncologic Day-Hospital (D-H) activity in the Pediatric Clinic of Trieste has been performed. Three years of activity, one immediately before and two after the beginning of the service, have been considered. For each period we have evaluated: total number of D-H admissions and traditional admissions in the ward, the number of first visits and subsequent controls, and the residence of the

patients (outside or inside the province) and the average days of hospitalisation. Qualitative analysis was performed with respect to the indication for hospital admission (simple criteria for usefulness were established) and as to the outcome the problem was totally or partially solved?). The average cost of the service was calculated on the basis of laboratory and instrumental examinations concerning the general D-H, and on the basis of examinations and drugs administered to the patients in relation to the oncology D-H. The total number of hospital admissions as well as the total number of first visits did not substantially change in the three years under consideration, whereas the number of traditional admissions in the ward diminished. The average length of hospitalisation (ward + D-H) diminished from 3.6 to 2.9 days, whereas the average of days of hospitalisation in the ward increased from 3.6 to 5.4, due to the almost exclusive utilisation of the ward for severe illnesses. The decrease of the average length of hospitalisation was not due to an higher number of admissions for a single patient, since the length of stay for a single patient is still very low: 4.3 days. These data do not show hyperutilisation of D-H: 'useless' admissions passed from 23% to 4% in the general ward and from 37% to 23% in D-H. The general D-H can be considered a service with a good outcome, since 85% of the problems were solved. Expenses for the staff did not increase in the period under consideration and the cost for general D-H service per day (about 21000 liras) and for the oncologic D-H service per day (about 52000 liras) appear reasonable (the higher cost for the oncologic D-H service is mainly due to the redundancy of examinations required in order to follow the multicentric protocols)

N2 - Child psychiatric consultations at a children's hospital have permitted earlier detection of children who show signs of a disequilibrium between their lines of development. A number of therapeutic principles were accepted: the notion that parents could no longer tolerate their children, the notion that nothing was possible without the parents' active participation in their children's therapy through weekly meetings with parents and mental health workers as specified in a preliminary 'contract' with the parents. The notion that these children were capable of rendering their parents incompetent was likewise acknowledged, and therefore care was taken to avoid making the parents feel guilty; to this effect, the staff explained their own limitations and failures with these children to their parents. Semiweekly hospitalization from Monday to Thursday appears to be the most advantageous solution in order to work intensively with the children, allow their parents time to recuperate, and ensure participation of parents at the weekly meetings. About thirty children have been treated in this fashion

over the past four years with variable success: one-third with good results, one-third with average results, one-third with poor results. At present, hospitalization for one day or for several hours at a specialized kindergarten outside of the hospital allows for treatment of a larger variety of psychiatric indications

N2 - Physical therapy for reducing muscle contracture, whether by passive stretch or active exercise, is often undermined by the joint position usually maintained outside the time of therapy. Any maintained joint position may be a serious problem, especially in the presence of spasticity, for example, upper extremity flexor pattern after a cerebrovascular accident or the total flexor or extensor responses of the limbs following head trauma or CNS infection. Plaster of Paris splinting that maintains the joint at the maximum comfortable range and allows further motion out of the contracted position can be effective in preventing further loss of range of motion and even in gaining additional range of motion. Such casts can be made in physical therapy with easily obtained materials. This case report illustrates this technique

N2 - The object of this investigation was to describe the clientele and working methods in a clinic for children in Copenhagen. During the period 1.1.1980-31.12.1980, the author registered consecutively all of the contacts with the children and families for whom he was responsible. This is thus registration of the work of one doctor and must be regarded as a momentary glimpse of social paediatric practice. A total of 97 children and their families were contacted (60% boys and 40% girls). The contact is described as contact at the outpatient clinic, activity outside the clinic and telephone contact. The time consumed is assessed and it is noted that social medical work is extremely time-consuming. The diagnoses and treatment emphasize the importance of prophylactic work and the requirement of close, current and frequently prolonged contact with the families

N2 - Nonhandicapped students served as playground tutors for three students in a class for the moderately retarded at a regular middle school. The nonhandicapped volunteers taught age-appropriate playground

recreation skills to their retarded peers in an effort to improve the playground behavior of the three retarded students and to facilitate positive interactions between retarded and nonhandicapped students. Results indicated substantial improvement in the percentage of appropriate playground behavior and in the percentage of contact between the retarded and nonhandicapped students. Follow-up probes indicated that, while the percentages of appropriate playground behavior and contact with nonhandicapped peers had decreased, they were considerably higher than during baseline

N2 - An 18-month-old boy was admitted to hospital after being strangled accidentally in the dependent loops of a rotary washing line. The line had been left upright but its radial arms had been folded down. A few minutes after he had gone to play outside his mother had found him kneeling by the line with three strands of cord wound tightly around his neck. He was unconscious and was not making any respiratory effort; peripheral pulses were not detectable. Initial resuscitation was performed by ambulance staff. On arrival at hospital he was breathing spontaneously and had a normal cardiac rhythm. He had widely dilated pupils, was hypertonic, and had intermittent clonic convulsions. He was given oxygen, and metabolic acidosis was corrected. Fluids were restricted and dexamethasone was given for 24 hours. He recovered rapidly and was discharged two days after admission, having suffered no permanent neurological damage. While playing with the loops of the clothes line he had presumably become entangled and had been asphyxiated during his struggles to free himself

N2 - A correlational study was conducted in an effort to examine the validity and reliability of role play tests for assessing social skills in children. Twenty-two male and twenty female elementary school children, ranging in age from 8-10 years, responded to role play scenarios involving social interactions. In addition to the role play procedure, a number of other assessment strategies were utilized: observations of behavior in naturalistic settings, sociometric ratings, and teachers' ratings. Results did not support the validity of the role play test. Correlations between role play performance and criterion measures were generally quite low. Test-retest reliability of the role play tests also was unacceptable. Further, results indicated that while several significant relationships were found between children's sociometric scores and teachers' ratings of interpersonal behavior, little association was found between these measures and global ratings of friendliness in role play and in vivo situations. Results are discussed in terms of the validity and utility of role play tests for children, the relationship of these data to previous research in social skills assessment, and the heuristic value of examining research concerning children's interpersonal functioning from developmental and social psychological perspectives

N2 - The Fitness-Performance Tests developed in 1965 by the Canadian Association for Health, Physical Education and Recreation have been criticized with regard to the validity of the 300 yard run as an endurance measure and with regard to the redundancy of some items involving lower limb performance. The purposes of this study were to identify a more appropriate endurance performance test item and to analyze the interdependence of the items which utilize leg power in their performance. A sample of 9000 young Canadians aged 6 to 17 years, was randomly selected from the 10 provinces and the 2 territories. Correlation coefficients were calculated between: standing long jump, the 50 m. run, and the endurance run (800 m. for 6-9 years, 1600 m. for 10-12 years and 2400 m. for 13-17 years). Among the different age and sex groups, the correlations between the endurance run and the 50 m. run varied from 0.40 to 0.49. The correlations between standing long jump, the agility run (4 x 10 m.) and the 50 m. run were from 0.69 to 0.83 for all the boys and girls. The correlations between these three items are even lower when performances are analyzed by age and sex groups. The highest variations are mainly in the preadolescent period for both sexes

N2 - The purpose of this study was to test the effectiveness of a teacher-mediated, peer feedback intervention package on the social interactions of withdrawn children. Three 10-year-old boys who were enrolled in a class for children with learning and behavior problems were the target subjects. Their class peers were eight boys who exhibited severe academic problems. During the initial baseline condition no attempt was made to influence the social behavior of the subjects in the daily 25-minute recess periods. During intervention, all target subjects were assigned the goal, 'Play more with friends during recess.' With the teacher's direction, the boys gave one another feedback as to whether the goal had been met the day before. This procedure resulted in an immediate and sustained increase in the positive social behaviors of the three target subjects. In subsequent return to baseline and intervention conditions, prior levels of subject behaviors were replicated

N2 - Recreation is a significant element of preventive health care, used by community health centres as an aid to rehabilitation, moderation of stress and maintenance of health. Although the amount of leisure available to the people is increasing, many are unable to take full advantage of it due to inadequate recreational education or other causes. Community health centres have an educative responsibility in this regard especially towards the unemployed. These centres organize therapeutic and socializing groups for patients in need. Examples are given. Recreational activities are also useful in the relief of stress, during breaks in production in work-places. The principles of safety need to be taught as an essential part of recreational education and the fitness of participants needs to be ensured by screening school children. The planning and erection of playground equipment needs supervision by competent professionals who exist in the community health centres. The conclusion recommends that safety check lists be available for all normal recreations and that everyone should receive adequate education to enable successful participation in recreational activities

N2 - Two experiments tested the applicability to human beings of findings with animals that the number of performances required for the reinforcement of one behavior affects the subsequent effort expended in other instrumental behaviors. In the first experiment, adult depressed psychiatric patients worked on a sorting task for the approval of a staff psychologist. The time spent and the work completed were increased by prior approval from a ward attendant for each completion of several custodial tasks, as compared to the ward attendant's approval for each completion of a single task or a no-pretreatment control condition. In the second experiment, preadolescent learning-disabled students who were required to read and spell correctly a greater number of words per reward token later spent more time and completed more work for reward tokens in mathematics, and handwriting. Two alternative interpretations of these results are evaluated: (a) The degree of accustomed effort per reinforcer becomes a learned component of behavior, or (b) high effort increases the habituation of frustration-produced disruptive responses. The results suggest that individual differences in general persistence may arise, in part, from an accumulation of effort training in the natural environment

N2 - To study the age difference in sweating during muscular exercise, two series of experiments were conducted under constant climatic conditions (29 + 1degreeC, DB, 60 + 5% RH, 0.45 + 0.05 m/sec air flow). In series A, 7 to 20 years old male subjects undertook 5-minute running or pedalling of a bicycle ergometer in various seasons. In this series of experiments, pectoral sweat volume, sweat chloride concentration, rectal and mean skin temperatures were in general determined every 5 minutes and, when necessary, the total body sweat volume was calculated from the body weight loss. In series B. the age difference in the sweating in relation to physical training was studied. Subjects, 3 to 20 years old received experimental physical training of 5-minute or 500m-running. Before and after the training, a work load or 3- or 5-minute outdoor running was assigned to them. Furthermore, before and after the training, 10 an 11 years old subjects were given a fixed mechanical work rate on a bicycle ergometer. In these experiments, most of the parameters described above were measured.

In series A, age differences in sweating during exercise were noticed to be dependent on the intensity of work load between pre- and post-adolescents. When the work load was heavy enough to cause a rapid increase in rectal temperature, the sweat volume became significantly less, the mean skin temperature was far higher, and the sweat chloride concentration was remarkably smaller in the pre-adolescent subjects than in the post-adolescent ones. In series B, an age difference in the effect of physical training was also found on sweating during exercise. The effect of physical training on sweating in the pre-adolescent individuals was generally less significant than in adults and sometimes showed a different pattern from that of adults. From these results, it can be concluded that sweating in the pre-adolescents is less adaptive, particularly to continuous severe exercise and that physical training is less effective in them than in the post-adolescents

N2 - Heart rate was telemetered from 6 preschool children during play sessions with their mothers. Their behavioural interactions was simultaneously recorded on videotape and rated on three dimensions of interaction status (submission-dominance), affect (hostility-warmth), and degree of involvement; 100 specific behaviors were coded in consecutive 4 second epochs. In exploring the relationship between heart rate and the behavioral measures, we applied two kinds of analysis - state analysis and transitions analysis. The usefulness of recording heart rate in a naturalistic setting was demonstrated by replicating the finding from more rigidly defined experiments that intense looking at an object is associated with cardiac deceleration. New findings were that submissive status and warm affect of the child and dominant status and warm affect of the mother were associated with low heart rate in the child and that the onset of smiling was associated with cardiac deceleration in most situations. The study demonstrates the feasibility and some of the potential uses of continuously telemetered heart rate for analyzing interactional and physiological variables in a naturalistic setting

N2 - Family is central to contemporary theories of delinquent and violent behavior. Yet, the processes by which families shape violent behavior in their children are not well understood. In the past, structural views posited that a weak family exposed a child to the evils of the street. More recently, functionalists have suggested that the family plays an active role in socializing youths to violent behaviors through supervision and discipline practices and modeling and reinforcement of antisocial behaviors. Integrated theories presume that socially disorganized families weaken children's conventional bonds and attachments, leading to associations with delinquent peers and in turn antisocial behavior. However, the influence of the family as a socializing environment may shift over time, and some suggest that its influence is overshadowed during adolescence by that of other social domains - schools, neighborhoods, peers, and work. This study describes the family processes and environments of (n = 98) chronically violent delinquents. Interviews with youths and their mothers assessed family social process and environments and the social domains and institutions with which they interact. Analyses of youth reports of family environments and processes yield three family types: 'interactionist' families exhibiting a high degree of internal interaction and bonding; 'hierarchical' families characterized by parental dominance and the presence of family bond and interaction patterns; and 'antisocial' families marked by criminality and family violence. Family variables have weaker explanatory power than do other social influences on violent delinquency. The relative contributions of family supervision practices and school environment varied by crime type. Social influences outside the family appear as stronger contributors to delinquency and violence during adolescence, regardless of early childhood experiences. The results underscore the importance of integrating social policies regarding family, crime, and neighborhood

N2 - Acute suppurative thyroiditis is uncommon in children. It usually follows an upper respiratory tract infection and presents with fever, dysphagia, cough and a tender left anterior neck mass. Dyspnea is less common but when present it may lead to complete upper respiratory tract obstruction. The radiographic diagnosis can be confirmed by computed tomography or ultrasonography, precluding the use of thyroid scan and the unnecessary exposure to radionuclide. Thyroid function tests do not appear to be indicated (outside the neonatal period) inasmuch as nearly all patients are euthyroid. The bacteria involved include the normal oropharyngeal microflora, and broad spectrum antibiotic therapy to include anaerobic coverage should be utilized initially. Definitive management requires incisions and drainage. A left pyriform sinus fistula communicating with the perithyroid space is a common finding and probably plays a role in the pathogenesis of AST. A barium esophagogram should be performed, and if present the fistula track should be extirpated

N2 - Cefuzonam (L-105, CZON), a new injectable cephalosporin, was used in 12 pediatric patients with infections. The 12 cases included 3 cases of tonsillitis (pathogen: *Haemophilus parainfluenzae* in 1 case, *Haemophilus influenzae* in 2 cases), 4 cases of pneumonia (*Staphylococcus aureus* in 1 case, pathogen unknown in 3 cases), 2 cases of nephropylitis (*Escherichia coli* in 2 cases), 1 case of purulent lymphadenitis (pathogen unknown), 1 case of purulent thyroiditis (mixed infection of *Streptococcus milleri*, *Haemophilus aphrophilus* and anaerobes), and 1 case of vulvar abscess (*E. coli*). Dose levels of CZON were 42.9-93.3 mg/kg/day divided into 3 or 4 times and the drug was intravenously injected for 6 to 12 days. Clinical efficacies were excellent in 4 cases, good in 5 cases, and poor in 3 cases, with an efficacy rate of 75.0%. The 3 cases with poor efficacy consisted of 1 case each of pneumonia complicated with chronic granulomatosis, purulent thyroiditis associated with piriform recess fistula, and purulent lymphadenitis of the armpit after surgical operation of congenital heart disease. In the first 2 cases satisfactory efficacy was not obtained by chemotherapy alone, and complete cure was seen after surgical operation. Side effects were not observed clinically. One case each of slight prolongation of prothrombin time and transient elevations of GOT and GPT values was noted but no severe abnormalities were found in laboratory tests. The above results are reasonable from the points of view of the broad spectrum, potent antibacterial activity, and pharmacokinetics of this compound; thus, CZON appears to be a useful new antibiotic in the pediatric field. The recommended dosage for general pediatric infections is about 20 mg/kg at a time, 3 or 4 times, by which the expected efficacy may be obtainable

N2 - Mentally retarded children are frequently observed either to be inactive or to engage in stereotypic behaviors and isolate play. In this study, sign posting, pictorial prompts, and feedback were used to increase the recreational behaviors of 45 moderately and severely mentally retarded children. Treatment was introduced sequentially in a multiple-baseline fashion for ballplay and jungle gym activities across two school recess periods. Results showed large increases in the percentage of children participating in these activities that corresponded with the introduction of treatment. Similarly, the average amount of time the children played was roughly tripled. These gains were maintained over a 12-week follow-up period during which the pictorial prompts and feedback were gradually faded. The results demonstrate the efficacy of a simple, inexpensive, and practical way of generating higher levels of recreational play in large numbers of mentally retarded children

 N2 - A double-blind study has been carried out in 40 allergic asthmatic children, average age 12 years, in order to evaluate the protective action of sodium cromoglycate, taken punctually or regularly for one month, on asthma induced exercise. RVA were measured 45 min. before an outdoors race of 8 min. then immediately, 3, 10, and 25 min. after exertion. The isolated intake of one placebo before exercise does not reduce the frequency of the crises, while cromoglycate reduces this frequency to 55 per cent ($p < 0.02$). After one month of treatment, only 5 per cent of the patients under active therapy had an asthma attack after exercise, versus 75 per cent of the patients under placebo ($p < 0.001$). Therefore Sodium cromoglycate prevents short term exercise induced asthma. Its regular administration increases its efficacy, possibly by decreasing bronchial hyperactivity

 N2 - Soil samples from children's play areas on the Island of Guam were examined for the presence of Salmonella bacteria. Twenty four (30.4%) of 79 samples were positive. Test sites with high soil positivity rates tended to be in villages with higher incidence rates of human salmonellosis and higher rates of stray animals

killed on public roads. It was concluded that there was widespread contamination of Guam's environment with Salmonella bacteria and that stray dogs and other unconfined animals could contribute to the unusually high incidence of salmonellosis reported on the island

N2 - In this study, the interaction of such factors as competence, potential for enjoyment, and potential for harm as postulated in the Model for Movement Confidence was studied by analyzing responses of 250 fifth-grade children in the Omaha Public schools to a Playground Movement Confidence Inventory (PMCI). The PMCI was designed to assess movement confidence and the bases for performance decisions. Multiple discriminant analyses and analytical cross-validation were used to determine an index of discriminatory power, stability of the instrument, and a validity coefficient for scale classification power. All three model factors were found to influence the confidence of children in performing the playground tasks in the inventory. The PMCI successfully classified 85.16% of total cases representing a .5726 proportional reduction in error over chance. The factor analysis model accounted for 54% of the total variance with 90% of this variance explained by the competency subscale. The enjoyment and harm subscales combined to account for the remaining 10%. Two categories of harm variables were also depicted by the factor analysis in this study. Findings of this study represent a significant step in the validation and elaboration of the Model for Movement Confidence. Identity, separability, and measurability of the factors postulated in the model were demonstrated and the probably multivariate nature of the harm, factor identified. Specific response pattern profiles of low and high confidence groups as a priori predictions of the movement confidence model were obtained. The theoretical formulations of the model sustained as factors of enjoyment and harm as well as competence, were found to modify confidence perceptions of tasks. In this study the discriminating variables operated with a high degree of task specificity

N2 - The literature often suggests that chronically ill adolescents show a delay in the development of independence, but clear-cut evidence is lacking. Cystic fibrosis (CF) is an example of a chronic illness with marked effects on growth and development. CF is a lethal genetic disease with mainly pulmonary and gastrointestinal problems; median life expectancy is about 18 years. In the authors' study 3 major psychological elements of CF are considered: its chronic nature, its fatal outcome, and the visibility of the handicap (retarded growth). In order to study the influence of these variables on adolescent independence, 3 reference groups have been chosen besides the CF-group (n = 39): adolescents with asthma (chronic, but not fatal; n = 26); healthy, but small adolescents (n = 45), and normal healthy controls (n = 70). Eight forms of independence were measured by an extensive questionnaire. Some of the main results: At younger ages (13-14) CF-adolescents show a delay in 'dating and mating', but in general they do not have less social activities outside the home than their healthy peers. At ages 15-17 CF-adolescents do have a smaller social range. Younger CF-adolescents are less independent in handling social conflicts. At ages 13-14 adolescents with CF or asthma bear less responsibility for their own body hygiene. Surprisingly, CF- and asthma-patients feel just as responsible for living according to health rules as their healthy peers. Also, there are no differences between the groups regarding the formation of ideals and the development of own ideas in politics, religion and ethics. In future research it will be necessary to avoid general labels such as 'immature' or 'dependent', and to differentiate further between different types of independence

N2 - As yet, there are no standards in Denmark for design or placing of playground equipment. An analysis of all contacts with the Casualty Department in Odense Hospital in 1982, where the injured were in the age-group 0-14 years and when the injury had occurred during play with swings, slides, seesaws, sandpits or climbing frames gave the following results: 279 children were injured and 33 of these were hospitalized; 24% of the children sustained fractures; the majority of the injured children were aged 5-9 years; the majority of the injuries occurred with swings and slides and the most serious accidents resulted from falls from climbing frames. If the distribution of accidents was correlated for the presence of the individual types of playground equipment, particular risks are found to be associated when playing with: climbing frames in schools, seesaws in public playgrounds and slides regardless of where these are. When the results are compared with a corresponding investigation carried out in Aarhus in 1979-80, the pattern and the frequencies of accidents are found to be practically identical. This confirmation of the findings from Aarhus should instigate efforts to establish Danish standards for playground equipment and rules for design of playgrounds including minimum norms for the shock-absorbing nature of the ground or flooring

N2 - A proposal is outlined to provide a quantitative descriptive research frame for analyzing the organization of spontaneous behavior in autistic children within and across natural settings such as home, school, daycare centre, and playground. A number of research questions are formulated and appropriate analyses are suggested. In particular the project aimed to detect periodicities in behavior, guided probably by 'clock-like' processes as have been found in the field of biological rhythms. A database has to be created by observing and notating a sufficient number of samples of behavior drawn from various settings in which the autistic children happen to live. Contrived settings may also be used

N2 - The social behavior of hyperactive and nonhyperactive conduct-disordered children at a treatment center was measured by teacher rating, direct observation of recess play, and peer rating. Hyperactive subjects were rated by their peers as more aggressive and somewhat less likable than nonhyperactives, and they were more likely to be the target of others' aggression. Though rated as less likable, hyperactives spent less time than nonhyperactives in solitary play. Hyperactives also spent less time observing the interactions of other children. Additional analyses indicated that the peer relations problems of hyperactive children in treatment cannot be attributed exclusively to their aggressiveness. These findings are discussed in terms of their implications for treatment and for the theoretical conceptualization of hyperactivity

CY - United States

N2 - In an increasing number U.S. communities, comprehensive health services - including family planning services - are being offered in clinics located in or near public health schools and junior high schools. Fourteen such programs operating in 32 schools are described here; they have caseloads ranging from about 500 to around 5,000 students per year and handle up to 20,000 patient visits annually. These clinics usually are staffed by teams consisting mainly of nurse practitioners, clinic aides and part-time physicians, as well as social workers, nutritionists and other professionals. Patients at school-based clinics generally are from low-income families, a reflection of the neighborhoods in which programs are located. Most school-based clinics serve only current students, but a few also serve former students. Most of these programs were originated by an individual from outside the school system. However, the cooperation and support of principals and teachers for student health services have been vital factors in gaining approval for in-school clinics. The programs also appear to enjoy the support of their local communities. However, their long-term funding remains uncertain. So far, private foundations have helped these programs become established, but they cannot be expected to provide continuing aid. Donations from schools, health providers and other groups have played an important part in keeping the cost of school-based programs low. Public funds, particularly from state departments of maternal and child health, social services and education, are being sought in order to expand existing programs to more schools and to start new clinics in other communities. School-based programs have been credited with improving students' health, lowering their birthrates, raising their levels of contraceptive use and improving their school attendance. However, there have been few reliable studies of these programs. Improved program evaluation will be useful in helping these clinics retain their financial and community support

N2 - Developmental aspects of taurocholate transport into ileal brush border membrane vesicles were studied in 2-wk-old (suckling), 3-wk-old (weanling), and 6-wk-old (adolescent) rats. Taurocholate uptake (picomoles per milligram protein) into brush border membrane vesicles prepared from 2-wk-old rats was similar under Na⁺ and K⁺ gradient conditions (outside greater than inside). By contrast, uptake in 3- and 6-wk-old rats was significantly enhanced at 20 s, and at 1, 2, and 5 min of incubation in the presence of a Na⁺ gradient when compared with a K⁺ gradient incubation (P < 0.05). Under isotope exchange conditions, a plot of active uptake velocity versus taurocholate concentration (0.10-1.0 mM) in 2-wk-old rat membrane vesicles was linear and approached the horizontal axis, suggesting the absence of active transport. However, similar plots in 3- and 6-wk-old rats described a rectangular hyperbola, indicating a Na⁺-dependent, saturable cotransport system. Woolf-Augustinsson-Hofstee plots of the uptake velocity versus concentration data from 3- and 6-wk-old rat brush border membrane vesicles yielded V(max) values that were not significantly different, 844 and 884 pmol uptake/mg protein per 120 s, respectively. The respective K(m) values were 0.59 and 0.66 mM taurocholate. The induction of an electrochemical diffusion potential by incubating K⁺-loaded vesicles with valinomycin did not significantly enhance taurocholate uptake in 2-, 3-, or 6-wk-old rat vesicle preparations. These data indicate that taurocholate transport into rat ileal brush border membrane vesicles is mediated by an electroneutral, sodium-coupled, cotransport system that is incompletely developed in the 2-wk-old suckling rat but fully developed by the time of weaning at 3 wk of age

N2 - From a prospective study in which 24 hour recordings of the electrocardiogram and respiratory activity (abdominal wall movement) were made on a population of full term infants, 22 recordings were obtained from 16 infants who later were victims of the sudden infant death syndrome. The average heart rate, average heart rate variability, average breath to breath interval, and average breath to breath interval variability over the whole of each recording for the 22 recordings were compared with those from a control group of 324 infants selected at random from the rest of the population. No significance was found in the number of recordings from those infants who suffered the sudden infant death syndrome which lay outside the 5th-95th percentile range of the control group for the four variables studied. In a group comparison no difference was found between the sudden infant death syndrome group and the controls either in terms of the respiratory variables studied or in terms of the average heart rate variability. The results did, however, suggest that there may be a group difference in terms of the average instantaneous heart rate

N2 - This paper presents a discussion of conceptual and technical issues considered critical to the understanding, design, and implementation of developmental research using behavioral and physiologic measures. Background information is presented demonstrating the effectiveness of naturalistic monitoring of infant 24-hour, sleep-awake cycles in determining state regulation, and the importance of this function as it relates to other physiologic subsystems and to infant risk. Also included is a comprehensive report, with illustrations, of a biotelemetry system for concurrent, continuous monitoring of infant behavior, heart beat, and respiration in the naturalistic setting for the purpose of assessing physiologic regulation in relation to caregiving activity

N2 - A material from a casualty department consisting of 177 accidents which occurred in children in primary schools is presented. 4.5% of the school children were injured during school hours to an extent which required medical treatment. This figure is high when the duration of the brief school day in Denmark is considered. The sites and mechanisms of the injuries are considered in relation to the various age-groups and the individual schools. The smaller children are injured most frequently by falls and while using playground equipment while the injuries in older children occurred mainly during sport and gymnastics. The majority of the injuries were slight but 6% of the cases required hospitalization. The severity and number of the injuries were relatively uniform in the various schools. In one school, however, an accumulation of accidents involving doors was observed and this was connected with the closing mechanism of the doors in that particular school

N2 - The concurrent validity of the Children's Action Tendency Scale (CATS), a self-report measure of aggressiveness, assertiveness, and submissiveness, was assessed using behavioral observations in naturalistic settings. Forty-five third- to fifth-grade children were observed over an 8-month period in a wide variety of school (and school-related) activities. Scores on the CATS subscales were found to correlate significantly with a variety of behavioral indices of aggressiveness, assertiveness, and submissiveness; these correlations tended to be higher for boys than for girls. Explanations for these sex differences and recommendations for the questionnaire's use are offered

N2 - The authors examined the amount and effects of underreporting in a passive surveillance system used by three schoolboards to monitor injuries to school children. We compared information collected through active surveillance of 50 randomly selected schools for a two month time period staggered throughout the school year with the findings of passive surveillance. This comparison showed that schools report less than 25% of injuries to children. Serious injuries are more likely to be routinely reported. It is estimated that one out of two serious injuries was reported routinely, while one in five injuries of a non-serious nature was reported. The playground is the major site of injury

N2 - There were 469 unnatural deaths among the Sheffield child population between 1947 and 1979, 226 of which were caused by traffic accidents. The annual incidence of these fatal traffic accidents has risen steadily since the early 1960s with boys being consistently more vulnerable. Fatal accidents were disproportionately higher among social deprived families and in poorer areas of the city. The environment rather than the child may be 'accident prone' and there is an urgent need for safer play areas in deprived areas

N2 - The article reports on a possible relationship between excessive television watching and childhood obesity. A Nielsen study reports that children spend more than 20 hours per week watching television, which does little to burn calories compared to physical activities outdoors. In addition, children viewing TV tend to eat food high in fats, which is influenced by commercials that give children a false sense of reality. To combat this, parents should limit children's TV time and promote better eating habits

N2 - The article focuses on the book "Breast Feeding and Human Lactation," 2nd ed., by Kathleen Auerback and Jan Riordan. Infants are less likely to be breast-fed today than at any other time in history. The World Health Organization estimated in 1996 that only about one third of the babies younger than 4 months exclusively receive breast milk. The median duration of breast-feeding internationally is about 18 months. Women who are poor and live in rural settings are most likely to breast-feed. The most important obstacle is the lack of "acceptance by society of the need for a mother and child to be together and the right of the breast-feeding dyad to participate in social, civic, and commercial activities outside the home." This second edition of a text published in 1993 has expanded clinical information on the breast-feeding process and techniques and has added a new chapter on maternal nutrition; appended to most chapters are sections on clinical implications. The book is a comprehensive reference that begins by reviewing the historical, cultural, and familial context of breast-feeding

VL - 29

IS - 8

N2 - Socially anxious children have been described in the literature as at risk of developing increasing emotional problems and of being deprived of valid learning experiences with peers. In order to enable teachers to detect social anxiety in preschoolers the authors developed a scale. The TRSA-"junior" (Teacher Rating Scale of Social Anxiety-"junior") is a brief Likert-type questionnaire for the identification of social anxiety in 5-to 6-year-old children. Reliability (internal consistency plus test-retest correlation) collected in 2 samples was high. Convergent and divergent validity of this newly developed rating-scale were also studied. A high level of social anxiety correlated with a low level of social participation, as observed on the playground. The TRSA-"junior" score correlated with "internalizing" as measured by the Behavior Questionnaire for Toddlers and Preschoolers (BQTP) and the Child Behavior Check List (CBCL), and with the subscales "anxious-depressed", "thought problems", "social problems" and "withdrawn behavior" of the CBCL. In the second study a high score on social anxiety appeared to be related to less positive sociometric judgments by peers. The authors conclude that the TRSA-"junior" may aid in the identification and prevention of social anxiety at an early age. In addition, the scale would appear to be a useful instrument in research, given its sound psychometric qualities. ABSTRACT FROM AUTHOR

N2 - This article focuses on a research by the Trust for Public Land (TPL), which reveals that three in four residents of large American cities do not have access to a nearby park, playground or open space. Children in park-poor neighborhoods play in streets, alleyways and vacant lots rather than in grassy parks, baseball diamonds or soccer fields. One of TPL's programs, Parks for People Initiative, works in cities and suburbs nationwide to build playgrounds, such as in Newark, New Jersey, and New York City. After selecting a new site and partner organization, TPL launches an extensive outreach and design process with the school and community

N2 - The article presents some suggestions by "Golf Digest" teaching professional Renee Powell on how to introduce children to golf, without having to watch them being turned off from the game. On a regular course, children have been suggested to tee off from the 150-yard marker. Parents have been suggested to give their children their own par and scorecard because, they might play a hole in four shots, but it can be seven or eight for their children. Parents have also been asked to visit the course at off-peak hours to avoid slowing down experienced players, and to pick up before the score gets to double digits

N2 - Several photographs relating to playground renovations being carried out in tsunami-ravaged areas in Sri Lanka are presented. One photograph shows National Recreation and Park Association member Curtis Stoddard posing with children during new playground construction. Other photograph shows Sri Lankan children posing on their newly built climber. In one photograph, locals are shown using string to test for plumb, while in other photograph a builder is shown enjoying his lunch. Another photograph shows locals passing concrete relay style from the mixing area to the equipment

N2 - Research has found that obese and overweight boys and girls are prone to less physical activity. In this study, we reinvestigate the relationship between physical activity and obesity among children. We examined the differences in physical activity between overweight and normal weight children. Onehundred and twenty six Hawaii school-system children participated in this study. The children were measured for height and weight, and answered questions about their activity level. Activity level was assessed by participation in physical education, active play during recess and lunch, and other activities during the past week. Children were divided into obese, overweight and normal weight based on their age and body mass index (BMI). Ageadapted BMI was used as overweight and obesity indicator. The hypothesis for this project is that physical activity will be greater with normal weight boys and overweight girls than it is with overweight boys and normal weight girls.

N2 - Air pollution contributes to preventable illness and death. Subgroups of patients who appear to be more sensitive to the effects of air pollution include young children, the elderly and people with existing chronic cardiac and respiratory disease such as chronic obstructive pulmonary disease and asthma. It is unclear whether air pollution contributes to the development of asthma, but it does trigger asthma episodes. Physicians are in a position to identify patients at particular risk of health effects from air pollution exposure and to suggest timely and appropriate actions that these patients can take to protect themselves. A simple tool that uses the CH2OPD2 mnemonic (Community, Home, Hobbies, Occupation, Personal habits, Diet and Drugs) can help physicians take patients' environmental exposure histories to assess those who may be at risk. As public health advocates, physicians contribute to the primary prevention of illness and death related to air pollution in the population. In this article we review the origins of air pollutants, the pathophysiology of health effects, the burden of illness and the clinical implications of smog exposure using the illustrative case of an adolescent patient with asthma

N2 - Objectives. The indoor environment has not been fully incorporated into the environmental justice dialogue. To inform strategies to reduce disparities, we developed a framework to identify the individual and place-based drivers of indoor environment quality. Methods. We reviewed empirical evidence of socioeconomic disparities in indoor exposures and key determinants of these exposures for air pollutants, lead, allergens, and semivolatile organic compounds. We also used an indoor air quality model applied to multifamily housing to illustrate how nitrogen dioxide (NO₂) and fine particulate matter (PM_{2.5}) vary as a function of factors known to be influenced by socioeconomic status. Results. Indoor concentrations of multiple pollutants are elevated in low socioeconomic status households. Differences in these exposures are driven by the combined influences of indoor sources, outdoor sources, physical structures, and residential activity patterns. Simulation models confirmed indoor sources' importance in determining indoor NO₂ and PM_{2.5} exposures and showed the influence of household-specific determinants. Conclusions. Both theoretical models and empirical evidence emphasized that disparities in indoor environmental exposure can be significant. Understanding key determinants of multiple indoor exposures can aid in developing policies to reduce these disparities

N2 - The present study examined the relationship between maximal oxygen uptake (VO₂max) and daily physical activity in a group of 7- to 12-year-old boys. VO₂max was assessed through the incremental treadmill test using an open circuit system. Physical activity level was obtained from heart rate telemetry outside of school time for 8 hrs during weekdays and during 40 min of physical education classes. The findings indicated that the absolute value of VO₂max increased with age, while relative to body weight it remained almost the same across age, with a mean of 48.4 ml.kg⁻¹.min⁻¹. Moreover, heart rate telemetry showed that the boys spent a limited amount of time on activities that raise the heart rate to a level above 160 bpm (an average of 1.9 percent. In addition, VO₂max was found to be significantly related to the percentage of time spent at activity levels at or above a heart rate of 140 bpm, but not with activity levels at or above a heart rate of 160 bpm

N2 - Objective: to determine the ongoing noise level equivalent to the one experienced by a student in his or her daily activity in public primary schools of Albacete. Material and method: cross-sectional descriptive observational study in 11 public primary schools of Albacete. Dependent variable: ongoing noise level equal to that experienced by the student (Leq in dBA). Independent variables: school and places in the school. The measurements have been performed using type 2.226 Bruel & Kjaer sound measurers with tripod. 95% Confidence intervals were calculated. Results: the average noise level equivalent to that in the classrooms of children between the age of three and five had a mean value of 75 dBA, for ages between six and seven it was 66 dBA and for ages between 8 and 11 it was 69 dBA. The sample distribution mean (ages between 3 and 11)

was 70 dBA. The average noise level equivalent in the hallway at the end of the school day had a mean value of 71 dBA and 83 dBA in the playground during break. Conclusions: the equivalent ongoing noise levels obtained exceed the limits established by the current legislation for schools. Therefore, students are exposed to elevated noise during their school activity

N2 - Over the last decade, the sport of mountain biking has experienced extensive growth in youth participation. Due to the unpredictable nature of outdoor sport, a lack of rider awareness and increased participation, the number of injuries has unnecessarily increased. Many believe that the actual incidence of trauma in this sport is underestimated and is just the 'iceberg'. The most common mechanism of injury is usually attributed to downhill riding and forward falling. Although rare, this type of fall can result in serious cranial and thoraco-abdominal trauma. Head and neck trauma continue to be documented, often resulting in concussions and the possibility of permanent neurological sequelae. Upper limb injuries range from minor dermal abrasions, contusions and muscular strains to complex particular fracture dislocations. These are caused by attempting to arrest the face with an outstretched hand, leading to additional direct injury. Common overuse injuries include repeated compression from the handlebars and vibration leading to neurovascular complications in the hands. Along with reports of blunt abdominal trauma and lumbar muscle strains, lower extremity injuries may include various hip/pelvic/groin contusions, patellofemoral inflammation, and various muscle strains. The primary causes of mountain biking injuries in children and adolescents include overuse, excessive fatigue, age, level of experience, and inappropriate or improperly adjusted equipment. Additional factors contributing to trauma among this age group involve musculoskeletal immaturity, collisions and falls, excessive speed, environmental conditions, conditioning and fitness status of the rider, nonconservative behavioural patterns, and inadequate medical care. The limited available data restrict the identification and understanding of specific paediatric mountain biking injuries and injury mechanisms. Education about unnecessary risk of injury, use of protective equipment, suitable bikes and proper riding technique, coupled with attentive and proper behaviour, are encouraged to reduce unnecessary injury. This article provides information on the causation and risk factors associated with injury among young mountain bikers, and recommendations to minimize trauma and enhance optimal performance and long-term enjoyment in this outdoor sport. N2 - The objective of this study was to investigate consumer behaviour issues in a summer children's camp setting. Specifically, the study aimed to: (a) identify the personal incentives that drive children to participate in summer camps, (b) test gender and age differences in children's personal incentives, and (c) investigate which of the incentives are the most important ones in predicting children's satisfaction, loyalty, and word-of-mouth communications. The sample of the study consisted of 453 (N =453) children, who participated in a camp located at the mainland of north Greece. The results indicated that: (a) six personal incentive dimensions revealed from a factor analysis of the personal incentive scale, named: Camp Experience, Socialization I (making new friends), Socialization II (meeting old friends), Independence, Activities Participation, and Parents' Decision, (b) Socialization I and Camp Experience were the two highest scored dimensions, (c) girls were more driven by Socialization II (meeting old friends) related incentives than boys, who scored higher on the Activities' Participation dimension, (d) older and more experienced campers expected more independence and social interaction than younger campers, who expected to participate in a variety of sport and cultural activities, and (e) the Camp Experience dimension was the most powerful and consistent predictor of satisfaction, loyalty and word-of-mouth communications. The managerial implications of these results are discussed. ABSTRACT FROM AUTHOR

N2 - Objectives: To investigate the occurrence of delayed neuropsychological and motor development in a community assisted through the Family Health Program and to evaluate its association with possible biological, environmental and socioeconomic risk factors. Methods: The sample consisted of 31 five-year-old children who were evaluated using the Neurological Development Test, following guidelines proposed by Coelho (1999)*.

The study was carried out at the Family Health Program (FHP) center in the Brasilit area of Recife, PE, Brazil. Data were collected using a questionnaire that sought information on the child, its mother/guardian, the family's socioeconomic status and residence. Fisher's exact test was used for the statistical analysis of the results, with a significance level of 5%. Results: Appendicular coordination was the parameter with the highest frequency of deficits (90%) and static balance was the item least compromised (12.9%). The frequency of static balance deficits was higher among children who did not attend day care centers ($p=0.0163$) and among those who spent less time with their mother ($p=0.0278$). Motor persistence deficits were statistically associated with age of entry into day care ($p=0.0415$) and father-child time ($p=0.0436$). Conclusions: The FHP was not only a valuable

setting for developing studies of this nature but also an appropriate setting for child development follow-up.

N2 - Background: Childhood obesity is epidemic, and Hispanic children bear a particularly high health burden because of it. Evidence suggests that obesity prevention is a better option than intervention. Because schools have decreased the amount of time spent in physical education classes, leisure time has become the time to engage in physical activity, which may prevent obesity. Social ecology theory posits that a person's interaction with the environment has a strong influence on health promoting behavior. Further, this theory suggests that cultural values also play a role. The extant literature points to the sedentary nature of Hispanic children.

However, it does not provide a description of the activities that children engage in during their leisure time, or how they are influenced by their family, culture, and community's environment

Purpose: The purpose of this study was to describe and provide an understanding of how leisure time is viewed by Hispanic families, and how family and culture influences Hispanic children's participation in leisure time activity. Two broad research questions were addressed: 1) How do Hispanic families describe leisure time activities? and 2) How do culture, family and the community environment influence a Hispanic child's participation in leisure time activities?

Methods: This ethnographic study incorporated photographs taken by English-speaking Hispanic mothers of children between 6 and 10 years old (n=10) as they engaged in leisure activities for one week. The participants engaged in photo-elicited interviews, describing the children's activities and performed initial data analysis by sorting the photos in the categories of activities

Findings: Girls were more sedentary, engaging in intellectually stimulating and creative play activities inside, with family members or alone. Boys were more active, engaging in unstructured play activities outside with family members or friends. The children engaged in these activities to promote their health, prepare for their adult lives, and for fun. Cultural tensions experienced by the children's parents had a profound influence on their

leisure time choices and decisions. Activities were used to prepare the children for a better life, and to teach them to balance work and fun. Ultimately, the participants wanted their children to live a balanced life; one that is happy, healthy, and successful

Relevance: The children engaged in purposefully planned leisure activities aimed to ensure their health, happiness, and success in the U.S. The participants acknowledged that to achieve a better life, the children must become expert multicultural navigators. While many of the activities were sedentary, they had important implications for the children's future. Health care providers must consider how patients view leisure time, and enlist their ideas in order to make children's activities more physically active

N2 - The purpose of this study was to examine the effects of a social skills and comparison intervention on peer social behaviors of 43 young children who were deaf and hard of hearing (D/HH). Both interventions were conducted in small groups consisting of children who were D/HH and hearing. Data were obtained on 15 social behaviors in four categories: peer interaction, play, child initiations/peer responses, and peer initiations/child responses. Social behaviors were recorded during free play (a) before the intervention (b) immediately after the

intervention ceased, and (c) 4 weeks after the intervention decreased their frequency of solitary and parallel play. These changes were maintained 1 year later in an outdoor play setting

N2 - This study assessed the effectiveness of an activity-based intervention program and a direct instruction program for preschool children with disabilities. Two groups of preschool students (average age =4.1 yr.), classified as having developmental delays or at risk for such delays, were selected. They were provided 15 weeks of physical education through activity-based intervention and 15 weeks of physical education by direct instruction. Instruction was provided three times a week for 30-min. each session. In the fall semester the morning group received physical education through activity-based intervention, while the afternoon group received physical education through direct instruction. In the spring semester delivery of instruction was reversed for each group. The curriculum and activities provided to each group were identical with only the instructional delivery format altered. Two sets of pre- and post-tests using the Test of Gross Motor Development were administered before and after each 15-wk. instructional period. Group improvement in skills was compared between instructional methods. Significant improvement in both locomotor and object control skills through the activity-based intervention was found compared to direct instruction. Activity-based intervention was shown to be easily adapted to a naturalistic educational setting befitting that of preschool education.

N2 - Discusses the responsibility of leisure providers toward disadvantaged groups, focusing on women with children under the age of five. Looks at community-based activities (the public sector), leisure provision in the private sector, and the importance of the voluntary sector in providing leisure opportunities. Reports that difficulties with transportation, time, finance, and confidence, as well as the generally unwelcoming attitude toward children in Britain, are major constraints on women's involvement in leisure activities outside the home. Shows how managers and entrepreneurs can increase leisure participation by this particular disadvantaged group by being aware of their difficulties and accommodating their needs

N2 - Abstract: The purposes of the present study were to (1) determine the internal plantar mechanical stresses in diabetic and healthy subjects during everyday activities, and (2) identify stress parameters potentially capable of distinguishing between diabetic and healthy subjects. A self-designed, portable, real-time and subject-specific foot load monitor which employs the Hertz contact theory was utilized to determine the internal dynamic plantar tissue stresses in 10 diabetic patients and 6 healthy subjects during free walking and outdoors stair climbing. Internal stress parameters and average stress-doses were evaluated, and the results obtained from the two groups were compared. Internal plantar stresses and averaged stress-doses during free walking and outdoors stairs climbing in the diabetic group were 2.5-5.5-fold higher than in the healthy group ($p < 0.001$; stair climbing comparisons incorporated data from five diabetic patients). The interfacial pressures measured during free walking were slightly higher ($f \sim 1.5$ -fold) in the diabetic group ($p < 0.05$), but there was no significant difference between the two groups during stairs climbing. We conclude that during walking and stair climbing, internal plantar tissue stresses are considerably higher than foot/shoe interface pressures, and in diabetic patients, internal stresses substantially exceed the levels in healthy. The proposed method can be used for rating

performances or design of footwear for protecting sub-dermal plantar tissues in patients who are at risk for developing foot ulcers. It may also be helpful in providing biofeedback to neuropathic diabetic patients.

CY - ;

N2 - A study has been conducted on a sample of 1368 children attending compulsory school in order to examine the relationship between the time spent watching television and physical activity. A distinction has been made according to the time of the day when the children watch television: before going to school, back from school throughout the afternoon, and after dinner. As far as physical activity is concerned, the weekly frequency and the duration both of the organized physical activity and of the outdoor games have been considered separately. The practice of organized physical activity does not have a considerable influence on television viewing unlike the physical activity carried out by children after school. In the afternoon, when children dedicate themselves to outdoor games and sport activities, the time spent watching television is inversely proportional to the physical activity practiced 8 hours per week by the youngest children and 5.9 by the grown-ups, against 5.8 and 7 hours per week spent by those children who attend primary school and by the adolescents of secondary school: those who did not practice any physical activity (group A and D), those who practiced physical exercises less than an hour a day (group B and E) and more than an hour a day (group C and F). It has been noted that, considering the groups of those children who practiced physical activity for a longer period of time, the hours spent watching television were significantly lower as far as the children attending primary school are concerned (2.55 +/- 1.19 vs 2.39 +/- 1.12 vs 2.16 +/- 1.14) (p < 0.005 A-C, p < 0.05 B-C) and those attending secondary schools (2.73 +/- 1.15 vs 2.55 +/- 1.03 vs 2.39 +/- 1.02) (p < 0.01 D-F, p < 0.05 E-F). These data is mainly due to a variation in the number of hours spent watching television during the afternoon by children attending both primary (1.28 +/- 0.87 vs 1.19 +/- 0.86 vs 0.99 +/- 0.81) (p < 0.001 A-C, p

< 0.05 B-C) and secondary schools (1.00 +/- 0.88 vs 0.89 +/- 0.84 vs 0.73 +/- 0.69) (p < 0.01 D-F, p < 0.01 E-F). The negative effects of a prolonged time spent watching television could be contrasted promoting any kind of physical activity and of outdoor games

N2 - The article discusses the growing clamor for more playground shade in view of the risks of staying outdoors for extended period with no sun protection. According to the article, while shades are used to keep playground equipment cool, part of the concern is the long term effect of sun exposure which with just one incident of severe sunburn in childhood doubles the risk of skin cancer later in life. As the awareness increases, shaded playground equipment has become the new norm in many states

N2 - The article discusses solutions for increasing physical exercise among U.S. students. According to the 2008 Physical Activity Guidelines for Americans, the U.S. Department of Health and Human Services suggested that children and adolescents must exercise at a minimum of 1 hour every day. The U.S. National Association of Sport and Physical Education created physical fitness guidelines that consist of before-school, during-school, and after-school plans including walking or biking to and from school, and a Learnercise program during recess times

N2 - Background: With more than 1.1 million high school athletes playing annually during the 2005-06 to 2009-10 academic years, football is the most popular boys' sport in the United States. Methods: Using an internet-based data collection tool, RIO, certified athletic trainers (ATs) from 100 nationally representative US high schools reported athletic exposure and football injury data during the 2005-06 to 2009-10 academic years. Results: Participating ATs reported 10,100 football injuries corresponding to an estimated 2,739,187 football-

related injuries nationally. The injury rate was 4.08 per 1000 athlete-exposures (AEs) overall. Offensive lineman collectively (center, offensive guard, offensive tackle) sustained 18.3% of all injuries. Running backs (16.3%) sustained more injuries than any other position followed by linebackers (14.9%) and wide receivers (11.9%). The leading mechanism of injury was player-player contact (64.0%) followed by player-surface contact (13.4%). More specifically, injury occurred most commonly when players were being tackled (24.4%) and tackling (21.8%). Conclusions: Patterns of football injuries vary by position. Identifying such differences is important to drive development of evidence-based, targeted injury prevention efforts. ABSTRACT FROM

N2 - On the basis of a previously prepared questionnaire the author carried out (1988-1989) the individual interviews with pre-school children (n=300, age: 6 years). Completing the investigation, she has collected the additional data from their parents and their nursery school teachers. The findings showed that the health-related values of various forms of recreation were appreciated by majority of children, parents and teachers.

Furthermore, according to the opinion of more than half of the interviewed parents and teachers, the participation in recreation activities makes the children more resourceful in their daily life (58,8 per cent of parents and 55 per cent of teachers) and lets spend their spare time in more profitable way (50 per cent of parents and 54 per cent of teachers). Symptomatic was the fact that much fewer teachers (31 per cent) than parents (51 per cent) stressed relaxation aspects of hiking and excursions. This difference of views results from the specific approach of a nursery school towards these recreation activities: the nursery school teachers are to fulfill didactic task rather than serve purposes related to health and relaxation

N2 - This article describes the development of the Triadic Intervention and Evaluation Rating Scale (TIERS), a 33-item instrument designed to evaluate patterns of parent, service provider, and child interactions during early intervention sessions conducted in natural environments. Twenty-eight parent-provider-child triads were videotaped in home and playgroup settings, quarterly over a 15-month period. Segments representing complete routines were selected and rated by service providers and research personnel. Scoring and scaling models were developed to evaluate the quality of triadic interactions during early intervention sessions. The TIERS (a) measured differences in providers' use of collaborative consultation strategies and parents' level of participation with service providers and their children; (b) distinguished features inherent in different sessions; (c) was easy to administer; and (d) showed appropriate psychometric properties. With additional validation efforts, this instrument may be used to evaluate the implementation of collaborative interactions between parents and early intervention service providers in natural environments

N2 - This session will focus on preparing parents and leaders for meeting the special needs of children while engaged in outdoor activities ranging from day hikes to extended backpacking and canoeing adventures. The emphasis of this workshop is how to include children in existing programming rather than creating trips and workshops especially for that age group. This outline should be useful to outdoor programmers at non-traditional colleges, on military bases, or young professionals looking at getting jobs at summer camps and other professional outdoor agencies. N2 - Physical inactivity is an important contributor to non-communicable diseases in countries of high income, and increasingly so in those of low and middle income. Understanding why people are physically active or inactive contributes to evidence-based planning of public health interventions, because effective programmes will target factors known to cause inactivity. Research into correlates (factors associated with activity) or determinants (those with a causal relationship) has burgeoned in the past two decades, but has mostly focused on individual-level factors in high-income countries. It has shown that age, sex, health status, self-efficacy, and motivation are associated with physical activity. Ecological models take a broad view of health behaviour causation, with the social and physical environment included as contributors to physical inactivity, particularly those outside the health sector, such as urban planning, transportation systems, and parks and trails. New areas of determinants research have identified genetic factors contributing to the propensity to be physically active, and evolutionary factors and obesity that might predispose to inactivity, and have explored the longitudinal

tracking of physical activity throughout life. An understanding of correlates and determinants, especially in countries of low and middle income, could reduce the effect of future epidemics of inactivity and contribute to effective global prevention of non-communicable diseases

N2 - Recent evidence indicates that many elementary schools have curtailed recess and Physical Education (Morrow, Jackson & Payne 1999). These findings are at variance with the goal of Healthy People 2010 to increase physical activity. The purpose of this study was to examine physical activity opportunities (PAO) in U.S. public elementary schools. Survey data obtained from the National Center for Education Statistics were analyzed using within grade (1-5 or 6) between group comparisons. Key findings included: a) PAO decreased from 222 to 204 minutes/week for grades 1 to 5; b) schools with smaller enrollments (<300 pupils) provided more PAO than schools in all larger categories ($p < .01$); c) schools in rural areas provided more PAO than schools in towns, suburbs, and cities ($p < .01$); d) schools with a low minority enrollment (<6%) provided more PAO than did schools with very high minority enrollment (>50%) ($P < .01$); and e) schools with fewer children enrolled in free/reduced price lunch (<35%) afforded more PAO than did schools with the highest rates (>75%) ($P < .01$). N2 - This article presents several sports-related news briefs. Destiny's Child may be bootylicious, but the NFL is going to great lengths to make that a mootlylicious point when BeyoncAc and the gals perform at the league's kickoff concert at Gillette Stadium on Sept. 9. Among the other acts-- NFL spokesman Brian McCarthy describes them as "popular but safe choices"--singing before the Patriots-Colts game are Elton John, Toby Keith and Lenny Kravitz. In King James, a new DC Comic book, LeBron James is crowned King of Basketball after dominating an underground tournament run by a "mysterious, secret organization." The cradle may rock, but Camden Yards won't. The Orioles backed out of an agreement that would have had Van Halen playing a concert at the stadium on Sept. 2. Not ones to slink away in their spandex, Eddie and the boys filed a breach-of-contract lawsuit against the team. The suit, which asks for at least \$2 million, contends that Van Halen "had to change the dates of other scheduled concerts and forgo other concert opportunities in order to accommodate the Oriole Park concert." The team won a legal battle with the Maryland Stadium Authority three years ago for the right to book bands there as a means of bolstering stadium revenue. Last week real estate agent Terrye Jackson of Springdale, Md., set a world record for the longest continuous television-watching session by taking in 50 hours and seven minutes of NBC's Games coverage. Raiders rookie defensive end Andre Sommersell has learned the value of keeping his mouth shut. The former Colorado State defensive end made it known in camp that he wasn't going to put up with any rookie initiations. Bad move. On Aug. 17, following practice, his teammates taped him to a goalpost, doused him with water and coated him with talcum powder and abandoned him

N2 - Healthy People 2010: Objectives for Improving Health (USDHHS, 2003) stated that more people with disabilities and women report no leisure-time physical activities than people without disabilities and men.

Similarly, children with disabilities are often not included in physical education and playground activities.

Therefore, girls with physical disabilities are confronted with a "double whammy" of gender and disability to

compromise their self-image. While little research exists that explores physical activity for females with disabilities specifically, it has been found that physical activity is important for their quality of life, sense of control, and autonomy. This preliminary study was conducted using a phenomenological approach to examine the perceptions of girls with physical disabilities regarding physical recreation pursuits. Results from in-depth interviews generated three themes: meanings of physical activity, ownership of disability, and poor access to role models. Recommendations for alternate research methodologies as well as future content areas are discussed

N2 - Child--parent pairs (n = 109) completed a questionnaire assessing whether changes in normal physical activity levels occurred (child) or were observed (parent) when the children wore a pedometer for 7 days. Over two-thirds of the children (78.5%) and almost half of the parents (47.3%) indicated an increase in the child's normal physical activity. Reduced television viewing (75.2%) and increased outdoor play on the weekend (35.8%) were the most frequently reported means of behavior change as reported by the children and parents, respectively. Results indicate that both children and parents perceive a reactive effect to wearing an unsealed pedometer

N2 - Purpose. Examine the effects of father-child involvement and neighborhood characteristics with young children's physical activity (PA) within a multilevel framework. Design. Cross-sectional analysis of the Early Childhood Longitudinal Studyf_"Kindergarten Cohort 1998. Setting. Nationally representative sample. Subjects. Data were available for 10,694 kindergartners (5-6 years; 5240 girls) living in 1053 neighborhoods. Measures. Parental report of child's PA level, father characteristics (e.g., time spent with child, age, education, socioeconomic status, hours worked), family time spent doing sports/activities together, and neighborhood quality (e.g., safety, presence of crime violence, garbage). Child weight status, motor skills, ethnicity, and television viewing were used as covariates. Analysis. Multilevel structural equation modeling with children nested within neighborhoods. Results. At the child level father-child time and family time doing sports together were positively associated with children's PA. At the neighborhood level parental perception of a neighborhood's safety for children to play outside fully mediated the effect of neighborhood quality on children's PA. Overall 19.1% and 7.6% of the variance in PA was explained at the child and neighborhood levels, respectively. Conclusions. Family-based interventions for PA should consider father-child time, with this contributing to a child's overall PA level. Further, neighborhood quality is an important predictor of PA only to the extent by which parents perceive it to be unsafe for their child to play outdoors. ABSTRACT FROM AUTHOR

N2 - BACKGROUND: National guidelines exist that define *f_oqualityf__* afterschool programs (3*f_*"6pm, ASP). No widely adopted national standards/policies exist, however, for ASP providers for the promotion of physical activity (PA). To address this gap, state-level ASP organizations have developed or adopted standards/policies related to PA. The extent to which standards and policies are uniform and disseminated is unclear. The purpose of this study was to review state-level ASP documentation to identify standards/policies for promoting PA within the ASP setting. METHODS: A systematic review of state-level ASP organizations' standards/policies was conducted to identify documentation that included language explicitly defining or related to the promotion of physical activity within ASP. State-level ASP organizations were identified from registries available from national ASP organizations. Documentation was retrieved from online sources and reviewed using a standardized content analysis protocol. RESULTS: Quality ASP definitions were retrieved from 47 states. Of these, 14 incorporated language related to the promotion of PA. This included the provision of adequate outdoor space for attendees to be active, provision of frequent PA opportunities, and promoting physical development. A total of 5 states had standards/policies that explicitly identified the amount of time for attendees to be physically active during ASP attendance, while 3 states outlined standards/policies regarding core competencies for ASP providers to promote PA. CONCLUSIONS: Overall, standards/polices related to promoting PA within ASP were largely absent. Those that do exist, however, can provide a foundation for future empirical tests. The testing of these standards/policies will assist in the development of national guidelines to promote PA within the ASP setting. ABSTRACT FROM AUTHOR

N2 - The transition from adolescence to young adulthood is associated with a sharp decline in physical activity, particularly for women. This article explores the relations between physical activity status and change and status and change in four life domains: residential independence, employment status, relationship status, and motherhood. Two waves of survey data from a representative sample of 8,545 Australian women, aged 18-23 at Survey 1 and 22-27 at Survey 2, were analyzed. Cross-sectionally, physical inactivity was most strongly related to being a mother, married, and not being in the labor force. Longitudinally, decreases in physical activity were most strongly associated with moving into a live-in relationship, with getting married, and with becoming a mother. When considered in combination, women who were married with children and not employed outside the home were the most likely to be physically inactive. The data suggest that adoption of adult statuses, particularly traditional roles involving family relationships and motherhood, is associated with reductions in physical activity for these women, although it is possible that the effect is driven by socioeconomic factors associated with early transitions. The data suggest a need for interventions to promote continued physical activity among young women who cohabit or marry and among those not in the workforce, in addition to those supporting young mothers to be physically active. Key words: physical activity, women, emerging adulthood, longitudinal ABSTRACT FROM AUTHOR

N2 - The development of sport and physical activity programs may improve psychological well-being and reduce risk factors of several health problems. Self-esteem has shown to have a strong position in the

explanation of human behaviour. The purpose of this study was to evaluate the effects of an Outdoor Adventure Activities Program on the self-esteem and physical self-perceptions of Portuguese school adolescents (n = 38). A translated version of the Physical Self-Perception Profile for Children and Youth (PSPP-CY) was used to assess self-esteem and physical self-perceptions. The main conclusions of this study showed that participants in general reported higher values on their self-esteem and physical self-perceptions after the program. Further experimental programs are required to confirm the results of this study

N2 - Schools have been identified as a central element in a system that ensures that children participate in enough physical activity to develop healthy lifestyles. Even with this recommendation, many school-based physical activity opportunities are being eliminated/minimized (i.e. physical education (PE), recess). With children spending much of their time at school, other supplemental physical activity opportunities are essential. One such opportunity is through classroom teacher led activity breaks. Very little evidence exists identifying the impact of classroom activity breaks on the daily physical activity patterns of children. Therefore, the purpose of this paper was to determine the impact of classroom teacher led activity breaks on the step counts and moderate-to-vigorous physical activity (MVPA) of 4th grade children at school. Participants in this pilot study included a 4th grade class (N=18; aged 9.2A ñ4 years; mostly Caucasian (n=14); BMI=19.9A ñ2.8) in a rural school district in the Northeast US. Children wore the NL-1000 piezoelectric pedometer for 2-weeks (a baseline week and an activity break week) during the winter of 2012. Activity breaks were created by the teacher/students to give them ownership in the program (activities included numerous classroom games and walking activities). At baseline, children averaged 4806A ñ639 steps and 17.7A ñ2.8 minutes of MVPA/day. During implementation of the physical activity breaks, children significantly increased both their steps (p<.01; 5651A ñ627; I"=845) and MVPA (p<.01; 22.3A ñ3.5; I"=4.6 minutes). Findings suggest that classroom activity breaks have the potential to increase children's daily physical activity patterns at school. Future studies are needed with a larger and more diverse population to support these findings. ABSTRACT FROM AUTHOR

N2 - To increase young people's physical activity (PA) levels it is important to understand the correlates of PA in children and adolescents. We sought to identify factors associated with children's and adolescents' PA by reviewing systematic quantitative reviews of non-intervention research. Systematic reviews examining associations between quantitatively measured variables and PA in young people (< 19 years) from 2000-2010 were identified using electronic and manual searches. Nine systematic reviews were identified.

Demographic/biological correlates of PA were age and gender. Psychological correlates of PA were positive motivation, positive body image and the existence of barriers to PA. Behavioural correlates of PA were previous PA, sport participation, smoking, and sedentary behaviour. Social/cultural correlates of PA were parental influence and social support, and environmental correlates of PA were access to facilities, distance from home to school, time spent outside, and local crime. The evidence is suggestive of a number of different types of correlates of PA for children and adolescents. Beyond age and gender, though, most are likely to have only small or small-to-moderate effects in isolation and may work best in interaction with other influences.

Psychologists must look to social, organisational and community-level correlates in addition to individual correlates. ABSTRACT FROM AUTHOR

N2 - Physical activity is of inestimable value for health and the motoric development of young people. But in the course of late childhood and adolescence, it becomes less important compared to other leisure activities which do not contain any physical strain. The decrease of physical activity and the resulting decline of motor fitness are reflected in the outcomes of various studies. Hence, strategies are needed to maintain the children's motivation in physical activity. The enormous popularity of Serious Games could possibly be one strategy because Exergames give an access to sport or to a more active lifestyle. As an isolated movement pattern, Serious Games are no alternative or even a surrogate for real physical exercise. It is difficult to enable a realistically social interaction during virtual sport which has a positive influence on social development. Furthermore indoor video gaming is not comparable to outdoor exercises due to the lack of external influences like wind or audience, which are important contributions to the "adventure" of sport. But in combination and addition to real sport, Serious Games can contribute to the preservation and increase of motor fitness and children's pleasure in motion. ABSTRACT FROM AUTHOR

N2 - Context: The shoulder is one of the most commonly injured body sites among athletes. Little previous research describes shoulder injury patterns in high school athletes. Objective: To describe and compare shoulder injury rates and patterns among high school athletes in 9 sports (football, soccer, basketball, baseball, and wrestling for boys and soccer, volleyball, basketball, and softball for girls). Design: Prospective injury surveillance study. Setting: Injury data were collected from 100 nationally representative US high schools via High School Reporting Information Online. Patients or Other Participants: Athletes from participating high schools injured while involved in a school-sanctioned practice or competition in 1 of the above sports during the 2005-2006 and 2006-2007 school years. Main Outcome Measure(s): Shoulder injury rates, diagnoses, severity, and mechanisms. Results: During the 2005-2006 and 2005-2007 school years, athletes in this study sustained 805 shoulder injuries during 3 550 141 athlete-exposures (AEs), for an injury rate of 2.27 shoulder injuries per 10 000 AEs. This corresponds to an estimated 232 258 shoulder injuries occurring nationwide during this time. Shoulder injuries were more likely to occur during competition than practice (rate ratio = 3.01, 95% confidence interval = 2.62, 3.46). Shoulder injury rates per 10 000 AEs were highest in football (5.09), wrestling (4.34), and baseball (1.90). Common shoulder injury diagnoses included sprains/ strains (39.6%), dislocations/separations (23.7%), contusions (11.5%), and fractures (6.6%). Although 44.8% of athletes sustaining a shoulder injury returned to play in less than 1 week, 22.9% were out of play for more than 3 weeks, and 6.2% of shoulder injuries required surgery. Common mechanisms of shoulder injury included player-to-player contact (57.6%) and contact with the playing surface (22.8%). Conclusions: High school shoulder injury rates and patterns varied by sport. Continued surveillance is warranted to understand trends and patterns over time and to develop and evaluate evidence-based preventive interventions. ABSTRACT FROM AUTHOR

N2 - Background: With more than a million high school athletes playing during the 2006-2007 academic year, basketball is one of the most popular sports in the United States. Hypothesis: Basketball injury rates and patterns differ by gender and type of exposure. Study Design: Descriptive epidemiology study. Methods: Basketball-related injury data were collected during the 2005-2006 and 2006-2007 academic years from 100 nationally representative US high schools via Reporting Information Online. Results: High school basketball players sustained 1518 injuries during 780 651 athlete exposures for an injury rate of 1.94 per 1000 athlete exposures. The injury rate per 1000 athlete exposures was greater during competition (3.27) than during practice (1.40; rate ratio, 2.33; 95% confidence interval, 2.10-2.57) and was greater among girls (2.08) than among boys (1.83; rate ratio, 1.14; 95% confidence interval, 1.03-1.26). The ankle/foot (39.7%), knee (14.7%), head/face/neck (13.6%),

arm/hand (9.6%), and hip/thigh/upper leg (8.4%) were most commonly injured. The most frequent injury diagnoses were ligament sprains (44.0%), muscle/tendon strains (17.7%), contusions (8.6%), fractures (8.5%), and concussions (7.0%). Female basketball players sustained a greater proportion of concussions (injury proportion ratio, 2.41; 95% confidence interval, 1.49-3.91) and knee injuries (injury proportion ratio, 1.71; 95% confidence interval, 1.27-2.30), whereas boys more frequently sustained fractures (injury proportion ratio, 1.87; 95% confidence interval, 1.27-2.77) and contusions (injury proportion ratio, 1.52; 95% confidence interval, 1.00-2.31). The most common girls' injury requiring surgery was knee ligament sprains (47.9%). Conclusion: High school basketball injury patterns vary by gender and type of exposure. This study suggests several areas of emphasis for targeted injury prevention interventions. ABSTRACT FROM AUTHOR

N2 - The article presents information on a study that examined the social variables predictive of higher lead levels in young Egyptian children. Children were recruited from 2 different areas in Giza, Egypt, a rural village and a lower-middle-class urban district. Houses were evaluated with respect to building materials, pavement, condition of paint, sleeping site of children and the type of floor in the house. Blood specimens were analyzed for lead by flameless atomic absorption at the Air and Industrial Hygiene Laboratory, California State Department of Health Services in Berkeley, California. Results of multiple linear regression analysis showed that blood lead levels (PbB) was significantly affected by age, traffic, mother's occupation, sleep site and street pavement. In the general population, children under the age of 5 have the highest PbB because of increased gastrointestinal absorption and exposure through behaviors such as playing outdoors and increased hand-to-mouth activity. The differences in the prevalence of elevated PbB levels between rural and urban children are likely to represent differences in housing characteristics and environmental exposure. Lead-contaminated soil and dust in high-traffic areas significantly contribute to the children's lead intake

KW - DISABILITIES-Motor impairments

RP - NOT IN FILE

CY - Gloucester, Ont.;

PB - Canadian Fitness and Lifestyle Research Institute

N2 - In this project, four interrelated studies were conducted to test the activity deficit hypothesis with children experiencing movement difficulties. This hypothesis states that children with movement difficulties are less physically active than children without movement difficulties. In two observational studies, data were collected on children with movement difficulties and children without movement difficulties during a regular physical education class and recess time at school. During regular physical education, children with movement difficulties were more often (a) not motor engaged when they are supposed to be and (b) engaged in a motor activity but in the wrong activity for the task. During recess time, it was found that children with movement difficulties were (a) less often vigorously active, (b) less often playing with large playground equipment (requiring a higher level of movement proficiency), (c) not observable for significantly more time, and (d) spent less time in positive social interactions with others of their own gender. A free leisure-time pursuit was administered during the third study. Overall, no major differences were found between children with and without movement difficulties. Finally, in the fourth study the exercise intensity level of children with movement difficulties was compared to that of children without movement difficulties during one weekend day. The intensity of physical activity was estimated by continuous monitoring of minute-by-minute heart rates using the Sport Tester PE 3000, a self-contained computerized telemetry system. No significant differences were found between both groups of children. Overall, it was found that the best setting to test the activity deficit hypothesis was a relatively free, unstructured play situation, in which the participants were free to choose participation. The setting having most of these characteristics was recess time. Accordingly, we suggest that the anecdotal evidence and current data support the activity hypothesis which is based on recent motivational theories. Children with movement difficulties have, on the average, developed a dangerous lifestyle. They have

developed a style that puts skill development, social interaction, health and fitness at risk. Implications of these results for fitness and lifestyle as well as future research needs are presented

Au moyen de quatre études, le but de ce projet était de vérifier si dans la vie courante l'hypothèse d'hypoactivité chez les enfants maladroits est supportée. Selon cette hypothèse, les enfants maladroits évitent plus souvent les situations de mouvement que leurs pairs du même âge n'ayant pas de problèmes de justesse motrice. Pendant deux études observationnelles, des enfants maladroits ainsi que des enfants n'ayant pas de problèmes de justesse motrice furent observés pendant une période d'éducation physique à l'école ainsi que pendant la récréation. Les résultats de nos observations pendant la période d'éducation physique indiquent que les enfants maladroits, comparativement aux enfants témoin, (a) accomplissaient moins souvent la tâche demandée, et (b) modifiaient la tâche de façon telle qu'une autre tâche était accomplie. La seconde étude indiqua que pendant la période de récréation les enfants maladroits (a) participaient moins souvent à des activités vigoureuses, (b) jouaient moins souvent avec de grosses pièces d'équipement situées sur le terrain de jeu, (c) étaient moins souvent visibles, et (d) passaient moins de temps en interactions positives avec leurs pairs du même sexe. Un questionnaire portant sur les activités pratiquées durant les loisirs fut administré lors de la troisième étude. Dans l'ensemble, ce questionnaire n'a pas révélé de différences significatives entre les groupes. Finalement, la quatrième étude compara l'intensité de la participation de ces enfants durant une journée de fin de semaine. L'intensité de l'activité fut mesurée à l'aide du Sport Tester PE 3000. Nous n'avons pas obtenu de différences significatives entre ces groupes. Dans l'ensemble, nous croyons que le meilleur environnement pour tester l'hypothèse d'hypoactivité était la récréation. C'est dans ce milieu non structuré que les enfants étaient libres de choisir ce qu'ils désiraient faire ainsi que l'intensité de leur participation. Conséquemment, nous concluons, en accord avec de nombreuses anecdotes ainsi que de récentes théories de la motivation, que l'hypothèse d'hypoactivité fut supportée dans ce projet. Les enfants maladroits ont, en général, développé un style de vie dangereux pour l'apprentissage de gestes, l'interaction sociale, ainsi que leur santé et leur condition physique. Les implications de ces résultats pour la condition physique et le mode de vie ainsi que les recherches ultérieures sont présentées

N2 - Most research on sexual abuse has been conducted within family settings (Fergusson & Mullen, 1999). In recent years, following several high profile convictions and scandals, research into sexual abuse has also encompassed institutional and community settings, such as sport and the church (Gallagher, 2000; Woolfe, Jaffe, Jette, & Poisson, 2003). Research into sexual abuse in sport, for example, began with both prevalence studies (Kirby & Greaves, 1996; Leahy, Pretty, & Tenenbaum, 2002) and qualitative analyses of the processes and experiences of athlete sexual abuse (Brackenridge, 1997; Cense & Brackenridge, 2001, Toftegaard-Nielsen, 2001). From such work, descriptions of the modus operandi of abusers in sport, and the experiences and consequences for athlete victims, have been provided, informing both abuse prevention work and coach education. To date, however, no study has provided empirical support for multiple associations or identified patterns of sex offending in sport in ways that might allow comparisons with research-generated models of offending outside sport. This paper reports on an analysis of 159 cases of criminally defined sexual abuse, reported in the print media over a period of 15 years. The main aim of the study was to identify the nature of sex offending in sport, focusing on the methods and locations of offenses. The data were analysed using multidimensional scaling (MDS) as a data reduction method in order to identify the underlying themes within the abuse and explore the inter-relationships of behavior, victim, and context variables. The findings indicate that there are specific themes that can be identified within the perpetrator strategies that include "intimate," "aggressive," and "dominant" modes of interaction. The same patterns that are described here within the specific context of sport are consistent with themes that emerge from similar behavioral analyses of rapist (Bishopp, 2003; Canter & Heritage, 1990) and child molester groups (Canter, Hughes, & Kirby, 1998). These patterns show a correspondence to a broader behavioral model--the interpersonal circumplex (e.g., Leary, 1957). Implications for accreditation and continuing professional education of sport psychologists are noted.

N2 - The article questions that should recess be more structured and supervised in order to increase students' physical activities. According to Bruce Brinkman, elementary physical education staff developer, Jordan School District, Utah some students with unstructured recess sometimes choose to do little or nothing. He believes that

structured recess is the simple answer to many elementary school problems. Their ultimate purpose as physical educators should be to guide children into being physically active for a lifetime. Unstructured free time does not guide children into anything. With structure, proper supervision, and choice, the students can practice the skills that they have learned in physical education, increase the time they spend being physically active, and have a safe and social atmosphere on the playground. Kendall L. Cook, physical education teacher at Walnut Grove Elementary School at Georgia State University, Atlanta, Georgia states that in schools today, children are constantly told what to do and when to do it. She feels that there should be more room for individuality and more time for kids to be themselves

N2 - Study aim: To compare the distributions of activities under two schedules of physical education (PE) classes in Poland. Material and methods: Two schedules were examined: 3 and 4 PE classes a week, lasting 45 mm each. The study was conducted in years 2002-2004 in one junior secondary school in Poznan. Heart rates of randomly selected children aged 13 years were monitored during physical education classes throughout one half-year term and the results classified into 4 exercise intensity zones. Results: The recommended volume and intensity of activities, i.e. at least 50 % of time at an intensity of at least 50 % of heart rate reserve (HRR) were recorded only for boys performing outdoor athletics and basketball. Conclusions: Like in other studies, physical education classes alone were shown to be of insufficient intensity to improve the health-directed fitness

N2 - Increased numbers of young children who are overweight have become a significant health problem in the United States. Public health investigators have hypothesized that increased caloric intake and low levels of physical activity may be associated with the troubling trend of weight problems among children. To enhance preschool children's moderate to vigorous physical activity on playgrounds the authors develop, implement, and evaluate two practical teacher-implemented activities. Direct observations of five children in two preschool programs during teacher-implemented activities indicate increased moderate to vigorous physical activity on intervention days relative to nonintervention days (i.e., business-as-usual conditions). The results and implications for preschool practitioners are discussed

N2 - In this paper we present initial information concerning a new direct observation system - the Observational System for Recording Physical Activity in Children Preschool Version. The system will allow researchers to record young children's physical activity levels while also coding the topography of their physical activity, as well as detailed indoor and outdoor social and nonsocial contextual information. With respect to interobserver agreement (IOA), the kappa and category-by-category agreement mean of those obtained for the three illustrative preschools were generally above .80. Hence, our IOA data indicated that trained observers in the three preschools frequently agreed on the eight observational categories and accompanying codes. The results for preschoolers' level of physical activity indicated they spent the majority of observational intervals in sedentary activity (i.e., more than 80 % intervals) and were observed in moderate to vigorous physical activity much less frequently (i.e., 5 % or fewer intervals). For the 15 indoor and 12 outdoor activity contexts, variability across both the activity contexts and the three preschools were evident. Nevertheless, three classroom contexts - transition, snacks, and naptime - accounted for the greatest proportion of coded activity contexts for the children. In the three preschools, 4 of 17 physical activity types - sit and squat, lie down, stand, and walk - accounted for the topography of much of children's physical activity behavior. Systematic observation of more representative preschool samples might better inform our present understanding of young children's physical activity in community preschool programs. N2 - Introduction Fathers have a major impact on various aspects of child health and development yet little is known about their roles in preventing injuries the most significant risk to their childrens health. While parents play a large role in mitigating childhood injury risks, particularly for younger children, the role of each parent differs substantially and requires investigation. Purpose Using a qualitative approach to develop to enhance our understanding of fathers safety-related attitudes and practices. Method Interviews were conducted with fathers of children aged 2f_ "7 years in British Columbia, Canada. Questions addressed fathers roles and typical activities with their children, concerns regarding child safety, safety practices, and access of safety-related resources. Grounded theory methods guided data analysis. Results A diverse sample of 32 fathers was interviewed. Central themes expressed by fathers included: exposure to risk plays an important role in childrens lives; accidents are part of life; not all injuries can be prevented; preventing serious injuries is important; injuries can represent learning experiences. Fathers focused on outdoor risk, rather than home-based risks and used supervision as an important strategy for injury prevention. Conclusion Fathers attitudes and practices are important to consider in designing prevention programs. Building on perceptions that promote injury prevention (eg, use of supervision), and considering perceptions that challenge the perceived need for prevention in programming (eg, acceptance of injuries and risk) can help ensure the relevance and success of messages.

VL - 35

IS - 3

N2 - Previous research indicates that Latinos have low rates of leisure time physical activity (LTPA). As a result, Latinos suffer from higher rates of obesity and other diseases associated with this lack of activity. Thus, the primary purpose of this exploratory study was to gain a greater understanding of LTPA among Latinos. The goals of this study were threefold: (1) gain an understanding of the similarities and differences between Latino male and female LTPA levels and their levels of walking (done in a variety of settings); (2) examine the types of environments where their LTPA occurs; and (3) gain insight into Latinos' attitudes and perceptions of social support and constraints to LTPA. The study included Latinos from two suburban Chicago communities. Data

were collected at local parks and in a sports complex. The findings indicated that 39.1% of the Latinos had engaged in vigorous LTPA 2.75 days in the previous week, and men were active for longer periods of time than were women ($F = 6.47$; $p = 0.021$). Additionally, 38.6% of the Latinos had engaged in moderate LTPA an average of 2.57 days in a week. The majority of participants indicated they walked at least 10 minutes per day (77.5%), and men spent significantly more time walking than did women ($F = 47.17$; $p = 0.001$). Men were more likely to exercise in parks whereas women were more likely to exercise at home. Most Latinos indicated high levels of social support for exercise, and men found LTPA more interesting than did women ($F = 4.23$; $p = 0.040$). The top constraint for women was lack of childcare and for men it was too tired after work. Consistent with previous findings, a large proportion of respondents were totally inactive and did not participate in moderate or vigorous LTPA. Findings indicated that men and women experienced constraints differently, but that for both groups constraints led to lower LTPA. ABSTRACT FROM AUTHOR

Des recherches antérieures indiquent que les Latinos ont un faible taux de participation à l'activité physique et de loisir (TPAPL). En conséquence, les Latinos souffrent de taux élevés d'obésité et autres maladies associées à ce manque d'activité. Ainsi, le but principal de cette étude exploratoire était d'acquiescer une meilleure compréhension du TPAPL chez les Latinos. Les objectifs de cette étude étaient: (1) d'acquiescer une compréhension des similarités et des différences masculines et féminines du TPAPL durant la marche (fait dans une variété de paramètres); (2) d'examiner les types d'environnements où le TPAPL se produit; et (3) de mieux comprendre les attitudes Latinos et les perceptions de soutien social et les contraintes du TPAPL. L'étude inclut des Latinos de deux banlieues de Chicago. Les données furent collectées dans des parcs municipaux et dans un complexe sportif. Les résultats indiquent que 39.1% des Latinos s'engageaient dans un TPAPL vigoureux de 2.75 jours dans la semaine précédente, et que les hommes étaient plus actifs que les femmes ($F = 6.47$, $p = 0.021$) pendant de longues périodes de ce temps. De plus, 38.6% des Latinos s'engageaient dans un TPAPL modéré avec une moyenne de 2.57 jours durant la semaine. La majorité des participants ont indiqué qu'ils marchaient au moins 10 minutes par jour (77.5%), et les hommes ont consacré beaucoup plus de temps dans leurs marches que les femmes ($F = 47.17$, $p = 0.001$). Les hommes étaient plus disposés à exercer dans les parcs alors que les femmes étaient plus disposées à exercer à la maison. La plupart des Latinos ont indiqué des niveaux élevés de soutien social pour l'exercice, et les hommes trouvent le TPAPL plus intéressant que les femmes ($F = 4.23$, $p = 0.040$). Les plus grosses contraintes pour les femmes Latino sont le manque de garderies d'enfants et pour les hommes Latino la fatigue après l'ouvrage. Conformément aux résultats précédents, une grande proportion de répondants sont totalement inactifs et ont un TPAPL très peu élevé. Tandis que les résultats indiquent que les hommes et les femmes expérimentent différentes contraintes, les contraintes pour ces deux groupes conduisent à une baisse du TPAPL. ABSTRACT FROM AUTHOR

N2 - The article examines the importance of playground exercise and recreation for young children. According to the article, children can attain two-thirds of their recommended daily dose of exercise in only a half-an-hour of playground time. It is a unique way to keep kids trim and to focus on weight loss while emphasizing fun. Particular focus is given to an energy expenditure study conducted at the University of Florida which focused on the number of calories kids burn at the playground

N2 - The objective of our research project was to establish the influence of natural (place of residence) and social (parents, family, school) environment on the rate of mountaineering activity of a child. Our sampling group consisted of 233 subjects (age 11,4 Añ0,3 years), who were all in fifth grade of elementary school in Slovenia. One part of the children resided in Ljubljana and its surroundings, while the other part resided in mountainous environment. The results showed that most of the children made one to three mountaineering trips per year within their family circle, as well as within their school activity programme. Natural environment from which they originate does have an impact on the rate of their mountaineering activity as the children living close to the mountains make mountaineering trips more often within the frame of their school activities, while children living in urban environment go to the mountains oftener with their parents. Parents with their good example have a major impact on the rate of mountaineering activity of their child. Most of the children from mountaineering families like to go to the mountains. Mountaineering is more popular with the children who have mountaineering organised within the frame of their school activities. ABSTRACT FROM AUTHOR

N2 - Teachers of introductory psychology courses were supplied with the names of students in their classes of several previous years and indicated with three degrees of certainty those which they could recall. They also checked from a key list reasons for recall of which they were aware and likewise added any further reasons which occurred to them. The main series involved 20 teachers and approximately seven thousand students. Under these conditions the average instructor recalled about 13 per cent of his students. For some instructors there was a negative correlation between effectiveness of recall and size of section. For other instructors no significant relation existed. Several instructors showed a significant tendency to remember better students of the opposite sex. Only one showed any possibly significant tendency to be more effective with his own sex. Several teachers showed a significant tendency to remember their good students in the sense of academic grades more readily than mediocre or poor ones. This tendency was a bit more marked with advanced than with elementary courses. There was no tendency for the poor students to leave a more lasting impression. Similarly some teachers tended to recall more readily students of higher intelligence. There was also an occasional significant tendency to remember those of lowest intelligence. Some teachers were definitely aware of the reasons for recall in most cases. For some of them the expressed reasons were mostly of one category while others scattered their reasons quite extensively. The reasons most frequently mentioned were personal appearance, conduct in class, followed by personal conferences, peculiarity of name, and contacts outside of class. Other reasons mentioned with less frequency were physical defects, peculiarity of name, location of seat in room, and presence in other classes taught by the same instructor. Occasional mention was made of grades, peculiarities of actions, voice, or handwriting. There appears to be no universal reason whereby students are remembered by their teachers. Individual differences on the part of the teachers evidently play a role, with some impressed by one aspect of a student and some with another. If one were to specify conditions under which the probability of recall by the teacher in general is enhanced, it would be something as follows: the student should be in a small class taught by an instructor of the opposite sex; should do good academic work in the class and should have high intelligence; should have something unusual about his appearance and something significant about his conduct in class; should have some personal conferences with the teacher, have a peculiar name, and should have some additional non-academic contacts outside of class. N2 - In the search for solutions to help at-risk youths, there has been a movement toward integration of various types of services within educational systems. Because of limited resources, it is especially imperative for institutions of higher education to develop partnerships with communities and schools. On the basis of this philosophy, the University of Utah College of Health (COH) and a Salt Lake City urban elementary school have formed a partnership to serve youths who are at risk. Team Lincoln was created to provide a program of organized recess activities for 450 at-risk children in grades 1 through 6. This article describes and evaluates the Team Lincoln school-based service learning program

N2 - Recess serves as a prime example of an underused social work intervention opportunity in schools. As members of the school community well know, recess is the time that both students and teachers look forward to everyday. However, the entire school climate can be negatively affected when problems occur on the playground. This article describes and evaluates a recess-based social skill intervention that targets elementary aged school children and their behaviors on the playground. Program effectiveness will be explored by examining changes in problem behaviors from before and during the program. Special attention will be paid to gender differences

N2 - This study examined whether feedback or feedback plus physical activity information could increase the number of pedometer steps taken during 1 school week. One hundred seventy-seven students (mean age 9.124 Añ 1.11 years) in three elementary schools participated. Schools were randomly assigned to control (CON), feedback (FB), or feedback plus information (FB+I) groups. Children wore pedometers during school time for 5 consecutive weekdays. The total steps of the groups were recorded at the end of each school day, with students in the FB and FB+I groups free to view their step counts. In addition, the FB+I group received information and ideas about how they could increase their daily steps. The CON group received no step-count feedback or information. Students in the FB+I group achieved significantly more steps per minute (17.17 Añ 4.87) than

those in the FB (13.77 A ñ4.06, p = 0.003) and CON (12.41 A ñ3.12, p = 0.0001) groups. Information, as well as step-count feedback, increased elementary students' school-based physical activity (number of steps) in the short term. A longer intervention period is necessary to assess the sustained impact of this type of approach.

N2 - The article explains the difference between spontaneous play invented by children during recess and the Inventing Games (IG) approach. It notes that the IG approach builds on children's natural instinct to play but has very clearly defined educational outcomes that allow students to cognitively learn about game constructs through a collective learning process. It describes the teaching games for understanding (TGfU) classification system of the IG approach which consists of 4 categories

N2 - QUESTION: What are the long term goals and normalisation strategies of families with parents and children living with HIV?

Design

Interpretive study based on symbolic interaction and using ethnographic data collection methods

Setting

Urban paediatric referral centre in the US

Participants

21 participants: 9 children with HIV infection (age range 7-15 y), 6 mothers and 1 father with HIV infection (mean age 38 y), and 5 uninfected adult family member caregivers (age range 30-79 y). Participants were of diverse ethnicity

Methods

Semistructured, open ended interviews were conducted individually for children (20-45 min) and adults (60-120 min), except for 1 mother and son who requested to be interviewed together. The interview guide included questions on family composition, disease disclosure, and symptom management. Interviews were audiotaped, transcribed verbatim, and data were analysed using constant comparison. Repeat interviews with 4 key participants validated and expanded findings

Main findings

Families had 3 goals to establish normalcy and stability: staying healthy, facilitating children's participation in school and social activities, and enhancing social and emotional wellbeing of family members. Strategies for staying healthy included lifestyle decisions (eg, balanced diet and exercise) and active participation in treatment regimens. Children related taking medications to staying healthy. To reinforce the necessity of the treatment regimen, parents often took their medication on the same schedule as their children; they also tried to allow children some freedom for normal activities within the necessary regimen. Parents juggled multiple responsibilities to care for family members; some focused on guarding their own health to keep their children healthy. In facilitating children's participation in school and social activities, schools served as markers of normal childhood activity and as resources. Management of stigma was important. All families were selective in disclosing information about infection to those outside the family and controlled their children's social lives in order to preserve their ability to be treated normally. Enhancing [the] social and emotional wellbeing of family members was achieved by having extended family members provide supplemental care for children. This helped parents by reducing their stress and increasing rest time, and children valued the relationships developed with extended family members. Families cited spiritual and religious beliefs and practices as important coping strategies. Psychological counsellors provided formal emotional support, whereas other professionals, such as nurses at the HIV centre, provided informal support. Non-infected children were a source of support and concern for parents and children

Conclusion

Families with parents and children living with HIV had 3 normalisation goals to foster normal living and used strategies to minimise stigma. [Original article accession number: 2000060336 (research)]

N2 - Recommended early intervention practices emphasize family-centered approaches provided within natural settings through interventionist interactions with caregivers. We defined this approach as participation-based and used the Home Visiting Observation Form (HVOF) and the Natural Environments Rating Scale (NERS) to describe 50 home visits and to examine the extent to which participation-based services could be identified and distinguished from traditional services. A minority of the sample visits were described as participation-based although participation-based services were clearly distinguishable from traditionally provided services.

Interventionists using participation-based approaches interacted with the caregiver-child dyad and caregivers were actively involved with their children during the session. Results from the study suggest the NERS can be used to describe characteristics of participation-based services and holds promise as a measure that might be used by interventionists, their supervisors, or by researchers to measure intervention fidelity during home visits

N2 - The average 12-year-old may not realize it, but many of the trappings that make it good to be a kid are the result of Pennsylvania ingenuity, including the first bottle of soda pop, the first nickelodeon (the precursor to the modern ciniplex), and the first batch of bubble gum. The same is true of another of Pennsylvania's kid-friendly creations, the Little League World Series, which kicked off its annual 10-day run in Williamsport. In 1947 Carl Stotz convened the first Little League National Tournament, a 12-team event that invited only one squad from beyond central Pennsylvania, the Hammonton (N.J.) All-Stars. In 1955, after years of bickering with the board of directors over sponsorships and other matters, Stotz was ousted in a court battle. Stotz never attended another Little League World Series and instead organized a competing youth baseball program called Original League, which debuted in 1955 and is still active, at Memorial Park. But in recent years Little League has taken steps to mend the rift with Stotz's family and supporters. In part to stimulate the raising of \$20 million for the construction of the 4,000-seat Volunteer Stadium, which opened in 2001 and enabled the tournament to expand from eight to 16 teams, Little League acted to heal old wounds by honoring Stotz with a granite memorial outside Volunteer Stadium. Little League also promotes the Original League field on the other side of the river as the birthplace of youth baseball

N2 - Purpose. To examine school socioeconomic status (SES) in relation to school physical activity-related practices and children's physical activity. Design. A cross-sectional design, was used for this study. Setting. The study was set in 97 elementary schools; (63% response rate) in two U.S. regions. Subjects. Of the children taking part in this study, 172 were aged 10.2 (standard deviation (SD) = 1.5) years; 51.7% were girls, and 69.2% were White non-Hispanic. Measures. School physical education (PE) teachers or principals responded to 15 yes/no questions on school physical activity-supportive practices. School SES (low, moderate, high) was derived from the percent of students eligible for free and reduced-price lunch. Children's moderate to vigorous physical activity (MVPA) during school was measured with accelerometers. Analysis. School level analyses involved linear and logistic regression; children's MVPA analyses used mixed effects regression. Results. Low-SES schools were less likely to have a PE teacher and had fewer physical activity- supportive PE practices than did high-SES schools ($p < .05$). Practices related to active travel to school were more favorable at low-SES schools ($p < .05$). Children attending high-SES schools had 4.4 minutes per day more of MVPA during school than did those at low-SES schools, but this finding was not statistically significant ($p = .124$). Conclusion. These findings suggest that more low- and moderate-SES elementary schools need PE teachers in order to reduce disparities in school physical activity opportunities and that PE time needs to be supplemented by classroom teachers or other staff to meet guidelines. CY - ;

N2 - This study aimed to examine the relationship of children's perceived competence in physical education to their enjoyment in the subject, and how boys and girls scoring high and low in enjoyment and perceived competence differed in their levels of physical activity. Year 6 primary school children (n = 922) completed questionnaires giving their physical activity the previous week, their perceived competence in, and enjoyment of, PE. Employing correlation, multivariate and univariate analysis of variance techniques, the results indicated

moderate positive and significant relationships between enjoyment in PE and perceived competence in PE for the whole sample ($r = .39, p < 0.001$). Children of high perceived competence participated in significantly more physical activity (quantity and intensity) outside school than those of low perceived competence, but there was no difference in enjoyment levels and quantity of physical activity. The boys scored higher than the girls on time spent on physical activity, on perceived competence and enjoyment. Motivation theory is utilized to examine the relationship of perceived competence and enjoyment in physical education to physical activity outside school

Cette etude a vise a examiner (1) la relation entre la competence percue des eleves en education physique (EP) et le plaisir eprouve dans la discipline, (2) comment les garcons et les filles qui obtiennent des resultats plus ou moins eleves dans le plaisir eprouve ou la competence percue se sont differencies quant a leur niveau d'activite physique. 922 eleves de l'ecole primaire ages de dix ans ont renseigne des questionnaires sur leur activite physique hebdomadaire, leur competence percue et le plaisir eprouve en education physique. A l'aide de correlations, d'analyses de variance multivariee et univariee, les resultats ont indique: (1) des relations moyennement positives et significatives entre le plaisir eprouve et la competence percue en education physique pour l'ensemble de l'echantillon ($r=.39, p < 0.001$); (2) les enfants qui ont une competence percue elevee ont participe significativement de maniere plus importante a une activite physique en dehors de l'ecole (quantite et intensite), que ceux qui ont une competence percue plus faible; mais il n'a pas eu de difference dans les niveaux de plaisir et la quantite d'activite physique; (3) les garcons ont des resultats plus eleves que les filles dans le temps d'activite physique, la competence percue et le plaisir eprouve. La theorie de la motivation a ete utilisee pour examiner la relation entre la competence percue et le plaisir eprouve en education physique, et dans l'activite physique en dehors de l'ecole. (HERACLES) Questionnaire soumis a 922 eleves d'ecole primaire ages de 6 ans, sur leur activite physique hebdomadaire, leur perception de leurs propres competences, le plaisir eprouve en education physique. Relation entre la competence percue, le plaisir ressenti, la motivation, la participation a des activites sportives extra-scolaires, chez les garcons compares aux filles

Die Studie untersuchte (1) die Beziehung zwischen der von Kindern selbst wahrgenommenen Kompetenz im Schulsport und ihrer Freude in diesem Schulfach; (2) wie Jungen und Maedchen, die besonders viel oder wenig Spass am Sportunterricht haben und ueber eine hohe oder niedrige selbst wahrgenommene Kompetenz verfuegen, sich in Quantitaet und Intensitaet der ausserschulischen koerperlichen Aktivitaet unterscheiden. 922 Sechstklaessler gaben dazu in einer schriftlichen Befragung ihre koerperlichen Aktivitaeten in der vergangenen Woche, die persoenliche Einschaeztung selbst wahrgenommener Kompetenz und ihren Spass am Sportunterricht an. Die Ergebnisse, die unter Verwendung von Korrelationen, multivariaten und univariaten Varianzanalysetechniken erzielt wurden, zeigen, (1) dass es einen schwach positiv signifikanten Zusammenhang zwischen dem beim Sportunterricht empfundenen Spass und der selbst wahrgenommenen Kompetenz fuer die gesamte Stichprobe ($r=.39, p < 0.001$) gibt; (2) dass Kinder mit hoher selbst wahrgenommener Kompetenz ausserhalb der Schule signifikant staerker koerperlich aktiv (in Quantitaet und Intensitaet) sind, als jene mit einer geringeren selbst wahrgenommenen Kompetenz. Kein Unterschied liess sich feststellen in Bezug auf das Mass an Freude und die Quantitaet koerperlicher Aktivitaet; (3) dass Jungen durchschnittlich mehr Zeit mit koerperlicher Aktivitaet verbringen, hoehere Werte bezueglich selbst wahrgenommener Kompetenz und meher Spass am Sport haben als Maedchen. Die Motivationstheorie wird verwendet, um den Zusammenhang zwischen der selbst wahrgenommenen Kompetenz und dem Spass am Schulsport in Beziehung zu setzen mit der koerperlichen Aktivitaet ausserhalb der Schule

N2 - Introduction: With this study we aim to distinguish which are the free time variables associated to the adherence to physical and sports activities. Materials and Methods: A sample composed of 719 children aged between 6 and 10 years old, subject to the application of a questionnaire, was analyzed. The contingency tables and de I_ (phi) value were used to verify the association between the free time variables and the practice of physical and sports activities. Results: The results' analysis allowed us to conclude that the places to spend free time (home, street, outdoor playground and public garden) and the time spent in these places are associated to the physical and sports activities. Discussion: There is a positive association between the time that children

spend in outdoor playgrounds, street, public garden and the practice of global physical activities. In regards to the practice in clubs, we verified a negative association between the time spent in the public garden, outdoor playground and street and the adherence to the practice. The time that they spend with video games is negatively associated to the formal practice. The time that they spend watching television is positively associated to the global practice, but negatively associated to the formal practice in business days. ABSTRACT FROM AUTHOR

Introducción: Con este estudio pretendemos discriminar las variables de tiempo libre asociadas a la adhesión a las actividades físicas y deportivas. Materiales y Métodos: Fue analizada una muestra de 719 niños con edades comprendidas entre 6 y 10 años, sujetas a la administración de un cuestionario. Las tablas de contingencia y el valor de (phi) habrán sido utilizados para verificar la asociación entre variables de tiempo libre y la práctica de actividades físicas y deportivas. Resultados: El análisis de los resultados permitió concluir que los locales de tiempo libre (casa, calle, parque infantil y jardín público) y el tiempo dispendido en esos locales están asociados a las actividades físicas y deportivas. Discusión: Existe una asociación positiva entre el tiempo que los niños pasan en el parque infantil, calle, jardín público y la práctica de actividades físicas globales. Relativamente a la práctica en el club, se verificó una asociación negativa entre el tiempo planchado en el jardín público, parque infantil y calle y la adhesión a la práctica. El tiempo que pasan en juegos de video está asociado negativamente con la práctica formal. El tiempo en que asisten televisivamente está asociado positivamente con la práctica global, pero negativamente con la práctica formal en los días hábiles. ABSTRACT FROM AUTHOR

N2 - Children's own perceptions of gender appropriateness of five common playground activities, playfighting, playchasing, real fighting, football, and skipping, were assessed at different ages and in two cultures (England and Italy). Four activities showed some degree of gender stereotyping while one did not. This pattern was similar across ages (5 to 10 years) and cultures. However, there was a general trend, in both England and Italy,

for the degree of gender stereotyping to lessen with age. This trend occurred earlier in the English children, for traditionally male activities, and was more obvious in girls than boys. A cultural difference in the perception of skipping was also noted. Possible reasons for these findings are discussed

N2 - Background: Despite the support in primary education that student-designed games enhance student contextualisation of skills and tactics, there has been little support in secondary education, nor any empirical research exploring these claims. This paper attempts to rekindle these beliefs and explores the use of student-designed games in an English secondary school. Aim: To provide a detailed account of classes of secondary students designing their own games, and to investigate their responses to the games-making process. Method: Two classes of boys (aged 14-16) at a school in England participated in the study. Each class was divided into three teacher-selected teams and attended one lesson per week, each lasting 40 minutes, for seven weeks. Lessons were adapted to give students four phases of development: a 2-week library-based planning and wiki construction phase; a 1-week outdoor modification and wiki update phase; three weeks of trials of the games with a wiki refinement phase; and a 1-week game and wiki finalization phase. In this time frame the pupils involved were challenged to design an invasion game that would be played in a subsequent unit. Data consisted of: teacher post-teaching reflections, interviews between a professor-researcher and the on-site participants, observations and analysis of wikis. Data analysis occurred on three levels. The first aspect was immediate and ongoing by the teacher-researcher to meet the 'on the spot' learning needs of his students. Secondly, the professor-researcher aided the teacher-researcher in systematic collection, organisation and analyses. Thirdly, peer debriefing occurred in which the research team analysed and critiqued the data during the collection and writing processes. Results: We found that students 'bought into' the process of games-making, were afforded an inclusive voice and worked as teams. Furthermore they engaged in immediate searches for innovation which were influenced by popular media, and shared ideas and learning with others to a degree that allowed them to exclude problematic skills. However, there was student frustration induced by watching others failing to properly play these games. Conclusions: We concluded that student-designed games 'freed' children to define competition at their own developmental level. This paper shows that by trusting pupils and supporting them to be creative in the games that they play it is possible to gain an insight into the processes by which students apply their knowledge about physical education. N2 - The article looks at how a director of physical activity (DPA) can implement physical activities during the school day for U.S. students. According to the author, a DPA needs administrative support, justified curriculum changes, and trained staff in order to integrate activities that align with the Comprehensive School Physical Activity Program (CSPAP) initiative. Recommended activities for students include reading on a stationary bike, physical activity as an incentive, and organized recess

N2 - Data from the National Traumatic Occupational Fatalities surveillance system were used to analyze occupational injury deaths of civilian 16- and 17-year-olds during 1980 through 1989. There were 670 deaths;

the rate was 5.11 per 100,000 full-time equivalent workers. The leading causes of death were incidents involving motor vehicles and machines, electrocution, and homicide. Workers 16 and 17 years old appear to be at greater risk than adults for occupational death by electrocution, suffocation, drowning, poisoning, and natural and environmental factors. Improved enforcement of and compliance with federal child labor laws, evaluation of the appropriateness of currently permitted activities, and education are encouraged. ABSTRACT FROM

PB - Northcentral University

N2 - The attitudes of U.S. nurses toward children with disabilities have not been adequately measured over time and after an educational intervention. Disability content has not been a priority in nursing education and, if present, the focus has been on adults with disabilities. The attitudes of nurses play a significant role in the provision of quality healthcare services they provide for children with disabilities. This quantitative, experimental research measured the attitudes of graduating nursing students (N= 88) toward children with disabilities utilizing the Attitudes Towards Disabled Persons Scale (ATDP-B) before and after disability education. The control group consisted of 44 nurses while a group of 44 nurses received the treatment. The differences between the groups was measured at pretest (time 1), immediate posttest (time 2) after an educational module, and delayed posttest (time 3) one month follow up, utilizing repeated measures analysis of variance (ANOVA). Multivariate tests for within subject effect of the ATDP-B demonstrated that the dependent variable of attitudes as measured by the ATDP-B scale changes over time and after an educational module based on children with disabilities were ($F = [2, 85] = 28.59, p < .01$). It was discovered that the ATDP-B level changes over time, dependent on the group ($F [2, 85] = 51.15, p < .01$). Also, the between subjects main effect of group was significant across ATDP-B measurements ($F = [1, 86] = 32.53, p < .01$). The results of this research suggest that there is a significant difference in means of ATDP-B measurements between groups which indicates that the graduating nurses who received disability education performed significantly better on an assessment of attitudes toward children with disabilities than those who did not receive the education. The findings of this research should compel nursing faculty to reevaluate curriculum content, provide specific attitude measurements of nursing students at various levels of education, and develop protocols that can assist students in learning to care for children with disabilities. Future research can be designed to measure attitudes of

nurses toward children with disabilities at various levels of nursing education, in several nursing education programs within or outside the U.S, or as a comparison to other healthcare professionals

N2 - The Carolina Panthers are predicted to finish fourth in the South Division of the National Football Conference. One week of training camp was all Stephen Davis needed to see the benefits of signing as a free-agent running back with the Panthers. Every time he looked into the crowds at Wofford College in Spartanburg, S.C., he saw his wife, Dee Dee, and their four children, who had rarely watched him practice during the seven seasons he spent with the Redskins. One morning when he trotted out of the locker room with quarterback Rodney Peete, Davis pointed to a small stadium at the end of a narrow street. That's where he played football for Spartanburg High. Ericsson Stadium in Charlotte is a mere hour and a half drive from the dream house he built in Columbia, S.C., two years ago. More important, Davis is returning to the role he enjoyed in Washington before Steve Spurrier brought his pass-happy Fun' n' Gun offense to the Redskins last season. Davis, a 6-foot, 230-pound workhorse who prefers 20 or more carries a game, averaged 17.25 an outing in '02 and gained only 820 yards. (He missed four of Washington's last nine games with a sprained right knee.) Davis won't have to worry about opportunities. The Panthers had the NFL's second-worst offense (267.5 yards a game) and ranked 25th in the league in rushing yards (99.1 per game) last season, and coach John Fox plans to rely heavily on Davis this year. Two free agents, guard Doug Brzezinski (Eagles) and wide receiver Ricky Proehl (Rams), should make immediate contributions, and first-round pick Jordan Gross will start at right tackle

N2 - The article profiles Denver Broncos football player Reuben Droughns. His three older brothers had experienced troubled childhoods, but Reuben had a different vibe. He wrote poetry and was a starter as a sophomore on the varsity football team, and when he carried the pigskin, nobody could stop him. He had a chance to be something special. And eventually he was, becoming the first member of his immediate family to attend a four-year college. (He's a semester shy of getting a degree.) When the season began the 26-year-old Droughns was the Broncos' little-known fullback, primarily a blocker who in his first four pro seasons gained all of 97 rushing yards. Now Droughns is one of the NFL's biggest surprise stories. Droughns sharpened his vision and instincts while playing fullback, leading the running backs into the holes. He's a violent runner for a man listed at 5'11", 207 pounds, a player who competes with a visible hunger. This is Droughns's time to shine. Old coaches and friends are calling to congratulate him. Fans recognize him in public. Vendors peddle his number 34 jersey. But those things don't matter to him nearly as much as having the opportunity to show that he really is special

PB - Indiana University

N2 - The purpose of this study is to examine the effect of a therapeutic recreation intervention, within a technology-based physical activity context, on the social interaction of male youth with autism spectrum disorders (ASDs). Youth with ASDs report greater feelings of loneliness and poorer quality friendships than youth without ASDs, due to deficits in social interaction inherent to the condition. Social rank theory stipulates that low social rank leads to de-escalating strategies, which include low self-esteem, avoidance and keeping a distance from peers. Youth with ASDs are typically in a position of lower social rank compared with peers. Implementing a situational reverse social rank (SRSR) to create reciprocal social interaction may decrease loneliness and increase friendship quality in this population. Six male youth ages 10-14 years with high functioning ASDs and 6 age and gender matched typically developing peers were recruited. Participants with ASDs were trained to use the Dance Dance Revolution [superscript](R) (DDR), a technology-based physical activity device, for three to six weeks. Following training, they taught a typically developing peer to play the DDR for four sessions. A combination of quantitative and qualitative methodologies was used to triangulate the effects of the intervention. Youth with ASDs reported significantly higher levels of loneliness and lower quality friendships than peers. Both groups reported significantly higher quality of friendship following the intervention. Qualitative information illustrated their desires for friendship and a cycle of losing friends. The results should prompt reconsideration of traditional peer-mediated interventions and suggest inclusion of social rank in social interventions for youth with ASDs. Traditional peer-mediated interventions may actually

jeopardize the development of friendship by increasing the gap in social rank between youth with ASD and their peers, because peers will continue to maintain a higher social status. A situational reverse social rank approach provides greater opportunities for generalization to natural settings and may improve the social status of youth with ASDs. This will help decrease levels of loneliness and increase quality of friendships in these individuals

N2 - Objectives. We examined whether schools' participation in the Recess Enhancement Program (REP) in the spring of 2011 was associated with higher rates of children's vigorous physical activity. Methods. In REP, a coach guides children through age-appropriate games aimed at increasing their physical activity. During recess at 25 New York City public elementary schools (15 REP, 10 non-REP), researchers visually scanned predetermined areas (n = 1339 scans), recording the number of sedentary, walking, and very active children. Results. Multivariate statistical analysis found that participation in REP was a significant predictor (P = .027) of the rate of vigorous physical activity (percentage very active in scan area) whose least-squares means were 41% in REP schools and 27% in non-REP schools. A significantly higher rate in REP schools persisted when the coach was not in the scan area, suggesting a change in the recess culture of REP schools. Conclusions. The rate of vigorous physical activity in REP schools was 14 percentage points, or 52%, higher than the rate in non-REP schools. This low-cost intervention might be a valuable addition to the tools for combating childhood obesity and worth replicating elsewhere. ABSTRACT FROM AUTHOR

N2 - Background: To improve student performance, teachers need to evaluate the developmental level of the child and to deliver feedback statements that correspond with the student's ability to process the information delivered. Therefore, feedback aligned with the developmental level of the child (aligned developmental feedback *f*_" ADF) is sometimes considered to be the most appropriate type of feedback for improving student learning. It is assumed that the provision of ADF is beneficial in bringing about improvement in the learning of motor skills and subsequently in performance. However, the extent of the influence of ADF on motor performance remains unclear. Purpose: This study examined the influence of ADF on students' performance of the overhand throw for force in a naturalistic physical education setting. Participants: Ninety-seven third-grade students (39 girls, 58 boys) with a mean age of 105.4 months ($SDf_{\%}=f_{\%}4.76$) participated in this study. All participants were selected from four intact classrooms in a mid-sized Midwestern (US) elementary school. Two of the four intact classes were randomly assigned to an ADF group (the experimental condition; $Nf_{\%}=f_{\%}48$, 21 girls, 27 boys), and the other two intact classes were assigned to a general feedback (GF) group (the control condition; $Nf_{\%}=f_{\%}49$, 18 girls, 31 boys). Research design and phases of the study: An experimental non-equivalent group design composed of pre-, post-, and retention phases assessed the influence of ADF on throwing performance. The study used a three-phase approach: Phase 1 involved the implementation of the control GF condition with the participants: a seven-day throwing unit using general feedback. After Phase 1 was concluded, the first part of the experimental condition was initiated (Phase 2): to train the physical education teacher (male, with seven years of teaching experience, who had no prior knowledge of developmental throwing sequences) to deliver the experimental condition (i.e. the ADF condition). Phase 2 concluded when the teacher was considered trained in the ADF condition. The final phase of the study (Phase 3) was the actual experimental

condition, consisting of a seven-day ADF instructional throwing unit. Data analysis: A chi-square analysis was used to examine the influence of ADF on the distribution of body component scores between the ADF and GF groups from the pre- to post- to retention phases as the body component data is ordinal in nature. An ANOVA with repeated measures on the highest ball velocity score was used to assess the influence of ADF on ball velocity scores. Findings: An ANOVA revealed that the ADF group had faster ball velocity than the GF group from pre- to post-intervention. Chi-square analyses revealed that the ADF group improved from pretest to posttest in the humerus and forearm components. The effects found at the end of the intervention program were maintained throughout the retention phase. Conclusions: The findings demonstrate the value of ADF in the learning process, and show how such feedback can enhance students' performance. ABSTRACT FROM

N2 - This study documents the response of a low-income border community to a Texas state law requiring coordinated school health programs in every elementary school by the academic year 2006-2007. Findings are summarized from a one-day conference with 176 attendees to familiarize them with the requirements of this law and to mobilize the community to design an approach that all elementary schools in the state of Texas could use to implement coordinated school health. Four discussion groups were held during the conference to address the

following questions: 1) What are schools in the El Paso, TX border region already doing for child health?; 2) What more could be done without funding to implement coordinated health education?; and 3) What more could be done with funding to implement coordinated health education? Recommendations from these discussion groups included asking influential adults like teachers, food service personnel, and parents to model healthy behavior for children such as volunteering in the cafeteria, eating school meals, and exercising with the children during recess and physical education classes. The El Paso CATCH program models what a low-income, primarily Hispanic community can accomplish with minimal funding and resources

N2 - Analysis of official documents and observation of day-to-day work reveals that the choice of activities taught during physical education clearly shows that a priority is given to some of them. Track and field athletics, and to a smaller extent, gymnastics and swimming are dominating all other activities taking place at school. As we can see from the choice of activities practised outside school, there is a considerable interest for physical activities taking place in stadiums or gymnasiums. A survey carried out on 4 985 students from high schools and secondary schools shows a strong gap between what is taught and what the students expect. It seems that activities where the follower faces uncertainties, whether from the environment or because of partners or opponents, are much more attractive than individual sports, totally out of surprise. This tendency is particularly clear as far as outdoor activities are concerned ; they rarely take place at school. Moreover they vary according to social classes

L'analyse des textes officiels et l'observation des pratiques reelles revelent que le choix des contenus enseignes en education physique confere une priorite indiscutable a certaines activites. L'athletisme et, dans une moindre mesure, la gymnastique sportive et la natation occupent une place preponderante parmi l'ensemble des activites physiques pratiquees a l'ecole. A l'image de ce que l'on peut observer dans la pratique extra-scolaire, l'institution accorde une importance considerable aux pratiques corporelles qui se deroulent en milieu stable. Une enquete realisee aupres d'un echantillon de 4 985 lyceens et collegiens revele le fort decalage existant entre ce qui est reellement enseigne et les attentes des eleves en matiere de pratiques corporelles. Il apparait que les activites ou le pratiquant est soumis a une incertitude - que celle-ci provienne de l'environnement physique ou soit due a la presence de partenaires et d'adversaires - exercent beaucoup plus d'attrait que les sports individuels completement denues d'imprevu. Cette tendance est particulierement nette en ce qui concerne les activites physiques de pleine nature ; activites tres peu souvent pratiquees dans le cadre scolaire. En outre, elle se nuance quelque peu selon l'appartenance sociale des eleves

N2 - The article offers information on the increasing rate of the childhood obesity in Texas. It states that national data from the Centers for Disease Control and Prevention (CDC) shows that the prevalence of obesity has increased by almost fourfold. It notes that the factors that contribute to the trends include the decline in physical education and recess requirement, decline in number of children who routinely walk and the increase in time of children watching television

N2 - Background: As interventions increasingly emphasize early child care settings, it is necessary to understand the state regulatory context that provides guidelines for outdoor physical activity and safety and sets standards for child care environments. Methods: Researchers reviewed regulations for child care facilities for 50 states, the District of Columbia and the Virgin Islands. We compared state regulations with national standards for 17 physical activity-and safety-related items for outdoor playground settings outlined in Caring for Our Children: National Health and Safety Performance Standards: Guidelines for Out-of-Home Child Care Programs (CFOC). State regulations were coded as fully, partially or not addressing the CFOC standard and state-level summary scores were calculated. Results: On average, state regulations fully addressed one-third of 17 CFOC standards in regulations for centers (34%) and family child care homes (27%). Data suggest insufficient attention to outdoor play area proximity and size, equipment height, surfacing, and inspections. Conclusions: Considerable variation exists among state regulations related to physical activity promotion and injury prevention within outdoor play areas. Many states' regulations do not comply with published national health and safety standards. Enhancing regulations is one component of a policy approach to promoting safe, physically active child care settings. ABSTRACT FROM AUTHOR

N2 - This study reports findings on the use of precision teaching techniques and assistive behavioral shaping strategies to facilitate age appropriate play behaviors among young children with severe genetic disorders. Training occurred in a natural environment using four common playground apparatus. Qualitative and quantitative analyses of children's behaviors were utilized. Observations of playground behaviors via a videotape data base confirmed increases in competence levels. Qualitative improvement in children's confidence levels while engaging equipment was also measured utilizing a checklist derived from the Griffin and Keogh (1982) model for movement confidence. Additional samples of participant behaviors and longitudinal research efforts are needed to determine the impact of improved movement skills on the quality and quantity of peer relationships. Empirically validated playground assessments and teaching techniques are important components toward building a science of playground skill development

N2 - Purpose. Examine associations between worksite physical activity promotion strategies and employees' physical activity and sedentary behaviors. Design. Cross-sectional. Setting. Seattlef_"King County, Washington and Baltimore, Marylandf_"Washington, D. C. regions. Subjects. Adults working outside the home (n = 1313). Mean age was 45 Añ 10 years, 75.8% of participants were non-Hispanic white, 56% were male, and 51% had income f% • \$70,000/year. Measures. Participants reported demographic characteristics and presence/absence of nine physical activity promotion environment and policy strategies in their work environment (e.g., showers, lockers, physical activity programs). A worksite physical activity promotion index was a tally of strategies. Total sedentary and moderate-to-vigorous physical activity (MVPA) min/d were objectively assessed via 7-day accelerometry. Total job-related physical activity minutes and recreational physical activity minutes were self-reported with the International Physical Activity Questionnaire. Analysis. Mixed-effects models and generalized estimating equations evaluated the association of the worksite promotion index with physical activity and sedentary behavior, adjusting for demographics. Results. A higher worksite promotion index was significantly associated with higher total sedentary behavior(Iý= 3.97), MVPA (Iý= 1.04), recreational physical activity (Iý = 1.1 and odds ratio = 1.39; away from work and at work, respectively) and negatively with job-related physical activity (Iý= .90). Conclusions. Multiple worksite physical activity promotion strategies based on environmental supports and policies may increase recreational physical activity and should be evaluated in controlled trials. These findings are particularly important given the increasingly sedentary nature of employment. ABSTRACT FROM AUTHOR

VL - 16

N2 - Objective In the period from 1995 to 2008, in Croatia, 2.553 children died because of injuries, making injury prevention efforts an important societal investment. The aim of this study was to establish the attitudes of primary healthcare workers in a sample comprised of gynaecologists and paediatricians working in the primary healthcare, family physicians and community nurses. Participants 373 primary healthcare workers (gynaecologists, paediatricians, family physicians and community nurses). Methods Anonymous self-administered questionnaire containing items on gender, age, length and type of work and the Croatian primary healthcare workers attitudes towards injury prevention/safety promotion for preschool children. Outcome Measures Attitudes towards injury prevention/safety promotion for pre-school children. Results The obtained results varied greatly for different questions. For example, almost all primary healthcare workers showed correct attitudes towards prevention of drowning during bathing, prevention of playground injuries and the prevention of traffic injuries by forbidding preschool children sitting in the front seat (366 or 98.1%) and forbidding standing between the front seats during the ride (367 or 98.4%). But only 46.4% subjects recognise provocation of vomiting after a child has swallowed a potential poison as an incorrect response. Conclusions Although a majority of primary healthcare workers demonstrated satisfactory attitudes, improvements are possible and necessary. A targeted, continuous education on the subject must be considered as one of the primary healthcare measures in the Croatian national program of healthcare measures. ABSTRACT FROM PUBLISHER

N2 - Background: Significant proportions of school children in the UK do not meet the minimum recommended daily requirements of 60-min moderate-intensity physical activity. Beyond taught classes, playtimes offer the opportunity for children to play and be physically active. Painted markings are one recent addition to school playgrounds that are inexpensive and have been shown to stimulate increased levels of physical activity among children during playtimes. Playground markings and supportive playground assistants can act as cues to increase physical activity. Purpose: While evidence exists to support the impact of playground markings on the levels of physical activity, no attempts have been made to assess the effects of playground markings on important indicators of psychological health such as self-esteem and physical self-concept. The way children view themselves from a physical perspective is likely to impact their future engagement in sport and physical activities. Given that the levels of physical activity have been found to be related to physical self-perceptions and self-esteem, and playground markings appear to facilitate increased physical activity, this study aimed to evaluate the effects of installing playground markings and training playground assistants on children's physical self-perceptions. Participants and setting: Participants were 218 primary school children (117 girls and 101 boys) aged 10 and 11 years. Informed consent was gained from all schools, and parents were given the choice to withdraw their child from the project before commencement of testing. Twelve schools received playground markings, while four further schools acted as controls. Playground assistants were trained to help facilitate use of markings by children. Playground markings consisted of painted lines and boxes. Data collection: The participants completed the Children and Youth Physical Self-Perception Profile under the supervision of trained research assistants. The behaviour of the children was also observed during the morning and lunch playtime periods prior to the installation of playground markings and again 8 months after installation. The System for Observing Children's Activity and Relationships during Play was used to assess playtime behaviour with 242 observations in total undertaken. Every sixth child to enter the playground was randomly observed for 10Amin. Data analysis: Mixed -model ANOVAs were used to test for differences in physical self-perceptions of the children on the basis of intervention and over time. Percentage changes in observed physical activity and pro-social behaviours were calculated to determine differences between schools that received markings and those that did not. Findings: No significant differences were found in physical self-perceptions on the basis of intervention or over time. However, boys did report significantly higher perceptions of sport competence, physical conditioning, physical strength and physical self-worth than girls. Observed physical activity was found to increase by 7.5% in schools that received markings as opposed to a 7.7% decline in control schools. In addition, pro-social behaviours were found to increase by 6.7% following the installation of playground markings. Conclusion: These findings indicate that while playground markings can facilitate

increased physical activity during playtimes, this does not translate into enhanced self-perceptions in children when evaluated 8 months after intervention. ABSTRACT FROM PUBLISHER

N2 - Based on a survey questionnaire completed by those running the campaign Hurrah, leisure time! under the auspices of the Union for Children's and Youth Sports, the current state of 70 Slovenian playgrounds (in all regions) was analyzed in terms of their size, proprietorship, management, and playing conditions. The current state needs to be improved considerably in terms of safety, usability and comfort so as to bring the playgrounds back to life. [ABSTRACT FROM AUTHOR]

N2 - The authors of the article researched the available information and investigated the incidence of injuries in playgrounds, the age groups of the injured children and the types of injuries. The number of injuries in the 'developed' world is on the increase and there are many fatal outcomes as well. The current situation in Slovenia has not yet been researched as records on children's injuries are not kept separately for playgrounds. In spite of that, the average 17 fatal outcomes yearly among preschool children due to inadvertent injuries (including road accidents) and poisoning is appalling and it is therefore reasonable to consider broadening the preventive measures, including those in children's playgrounds. N2 - The rapid growth of the elderly population coupled with research demonstrating the existence of ageist stereotypes even among very young children have led to the rise of intergenerational programs. Very limited research has been conducted, however, to demonstrate the effectiveness of these programs in producing attitudinal change or other beneficial outcomes for at-risk children. This study examined the impact of an intergenerational program on children's attitudes toward elders and on their school-based behaviors. Eighty-one 4th grade children enrolled in an inner-city school participated in the study. Forty-one children, with matched seniors partners, engaged in activities based on the 4th grade core curriculum within an outdoor classroom environment, while the remaining 40 children participated in usual core curriculum activities. At the conclusion

of the program those children who participated in the program had significantly more positive attitudes towards the elderly and significantly better school behavioral grades than did non-participating students. Implications and recommendations for intergenerational programming are discussed

N2 - This paper reports on the use of cameras by children to record how they used their play environments during after-school play in an Australian provincial city. The study was one of six carried out concurrently to illuminate the complexity of children's after-school leisure and the environment in which it takes place. Twenty four children, twelve boys and twelve girls, were issued with disposable cameras to photograph their play in after-school time and leisure space. They produced 342 usable images which were analyzed by location, setting and activities. There was no measurable gender difference in choice of play location, but place of residence strongly influenced this choice. Both boys and girls had a strong tendency to choose open and natural locations, and naturalistic settings dominated play spaces. While the expected multiplicity of activities in children's free play is demonstrated in the photographs, so is the importance of solitude and reflection. The photos also reveal a much higher incidence of mixed-gender play than is commonly reported for this age group

Le present article traite de l'utilisation d'appareils photos par les enfants d'une ville provinciale de l'Australie afin d'illustrer la maniere dont ces jeunes utilisent leur environnement lorsqu'ils jouent apres l'ecole. Il s'agit d'une de six etudes concomitantes visant a jeter un eclairage sur la complexite du loisir des enfants et de l'environnement ou ces activites se deroulent une fois l'ecole terminee. Vingt-quatre enfants, dont douze garcons et douze filles, ont recue un appareil jetable leur permettant de photographier leurs jeux dans leur environnement de loisir. Ils ont pris 342 photos qui ont ensuite ete analysees en fonction du lieu, de l'environnement et des activites elles-memes. Aucune difference ne ressort entre les filles et les garcons quant au choix du lieu; qui depend en grande partie du domicile des jeunes. Tous manifestent une tendance marquee en faveur des espaces naturels comme lieux et environnements de jeu. En outre, bien que les photos revelent, comme on s'y attendait, la grande diversite des activites de jeu libre des enfants, elles font egalement ressortir l'importance de la solitude et de la reflexion. Elles permettent aussi de constater que les jeux regroupant les jeunes des deux sexes sont beaucoup plus frequents que ne le laissent generalement entrevoir les etudes sur ce groupe d'age

N2 - The increased risk of morbidity and mortality among adults and children with pre-existing cardiovascular or respiratory illness from emission-derived particulate matter (PM) is well documented. However, the detrimental effects of PM inhalation on the exercising, healthy population is still in question. This review will focus on the acute and chronic responses to PM inhalation during exercise and how PM exposure influences exercise performance. The smaller ultrafine PM (<0.01 μ m aerodynamic diameter) appears to have the most severe health consequences compared with the larger coarse PM (2.5 <PM <10 μ m aerodynamic diameter). While the response to PM inhalation may affect those with a pre-existing condition, the healthy population is not immune to the effects of PM inhalation, especially during exercise. This population, including the competitive athlete, is susceptible to pulmonary inflammation, decreased lung function (both acute and chronic in nature), the increased risk of asthma, vascular endothelial dysfunction, mild elevations in pulmonary artery pressure and diminished exercise performance. PM exposure is usually associated with vehicular traffic, but other sources of PM, including small engines from lawn and garden equipment, cigarette smoke, wood smoke and cooking, may also impair health and performance. The physiological effects of PM are dependent on the source of PM, various environmental factors, physical attributes and nature of exercise. There are a number of measures an athlete can take to reduce exposure to PM, as well as the deleterious effects that result from the inevitable exposure to PM. Considering the acute and chronic physiological responses to PM inhalation, individuals living and exercising in urban areas in close proximity to major roadways should consider ambient air pollution levels (in particular, PM and ozone) prior to engaging in vigorous exercise, and those exposed to PM through other sources may need to make lifestyle alterations to avoid the deleterious effects of PM inhalation. Although it is clear that PM exposure is detrimental to healthy individuals engaging in exercise, further research is necessary to better understand the role of PM on athlete health and performance, as well as measures that can attenuate the harmful effects of PM. N2 - This study examined the validity of the Caltrac motion sensor for measuring physical activity in young children and described change over time in physical activity among 47 preschool children from obese and nonobese families. Children were videotaped in a controlled setting while wearing Caltrac motion sensors and

also wore Caltracs at home. Caltrac readings and an observational measure of physical activity were significantly related in both Year 1 ($r=.86$) and Year 2 ($r=.83$), and outside play was associated with higher Caltrac scores ($r=.43$). In addition, physical activity among young girls with obese parents decreased significantly from Year 1 to Year 2

N2 - Surprisingly there apparently have been no studies which have investigated childhood experiences in angling and other types of outdoor recreation within the context of an urban setting. Such experiences obviously confront problems with access, availability, and ever increasing problems with polluted waters and contaminated fish. The concepts of race, gender, residence and angling socialization are applied to angling participation by urban youth in a mid western setting. Data from a sample of 751 teenagers representing students enrolled in science classes in 10 different schools in a midwestern city suggest that gender appears to be a more important factor in angling socialization than either race or residence. Angling socialization in turn is very important in determining the children's angling activities. Children who have anglers in their households are more likely to engage in fishing more frequently and are more likely to enjoy angling as a leisure activity than are children who do not have anglers in their households. Because males are more likely to enjoy angling than are females, teenage boys are more active within the urban context. In such a context although black teenage boys are not more likely to fish in polluted waters, they do appear to run a higher risk of consuming contaminated fish

N2 - Background: Over 7 million students participate in high school athletics annually. Despite numerous health benefits, high school athletes are at risk for injury. Hypothesis: Severe injury rates and patterns differ by gender and type of exposure. Study Design: Descriptive epidemiology study. Methods: Sports-related injury data were collected during the 2005-2007 academic years from 100 nationally representative United States high schools via RIO (Reporting Information Online). Severe injury was defined as any injury that resulted in the loss of more than 21 days of sports participation. Results: Participating certified athletic trainers (ATCs) reported 1378 severe injuries during 3 550 141 athlete-exposures (0.39 severe injuries per 1000 athletic exposures). Football had the highest severe injury rate (0.69), followed by wrestling (0.52), girls' basketball (0.34), and girls' soccer (0.33). The rate in all boys' sports (0.45) was higher than all girls' sports (0.26) (rate ratio [RR], 1.74; 95% confidence interval [CI], 1.54-1.98; $P < .001$). However, among directly comparable sports (soccer, basketball, and baseball/softball), girls sustained a higher severe injury rate (0.29) than boys (0.23) (RR, 1.28; 95% CI, 1.08-1.52; $P = .006$). More specifically, girls' basketball had a higher rate (0.34) than boys' basketball (0.24) (RR, 1.43; 95% CI, 1.10-1.86; $P = .009$). Differences between boys' and girls' soccer and baseball/softball were not statistically significant. The severe injury rate was greater in competition (0.79) than practice (0.24) (RR, 3.30; 95% CI, 2.97-3.67; $P < .001$). Nationally, high school athletes sustained an estimated 446 715 severe injuries from 2005-2007. The most commonly injured body sites were the knee (29.0%), ankle (12.3%), and shoulder (10.9%). The most common diagnoses were fractures (36.0%), complete ligament sprains (15.3%), and incomplete ligament sprains (14.3%). Of severe sports injuries, 0.3% resulted in medical disqualification for the athletes' career, and an additional 56.8% resulted in medical disqualification for the entire season. One in 4 (28.3%) severe injuries required surgery, with over half (53.9%) being knee surgeries. Conclusion: Severe injury rates and patterns varied by sport, gender, and type of exposure. Because severe injuries negatively affect athletes' health and often place an increased burden on the health care system, future research should focus on developing interventions to decrease the incidence and severity of sports-related injuries. N2 - **BACKGROUND:** Educational disengagement is a public health concern among Aboriginal populations in many countries. It has been investigated previously in a variety of ways, with the conventional focus being on the children themselves. Activity settings are events and places, theorized in terms of their symbols, roles, time frame, funds, people, and physical location. According to the theory, particular behaviors and experiences are shaped by different configurations among these elements. This study explored how activity settings theory might provide new insight on school engagement. **METHODS:** Ethnographic study was undertaken at a grades primary to 12 school in a remote First Nations community in Canada's Northwest Territories. We collected data through interviews, focus groups, archival material, and field notes from 7 months of participant observation. An activity settings model acted as template for data collection and interpretation. **RESULTS:** Different aspects

of the school's physical layout, routines, procedures, transport systems, mix of people, and rules were able to be systemically assessed and classified as either creating or eroding engagement. CONCLUSION: This study applies an activity setting analysis to school engagement, thereby allowing researchers to investigate the dynamic and nested nature of context or environmental influences on engagement. It provides grounded observations that invite direct opportunities for action on dimensions that teachers and practitioners might not otherwise 'see.' ABSTRACT FROM AUTHOR

N2 - Based on the sample of 58 male respondents (30 respondents were a part of experimental group and 28 of control group) age from five to five and a half years old, initial and final measuring was conducted with the aim to determine global quantitative changes in motor abilities between these two groups. Experimental group carried out specially designed physical education program suitable for pre-school children that lasted for three days, weekly totally 60 minutes in the Gym managed by physical education professor, while control group followed current program for pre-school education in the classroom (playground) managed by kindergarten teacher. Possible differences were determined between experimental and control group in initial and final measuring in a period of three months participation in physical education program To test motor abilities we applied 6 tests. We applied canonic discriminative analysis to determine global quantitative differences between these two groups in the area of motor abilities. Obtained results indicate there are no differences between groups in initial measuring, but in final measuring we noticed statistically significant differences regarding experimental group which means there has been some positive transformations in motor abilities of this group. Possible reason lies in program organized for experimental group as well as different approach to realization of treatment and material working conditions where the classes were carried out. N2 - Purpose. This study investigated the variance in sitting, walking, and moderate and vigorous physical activity explained by neighborhood design and recreational environmental variables above and beyond the variance accounted for by individual demographic variables. Design. Cross-sectional analyses of self-reported survey data. Setting. A random sample of inhabitants of Ghent, Belgium, aged 18-65 years, was drawn. Subjects. Five hundred twenty-one adults completed questionnaires (52.1 % response rate). The average age of the sample was 41 years, and 48.2% were female. Measures. A questionnaire developed to assess neighborhood design and recreational environmental variables with a total of 81 items was administered. The environmental questionnaire showed acceptable to good reliability and acceptable validity. The previously validated International Physical Activity Questionnaire (IPAQ) was used to quantify physical activity in the past 7 days. Additional demographic information was also obtained. Results. Regression analyses showed that environmental variables were related to all types of physical activity in both sexes. However, the range of variance explained by the models including demographic and environmental variables was low, only 5 % to 13%. Minutes of walking and of moderate-intensity activity were related to quality of sidewalks and accessibility of shopping and public transportation. Vigorous physical activity was related to presence of activity supplies in the home and number of convenient activity facilities outside the home. Conclusions. Both neighborhood design and recreational environment variables had small but significant associations with multiple types of physical activity in a sample of Belgian adults. ABSTRACT FROM AUTHOR

N2 - Context: Although the number of US ice hockey participants doubled from 1990 to 2006, no nationally representative studies have examined US ice hockey injuries among participants of all ages during this period. Objective: To describe patients with ice hockey injuries presenting to a representative sample of US emergency departments (EDs) from 1990 through 2006. Design: Prospective injury surveillance study. Setting: The US Consumer Product Safety Commission collects data from 100 nationally representative EDs via the National Electronic Injury Surveillance System (NEISS). Patients or Other Participants: Individuals injured while playing ice hockey and presenting to a NEISS-affiliated ED from 1990 through 2006. Main Outcome Measure(s): Incidence and patterns of ice hockey-related injuries. Results: From 1990 through 2006, 8228 patients with ice hockey-related injuries presented to NEISS-affiliated EDs, representing an estimated 302 368 ice hockey-related injuries sustained nationally during this time. Injuries occurred predominantly among males (93.5%). More than half of the injured were aged 9 to 14 years (28.9%) or 15 to 18 years (30.1%), and injury incidence in these age groups increased over the study period ($P = .009$ and $P < .001$, respectively). The most commonly injured body sites were the face (19.1%), wrist/hand/finger (14.1%), shoulder/upper arm (13.8%), and lower leg/ankle/foot (11.1%). Lacerations (27.0%), contusions/abrasions (23.6%), fractures (17.3%), and sprains/strains (16.9%) were the most common injuries. Falls (16.5%), contact with boards (13.6%), and contact with stick (13.0%) were the most common injury mechanisms. Compared with those aged 9 to 18 years, those aged 2 to 8 years and

those older than 18 years sustained larger proportions of face (injury proportion ratio [IPR] = 2.66; 95% confidence interval [CI] = 2.29, 3.08) and mouth (IPR = 4.34; 95% CI = 2.87, 6.56) injuries. Concussions were more common among those aged 2 to 18 years (9.0%) than in those who were older than 18 years (3.7%) (IPR = 2.47; 95% CI = 1.75, 3.49). Conclusions: Ice hockey injury patterns vary by age and sex. Our findings indicate that many trips to the ED might be prevented by using protective equipment appropriately.

N2 - Background: This paper reviews the recent literature on rhinitis in athletes and the relationship of nasal and exercise physiology with environmental factors with a negative impact on sport performance, including the relationship between allergic rhinitis and exercise-induced asthma. The management and therapeutic plan for the elite athlete with rhinitis is also reviewed. Methods/Data base: Computer-assisted literature search on Medline for published data on rhinitis and exercise, or rhinitis and athletes. Published articles, abstracts, and conference proceedings were selected. Results: A high prevalence of rhinitis and rhinoconjunctivitis has been reported in training athletes (13.3-41%). In athletes with rhinitis, factors with a potential negative impact on sports performance include outdoor exposure to pollen and pollutants (ozone and particulate mater), or to sport-specific environmental conditions (e.g., cold dry air, indoor chlorine). Allergic rhinitis and sensitization to seasonal allergens is associated with exercise-induced bronchoconstriction in young adults and, in athletes, with decreased quality of life and athletic performance. The management of rhinitis in elite athletes includes: avoiding exposure to peak levels of allergens and pollutants, reducing symptoms and improving nasal function, and using therapies according to practice guidelines and complying with anti-doping regulation (which may require a medical notification). Conclusions: Rhinitis is a very common disease that, in athletes, can significantly impair exercise performance and increase the risk of exercise-induced symptoms. An early recognition and diagnosis are crucial for adequate management, aiming to improve nasal function and reduce the risk of asthma during exercise and competition

N2 - The purpose of the present study was to investigate the effect of an eight-week health-related fitness and nutrition education program on fitness components and dietary habits in upper elementary school students. Forty children from the fifth and sixth grade, 10 to 12 years of age ($M = 11.2$, $SD = 1.1$), participated in the study. The experimental group consisted of 20 children who participated in the program three days per week for one hour outside the time allotted for school physical education. The control group participated in the typical school physical education program. Health-related fitness components (cardiorespiratory endurance, abdominal strength and endurance, flexibility, and body composition) were assessed with the Prudential Fitnessgram test battery (Cooper Institute, 1992). Also, children's dietary habits were assessed based on the Health Behavior Questionnaire (HBQ) of Parcel et al. (1995) that recorded their dietary habits, after being modified to fit in the Greek diet (Bebetsos 1999). The multivariate analysis of variance for repeated measures (2×2) indicated that the group \times measure interaction was significant. Children in the experimental group had better scores on cardiorespiratory endurance, on abdominal strength and endurance, and on dietary habits than those in the control group. These findings indicate that certain health-related fitness components and dietary habits as well can be improved with a three hour a week program consisting physical fitness and nutrition education activities

N2 - This study employed ordinal logistic regression analyses to investigate the relationship between American adolescents' participation in physical activity and depressive symptomatology. Data were drawn from the second Child Development Supplement to the Panel Study of Income Dynamics (CDS II), which was conducted over 2002-2003. Fewer than 60% of adolescents were found to accumulate 60 min of moderate-to-vigorous physical activity (MVPA) outside of school hours on week or weekend days. Accumulated duration of MVPA was not, however, significantly associated with severity of depressive symptoms for either gender. Males who were not involved in sporting clubs or lessons were more likely than males who were highly involved to experience greater severity of depressive symptoms (OR = 3.24, CI = 1.33, 7.87). Results highlight gender variability in the psychosocial correlates of sporting participation and prompt further investigation of the relevance of current physical activity guidelines for mental health in adolescence. N2 - Background and significance. Currently there are no simple-to-use tools available to identify sleep problems in the clinical setting. Polysomnography (PSG), the "gold standard" for sleep analysis, requires an overnight stay in a sleep lab. More recently, actigraphy has been used to estimate sleep-wake patterns from activity/inactivity in naturalistic settings. The reliability and validity of these devices have not been established for all age groups or clinical populations

Purpose. The overall purpose of this study was to develop a process by which practitioners could assess for factors that influence sleep in young children. Aim 1 evaluated the reliability and validity of the Actiwatch-64RTM (Mini-Mitter, Sunriver, OR) actigraph in young children by comparing it to attended PSG. Aims 2 and 3 assessed the reliability and validity of the researcher-developed Toddler and Preschool Sleep Problems Screening Tool (TPSPST) by comparing it to the Actiwatch-64RTM

Design. An instrumentation research design was used

Methods. Subjects aged 1--5 years (n = 40) wore the Actiwatch-64RTM during a standard attended PSG. Two subjects in each age range wore two devices each to assess interdevice reliability. Next, a convenience sample

(n = 200) of parents of children 12--60 months old from day care centers completed the TPSPST. Lastly, a convenience sample of children 12--60 months old (n = 40) completed the TPSPST and wore the Actiwatch-64RTM for 72 hours

Results. All the sleep parameters significantly correlated between the Actiwatch-64RTM and PSG as well as epoch-by-epoch sleep-wake scoring for the dual watch subjects. A one-way ANOVA showed no statistical difference between the groups for the TPSPST raw scores. A Kruskal-Wallis showed no statistical difference for categories between the groups. There was a trend toward higher scores on the night-waking subscale of the TPSPST and lower sleep efficiency, although it was not statistically significant. A factor analysis was done to identify the factors that describe the association between variables measured by the TPSPST and to assess if the tool measured the dimensions that were expected

JF - Journal of Adventure Education & Outdoor Learning

VL - 5

IS - 1

N2 - This paper reports on research conducted as part of a project, the aim of which was to utilise outdoor and adventurous experiences to help schools address their 'if only' factor -- that aspect of learning perceived to be key to raising standards, whether it be the acquisition of knowledge, skills or a change in attitudes to learning. The project involved nine schools and 671 children, all engaged in the "I Can~" project and the follow-up activities that took place at schools. The research was carried out with children, teachers and parents and consisted of a series of focus groups and analysis of children's work. Limitations inherent within the research opportunity prevent the confident attribution of causation. However, the study's findings do offer insight into an under-researched, yet potentially valuable educational experience. The findings suggest that outdoor and adventurous activities can impact upon children's learning in school by addressing their intellectual, affective and social development.

N2 - The purpose of this study was to define the normal systolic blood pressure (SBP) response to exercise in a large group of healthy competitive athletes training in various sports. 2111 competitive athletes in the age range 14-18 years participated. An additional 550 healthy active individuals not competing in any particular sport were included for comparison. Testing was carried out on a cycle ergometer. To provide valid comparison at equivalent physiological strain, SBP was presented in relation to heart rate at any given power load. Data was presented by age group and by sport discipline. All groups fell within the 25-75 per cent range for this population. The SBP response appeared to be higher than that of non trained individuals reported in the literature. Using this data, individuals falling outside the norm can be defined and appropriate measures taken

N2 - ISSUE ADDRESSED:

Reducing children's exposure to ultraviolet (UV) radiation is a major focus for public health efforts to prevent skin cancer in Australia. Schools have a role to play in reducing children's exposure to UV radiation. In 1993 a SunSmart Schools Accreditation program was developed to encourage and support primary schools in Victoria to introduce sun protection policies. A SunSmart School sign provided recognition for schools that met accreditation standards as well as promoting the program to other schools

METHODS:

In 1997 the prevalence of sun protection policies and practices of a representative sample of Victorian primary schools was assessed. Principals from 259 schools reported on the sun protection policies and practices at their schools. At the time of this study 38% of schools had SunSmart accreditation

RESULTS AND CONCLUSIONS:

Results suggest that the majority of Victorian primary schools have addressed strategies such as hat wearing, sunscreen provision and curriculum-based sun protection education. However, shade provision and the scheduling of outdoor activities to avoid peak UV periods remain areas needing further improvement. SunSmart accreditation was more strongly associated with better sun protection in some strategy areas than policies that weren't accredited. Nevertheless non-accredited policies appear to have benefits over the lack of a sun protection policy. Moreover there was an association between sun protection practices in schools and whether these were specifically addressed in the policies

SO WHAT?

Providing support for schools to introduce policies and setting standards for sun protection are likely to improve sun protection practices in schools

VL - 78

IS - 4

N2 - Over the past decade, school boards across Ontario have adopted the 'balanced school day'; wherein classroom time is divided into three blocks of 100 minutes separated by two 40 minute nutrition/activity breaks. The traditional schedule consists of a morning and afternoon recess of 15 minutes and one longer lunch break. Educators advocate that the balanced school day improves classroom learning; however, little evidence exists to support this. Given that classroom scheduling impacts time allocated for eating and play, scheduling is also an important component to children's overall health. To date, no systematic evaluation of the related health effects of scheduling on student nutrition and exercise has been done. The purpose of this article is to review the current literature in relation these questions and to reflect upon potential implications of this altered schedule.

ABSTRACT FROM AUTHOR

Au fil de la derniA"re dAccennie, les conseils scolaires de l'Ontario ont commencAc Aĳnstaurer le principe de la A@jourNAce d'Accole AcquibrAce A . Il s'agit d'une journAce d'Accole oA1 les heures de classe sont rAcparties en trois blocs de 100 minutes avec deux pauses de nutrition/activitAc intercalAc de 40 minutes, alors que l'horaire traditionnel prAcvoit deux pAcriodes de rAccrAcation de 15 minutes, l'une en avant-midi et l'autre en aprA"s-midi, avec une pause plus longue pour le repas du midi. MalgrAc la pAcnurie de donnAcas probantes Aĳcet effet, les enseignantes et enseignants sont d'avis que la journAce d'Accole AcquibrAce favorise l'apprentissage des AclA"ves. Puisque l'horaire scolaire a des incidences sur l'alimentation et le jeu, l'organisation de l'horaire de l'Accole constitue une composante clAc de la santAc globale de l'enfant. Aucune Acvaluation systAcmatique n'a ActAc menAc jusqu'ici pour dActerminer les effets de l'horaire sur deux composantes de la santAc des AclA"ves, soit la nutrition et l'exercice. N2 - Physical activity of first grade pupils in relation to parents' social economic position is analysed in this article. The study was carried out in randomly selected Siauliai region schools in 2008. Questionnaires were distributed among 630 randomly selected first grade pupils and filled-in by 515 parents (response rate 81.8%). Physical activity of pupils was assessed according to parents' education, income and living place. It was established that sport or dancing clubs were attended by 39.6% of children. The highest number of pupils attending the clubs was among those whose parents (mother or father) had the university education (52.8 and 59.5%, respectively). In families where parents had the vocational or the lower educational level this number was lower. More first grade pupils in cities attended sport or dancing clubs (45.5%) than in villages (35.4%, $p < 0.05$). More than half of children go to school (58.8%) and come from it (72.2%) on foot, 1.2% ride a bicycle. One third of children were brought to school by their parents in a car but only one fifth of them was brought back. The relation between the number of children brought to school by car and parents' income was observed: the highest number of children was in the families where parents' income was the highest (31.1% in families with low income and 46.3% with high income). One third of pupils (36.9%) spent their time playing out-of-doors for 3 or more hours on workdays and majority of them (87.1%) spent the same time at weekends. The study showed that first grade pupils spent much time passively playing computer games or watching TV. Mostly children used a computer for one hour per day (33.9% on workdays and 28.5% at weekends), mostly watched television for 2 hours on workdays and for 3 hours or more at weekends (45.1 and 41.4%, respectively). Conclusions: 1) Physical activity of first grade pupils is insufficient. The majority of them do not attend sport or dancing clubs, children spend much time passively watching TV or playing on a computer. 2) There are relations between social economic factors and children's physical activity. Most pupils attending sport or dancing clubs and playing on a computer were in families where parents had the highest educational level as well as in the families with the highest income. 3) First grade pupils from villages participate in sports and play computer games less than their peers in cities, they spend more time playing out-of-door. N2 - Purpose. To assess physical activity levels during active video game play over time and compare this to 'free play' associated with recess activity in a sample of British primary school children over a 6-week period. Basic procedures. Thirty children (ages 10-11, 12 boys, 18 girls) from central England were randomly selected to participate in a 6 week, recess based, active video gaming intervention (n = 15) or act as controls (n = 15). Repeated measures analysis of covariance (controlling for body fatness) was used to examine any differences in physical activity, determined by pedometry and heart rate monitoring over time and between intervention and control groups. Main Findings. Children in the intervention accumulated significantly greater steps/day than the control group during the first week of the intervention. This pattern was reversed at the mid and end points of the intervention (p = .03). Irrespective of time point, children engaging in active video game play spent a lesser percentage of time engaged in MVPA than the controls undertaking 'traditional' recess activity (p = .0001). Conclusions. Active video game play does not appear to be a sustainable means to enhance children's physical activity. Although physical activity (steps/min) was greater on initial presentation of active video games compared to 'traditional' recess activity, this appears to be an acute effect. ABSTRACT FROM AUTHOR

N2 - The article discusses a study which examined the levels of physical activity during active videogame play and compared it to free play in a sample of primary school children in Great Britain. The differences in physical activity were determined using pedometry and heart rate monitoring. Findings revealed that greater steps per minute were accumulated by children in the intervention group during the first week of research. In addition, a lesser percentage of time was spent by children engaging in active video game play

N2 - The shared space of school grounds can provide a rich educational resource in addition to a safe environment for play, enjoyment and relaxation. The project described in this paper developed guidance for schools on grounds development and also provided direct support to three schools to enable them to improve their grounds and to work towards Eco Schools and Health Promoting Schools accreditation. The evaluation demonstrated a relationship between improved grounds and a reduction in negative playground incidents, improved co-operation at break times, children having more pride in their school, children feeling happier at break time, increased sun awareness and the use of school grounds as a teaching resource. The project also achieved some influence at a more strategic level

N2 - 'Uptime' can be defined as time spent in the upright position. The opposite of uptime is 'downtime', which is a measure of time spent in the recumbent position. The concept and usage of these terms have been common parlance in research into chronic pain for over 20 years. Measures of uptime have been used to evaluate changes in a person's functional performance. Uptime provides new information about a patient's response to rehabilitation that complements other outcome measures currently in use. In patients with chronic pain it has been shown that as uptime increases in symptoms of pain and an improvement in functional capacity. However, no research to date has reported the measurement of uptime in children. This could be a useful outcome measure when the focus of rehabilitation was on enhancing a child's ability to stand, walk or move around in the upright position. An accurate way to measure uptime is by direct observation. However, this is not practical for long periods of time, or large numbers of subjects. 'Uptimers' are battery-operated devices that record uptime by the activation of a mercury tilt switch. These devices are attached to the outside the thigh, and when they are seated or reclining the device records downtime. The reliability and validity of uptimers in adults have been demonstrated by comparing uptime as recorded by an uptimer with recorded by an independent observer.

N2 - Problem Statement: Once a child starts its school experience, the learning process is triggered, as it is considered that it has to develop on the basis of a healthy organism, due to the fact that the intellectual effort requires a greater physical resistance. Furthermore, knowing children's anatomic and physiologic particularities is a necessary condition for a good proceeding of the Physical Education lesson in school, because it enables the members of the didactic staff to understand the importance of physical education for primary school pupils, and the necessity of these lessons to be realised in an organised and systematic manner. Somatic parameters are a barometer for the didactic staff, and a comparative presentation of these parameters could represent a starting signal for the didactic process. Purpose of Study: This research started from the hypothesis according to which there are significant differences in the somatic development of children in urban areas, as compared to those living in rural areas, and we believe that these differences occurred due to the lack of movement. The present research was undertaken on a group of 20 subjects: 10 subjects living and learning in urban areas, and other 10 in rural areas. Research Methods: For our research we used the bibliographic study method, observation method, enquiry method (discussion, conversation, Lexical association - La, etc.), pedagogical experiment method, statistical-mathematical method, and graphical method. Findings: The purpose of this research was to observe if significant differences occur in the somatic development for children from urban areas, which have only two Physical Education lessons are more sedentary, as compared with children from rural areas, who, in addition to the two lessons of Physical Education they have in the weekly syllabus, spend about 2-3 hours a day outdoors playing ball, running or playing several specific countryside childhood games (catch, hide and seek, etc). Conclusions: Therefore, Physical Education lesson combined with leisure activities has a positive effect on children's growth and development, an aspect which should be taken into consideration, and we should offer more outdoor time for children living and studying in urban areas. N2 - To supplement the present weekly allotment of 30 minutes of physical education, a school district in southeastern North Carolina identified recess time as part of the state mandated (HSP-S-000) 150 minutes of physical activity (PA) per week and have purchased fitness equipment (recess packs) for the children to use. Twelve participants were selected from four elementary schools that had recently received the recess packs equipment and training. The participants were; (a) four principals, (b) four teachers, and (c) four students. They were selected by a purposeful sampling technique. Qualitative data analysis procedures were used to explore participants 'views on how the recess packs had impacted PA levels during recess. Several themes emerged during the interviews including: (a) gender differences in the types of activities performed during recess before and after the introduction of the recess packs, (b) how the type and the developmentally appropriateness of activities had been affected by the recess packs, (c) how the recess packs initiative had changed the teacher 's role during recess, (d) the importance of addressing nutritional concerns in addition to encouraging more physical activity during recess, and (e) the training that principals and teachers had received. Overall, the study demonstrates the PA benefits in providing equipment during school recess periods. Also, it stresses the importance of training principals and teachers to effectively plan and deliver developmentally appropriate activities resulting in more intense bouts of PA. N2 - Mountaineering trips represent a widespread form of outdoor activities. The main goal of mountaineering trips is to educate and teach students how to accept mountaineering as a way of living. In this paper we presented a way of planning and organizing trips that can help teachers in an efficient way while they implement and realize the extracurricular activities within the school subject of Physical and Health Training. We presented a preparation for a trip (the equipment for a daily hiking and dayslong hiking), days-long trips and staying overnight in the mountains, including exercise and stay in the mountain. Mountaineering trips are interdisciplinary activities that are realized in different circumstances. It is very important to respect the sequence of planned activities in the process of organizing the trip, especially when we work with children who possess a lower level of anthropological potential. N2 - The aim of this study was to examine whether early and sustained organized youth sport during childhood and adolescence predicts frequency of leisure-time alpine-skiing at age 27. A 5-year longitudinal study of 180 adolescents was conducted to practice alpine-skiing after faculty. The correlation coefficients tended to be higher among males and decreased over time both in females and males. The age at becoming a member in organized sport and duration of participant in organized outdoor activity in winter during adolescence predicted 9 % of the variance of young adult alpine-skiing. The correlations were higher in males than in females, but these differences were not significant. Organized youth sports during childhood and adolescence was positively related to frequency of leisure-time alpine-skiing in young adulthood. ABSTRACT FROM AUTHOR

VL - 75

IS - 3

N2 - Background. Knowledge about factors that affect participation, as preference of activities, has major intervention implications. Purpose. To evaluate culture and gender effects on Israeli Jewish and Druze children's preference of activities performed outside mandated school. This study used the "Preference Assessment of Children" (PAC) (King et al., 2004). Findings. On most scales, the Jewish children showed significantly less interest in activities than the Druze children. Among the Jews, girls showed higher preference in most PAC scales than boys while among the Druze girls showed higher preference than the boys only in social skills. Implications. Culture and gender may influence children's preference of activity. More studies should elaborate the knowledge about individuals' preferred activities; understanding the factors that affect these preferences may enhance occupational therapy evaluation and intervention processes. Canadian occupational therapists, as health care professionals in a multicultural society, must develop cultural competency and explore people's experience as cultural beings. ABSTRACT FROM AUTHOR

Description. Les connaissances sur les facteurs qui influent sur la participation, comme les préférences en matière d'activités, ont des conséquences majeures sur l'intervention. But. Évaluer les effets de la culture et du sexe sur les préférences d'enfants juifs et druzes israéliens face à des activités récréatives à l'extérieur d'une école mandatée. Cette étude a été effectuée à l'aide de la A® Preference Assessment of Children A[®] (PAC) (King et al., 2004). Résultats. À la plupart des échelles, les enfants juifs ont manifesté moins d'intérêt pour les activités que les enfants druzes. Parmi les enfants juifs, les filles ont montré une plus grande préférence que les garçons dans la plupart des échelles de la PAC, alors que chez les enfants druzes, les filles ont montré une plus grande préférence que les garçons seulement pour les habiletés sociales. Conséquences. La culture et le sexe peuvent influencer les préférences des enfants face à différentes activités. La plupart des études devraient chercher à produire des connaissances sur les activités préférées par les enfants; une meilleure compréhension des facteurs qui influent sur ces préférences pourrait permettre d'améliorer les processus d'évaluation et d'intervention en ergothérapie. Les ergothérapeutes canadiens, de même que les professionnels de la santé évoluant dans une société multiculturelle doivent acquiescer des compétences culturelles et examiner l'expérience des gens en tant qu'êtres culturels. N2 - Games with one basket are basic basketball games where players learn about the essential elements of the basketball game (5:5 with two baskets) as well as systematically build up and broaden their knowledge. These games are simpler because a smaller number of players is involved; however, they are suitable for strengthening and maintaining many motor and functional abilities and they also impact significantly on the development of man's psycho-social dimensions. One can say that games with one basket positively affect the development of one's personality and also have an important educational function. Owing to the above and the fact that many times in sports halls and also on outdoor basketball courts it is not possible to play basketball with two baskets (smaller sports halls, only one-half of the court can be used, too many children), games with one basket also represent important contents of physical education classes. The article presents the methodology for learning basketball games with one basket, some other games with adjusted rules as well as types of competitions in games with one basket. N2 - The prevention of injuries to children and staff is of critical importance to recreation providers. Although program providers often document participant illnesses and injuries, the power of intentionally monitoring and sharing this information has not often been tapped in the recreation field. This article demonstrates how an injury and illness surveillance program was used to reveal patterns of injuries and illnesses within day and resident camps. These patterns suggested that children are less likely to be injured in day and resident camp settings when compared with participation in community-based sports, and, additionally, illustrated an organizing framework for injury and illness prevention that may be useful to other youth program providers. Primary injury topics appeared to be supervision patterns, falling on uneven terrain, and head injuries.

Preventative strategies suggest analysis of levels of supervision, footwear policies, and activity-specific head protection. Two significant clusters of illness were identified. One included throat, nose, lung, ear, and eye maladies, while the second was comprised of upper and lower gastrointestinal illnesses, those often associated with what one eats or is exposed to (e.g., Norwalk virus). Proactive approaches to illness management center on maintaining resilience so people are less susceptible to pathogens and implementing practices that minimize the potential that someone will get ill. The innovation of sharing of data in a systematic way proved helpful in understanding illness and injury. The systematic investigation of when, where, and how injuries and illnesses occurred brought to light trends that yielded specific, practical strategies that administrators can implement to improve safety for staff and participants. This new approach to understanding what is happening in youth programs allows for targeted intervention based on real data rather than perceptions of trends. As program administrators work to improve health and safety, understanding the trends related to illness, injury, and proactive management can make a difference in safety improvements. N2 - The aim of the present study was to describe the daily physical activity (PA) during recess of primary-school children and its relationship with the play area and their age. 738 children (8.5A ñl.7 years, range six to eleven years) participated in the study. The playground recess PA of each child was measured using accelerometry. An ANOVA was used to determine the differences in PA by play area (large >15 mA ŷ/child and small area <8 mA ŷ/child) in each age group. In general, the children in larger play areas were more active than the children in small play areas (effect size = .36). This difference was larger in nine-year (effect size = .81), ten-year (effect size = .60) and eleven-year old children (effect size = .55). It seems necessary to carry out strategies that provide a greater opportunity for PA in small playgrounds with a high density of children.

N2 - This article presents information on the Play Day, a widespread fitness event organized by the Austin Parks and Recreation Department (APARD) where more than 700 children joined the mayor of Austin in a one-mile walk along Austin's hike and bike trail. This special event took place on June 8, 2005 in Texas. Campers from 30 playground sites and 16 recreation centers participated in this opening ceremony as part of the 2005 Play Day Initiative, created by the APARD and supported by two local programs--Walk Texas and Steps to a Healthier Austin

N2 - Of the many factors that come to influence elementary school children's play, the role of the supervising adult has been infrequently studied. This paper commences with some reflections from an earlier study of children's play and the role taken by the teachers on duty in a midwestern American school. It then describes the findings of a broader study, this time located in Australian primary schools, which had as its focus an investigation of the attitudes and role of teachers on playground supervision or 'yard duty' as it is called in Australia. The study found that the teachers saw yard duty in much the same way as their American counterparts. That is, as a necessary but generally unwelcome task. They saw themselves as fulfilling multiple roles including that of police officer, nurse, lawyer, psychologist, and social worker. The number and nature of the interactions between teachers and children varied with age and gender. This study concludes that the teacher role is an important one, and that there is a sound argument for not only more research in the area, but more attention to the education of teachers for their role as supervisor

N2 - In recent years, a variety of policy documents issuing from major providers of sport in the UK and elsewhere (for example, Sports Council UK, 1994 a,b; Sports Council for Wales, 1995a; Sports Council for Northern Ireland, 1996) have highlighted, amongst many other things, the significance of in-school and extra-school Physical Education (PE) in any endeavour to promote equity and greater participation of girls and women at all levels in school and community physical activity and sport. With reference mainly to the most recent of these policy texts, the Sports Council for Northern Ireland (SCNI) Women in Sport Policy Framework, published in 1996, and calling on research carried out by the authors of this paper on PE in primary and secondary schools in England and Wales, this paper adds further weight to the claim expressed in these texts that PE in the primary sector in particular, is a critical site of influence upon children's thinking about themselves and others, both in physical activity and sport. Lesson time PE and more informal playground activity are in dire need of attention. And unless women, the majority of teachers in primary schools in England and Wales, are positioned as leading agents in curriculum innovation and change, progress towards greater equity in PE and sport is unlikely to be achieved. Finally the paper considers whether the arrival of a National Curriculum PE (NCPE) will help promote the interests of girls and women in PE and sport in both primary and secondary schools and prepare them for their futures in leisure and paid work

N2 - Headlines greet us on almost a daily basis lamenting the declining health of Australian children. They are said to be inactive, unfit, overweight and lacking in fundamental motor skills. It is a disturbing picture. Calls have gone out to parents to encourage their children to be more active and for schools to counter these problems by allocating more time to sport and physical education however, in both instances, there are particular problems to be addressed. One aspect of schooling that is rarely considered in discussions about how to increase children's activity levels is recess. This article examines the problems facing physical education and offers some suggestions as to how schools might preserve and promote physical activity during recess breaks

N2 - This study investigated the effects of early-life experiences on an individual's environmental beliefs. Data from a survey of 533 university undergraduate students from 20 areas of academic study were analyzed using sequential regression to determine the degree to which current environmental beliefs could be explained by early childhood experiences. Results showed that four of the seven independent variables (appreciative outdoor activities, consumptive outdoor activities, media exposure, and witnessing negative environmental events) explained 14% of the variance in the eco-centric/anthropocentric beliefs. Three of the independent variables

(early-life participation in mechanized outdoor activities, education, and involvement with organizations) were not significant predictors of eco-centric/anthropocentric beliefs. Implications for research and practice were discussed. ABSTRACT FROM AUTHOR

N2 - The article focuses on the importance of physical education in schools. In the United States and Great Britain, guides are published that emphasize on the roles of the physical education and suggest that school children should work out at least for 60 minutes per day to maintain their physical, physiological and psychological developments. The article also tries to correlate physical activity with the educational progress. During elementary education, children should be involved in physical education so that they remain active in it through out their educational time span. The article reviews literature of physical education and tries to define terms and concepts of physical activities which could be taught during physical education sessions. The article also provides the assessment modes to measure physical activities of students

CY - ;

N2 - The first part of the paper presented contains definition of leisure time and the critique of these definitions from a woman's perspective. The second part contains results from different studies that have taken place during the last years. These studies show that women have less time for their own disposal. They are also less involved in organized activities outside the home compared to men. A large study from Sheffield in England showed that gender had great significance for the leisure behaviour. Particularly in milieus where homework and taking care of the children first of all were done by women. Existing norms about what is suitable behaviour for women seemed to be a significant barrier. The next part of the article discusses what conclusions can be drawn in relation to the Nordic countries. The question asked is if it is reasonable to suggest that women should prefer physical exercise before other leisure time activities? In this connection it focuses on the difference between the male and the female culture. The last part of the article contains results from a Norwegian study which covered married 30 year old women with children from 2 different parts of the city of Oslo, Norway. This study shows that women participate in traditional sport disciplines which can be done individually, independent of other people and independent of special sport facilities. The conclusion is that this is in many ways a logical consequence of a mother's everyday life

N2 - This study evaluated the relationship between leg strength and endurance run performance, independent of aerobic capacity (VO₂peak), body size, and gender, in children and adolescents with mild or moderate mental retardation. Twenty-six individuals (15 boys and 11 girls) volunteered and underwent tests of VO₂peak, isokinetic leg strength, and endurance run performance (600-yard run/walk and 20-m shuttle run). Results showed that leg strength was significantly related to both types of run performance; however, when controlling for VO₂peak, body size, and gender, leg strength was a more significant contributor to the 600-yard run/walk than to 20-m shuttle run performance. Gender did not influence these relationships. These data suggest that leg strength has a significant influence on endurance run performance in children and adolescents with mild or moderate mental retardation

N2 - All public buildings should be accessible to all. Accessibility should be universal. In present research 107 primary and secondary schools from 5 Slovene regions were involved. We found out 53% of schools don't have suitable access to enter the school, 55% don't have suitable access in a school sport hall, a restrooms are accessible inappropriately still (60%). No school has suitable access to outside playgrounds. Largest barriers are a stairs, too narrow or rotating door and narrow corridors. Results demand suitable treatment and deliberation now and of course at that time, when possible modernizations and renovations of our schools and school gymnasia would take place. N2 - Over the last decade or so, young people have increasingly become a focus of UK sport policy. Fuelled in part by concerns such as the increasing levels of childhood inactivity and obesity, and the lack of international success in sport, a plethora of policy initiatives aimed at young people have been developed. In April 2000, the government published its sport strategy document, A Sporting Future for All, pulling together all the threads of recent policies, and in it, restating its commitment to youth sport, sport in education, excellence and sport in the community. One such policy initiative, the School Sport Co-ordinator programme, is the focus of this paper. The School Sport Co-ordinator programme, currently being introduced into schools in England, is an initiative that involves two government departments (sport and education) and a number of other agencies, reflecting the government's current agenda to ensure 'joined up policy' thinking. It aims to develop opportunities for youth sport through co-ordinated links between PE and sport in schools, both within and outside of the formal curriculum, with those in local community sports settings. The essence of the School Sport Co-ordinator programme is to free up nominated teachers in schools from teaching to allow them time for development activities, specifically to encourage schools and community sports providers to work in partnership. This paper draws on data from an ongoing research project examining the implementation of one School Sport Co-ordinator partnership, Northbridge'. Drawing on in-depth interviews, it explores the perceptions of the newly established School Sport Co-ordinators of their changing role. The paper highlights some of the initial tensions and challenges for them in their task of working across different educational and sporting contexts

N2 - The main objective of the present investigation was to continue the research initiated by Hay and colleagues (2004) in examining the efficacy of the Children's Self-Perceptions of Adequacy in and Predilection for Physical Activity (CSAPPA) scale as a proxy for the short form .of the Bruininks-Oseretsky Test of Motor Proficiency (BOTMP-SF) in screening for Developmental Coordination Disorder (DCD) in children. To better appreciate DCD knowledge outside Canada, the measurements of this investigation were expanded in Greece. A translated Greek CSAPPA scale and the BOTMP-SF were administered for the first time in Greek children. A second objective was to investigate the relationship between DCD and various risk factors of coronary artery disease (CAD) in Canadian and Greek children. A sample of 591 (Ms=322; Fs=269) Canadian and 392 (Ms=211; Fs=181) Greek children, aged 9 to 13 years, consented to the BOTMP-SF, CSAPPA Scale, participating in physical activity questionnaire, Leger 20-meter Multistage Shuttle Run test, and body fat using bioelectric impedance. Prevalence of DCD in Canada and Greece was 8% and 19%, respectively. Significant agreement ($p < 0.001$) was confirmed when comparing the CSAPPA scale to the BOTMP-SF test in both countries. Canadian children revealed significantly lower percent body fat, CSAPPA scores, and participation in physical activity, as well as higher aerobic fitness levels and BOTMP-SF compared to their Greek peers.

Clumsiness was associated with increased percent body fat and low aerobic fitness values. Physical activity was a significant mediator in the clumsiness-aerobic fitness relationship. It is concluded that the CSAPPA scale is an accurate, practical, and inexpensive screening tool for DCD, and that motoric competence is associated with aerobic fitness through physical activity participation

N2 - The article focuses on the engagement of the physical activity as a way for helping the family in adopting the healthy lifestyles and spending more time together. It says that one of the most cost-effective strategies for physical activity is the outdoor activities. It adds that bone-strengthening benefits for both the parents and children can be offered by jumping rope. The likelihood of the children in adopting a healthy lifestyle can be influenced by a physically active family environment

N2 - The focus of this research was to gain an understanding of physical activity in elementary school-aged children with mental retardation (MR). The primary purpose of the first study was to investigate physical activity levels of children with and without MR in both school and out of school environments. The secondary purpose of the first study was to determine if there is a relationship between physical activity and motor skills in children with MR. Physical activity levels of 9 children with MR and 37 without were recorded over 7 days using an accelerometer. Motor skills were assessed using the Movement Assessment Battery for Children. Physical activity levels for children with MR were significantly lower during the school day. Children without MR were 53% more active during recess and 133% more active during physical education than children with MR. The disparity in physical activity continued outside of school where children without MR were 52% more active after school and 33% more active on the weekend than children with MR. There were no significant correlations between physical activity times and motor skills in either group. These findings indicate that interventions to increase physical activity in individuals with MR should to begin in the elementary school years. The primary purpose of the second study was to investigate if children with MR spend more time watching TV or on the computer than children without disabilities. The secondary purpose of study was to determine if total screen time correlates with physical activity levels. Parents of the participants recorded TV time and computer time over four days. Physical activity levels of the children were recorded with accelerometers. There was no difference in TV time or computer time in children with MR and children without MR. The correlation between after school physical activity and screen time was moderate in children with MR ($r=.69$ and low for children without MR ($r=-.32$). The results of this research suggest that there might be different patterns in the development of sedentary behaviors between children with and without MR, indicating that unique interventions may be needed for individuals with MR

N2 - This study investigated blood pressure responses (BP) during bilateral leg extension in healthy children at different numbers of repetitions. BP was measured non-invasively during 1 repetition maximum (1RM), 5 repetitions at 85-90 % of 1RM (5 R), 30 repetitions at 35-40 % of 1RM (30 R) and during 5 s of maximal isometric work (5SM). It is important to investigate if maximal strength testing in healthy children provokes an unfavourable rise in BP, in order to be able to do further research on hypertensive risk groups of children. 39 (18 male and 21 female) healthy children (10.5 A ñ 2.0 years old) participated in this study. Peak BP values and peak HR increased significantly with increasing number of repetitions. Peak BP increased from 1RM (144 A ñ 16/110 A ñ 19 mmHg) to 30R (170 A ñ 26/123 A ñ 21 mmHg) and peak HR increased from 1RM (122 A ñ 10 bpm) to 30 R (147 A ñ 14 bpm). 30R also gave significantly higher BP and HR than 5SM (156 A ñ 24/120 A ñ 23 mmHg and 131 A ñ 16 bpm, respectively). The boys had significantly higher diastolic BP during 1RM than the girls and significantly higher BP during 5SM. In conclusion, maximal strength testing induced lower increases in BP than submaximal strength testing with more repetitions, and may be performed in healthy children within safe BP limits (< 225 mmHg in systolic BP). N2 - A novel test instrument was designed to objectively quantify the progress of persons who participated in therapeutic horseback riding programs. Nineteen handicapped children, ages 7 to 14 years, with heterogeneous impairments were evaluated before and after riding. For measures of sitting balance and coordination, and hand, hip, knee, and ankle strength, marked improvements were noted for most children. Clinical impressions of therapists and parents suggested concomitant progress in characteristics such as self-confidence and interaction with others. Results from this pilot study appeared to support the use of the apparatus in that field setting.

N2 - Only a few decades ago children had the possibility to spend their whole leisure time in the open air. In many places they found natural playing spaces where they could move freely about and which they could perceive with all their senses. They had even the opportunity to modify and design their environment in a variety of ways. This article deals with the importance of spaces for moving about and gathering experiences for the development of children and presents project ideas for changing the outside area of a nursery school to a natural playing space

Il y a peu de decennies, les enfants avaient la possibilite de passer tout leur temps libre a l'exterieur. A maintes places ils trouvaient des espaces de jeu naturels, dans lesquels ils pouvaient se mouvoir librement et qu'ils pouvaient percevoir avec tous les sens. De cette facon ils avaient aussi la possibilite de changer et de creer leur environnement. La contribution traite de l'importance de l'espace de jeu de mouvement et d'exploration pour le developpement de l'enfant et presente des idees de projet concernant la transformation de l'exterieur d'une classe prescolaire en un espace de jeu naturel

Noch vor wenigen Jahrzehnten hatten Kinder die Moeglichkeit, ihre gesamte Freizeit im Freien zu verbringen. Vielerorts fanden sie naturbelassene Spielraeume vor, in denen sie sich frei bewegen und die sie mit allen Sinnen wahrnehmen konnten. So hatten sie auch die Moeglichkeit, ihre Umgebung zu veraendern und zu gestalten. Der Beitrag thematisiert die Bedeutung des Bewegungs- und Erfahrungsspielraumes fuer die kindliche Entwicklung und stellt Projektideen zur Umgestaltung eines Kindergartenaussengelaendes zu einem naturnahen Spielraum vor

N2 - Purpose. To use Ecological Momentary Assessment with mobile phones to describe where and with whom children's leisure-time physical activity occurs. Design. Repeated assessments across 4 days (Friday to Monday) during nonschool time (20 total). Setting. Chino, California, and surrounding communities. Subjects. Primarily low to middle income children (N = 121; aged 9-13 years; x = 11.0 years, SD = 1.2 years; 52% male, 38% Hispanic/Latino). Measures. Electronic surveys measured current activity (e.g., active play /sports/exercise, watching TV/movies), social company (e.g., family, friends, alone), physical location (e.g., home, outdoors, school), and other perceived contextual features (e.g., safety, traffic, vegetation, distance from home). Analysis. Multilevel linear and multinomial logistic regression. Results. Most of children's physical activity occurred outdoors (away from home) (42%), followed by at home (indoors) (30%), front/backyard (at home) (8%), someone else's house (8%), at a gym/recreation center (3%), and other locations (9%). Children's physical activity took place most often with multiple categories of people together (e.g., friends and family) (39%), followed by family members only (32%), alone (15%), and with friends only (13%). Age, weight status, income, and racial/ ethnic differences in physical activity contexts were observed. Conclusions. The most frequently reported contexts for children's leisure time physical activity were outdoors and with family members and friends together. ABSTRACT FROM AUTHOR

N2 - The following paper deals with the youth organisations in Alsace and covers the inter-war years (1918-1939). This period mark indeed a significant change in the educational practices, now characterized by an expansion and renewal of the organisations being in charge of the youth outside school time. The study is based on the ideas of the people in charge and on the sociability practices offered to the young Alsatians in these movements. In this frame, the valorization of nature as the privileged environment for socialization appears to be a transversal process. This trend is backed up by the use of physical exercises (walk and collective sports game for example) that become major teaching aids. The sources used in this paper are original and rarely capitalized on in the STAPS field (archives from the Strasbourg's Bishopric, the Alsace-Lorraine's Directory of the Augsburg's Confession, internal archives of organisations, former members' accounts etc.). These sources help to pay attention to a whole range of physical practices that have an educational ambition. As a region shaped by a unique history and particular social links, the example of Alsace allows us to reach an understanding of the objectives and means of mobilization of the youth at the beginning of the twentieth century. L'etude proposee prend pour objet les organisations de jeunesse en Alsace. La periode considerée est celle de l'entre-deux-guerres (1918-1939). Moment de mutations importantes par rapport aux pratiques éducatives de l'avant-guerre, elle se caractérise par un essor et un renouvellement des structures de la prise en charge des jeunes hors du temps scolaire. L'objectif de la recherche est d'approcher les conceptions des responsables et les pratiques de sociabilité proposées aux jeunes Alsaciens dans ces groupements. La valorisation de la nature en tant qu'espace privilégié de socialisation émerge dans ce cadre comme une tendance transversale. Ce processus s'accompagne de l'utilisation d'exercices physiques (marche et jeux sportifs collectifs notamment) comme supports pédagogiques prioritaires. L'étude entreprise s'appuie sur des sources originales et peu exploitées dans le champ des STAPS (archives de l'Evêché de Strasbourg, du Directoire de l'Eglise de la Confession d'Augsbourg d'Alsace-Lorraine, archives internes des organisations, témoignages d'anciens membres ...); celles-ci incitent à prendre en compte un ensemble de pratiques corporelles qui ont une ambition éducative. Terrain singulier d'histoire et de liens sociaux, l'Alsace constitue ici un exemple particulièrement riche des enjeux et moyens de la mobilisation de la jeunesse au début du XXe siècle.

Lo studio proposto ha per oggetto le organizzazioni della gioventù in Alsazia. Il periodo considerato è quello tra le due guerre (1918-1939). Momento di trasformazioni importanti in rapporto alle pratiche educative del secondo ante-guerra, esso si caratterizza per uno stimolo ed un rinnovamento delle strutture della presa in carico dei giovani al di fuori del tempo scolastico. L'obiettivo della ricerca è di avvicinarsi alle concezioni dei responsabili a delle pratiche di sociabilità proposte ai giovani alsaziani in questi raggruppamenti. La valorizzazione della natura, in quanto spazio privilegiato di socializzazione, emerge in questo quadro come una tendenza trasversale. Questo processo è accompagnato dall'utilizzazione di esercizi fisici (in particolare la marcia ed i giochi sportivi collettivi) come supporti pedagogici prioritari. Lo studio intrapreso si basa su fonti originali a poco sfruttate nel campo degli STAPS (archivi del Vescovo di Strasburgo, del Curia della Chiesa di Augsburg dell'Alsazia Lorena, archivi interni delle organizzazioni, testimonianze di vecchi membri, ecc.); questo ultimi invitano a prendere in considerazione un insieme di pratiche corporee che hanno un'ambizione educativa. Terreno singolare di storia e di legami sociali, l'Alsazia costituisce qui un esempio particolarmente

ricco delle poste in gioco a dei mezzi di mobilitazione della gioventu all'inizio del XX secolo

El estudio tiene por objetivo analizar las organizaciones de los jovenes de la Alsace en el periodo considerado entre las dos guerras (1919-1939). Momentos de cambios importantes en relacion a las practicas educativas antes de la guerra, esto se caracteriza por un desarrollo y una renovacion de las estructuras que tienen a cargo a los jovenes despues de las horas escolares. El objetivo de la investigacion es de aproximar las concepciones de los responsables y las practicas de sociabilidad propuesta a los jovenes Alsacianos. La valorizacion material que emerge como proceso socializador es una tendencia transversal. Este proceso es acompañado de ejercicios fisicos (caminatas, juegos deportivos colectivos) como soportes pedagogicos prioritarios. El estudio emprendido se apoya en fuentes originales y poco explotadas en el campo de las STAPS (archivos del arzobispado de Estrasburgo, del directorio de la iglesia de la Confesion de Ausburgo de Alsace Lorrain, archivos internos de las organizaciones, testimonios de miembros antiguos), ellos invitan a tomar en cuenta el conjunto de practicas corporales que tienen una ambicion educativa

Die vorliegende Studie befasst sich mit Jugendorganisationen im Elsass zwischen den Weltkriegen (1918-1939). Als eine Periode wichtiger Mutationen hinsichtlich erzieherischer Praktiken vor dem Krieg ist diese Zeit gekennzeichnet durch ein Aufkommen und eine Erneuerung von ausserschulischen Strukturen der Jugendbetreuung. Ziel der Untersuchung ist es, die Konzeptionen der Verantwortlichen und die in diesen Strukturen den jungen Elsaessern gebotenen Soziaabilitaetspraktiken in Beziehung zu setzen. Bei diesem Prozess dienen die Leibesuebungen (besonders Maersche und Mannschaftsspiele) als vorwiegendes paedagogisches Mittel. Die Studie stuetzt sich auf wenig ausgewertete Originalquellen im Bereich der Sportwissenschaft (Archive des Bistums Strassburg, der Kirchenverwaltung der Augsburgischer Konfession von Elsass-Lothringen, interne Archive der Organisationen, Augenzeugenberichte...), die auf koerperliche Praktiken mit erzieherischen Ambitionen verweisen. In seiner historischen und sozialen Einzigartigkeit zeigt sich das Elsass hier als ausserordentlich reiches Beispiel, bei dem es um die Mobilisierung der Jugend Anfang des 20. Jahrhunderts ging

CY - ;

N2 - Few studies have attempted to identify the effects of training on performance measures related to ice hockey. The present study was designed to examine the effects of a 7-week hockey-specific training program on the on- and off-ice test performance scores of 14- and 15-year-old (Bantam) hockey players. Pre- and post-training tests of percent fat (ultrasound), center of gravity location, 40-yard dash, vertical jump, and on-ice test of top speed, acceleration, and cornering ability were completed on 28 male subjects (16 in a training group, 12 in a control group of summer league participants). The training group showed significant improvements (p is less than .01) in percent fat, top speed, acceleration, and cornering test performance whereas only percent fat was significantly improved for the control group. The results suggest that performance on tests related to ice hockey can be improved by training specifically for hockey but that performance is not affected by summer league play alone

Peu d'études se sont arrêtées à identifier les effets de l'entraînement sur des mesures de performance au hockey sur glace. La présente étude porte sur les effets d'un programme d'entraînement de sept semaines spécifique au hockey sur des mesures de performance sur glace et hors glace chez des jeunes de 14 et 15 ans (Bantam). Les mesures suivantes sont enregistrées avant et après ces sept semaines d'entraînement: le pourcentage de graisse par ultrasonographie, la localisation du centre de gravité, le temps de performance sur 40 verges, la hauteur de saut vertical, la vitesse maximale sur glace, l'accélération en patins, et l'habileté dans les coins de patinoire.

Vingt-huit sujets d'un camp d'été, soit 16 dans le groupe expérimental et 12 dans le groupe témoin, participent à l'étude. Le groupe expérimental améliore significativement son pourcentage de graisse, sa vitesse maximale, son accélération, et sa performance dans les coins de patinoire; le groupe témoin n'améliore que son pourcentage de graisse. Les résultats suggèrent qu'on peut améliorer la performance à des tests reliés au hockey sur glace mais qu'un camp d'été seul ne suffit pas

N2 - The article presents the author's reflection on the memories of her father that involve tenderness, cherishing and a fierce love of a child. The author asserts that such masculine tenderness towards a child, does not diminish his father's masculinity. She cites seeing young boys in a school playground, who were delightedly

and confidently passing around a baby and competing to get the child laughing. On the other hand, she laments the paranoid suspicion of the male in public, with kids

N2 - Examines the effect of participation in competitive sport outside and inside the school on children's achievement motivation as measured by the motoric motivation test in 3 realms of behavior - motor activity, level of motivation and stability. Subjects were students chosen for sports classes, candidates for sports classes and ordinary students. Students in sports classes differed from other students by attaining a greater level of effort, but were more threatened by failure and it is suggested that this was a result of previous sport experience. After one year in the sport class, a favorable effect was found. Concludes that the organization of children's competitive sport in school can help with the negative effects in the competitive experience of child athletes

N2 - This study has attempted to answer the question: What is the relation of unsettled or broken home conditions to the academic success of high school pupils ? The following six factors were considered broken home conditions: loss of father by death, loss of father by divorce or separation, unemployment of father, loss of mother by death, loss of mother by divorce or separation, or employment of mother outside the home. Fifty pupils were located for each of these six broken home conditions. They were paired with pupils from normal homes on the bases of intelligence, chronological age, grade in school, sex, and nationality. An honor point average based upon teachers' marks was computed for each of the 600 pupils and used as the measure of academic success. The data indicate that the school achievement of pupils from broken homes is inferior to that of pupils from normal homes. This is true for seven comparisons; four of the comparisons reveal differences which are distinctly significant statistically; two differences approach statistical significance. Experimental and control pupils were then compared on the following factors: amount of absence, amount of tardiness, occupation of the father, number of brothers, number of sisters, number of only children, language spoken in the home, amount of outside employment, amount of outside work at home, participation in club activities and athletics, number of consultations with a doctor, amount of absence due to illness, amount of home study, study conditions at home, and type of high school curriculum. These comparisons revealed slight differences, if any, and failed to indicate any causal relation to the differential achievement of the experimental and control pupils.

VL - 16

N2 - Background Violence, in its varied presentation forms is common among youth. Risk factors have been identified in diverse populations for different types of violence. In this study we assessed victimisation for specific types of violence common among young people, and determined what the personal, familial and school protecting factors are. Methods Students (12f_"14 years old) in 35 randomly selected junior high schools were from the Jerusalem Hebrew (secular and religious) and Arab educational system (n=2610). They answered an anonymous questionnaire, addressing personal, family, and school characteristics, unintentional injuries and violence. Victimisation included experiencing at least one of the following: was bullied, mocked, boycotted, was stolen or was taken personal belongings by force. Results Only 24.2% did not experience violence in the last term. In a multivariate analysis independent protective factors from victimisation were: type of school, being older, female (OR 1.76, 95% CI 1.40 to 2.21), being participated in activities (OR 4.33, 95% CI 2.82 to 6.63), having two or more close friends (OR 1.82, 95% CI 1.07 to 3.10), having good relations among students (OR 2.73, 95% CI 1.04 to 7.15) and having a high family support (OR 1.53, 95% CI 1.19 to 2.00). Hours of television viewing, participating in sports activities, membership in a youth movement or the reported family socioeconomic status were not significant protective factors. Conclusions Few children are not victims of violence in school. Protective factors for violence are positive personal, family and school relations. Interventions addressing these positive factors may help to reduce violence in young people and their natural environment. ABSTRACT FROM PUBLISHER

N2 - Exercise challenge test (ECT) may help in the diagnosis of asthma. Asthma is season dependent (relative summer nadir). This study was designed to prospectively show that ECT sensitivity decreases when performed in summer and/or out of personal asthma season. We performed two ECTs in 49 patients with suspected asthma, at baseline and at least 6 months later. Test positivity was defined as a $\geq 10\%$ drop of forced expiratory volume in 1 second after exercise. Patients were defined as having exercise-induced bronchoconstriction (EIB) if at least one of the two tests was positive. We analyzed the impact of season and of patient-reported asthma season on ECT sensitivity. We performed 21 ECTs in the summer and 77 in other seasons. Summer tests were positive in 14.3% of patients versus 33.8% in other seasons ($p = 0.11$). In patients with confirmed EIB, the sensitivity (95% CI) of a summer test was 0.25 (0.007-0.57), compared with 0.76 (0.58-0.89) in other seasons. Tests performed out of personal asthma season were positive in 10.0% of tests compared with 37.1% of tests during personal asthma season ($p = 0.007$). In patients with confirmed EIB, the sensitivity (95% CI) of a test performed out of asthma season was 0.27 (0.07-0.61), compared with 0.74 (0.55-0.87) during season. The sensitivity of ECT performed in the summer or outside of the personal asthma season is about one-third of ECT performed not in the summer or during personal asthma season. We suggest performing ECTs during personal asthma season and not in the summer if there is no asthma season known

N2 - THE AUTHORS OF THIS JAPANESE MULTICENTER (12 HOSPITALS and 8 outside physicians), randomized, double-blind, placebo-controlled, parallel-group trial investigated whether vitamin D supplements might impact the incidence of influenza A in school children during winter and early spring. Children aged 6-15 years (mean age 10.2 years, with 65% having started nursery school or kindergarten at 3 years or older) were enrolled from November to early December in 2008 and then asked to begin taking their study drugs within the first 2 weeks of December. Subjects were randomized to receive daily divided doses of either 1,200 IU of vitamin D3 or placebo from December 2008 through March 2009. Parents were provided with eight numbered bottles, each containing 90 tablets of either 200 IU vitamin D or placebo identical in appearance. The children were to take 3 tablets twice daily. Pre-study questionnaires collected demographic data and medical history, while the post-study questionnaire focused on answers to questions about compliance with study protocol, outdoor activities, specific food intake, and illnesses that may have occurred. Daily logs were also completed. Compliance was measured in part by direct viewing of the supplement bottles on clinic visits. Primary outcome of interest was the incidence of influenza A, diagnosed by outpatient rapid influenza antigen testing using a nasopharyngeal swab specimen. A total of 430 schoolchildren/parent pairs were randomized but there was significant study attrition, with 50 and 46 children being lost to follow-up in the active and placebo groups, respectively (intention-to-treat analysis was used). Compliance with the study medication was very high (96%). Influenza A occurred in 18/167 (10.8%) of children in the vitamin D group compared with 31/167 (18.6%) in the placebo group (relative risk [RR] = 0.58), with peak incidence occurring from middle to late January. Between days 31 and 60, influenza A occurred significantly less often in the vitamin D group than in the placebo group (5.4% vs. 13.2%; RR = 0.41), but there was no difference in the development of influenza A between the two groups early or late in the trial. In subgroup analysis it was shown that a reduction in occurrence in influenza A was more prominent in children who previously had not been taking vitamin D and in those who had started nursery school after age 3 years (starting nursery school before age 3 years may increase the chances of exposure to influenza and of obtaining immunity). In children with a previous history of asthma, exacerbations occurred in 2 children taking vitamin D3 vs. 12 children in the placebo group (RR = 0.17). The incidence of influenza B and antigen-testing negative flu-like illness was not different between the two groups. No serious adverse effects were identified, including urinary stones. The authors concluded that vitamin D3 supplementation during the winter and early spring may have a preventive effect against the development of childhood influenza A infection. ABSTRACT FROM AUTHOR

JA - Applied Research in Coaching & Athletics Annual

VL - 18

CY - ;

N2 - Historically, very few of the great and talented athletes from the United States are deliberately selected through a structured, scientific system. Most American athletes begin participation in sports because of a role model, either a parent, a coach or a professional athlete. Continued participation seems to depend upon several factors; including, enjoyment of the sport, successful participation and/or peer pressure to name a few. The development of a talent identification process would allow children to experience greater enjoyment and reduce the possibility of selecting a sport in which the child had a very limited potential for success. There are numerous opportunities for children in organized sports, but they would probably enjoy these attempts at structured activity much more if they are successful and are having fun. Therefore, the development of a process to predict success for children in specific sports would seem to be an attractive alternative to selection and participation on a random basis. The purpose of this study was to update KidTest, a talent identification test inventory which provides a subjective evaluation of the potential talent that a child may exhibit for success in specific sports. A total of 173 (75 boys, 98 girls) were randomly selected from grades 6, 7 and 8 from three different schools. Data was collected during physical education classes at A.E. Phillips Laboratory School, Mann Middle School and Vernon Intermediate School. This study replicates an earlier study completed in 1999 on kindergarten through fifth grade students. Nine (9) physical fitness components were administered and the data was collected to develop a working model for identifying talent in specific sports. Using a three-digit composite, norms were established for student subjects, sixth through eighth grade, based on performance on various tests in aerobic power, motor skills and coordination. A predicted Max VO₂ score was established by the Houston Non-exercise Test. Percent body fat was done as a means of cross-validation. Results indicated relatively high validity across the three grade levels. An aerobic run was performed with all three-grade levels doing a one-mile walk/run. The motor ability tests consisted of a forty-yard dash measuring speed, a fifteen-yard shuttle run for agility and the standing long jump testing leg power. Hand-eye-foot coordination was measured by a catching test along with throwing and kicking tests for accuracy and distance along. Each of the three composite scores was averaged on a scale from one to five. A legend was developed utilizing the mean and standard deviation to cross reference numerous sports activities with a corresponding three-digit composite score for each sport

N2 - OBJECTIVE: To investigate the association between the child-care environment and physical activity of 2- and 3-year-olds. Based on an ecological view of environmental influences on health behavior, we hypothesized that the social and physical environment, as well as child characteristics (age and gender), would show independent and interactive effects on children's physical activity intensity. DESIGN: Observations of physical activity intensity were performed among children (N = 175) at 9 Dutch child-care centers. Aspects of the child-care environment were assessed using the validated Environment and Policy Assessment and Observation (EPAO) Instrument. Multilevel linear regression analyses examined the association of environment and child characteristics with children's activity intensity. Moderation was tested by including interaction terms in the analyses, with subsequent post hoc analyses for significant interaction terms. MAIN OUTCOME MEASURE: Observed child physical activity intensity, measured with the Observational System for Recording Physical Activity in Children-Preschool Version. RESULTS: A large proportion of the observed activities were classified as sedentary, while far fewer observations were classified as moderate or vigorous. Activity opportunities in the physical environment (assessed using EPAO) and prompts by staff and peers were significantly and positively related to physical activity intensity, while group size was negatively related to activity intensity. The influence of the physical environment was moderated by social environment (peer group size), while the social environment in turn interacted with child characteristics (age and gender) in determining activity intensity. CONCLUSION: Our findings are in line with the ecological perspective regarding environmental influences on behavior, and stress the importance of incorporating the child-care environment in efforts to prevent childhood overweight and obesity

N2 - The abnormal chiasmatic crossing characteristic of all albino mammals brings two discordant representations of the visual field to the central visual relays. The representation from the nasal retina is normal whereas the one from the temporal retina is disrupted, a part representing the contralateral visual field as is normal and a part coming from the ipsilateral visual field as a mirror image of a part of the normal representation. Experiments that were designed to define the rules on the basis of which the abnormal representations can be established in the lateral geniculate nucleus and visual cortex are described. These experiments are related to more recent studies of albino cats, and the observations of the visual pathways are related speculatively to abnormalities seen in the auditory pathways of albinos. The possibility is raised that the auditory abnormalities are secondary to the visual abnormalities, produced by a failure of the two systems to establish normally matching maps of sensory space

N2 - Background: This study was designed to model the relationship between an ActiGraphbased "in-school" physical activity (PA) and the daily one among children and to quantify how school can contribute to the daily PA recommendations. Method: Fifty boys and 43 girls (aged 8 to 11 years) wore ActiGraph for 2 schooldays of no structured PA. The daily moderate-to-vigorous PA (MVPAd) was regressed on the school time MVPA (MVPAs). Then, a ROC analysis was computed to define the required MVPAs. Results: Children spent 57% of their awaking time at school. School time PA opportunities (ie, recesses: $f^{\wedge}18\%$ of a child's awaking time) accounted for $>70\%$ of the MVPAd among children. Then, MVPAd (Y) could be predicted from MVPAs (X) using the equation: $Y = 2.06 X^{0.88}$; $RA \hat{y} = .889$, $P < .0001$. Although, this model was sex-specifically determined, cross-validations showed valid estimates of MVPAd. Finally, with a sensitivity of 100% and a specificity of 90%, MVPAs, a 34 min.d-1 was required to prompt the daily recommendation. Conclusions: The current study shows the contribution of MVPA at school to recommended activity levels and suggests the value of activity performed during recesses. It also calls for encouraging both home- and community-based interventions, predominantly directed toward girls. ABSTRACT FROM AUTHOR

N2 - This study was designed to analyze the significance of the recess period and the effect of its duration on children's daily physical activity. Thirteen pupils attending school in a rural area were monitored with accelerometers during the study weeks. The intervention consisted of modifying regularly scheduled recess period for a month. Data from two school days during the third week were recorded for analyses. Analyses indicated that, according to the recommended 2 OE 15 min recess schedule, children spent on average from 16.9 +/- 5.7 min to 22.8 +/- 3.7 min each day in moderate-to-vigorous physical activity (MVPA) at recess; that is, 16.3% to 20.0% of their daily MVPA (comprised between 103.4 +/- 32.5 min and 113.9 +/- 32.5 min). This level of activity increased with the increased recess duration. A 1.2% increase of the time spent at recess

resulted in a 6.6% increase of their activity (average 23% to 26.5%). It appears that a more appropriate reorganization of school schedule, including recess period and proper physical education classes, may be beneficial for school children to experience adequate amount of physical activity

N2 - This study compared the self-reported physical activity, perceived social support for, and perceived barriers to, physical activity of primary and secondary school children from Hong Kong and Australia. Hong Kong boys and girls reported spending significantly less time, outside of school hours, on physical activity than their Australian contemporaries ($p < .05$). There was significantly higher perceived support for activity from Australian parents ($p < .001$), teachers ($p < .001$) and peers ($p < .001$) compared to their Hong Kong counterparts. Parental support significantly correlated with self-reported activity in Australia, but not in Hong Kong. These data add support to the notion that strategies to increase physical activity need to embed family and school. ABSTRACT FROM AUTHOR

N2 - The article provides information on strategies and ideas for physical education teachers to get parents and other significant adults involved in helping to get children physically active as a lifestyle habit. Physical activity calendars may be used, which are easy to create and may provide students with active habits outside physical education. It also serves as a medium for communicating with parents about physical education, physical activity and health. Designing charity events around physical activity is also effective not only in providing an active lifestyle but in raising money for physical education as well. Special events called Fun Days could be established with parent participation to create anticipation at the start of the school year or late in the year to celebrate the end of the great school year that passed

N2 - This article draws from the Second Worldwide Survey of the situation of physical education (PE) in schools. The Survey was undertaken as a contribution to the UN dedicated 2005 Year of Sport and PE and in response to inter-governmental agencies' calls for regular monitoring of developments in school PE in the form of a 'reality check'. The overall purpose of the Survey was to assess the worldwide situation of school PE as well as developments since the Physical Education World Summit held in November 1999 in Berlin for which a multi-method/pluralistic approach was adopted with analysis of a range of sources comprising globally and regionally as well as on-line disseminated questionnaires, national surveys, continental regional and national

PE-related projects, case studies and a comprehensive literature review. The pluralistic methods facilitated data collection on national level policies and practice-related issues in school PE, the PE curriculum, resources (human and material), the PE environment (school subject and PE teacher status; and pathway links to PE activity in out-of-school settings) and 'Best Practice' exemplars. The data generated provide an indication of patterns and trends in school PE in countries and regions across the world. The 'reality check' indicates that positive developments and policy rhetoric are juxtaposed with adverse practice shortcomings. Thus, the overall scenario is one of 'mixed messages' with evidence that national and/or regional governments have committed themselves through legislation to making provision for PE but some have been either slow or reticent in translating this into action through actual implementation and assurance of quality of delivery. Essentially, the situation especially in economically under-developed and developing regions has changed little since the 1999 Berlin Physical Education Summit. Continuing concerns embrace: insufficient curriculum time allocation, perceived inferior subject status, insufficient competent qualified and/or inadequately trained teachers (particularly in primary schools), inadequate provision of facilities and equipment and teaching materials frequently associated with under-funding, large class sizes and funding cuts and, in some countries, inadequate provision or awareness of pathway links to wider community programmes and facilities outside of schools. More generally, there is disquiet over the falling fitness standards of young people, rising levels of obesity amongst children of school age and high youth dropout rates from physical/sporting activity engagement. Whilst some improvements in inclusion (related to gender and disability) policy and practice can be identified since the Berlin Physical Education Summit, barriers to equal provision and access opportunities for all still remain. However, current intergovernmental initiatives (European Parliament's 2007 Resolution on the Role of Sport in Education and UNESCO advocacy action) place PE on the political agenda. With such inter-governmental commitments to policy principles and action advocacy, a secure and sustainable future for PE appears to be realizable. ABSTRACT FROM AUTHOR

N2 - In the climate of unpredictable availability of health care in the United States, a prevalent discussion is the prevention of disease and illness. Recreation participation is one route to maintaining physical and mental well-being. Perceived self-efficacy is an indicator of maintenance, effort, and performance of various behaviors, including recreational activities. Recreational and therapeutic recreational programming can be structured to enhance participants' efficacy regarding specific recreation activities. This can be done by addressing the four sources of efficacy information (verbal persuasion, vicarious experience, affective state, mastery experiences)

that participants' use to make judgments regarding their ability to perform a particular recreation activity. The purpose of this study was to evaluate the effectiveness of one of the sources of efficacy information, vicarious experience via modeling, in enhancing efficacy beliefs of at-risk youth who are participating in a wilderness therapy activity. This study also investigated the influence of activity specific efficacy perceptions on both self-regulatory self-efficacy and perceived performance in the specific activity. Three groups of youth at-risk participated in three separate rock climbing sessions at the Clemson University Outdoor Laboratory's climbing tower. The participants (N = 38) in this study, both male and female and ranging in age from 6--18, were drawn from a year-round private school for at-risk youth. Upon arrival, each group took a rock climbing and self-regulatory self-efficacy questionnaire. This questionnaire included a previous rock climbing experience measure. Then, prior to rock climbing, one of the groups observed a youth model the rock climbing activity, one of the groups observed an adult model the rock climbing activity, and one of the groups did not observe a model. Directly after this each group took another rock climbing and self-regulatory self-efficacy questionnaire. This questionnaire also included a perceived 'similarity to model' measure. After each participant performed the activity of rock climbing, he or she took a third rock climbing and self-regulatory self-efficacy questionnaire. This questionnaire additionally included a perceived performance measure. Multivariate analysis of covariance indicated that groups who observed a model had significantly higher rock climbing self-efficacy and self-regulatory self-efficacy than the group that did not observe a model. There was no significant finding with regard to influence of previous rock climbing experience, model type, or perceived similarity to model. Significant relationships were found between self-regulatory self-efficacy, rock climbing self-efficacy, and perceived performance.

Because the participants did not perceive there to be a difference between the models, these results do not provide us with information regarding the influence of perceptions of similarity to the model. These results do show that groups observing a model demonstrate rock climbing during ground school are significantly more likely to show increase in both rock climbing and self-regulatory self-efficacy than groups who do not observe a demonstration. In light of this research it is apparent that providing a model is an effective tool that can be used to assist participants in achieving the positive outcomes of a rock climbing experience, and potentially those of other outdoor and indoor educational pursuits. Further research regarding self-efficacy may indicate that, when teaching or promoting recreation activities, using a self-efficacy based curriculum provides individuals with the best possible chance of becoming life-long recreators.

VL - 20

N2 - National guidelines recommend accumulation of at least one hour of moderate to vigorous physical activity each day for students. Since school recess provides scheduled periods of time to accumulate some of these much-needed minutes of moderate to vigorous physical activity, the purpose of this study was to determine the proportion of elementary students in a rural, northeast Missouri school district who were physically active at the intensity level recommended by the national guidelines during their recess periods. A modified version of the System for Observing Play and Leisure Activity in Youth (SOPLAY) was used to collect observational data on the number of students, their gender, and their physical activity intensity levels in defined areas of the playground during recess. Overall, the majority of students seemed to meet the guidelines for moderate to vigorous physical activity levels during recess, but the addition of more open play space and more game equipment may help move many from the moderate to more highly active levels. It is recommended that school districts increase the amount of recess time as their school schedules permit to help students meet national guidelines for accumulated physical activity time. VL - 16

N2 - Problem and Objective Studies focusing on the socioeconomic distribution of fall injuries among children are few and show mixed results. Previous studies are mainly area-based and no studies have investigated the relationship between family socioeconomic position and subgroups of fall injuries. The current study examines whether socioeconomic position affect the risk of having fall related injuries of different types. Method This population-based cohort study links Swedish national register data for a cohort of 1 544 047 individuals born between 1977 and 1991. Individual records from the 1985 census were linked to the National Hospital Discharge Register for the period 1998f_ "2004. Fall injuries requiring hospitalisation were recorded (n=38 529). Logistic regressions were used to measure the effect (odd ratios) of socio-economic position on eight

subgroups of fall injuries (based on external codes, ICD-10). Results An analysis of all types of fall aggregated (W00-W19) showed no significant differences between young people from different socioeconomic groups. However, analyses of subgroups of falls showed that children of manual workers had significant higher odds of having injuries related to falls from playground equipment (OR 1.35 (1.21 to 1.50), stairs (OR 1.48, CI 1.30 to 1.69), trees (1.36 (1.17 to 1.58) and falls from buildings (OR 1.38 CI 1.18 to 1.60). On the other hand, children in lower socioeconomic groups had significantly lower odds for sport related falls compared to children of parents who are intermediate- and high level salaried employees. Conclusion This study indicates that when falls are split into subgroups the effect of low socioeconomic position can be both protective and aggravating.

N2 - In view of the persistence of health inequalities and declines in leisure-sport participation over the life course, several quantitative investigations have explored the links between participation and other leisure activities, which have their foundations in childhood and youth, as a means of understanding adults_f_T health behaviours. This paper presents new qualitative evidence to examine the largely under-explored relationship between leisure-sport participation and health within the context of educational transitions among a sample of 30f_"35-year-olds in north-west England. Drawing on semi-structured interviews conducted with 19 participants between July and August 2009, the paper illuminates the differential impact that gender and social class had on sports participation, and other health-related behaviours (e.g. drinking and smoking), among different groups of adults during the inherently transitional life-stage of youth. The findings suggest that while significant, the length of time spent in education and the differential educational experiences recalled by adults cannot adequately explain the observed differences in health and leisure-sport participation. The major sources of difference, while associated with educational transitions, appeared to lie instead in the broader inequalities that characterized adults_f_T lives and it is argued that simply enhancing leisure-sport participation and

individual lifestyle change, as a means of health promotion, is a futile endeavour that does little to tackle the socio-economic structural determinants of health. We conclude by suggesting that until this is recognized by government and those both inside and outside of the health and sport policy communities, stubborn differences in leisure-sport participation rates and health inequalities *f* "that have their foundations in childhood and youth, but extend over the life course *f* "are likely to remain intact, and the unequal lives people currently lead are likely to become even more unequal in the future. CY - ;

N2 - This paper investigates the impact of a Physical Education (PE) approach based on the concept of Physical Literacy (PL). Using Whiteheads (2001) definition of PL, the paper looks at how this philosophical viewpoint can be used in a practical PE setting. The Qualifications and Curriculum Authority (QCA, 2002) identification of high quality PE outcomes corresponds, in part, with Whitehead's definition of PL. This study concludes that for PE to be considered 'high quality', it should actively aim to prepare children to participate in lifelong physical activity (LLPA) by focusing on skills and attitudes to be used outside limited curriculum time. Further considerations relate to teacher education with a focus on generic skills and strategies fundamental to learning in PE, rather than activity specific content. [ABSTRACT FROM AUTHOR]

N2 - Objective: To solicit school principals_{f_T} and teachers_{f_T} perspectives on children_{f_T}s screen-related sedentary behaviour and to identify possible solutions to reduce sedentary behaviours among school-aged

children. Method: In-person interviews using a semi-structured interview guide were conducted with school principals and grades five and six classroom teachers in 14 randomly selected elementary schools in London and Middlesex County, Ontario. Fourteen principals and 39 classroom teachers participated in the study. Inductive content analysis was performed independently by two researchers. Results: Both principals and teachers were very concerned about children's excessive screen viewing activities, but they did not perceive that they could play a key role in reducing these behaviours. Key barriers were identified to reducing screen-related sedentary behaviour and to children's active living both at and away from school. They included competing demands from other subjects, limited gym resources/space within the school, a lack of control over the home environment, and a perception that parents were poor role models. Notwithstanding the above barriers, principals and teachers still recommended increasing children's daily physical activity both within and outside of school hours. Furthermore, they stressed the need for parents to play a key role in reducing their children's screen-related sedentary behaviours and increasing their level of physical activity. Conclusion: School principals and teachers were very concerned about excessive screen-related behaviour among school-aged children when away from school and suggested that interventions should emphasize increasing daily physical education, promoting recreational sports at or away from school, and engaging parents in regulating screen time at home. N2 - Organizations such as park and recreation departments, not-for-profit youth groups, churches, and resident and day camps offer opportunities to promote positive youth development through structured recreation activities. Researchers involved with organized camp programs have documented some values of camp experiences relative to growth and development, yet more is to be learned about how camp structures and settings influence positive youth development and how the outcomes of youth development can be measured. The purpose of this analysis was to explore indicators of youth development outcomes through a comparison of two forms of data collected at six camps. The results of comparing quantitative and qualitative data sources to determine if indicators of positive youth development can be observed in a short period of time in the recreational and educational setting of summer camp is described. Quantitative data came from a study that sampled families representing American Camp Association (ACA) accredited camps from across the United States. The data included pre- and post-questionnaires given to campers to measure domains such as positive identity, social skills, positive values, and thinking and physical skills. The instrument used was called the Camper Growth Index-Children (CGI-C). Qualitative data came from on-site observations in six camps that had participated in the quantitative study the prior year. A guided outline was used as the basis for field observations and informal interviews. The observation rankings/ratings and the quantitative results were compared. Two of the three camps showing statistically positive developmental change in campers also were ranked higher in using the focused qualitative observation. Two of the three camps showing no statistically significant change were also identified as ranking lower through the observation process. Observing opportunities for adventure and exploration activities as well as leadership and independence displayed by campers were easiest to observe. Observing indicators for developmental outcomes, including environmental awareness, positive identity, and positive values, were more difficult. Although consistent agreement did not exist in this comparison of quantitative and qualitative data, the two approaches provided some convergence and complementary data. This study provided an opportunity to explore the measurement of camp experiences from an external view along with an internal self-report approach. We examined the micro data obtained from the individual campers in relation to the social environmental macro structure of the camp. Implications exist for triangulating data and validating methods in other recreation organizations to better understand how and why youth development programs in recreation and camp settings work. Given the complexity of the desired outcomes and the individual nature of growth and development, mixed methods and systematic multimeasure approaches offer information for supporting youth development. N2 - This study describes the dramatic rise in childhood obesity within the United States and explores the influence of elementary-school programs on the number of overweight children or on those at risk for overweight status. The relationship between the prevalence of overweight status in children at the elementary-school level and the amount of time these students spend in physical activity and education related to a healthy lifestyle during the school day, available playground equipment, and school lunches is explored. This study also examines the relationship between overweight status in kindergarten and third-grade students and their academic achievement. The findings indicate that school lunches, the ethnic makeup of schools, and the percentage of students participating in the free or reduced lunch program are all associated with incidence rates of overweight children within these age-groups. The study also found that school playgrounds and nutrition-and-health instruction are often inadequate. An association was also found between overweight status in elementary-school students and low performance on the standardized test determining the readiness to learn and acquired learning for kindergarten and third-grade children

N2 - Over the past decade the outdoor play spaces designed for children in Canada have been largely shaped by fear and profit, rather than by what we know about children's play and development. Since the early 1980s the Canadian Standards Association (CSA) has played an increasingly important role in this transformation as their

technical standards for children's outdoor play spaces have been gradually adapted as policy by local and regional agencies. While the CSA has historically regulated industrial and commercial projects that enable international trade and harmonization with countries such as the United States, their extension of influence to early childhood is problematic; particularly when applied to childcare centres. The following describes some of the issues that arise from the use of safety standards as policy, and the problems these standards cause when applied to childcare centres

VL - 15

IS - 1

N2 - Our goal was to describe normal heart rate (HR), QT interval, and Bazett's-corrected QT (QTc) values during exercise testing in children, and to test our hypothesis that hyperventilation is associated with QTc prolongation in children. This study was a retrospective review of 200 consecutive normal exercise tests in 108 males and 92 females with low likelihood of Long QT Syndromes (LQTS) and no evidence of cardiac disease, with mean age 14.7 \pm 4.0 yrs. The QT interval and RR interval were measured throughout exercise testing and hyperventilation. The QTc values were calculated using Bazett's formula. A database of HR, QT, and QTc values is presented for standing baseline and hyperventilation, and throughout exercise and recovery. Heart rate and stage of testing had independent effects on repolarization throughout exercise and recovery, while age and sex did not. We constructed reference tables of mean QT and QTc values during exercise and recovery, referenced by HR and stage. With hyperventilation, mean HR increased by 22.7 \pm 12.8 beats \cdot min⁻¹, QT shortened by 26.3 \pm 21.6 ms, and mean QTc lengthened by 30.3 \pm 25.4 ms ^{1/2} to 442 \pm 26 ms ^{1/2} (P<0.001). There were no significant sex, age, or HR effects on the magnitude of QTc prolongation with hyperventilation. This study provides the largest data set for repolarization behavior during exercise testing in children without evidence of heart disease. This is also the first time that the QTc has been shown to prolong with hyperventilation. It is unknown whether this is specifically related to hyperventilation or simply explained by a limitation in Bazett's formula. It highlights exercising caution when using Bazett's formula outside the narrow reliable HR range, especially in children and even more so during exercise. Database of normal population data is perhaps more reliable in those situations, although further validation must be done to confirm its utility. ABSTRACT FROM AUTHOR

N2 - Provided information on the free-play behaviors of children ages 6-8 and defined the relationship between participation in competitive sports and free-play behaviors. Focused on a comparison of children's behaviors in structured, competitive sports and those not in sports in relation to: social grouping, classification of play, and characteristics of playfulness. Observations of the subjects' (n=84) play behaviors were recorded during scheduled recess periods. An instrument was designed in order to code the behavior. Concludes that the free play behaviors of children in structured, competitive sports differ from those of children not in sport. Children in sport participated more in group activities, were more often involved in playing-at-a-game, and displayed fewer total expressions of playfulness

N2 - Physical activity (PA) in children has a decisive role in motor development and prevention of childhood obesity. The available evidence suggests that there is high prevalence of low levels of PA in children, but little is known about the level of PA in preschool children. The objective of this study was to identify the prevalence and the factors associated with low levels of PA in preschool children. This was a cross-sectional study performed in private schools in the municipality of Olinda (state of Pernambuco), with data collection through parent's face-to-face interviews. The study included 265 children (54.3% girls) with mean age of 4.9 years (SD=0.8). Children who did not perform at least 60 minutes/day of outdoors physical activities were considered exposed to low levels of PA. Data analysis was performed by logistic regression considering low level of PA as the outcome. The results showed that 65.3% (95%CI: 9.4-70.8) of children were classified as exposed to 'low level of PA'. Analysis showed that higher parental education (OR=2.41; 95%CI: 1.13-5.10), lack of space for playing at home (OR=2.36; 95%CI: 1.17- 4.78), and attending school in the afternoon (OR=2.92, 95%CI 1.55-5.49) or full-time (OR=57.1, 95%CI 6.57-496.2) were associated with low levels of PA. Preschoolers from families with higher number of children had lower likelihood of low level of PA (OR=0.49; 95%CI 0.26-0.93). It can be concluded that the proportion of children exposed to low levels of PA is high compared to the results of similar studies and that parental and environmental factors are associated with physical activity level in preschool-aged children. N2 - The article focuses on family recreation. One of the key elements required for family development is simply time spent together. It is no secret that an activity promotes physical and mental health. Recent trends toward reducing obesity in children in the U.S. and even legislative efforts to promote physical activity such as the Get Outdoors Act, clearly indicate that recreation improves individual health which is the basic platform for improved family health. Communication is the key to many different forms of success, and relationships that help each other communicate more effectively are essential to family function. Communication and interaction between siblings and parents are no exception. Recreation environments provide a neutral, safe and fun arena for these interactions to occur. Family recreation, in general, is families participating in leisure activities together. To be successful, families must implement the physical, social and emotional elements into their lives. Physical elements are the most commonly recognized forms of recreation involving gross and fine motor skills which need development and conditioning at all ages

N2 - The article discusses the importance of proper outdoor play environment for school children. The author feels that the professionals of the American Alliance for Health, Physical Education, Recreation and Dance (AAHPERD) have failed to impress upon other educators and the general public the importance of creating meaningful play environments for school children. The professionals in these fields are least bothered and have allowed people, who have little knowledge about the importance of play in children's lives, plan the environments where children spend up to one-sixth of their time in school. While school boards allocate millions of dollars to build the inside infrastructure, less is done for outside environments. The results are that outside play environments do little to promote the physical, emotional, social, or intellectual skills and abilities of children. The author feels that the AAHPERD professionals need to get involved in the planning process of schools for promoting the well-being of children. This involves seeking ways to get on the planning committee for any new school or the renovation of older schools

N2 - In a group of 11-, 13-, 15-, and 17-years-old rural pupils (N = 780), the perception of their health, body image and physical activity in leisure time was studied. The survey was based on the Health Behavior in

School-Aged Children (HBSC) a WHO Cross-National Study. The majority (84.7 %) of subjects considered themselves as 'healthy', or 'very healthy'; chronic diseases were found in 11 % of rural adolescents. Many adolescents have common ailments and emotional states. The most frequent were nervousness (39 %), irritability or bad mood (29 %) and headache (18.8 %). The majority of rural youths studied (77 %) reported their fitness as 'very good' or 'good'. Every fourth boy and every second girl do not intense exercise enough, and exercise too seldom every week outside school hours. Due to the discontent with their appearance, 4.7 % of boys and 14.8 % of girls used slimming diets, and another 9.7 % of girls and 26 % of boys thought they ought to go on a diet to lose weight. The results of this study can be useful for planning health care and health education for rural adolescents

N2 - Abstract: Children with additional support needs (ASNs) often require physiotherapy intervention to help maximise their participation within the primary school setting. The aim of this research was to investigate paediatric physiotherapy practice in supporting primary school aged children with ASNs, in order to identify a language to describe this, which could be used to support communication with teachers, parents and others outside the profession. Design: Using a qualitative research multiple methods design, 2 focus groups and 5 structured interviews were held to investigate physiotherapy practice for this group. Participants: Senior

paediatric physiotherapists (n =13) from a range of specialities, with experience of supporting primary school aged children with ASNs. Analysis: Focus groups and interviews were digitally recorded, transcribed verbatim and analysed to establish links and patterns: followed by a cyclical process of respondent validation, and expert review. Results: Eight targets for physiotherapy intervention and twelve technique headings were synthesised from the data. The language used for labelling and description of these was aimed to be easily understood by colleagues outside the profession. Conclusions: The findings clearly identified the role of the paediatric physiotherapist as being to support primary school aged children with ASNs to acquire aspects of postural control, mobility and cardio-respiratory function. By grouping the data into eight areas of challenge as the focus of intervention, and twelve commonly used techniques, the researchers generated a language which can be used by paediatric physiotherapists to support communication with teachers, parents and others outside the profession, when describing their intent and interactions regarding these children. N2 - This article describes the game scooter board basketball that is played using scooter boards. The author notes that games played on scooter boards are excellent group activities for any age or ability. For scooter board basketball, the author gives information on how to play discussing the rules and equipment needed. The game should include two baskets and three foam balls and enough scooters and pinnies to have two teams. Each player is not permitted to move while in possession of a ball but may move anywhere in the playing field at any other time. Shots must be made from outside a designated crease area. The ball may not be grabbed from an opponent's hand. One point is awarded for each shot that lands in the basket. Safety considerations and game modifications are also included

N2 - Purpose: Interviews with Southeast Asian families and Head Start staff, participant observation of family and staff conferences, observations of teacher-child and parent-child interactions, and a review of all written Head Start information given to parents were used to gain information regarding how Southeast Asian parents, children, and Head Start staff make sense of early childhood education, their roles in child learning, and the identification of disabilities or learning problems. Methods: Nine Southeast Asian families and 10 children were participants. One Vietnamese and 3 EuroAmerican Head Start staff members participated in a series of two or three semistructured individual interviews. Additionally, 3 families were observed during scheduled conferences with Head Start staff. Each child was observed at Head Start during meals, center time, and outdoor play time. All literature routinely given to parents was analyzed. Ethnomethodology (the study of how participants make sense of their world) was used in collection and analysis of the data. The constructs of organizational culture (Schein, 1987, 1992), independence/interdependence, and power/distance relationships were used to help to make sense of the data themes. Clinical Implications: Both families and staff were unaware of differences in their beliefs and values in the areas of education, parenting, child learning, and disability, which led to confusion and misunderstanding. All early childhood staff need to be aware of their underlying assumptions and how these may affect their interactions with children and families who may have different assumptions and expectations

N2 - Background: With the rapid increase in obesity rates among youth, efforts to increase physical activity (PA) have become a priority. School-based strategies for PA promotion must be cost-effective, unobtrusive, and linked to improved academic performance. Efforts to maximize recess PA are advocated because of both health and academic benefits. The purpose of this manuscript was to review recess interventions aimed to improve PA among youth, and make recommendations to develop related best practices. Methods: An extensive literature search was conducted to include all primary research articles evaluating any recess intervention with PA as an outcome. Results: The included 13 interventions represented both settings within the U.S and internationally, among preschools and elementary/primary schools. A variety of strategies were used within the design and implementation of each of the interventions including: added equipment/materials, markings, zones, teacher involvement, active video games, activity of the week, and activity cards. Of the included studies, 95% demonstrated positive outcomes as a result of the recess intervention. Conclusions: A number of simple, low-cost strategies can be implemented to maximize the amount of recess time students are allotted. Long-term follow-up studies are warranted for each of the recess strategies identified to be effective. ABSTRACT FROM AUTHOR

N2 - Relations between school achievements and motivation for involvement in PE classes were investigated in a sample of 185 6th graders of both genders in elementary school. The independent variables included: the general success of the previous grade; PE grade; students' opinions about the sufficiency of knowledge acquired in physical education classes and students' engagement in sport. The scale for measurement of motivation consisted of 29 items obtained by adaptation of the Scale for measurement of the motives of sports achievement. The data were analyzed by multiple regression analysis and IØA ý test. It was established that there is a greater motivation for engagement in sport of male students compared to females. The following assumptions were not confirmed: that males will have higher PE grade compared to females; that the success of male students was negatively associated with sport commitment; that general success is negatively related to students' engagement in physical education and that PE grade is positively related to motivation for engagement in classes. However, in contrast to the results obtained in the sample of 7th graders, it was confirmed that the PE grade was associated with engagement in sport. Additionally, it was shown that students' general success and PE grade are not statistically significant predictors of student motivation for active participation and engagement in physical education classes, and that at this age, gender, students' engagement in some sport outside regular curricular activities and their opinion on the amount of knowledge acquired in PE classes are significant predictors.

N2 - Background: The knee joint is the second most commonly injured body site and the leading cause of high school sports-related surgeries. Knee injuries are among the most economically costly sports injuries and may require subsequent surgery or extensive and expensive rehabilitation. Purpose: To report the incidence, risk, and severity of high school knee injuries across sports, genders, and type of exposure. Study Design: Descriptive epidemiology study. Methods: During the 2005-2006 and 2006-2007 school years, 100 US high schools were randomly selected for a nationally representative sample. Certified athletic trainers tracked injuries using an online injury surveillance system, High School RIO[®], in 9 high school sports. Results: There were 1383 knee injuries reported during 3 551 131 athlete exposures for a rate of 3.89 knee injuries per 10 000 athlete exposures. Although boys had a higher overall rate of knee injury (rate ratio, 1.38; confidence interval, 1.22-1.55), girls were twice as likely to sustain knee injuries requiring surgery (major knee injuries) than were boys (injury proportion ratio, 1.98; confidence interval, 1.45-2.70) and twice as likely to incur noncontact major knee injuries (injury proportion ratio, 1.98; confidence interval, 1.23-3.19) as were boys. Although illegal play was identified as a contributing factor in only 5.7% of all knee injuries, 20% of knee injuries resulting from illegal play required surgery. Conclusion: Knee injury rates and patterns varied by sport, gender, and type of exposure. Identified gender differences included differences in injury rates, injury severity, and basic injury mechanism. Further surveillance is crucial for the development of targeted, evidence-based injury prevention strategies to reduce the morbidity and economic impact of knee surgeries. ABSTRACT FROM AUTHOR

N2 - Abstract: Objectives: To present the results of the process evaluation of the PLAYgrounds program, using the RE-AIM framework. Design: This study provides information regarding Reach, Adoption, Implementation and Maintenance. Methods: The PLAYgrounds program promotes increasing levels of physical activity in 6f_12 years old children and was evaluated using the RE-AIM framework in 4 intervention schools. Data collection consisted of a physical activity questionnaire with children (n =765, Reach), SOPLAY observations (Implementation and Maintenance), questionnaires on the satisfaction of the implemented elements with teachers (n =59) and children (n =730, Implementation) and interviews for increased depth of information. In addition a simple counting of participating schools, describing of non-participating reasons and characteristics of the schools were documented (Adoption). Results: Reach of the target population (i.e. inactive children) was 60.7% (n =464) and the target population was representative for populations in low-SES neighbourhoods. The PLAYgrounds program was adopted by 4 schools (80%), at which 5 (from 7) program elements were successfully implemented. At 18 months follow-up, 3 of those 5 elements were completely maintained. Conclusions: Adoption, Implementation, and Maintenance proved to be very high. Most likely due to the PLAYgrounds program being a complete intervention package that included financial, material, and staff support. Therefore, it is recommended to retain this high level of support when introducing the PLAYgrounds (or any other intervention) program in schools. In the future it would be recommended to evaluate the PLAYgrounds program on maintenance in schools where the key-person is employed at the school and funding is not available. N2 - Participation is recognised as a key to health and wellbeing and is considered to be a vital part of the development of children and youth. The purpose of this study was to examine the participation patterns of children and adolescents in their time outside formal school. More specifically, the influence of age and gender on after-school participation patterns was explored. Method: Three hundred and thirty-two children and adolescents (5 to 18 years old) were divided into five age groups and completed the Children's Assessment of Participation and Enjoyment (CAPE). To test the interaction effect of gender and age on participation measures, ANOVAs were conducted. Results: The results indicated differences with moderate to high effect size in participation patterns across age, where a decline in participation was detected as children made the transition to adolescence. Differences with negligible effect size in participation were found between boys and girls in some of the activity types. No interaction effect between age and gender was observed. Conclusion: Participation patterns change with age, particularly as children make the transition to adolescence; however, this change does not depend on gender. Intervention strategies might take into account these inherent changes. Future studies might consider additional factors (for example, environment) while examining participation throughout age

N2 - A probabilistic model (SHEDS-Wood) was developed to examine children's exposure and dose to chromated copper arsenate (CCA)-treated wood, as described in Part 1 of this two-part article. This Part 2 article discusses sensitivity and uncertainty analyses conducted to assess the key model inputs and areas of needed research for children's exposure to CCA-treated playsets and decks. The following types of analyses were conducted: (1) sensitivity analyses using a percentile scaling approach and multiple stepwise regression; and (2) uncertainty analyses using the bootstrap and two-stage Monte Carlo techniques. The five most important variables, based on both sensitivity and uncertainty analyses, were: wood surface residue-to-skin transfer efficiency; wood surface residue levels; fraction of hand surface area mouthed per mouthing event; average fraction of nonresidential outdoor time a child plays on/around CCA-treated public playsets; and frequency of hand washing. In general, there was a factor of 8 for the 5th and 95th percentiles and a factor of 4 for the 50th percentile in the uncertainty of predicted population dose estimates due to parameter uncertainty. Data were available for most of the key model inputs identified with sensitivity and uncertainty analyses; however, there were few or no data for some key inputs. To evaluate and improve the accuracy of model results, future measurement studies should obtain longitudinal time-activity diary information on children, spatial and temporal measurements of residue and soil concentrations on or near CCA-treated playsets and decks, and key exposure factors. Future studies should also address other sources of uncertainty in addition to parameter uncertainty, such as scenario and model uncertainty. ABSTRACT FROM AUTHOR

VL - 27

IS - 2

N2 - Because of their mouthing behaviors, children have a higher potential for exposure to available chemicals through the nondietary ingestion route; thus, frequency of hand-to-mouth activity is an important variable for exposure assessments. Such data are limited and difficult to collect. Few published studies report such information, and the studies that have been conducted used different data collection approaches (e.g., videography versus real-time observation), data analysis and reporting methods, ages of children, locations, and even definitions of $f_{\text{omouthing}}$. For this article, hand-to-mouth frequency data were gathered from 9 available studies representing 429 subjects and more than 2,000 hours of behavior observation. A meta-analysis was conducted to study differences in hand-to-mouth frequency based on study, age group, gender, and location (indoor vs. outdoor), to fit variability and uncertainty distributions that can be used in probabilistic exposure assessments, and to identify any data gaps. Results of this analysis indicate that age and location are important for hand-to-mouth frequency, but study and gender are not. As age increases, both indoor and outdoor hand-to-mouth frequencies decrease. Hand-to-mouth behavior is significantly greater indoors than outdoors. For both indoor and outdoor hand-to-mouth frequencies, interpersonal, and intra-personal variability are $f^{\sim}60\%$ and $f^{\sim}30\%$, respectively. The variance difference among different studies is much bigger than its mean, indicating that different studies with different methodologies have similar central values. Weibull distributions best fit the observed data for the different variables considered and are presented in this article by study, age group, and location. Average indoor hand-to-mouth behavior ranged from 6.7 to 28.0 contacts/hour, with the lowest value corresponding to the 6 to <11 year olds and the highest value corresponding to the 3 to <6 month olds. Average outdoor hand-to-mouth frequency ranged from 2.9 to 14.5 contacts/hour, with the lowest value corresponding to the 6 to <11 year olds and the highest value corresponding to the 6 to <12 month olds. The analysis highlights the need for additional hand-to-mouth data for the <3 months, 3 to <6 months, and 3 to <6 year age groups using standardized collection and analysis because of lack of data or high uncertainty in available data. This is the first publication to report Weibull distributions as the best fitting distribution for hand-to-mouth frequency; using the best fitting exposure factor distribution will help improve estimates of exposure. The analyses also represent a first comprehensive effort to fit hand-to-mouth frequency variability and uncertainty distributions by indoor/outdoor location and by age groups, using the new standard set of age groups recommended by the U.S. Environmental Protection Agency for assessing childhood exposures. Thus, the data presented in this article can be used to update the U.S. EPA's Child-Specific Exposure Factors Handbook and to improve estimates of nondietary ingestion in probabilistic exposure modeling. N2 - Since the reform and the opening to the outside world, the Chinese women's social position has been raised remarkably. Numerous women have been entitled to participate in the deliberation and administration of state affairs and enjoy equal pay for equal work, which shows the advantages of the socialist system. These are superior to those of the Japanese women of the same era. In respect of sports life, the proportions of the Chinese and Japanese women' participation in sport are lower than those of the men's. The rate of the Japanese women's participation is higher than that of the Chinese women's. Therefore, to encourage and support the vast women to participate in physical activities is of much significance in their physical and mental health as well as in the education of their children. And it is also the important contents of their healthy life style. In physical education reform and development, more attention should be paid to the work of women's sport

N2 - Report on the second year of a 4-year experiment in voluntary after school physical education. Teachers and specialized instructors gave 259 pupils in 3 elementary grades one hour of instruction daily in one or more elective physical activities. Information was collected on pupil's attitudes toward sport and a number of other variables. Provisional results indicate that voluntary after school programs may be useful supplements to in school activities and that participation of outside instructors is successful

CY - ;

N2 - This article reports findings of an exploratory research project to examine specific aspects of lifestyles of children who lived in an extremely dense urban areas in Hong Kong. The Behavior Eating and Activity for Children's Health Evaluation System was used to characterize physical and social environments, physical activity, ingestion of food, and interactions relating to food intake and levels of physical activity of 40 children (N = 40; M = 15; F = 25; CA 6-8 years). Data were derived from momentary sampling frequencies. Means, standard deviations, and chi square statistics were utilized. Findings showed children might experience constrained lifestyles, possibly influenced by adults and social conditions of their environments. They did not participate at levels of physical activity of sufficient intensity to have any effects on fitness and health.

Moreover, school recesses were associated with snacking, rather than participating in vigorous activities

Cet article fait état des résultats d'une recherche exploratoire ayant pour but d'examiner certains aspects particuliers de styles de vie d'enfants vivant dans des milieux urbains à très haute densité. Une catégorisation d'environnements physiques et sociaux; d'activités physiques; de consommation de nourriture et d'interactions existant entre la consommation de nourriture et la pratique d'activités physiques a été faite auprès de 40 enfants (H = 15, F = 25; CA 6-8 ans) à partir du "Behavior Eating and Activity for Children's Health Evaluation

System". Les donnees ont ete traitees a partir de moyennes, ecart types et khi carre. Les resultats demontrent que les enfants sont possiblement exposes a des styles de vie contraignants, probablement influences par les adultes, et conditions sociales inherentes a leur environnement. Selon les resultats les enfants ne pratiquent pas d'activites physiques a une intensite suffisante pour que ces dernieres aient un effet sur leur niveau de conditionnement physique et leur sante. De plus les recreations a l'ecole sont pour la plupart associees a des collations, au lieu d'activites physiques vigoureuses

Der Artikel berichtet ueber Ergebnisse eines Forschungsprojektes, das spezifische Aspekte der Lebensgewohnheiten von Kindern in Staedten mit sehr hoher Bevoelkerungsdichte untersucht hat. Das "Behavior Eating und Activity for Children's Health Evaluation System" Instrument wurde verwendet, um die physische und soziale Lebensumwelt der Kinder, Art und Umfang ihrer koerperlichen Betaetigung, Ernaehrung sowie mit der Ernaehrung in Zusammenhang stehende Interaktionen von 40 Kindern (M = 15, W = 25; CA 6-8 Jahre) zu erfassen. Daten wurden mit Hilfe des "momentary sampling frequencies" Verfahrens erhoben. Mittelwerte, Standardabweichungen und Chi Square Statistiken wurden errechnet. Die Ergebnisse zeigten, dass Kinder, moeglicherweise beeinflusst durch Erwachsene sowie die sozialen Bedingungen ihrer Lebensumwelten, in ihren Lebensgewohnheiten eingeschraenkt sein koennten. Die Kinder waren nicht in ausreichendem Mass koerperlich aktiv, dass es sich positiv auf ihre Fitness und Gesundheit ausgewirkt haette. Ausserdem wurden Schulpausen eher zum Essen als zur koerperlichen Betaetigung genutzt

VL - 22

IS - 4

N2 - Universal need for, or reactions to, risk communications should not be assumed; potential differences across demographic groups in environmental risk beliefs, attitudes, and behaviors could affect risk levels or opportunities for risk reduction. This article reports relevant findings from a survey experiment involving 1,100 potential jurors in Philadelphia concerning public responses to outdoor air pollution and air quality information. Flynn et al. (1994) and Finucane et al. (2000) found significant differences in risk ratings for multiple hazards, and in generic risk beliefs, between white men (or a subset) and all others (white women, nonwhite men, and nonwhite women). This study examined whether white men had significantly different responses to air pollution and air pollution information. An opportunity sample of volunteers from those awaiting potential jury duty in city courts (matching census estimates for white versus nonwhite proportions, but more female than the city's adult population and more likely to have children) filled out questionnaires distributed quasi-randomly. On most measures there were no statistically significant differences among white men (N = 192), white women (N = 269), nonwhite men (N = 165), and nonwhite women (N = 272). Nonwhites overall

(particularly women) reported more concern about and sensitivity to air pollution than whites, and were more concerned by (even overly sensitive to) air pollution information provided as part of the experiment. Nonwhites also were more likely (withinf_"gender comparisons) to report being active outdoors for at least four hours a day, a measure of potential exposure to air pollution, and to report intentions to reduce such outdoor activity after reading air pollution information. Differences between men and women were less frequent than between whites and nonwhites; the most distinctive group was nonwhite women, followed by white men. Flynn et al. (1994) and Finucane et al. (2000) found a far larger proportion of significant differences, with white men as most distinctive, probably due to use of different measures, study design, and population samples. However, all three studies broadly confirm the existence of gender and race interactions in risk beliefs and attitudes (particularly for white men and nonwhite women) that deserve more attention from researchers. ABSTRACT

N2 - Damage from long-term, cumulative effects of sun exposure, while slow to develop, can become life-threatening. The cutaneous effects of ultraviolet light include sunburn, photosensitivity, immunosuppression, premature aging, and several types of skin cancer. Clinicians need to know the characteristic appearance of premalignant lesions, basal cell carcinoma, squamous cell carcinoma, and malignant melanoma. Also, patients who are active outdoors need education about sun protection, including avoidance at peak hours, clothing, sunglasses, and sunscreens. Care for sunburn may involve cool compresses, corticosteroid cream, oral antihistamines, and anti-inflammatory drugs

N2 - Study design:Post hoc analysis from a randomized controlled cellular therapy trial in acute, complete spinal cord injury (SCI).Objectives:Description and quantitative review of study logistics, referral patterns, current practice patterns and subject demographics.Setting:Subjects were recruited to one of six international study centers.Methods:Data are presented from 1816 patients pre-screened, 75 participants screened and 50 randomized.Results:Of the 1816 patients pre-screened, 53.7% did not meet initial study criteria, primarily due to an injury outside the time window (14 days) or failure to meet neurological criteria (complete SCI between C5 motor/C4 sensory and T11). MRIs were obtained on 339 patients; 51.0% were ineligible based on imaging criteria. Of the 75 participants enrolled, 25 failed screening (SF), leaving 50 randomized. The primary reason for SF was based on the neurological exam (51.9%), followed by failure to meet MRI criteria (22.2%). Of the 50 randomized subjects, there were no significant differences in demographics in the active versus control arms. In those participants for whom data was available, 93.8% (45 of 48) of randomized participants received steroids before study entry, whereas 94.0% (47 of 50) had spine surgery before study enrollment.Conclusion:The 'funnel effect' (large numbers of potentially eligible participants with a small number enrolled) impacts all trials, but was particularly challenging in this trial due to eligibility criteria and logistics. Data collected may provide information on current practice patterns and the issues encountered and addressed may facilitate design of future trials. ABSTRACT FROM AUTHOR

N2 - The article lays emphasis on need to have a cognitive recess curriculum that strengthens the need for physical education and benefits the learning process throughout the school. A cognitive recess curriculum offers four learning centers, with an additional free play area. The learning centers consist of a math center, science center, language development center, and music or art center. Classroom teachers would provide prepared descriptions of several cognitive games like playing school, math bingo, etc. that children would likely enjoy playing during their recess period. Also included are early versions or variations that can still be played today to improve communication and interaction

N2 - The article presents the author's views related to children and of baseball athletes. According to the author, team Florida Marlins manager Jack McKeon knows how important family is to the players, and he graciously allows the kids be a part of clubhouse life. The players, in turn, know how much of a privilege that is. The author's 10-year-old son's day at the yard begins around 2 o'clock. He dresses in his own locker at Dolphins Stadium, then joins about a half-dozen other kids at the indoor batting cage to plot the day's activities. If the athletes win, their children are paraded into the clubhouse afterward to join their fathers

N2 - Background: The knee joint is the second most commonly injured body site after the ankle and the leading cause of sport-related surgeries. Knee injuries, especially of the anterior cruciate ligament (ACL), are among the most economically costly sport injuries, frequently requiring expensive surgery and rehabilitation. Objective: To investigate the epidemiology of ACL injuries among high school athletes by sport and sex. Design: Descriptive epidemiology study. Main Outcome Measure(s): Using an Internet-based data-collection tool, Reporting Information Online (RIO), certified athletic trainers from 100 nationally representative US high schools reported athlete-exposure and injury data for athletes from 9 sports during the 2007/08-2011/12 academic years. The outcome of interest in this study was ACL injuries. Results: During the study period, 617 ACL injuries were reported during 9452180 athlete exposures (AEs), for an injury rate of 6.5 per 100000 AEs. Nationally, in the 9 sports studied, an estimated 215628 ACL injuries occurred during the study period. The injury rate was higher in competition (17.6) than practice (2.4; rate ratio [RR] = 7.3, 95% confidence interval [CI] = 6.08, 8.68). Girls' soccer had the highest injury rate (12.2) followed by boys' football (11.1), with boys' basketball (2.3) and boys' baseball (0.7) having the lowest rates. In sex-comparable sports, girls had a higher rate (8.9) than boys (2.6; RR = 3.4, 95% CI = 2.64, 4.47). Overall, 76.6% of ACL injuries resulted in surgery. The most common mechanisms of injury were player-to-player contact (42.8%) and no contact (37.9%). Conclusions: Anterior cruciate ligament injury rates vary by sport, sex, and type of exposure. Recognizing such differences is important when evaluating the effectiveness of evidence-based, targeted prevention efforts. ABSTRACT FROM AUTHOR

CY - ;

N2 - We propose 3 experimental approaches to test the capacities of 5-6 year-old children in orientation with a map. The first 2 are essential preconditions in order to put the third to the test. We first submitted the children to an electronic maze test. This showed a very significant difference between the performance of the 5 year old children compared with the 6 year olds. We then trained them to read a series of simple maps ranging from their classroom to a playground. The children succeeded in using these maps, to find landmarks, but they were unable to orientate themselves with a more complex street map. Only the older children took part in an orienteering race, the results of which did not correlate with those of the maze test. Finally, we asked every child to use a map, in order to find their way back on a caving trip, previously prepared. It turned out that they were unable to do that, probably for some because the emotion triggered by this first speleological experience causes a regression of their cognitive capacities. For the others, we think that this task was too complex, we would have needed time and a fitting-in the situation in order to help them to be successful

N2 - The main objective of our research was to analyse ways in which Slovenian secondary school children spend their summer holidays. We included 2,369 young people attending secondary schools in our research. For the analysis a special questionnaire has been used which did tested individuals at home answer. The collected data has been analysed with the calculation of Pearson's Chi2 coefficient, Spearman's coefficient of the correlation range and the discriminate analysis. The analysis has shown that the rhythm of young people's daily activity during the summer vacation is worrying. Roughly one fifth of secondary school children quite often go to sleep after 1 o' clock in the morning, and they start their day rather late. Young people spend too much time

lying in bed or in front of TV screens, and they are insufficiently physically as well as mentally active. We have also found out that only 22.1 % of secondary school youth practices sport every day during their summer vacation, and as much as 13.6 % never practice sport at all. Girls and boys differ in participation ($p < .000$), and their involvement in summer sports programmes is also different ($p < .000$). The analysis of the sports activity frequency of secondary school youth, implementing discriminate analysis, has shown that their participation is mostly influenced by their former experiences with sport, acquired at home (activity of their parents), and at school (opinion, self-esteem and their mark from physical education at school). The same characteristics also mostly differentiate young people among themselves during summer holidays when being involved in the sports programmes. The overview of sports activity participation indicates that boys prefer team sports (football, basketball), and girls more tend to select individual sports activities (athletics, aerobics, trekking) and other activities requiring less physical efforts (cycling, roller-skating, volleyball, badminton). Secondary school children also wish to participate in open area sports activities, quite often linked with other activities, where they do not express any reservations against sports exercises organised by schools during holidays, as long as they are organised in a way acceptable for them. According to the obtained issues we would like to suggest introducing a national project on putting lights to outdoor sports facilities and sports areas which would so enable secondary school children to organise sports activities by themselves with help of their mentors

N2 - Background: Parks are important settings for physical activity (PA), but few studies have documented the actual behaviors of park users. The purpose of this study was to examine the individual and joint effects of various park user demographic characteristics on observed PA intensity levels. Methods: Four parks were observed using the System for Observing Play and Recreation in Communities. Observers recorded the age group, gender, race, and intensity level of all park users in 83 activity areas over two weekends at each park. Logistic regression examined whether male/White, female/White, and male/non-White users were more likely

than female/non-White users to be observed engaging in moderate-to-vigorous PA (MVPA) rather than sedentary activity across 4 age groups. Results: In total, 8612 users were observed during the study. In the child age group, male/White users were significantly more likely to be observed in MVPA than female/non-White users. For teens, female/White and male/White users were less likely to engage in MVPA. For both adults and seniors, female/White and male/White users were more likely to be observed in MVPA. Conclusion: Observations revealed significant differences in intensity levels across gender, age, and race groups. Future interventions should emphasize park design that promotes increased MVPA among diverse groups.

N2 - The article discusses the importance of increasing the physical activity opportunities for elementary school students through recess, extracurricular activities, and active classroom in the U.S. In the research on physical activity (PA) and recess, the authors recommended 40% of playtime to be spent in moderate-to-vigorous physical activity (MVPA), however, they found that recess activity accounted for one-third of the 60 minutes per day of the MVPA recommendation. It also found that maximal school PA can be achieved in extracurricular programs when it is taught by a well-trained staff, and strong and unwavering administrative support. Moreover, it recommended that more attention should be given to classroom setting as a supplement to regular physical education class

N2 - Background: There is evidence showing that fundamental movement skills and physical activity are related with each other. The ability to perform a variety of fundamental movement skills increases the likelihood of children participating in different physical activities throughout their lives. However, no fundamental movement skill interventions implemented with junior high school students have yet been reported. Purpose: To

investigate the changes in students' locomotor, manipulative, and balance skills and their level of self-reported physical activity during the specific intervention program aiming to increase students' fundamental movement skills in Finnish junior high school physical education. Participants and setting: 446 Finnish Grade 7 students (13 years old) from Central Finland. Research design: A quasi-experimental intervention study with pre-, middle-, post-, and retention tests was used. The experimental group consisted of 199 students taught by 4 teachers and the control group included 247 students taught by 6 teachers. The intervention consisted of 33 sessions, 25 minutes of each, and included training of fundamental movement skills within naturalistic physical education classes during one academic year. Data collection: There were four waves of measurement for fundamental movement skill tests and self-reports of physical activity. Data analysis: Repeated measures MANOVAs were conducted to analyze interactions between condition (experimental/control) and time (four measurement points). In cases with an interaction between condition and time, follow-up post hoc tests were performed to examine which group means differed from each other. Findings: Results indicated significant condition \times time interaction in static balance, dynamic balance, balance skills sum score, movement skills sum score, and self-reported physical activity. The experimental group demonstrated more positive development of these variables compared to the control group. Conclusions: This study revealed that it is possible to develop junior high school students' fundamental skills through physical education. These changes seem to be more obvious when focusing on students' balance skills. Although further longitudinal investigation is needed, the fundamental movement skill intervention seemed also to prevent the typical decline in physical activity within junior high school students. N2 - How do young children portray and describe their relationships with nature? In what ways do young children's relationships with nature vary by grade level? These two research questions guided this phenomenographic study, which investigated developmental differences in children's relationships with nature. A total of 176 children, aged 6-11, from ten classrooms in grades 1-5 participated and were asked to draw pictures of themselves outside doing something and write about their picture and their relationship with nature. The draw and write methodology was employed within a constructivist framework. Drawings were analyzed using binary quantitative visual content analysis procedures and were further statistically investigated using SAS/STAT. Written narratives were analyzed with NVIVO 8 to further triangulate findings. Results indicated that at all grade levels, children demonstrated a positive relationship with nature. Variations were found between grade level groups with increasing or decreasing trends in the types of activities, settings, and people portrayed. Younger children included more family, friends, insects, and animals, while older children included more natural areas, chores, and hiking. The implications of considering the range of children's relationships with nature for environmental education are explored. [ABSTRACT FROM AUTHOR]

T1 - A critical study of sports talent selection and promotion of sports participation, at young age

A1 - Kansal,Devinder K.

Y1 - 2010/09/02/

KW - SportDiscus

RP - NOT IN FILE

SP - i65

EP - i66

JF - British Journal of Sports Medicine

JA - BJSM online

VL - 44

N2 - It has been a long drawn effort of the author to draw attention of the authorities to the importance and emphasis needed to be given to the question of most appropriate talent selection at young age for prospective excellence in sports. Unfortunately non-existence of graduation degree in sports coaching in India and wide spread unawareness, among departments and institutions of higher education in physical education and sports to the fields of physical growth, development, physique and physiological variations prevalent in India, children are left to select mostly sports unsuitable to their adult body potentials. The present study has been based on survey and critical analysis and new interpretations of existing research data on Olympic Champions (Carter 1984; Hirata 1979; Tanner 1964). In general, coaches and sports federations in India have been found to lack not only in the application of existing scientific principles but also in developing or maintaining any library or any literature on talent selection, or on measurement and evaluation even at any offices of national and state level sports associations/federations. The study has presented the scientific results on talent selection in a suitable form to make it easy to be used by the sports trainers and sports counsellors. Critical points of failure in the talent selection at young age have been dealt with scientifically along with a mapping of the long term plans and easy solutions for removing many hurdles currently in implementation of scientific preparation of Indian teams for national and international participation. Findings have also been reported to improve the number of sports participants in the country through proper talent selection at young age. The present population of sportspersons in India is extremely less, being less than 1% of the students up to middle schools and less than 10% of the students in colleges and universities. It has been proposed for better sports talent grooming that all high schools should be given sports infrastructure for training and participation in atleast one outdoor sport and one indoor sport/fitness activity. Each school must be accordingly required to participate in inter scholastic competitions in atleast these two sports or one sports and one fitness event. Prediction of adult physique at young age and scientific selection of most suitable sports has been presented in the present paper, to be presented in the Commonwealth Games 2010 Conference. It has also been explained that there is an urgent need to start an international CAKE (ie, Centre of Application of Knowledge Existing in the field of Sports research literature for preparing key guidelines for talent selection at young age). Sports participation will be increased many fold if children are guided properly to select a right sport as per their adult physiques and sports potentials.

N2 - Many students with Attention-Deficit Hyperactivity Disorder (ADHD) present with behavioral problems that are particularly evident in out-of-class settings (in the lunch room, on the playground, during field trips and special assemblies, etc). Barkley's (1997) technique has been known to help parents handle ADHD children's behaviors in out-of-home situations, and so its effectiveness to reduce problems in out-of-class settings was investigated with 65 teachers of male students previously diagnosed with ADHD. ANOVA revealed that Barkley's technique was effective in reducing the students' behavioral problems in out-of-class settings. This technique is easy to administer and school psychologists will likely find it useful in assisting teachers to handle ADHD students' behavioral problems

N2 - We aimed to evaluate whether an intervention program emphasizing in increased fluid intake can improve exercise performance in children exercising in the heat. Ninety-two young athletes participated in the study (age: 13.8 A ñ 0.4 years, weight: 54.9 A ñ 1.5 kg). Thirty-one (boys: 13, girls: 18) children served as the control group (CON) and 61 (boys: 30, girls: 31) as the intervention (INT). Volunteers had free access to fluids. Hydration was assessed on the basis of first morning urine. A series of field tests were used to evaluate exercise performance. All tests occurred outdoors in the morning (mean ambient temperature=28 A øC). After baseline testing, INT attended a lecture on hydration, and urine color charts were mounted in all bathrooms.

Additionally, water accessibility was facilitated in training, dining and resting areas. Hydration status was improved significantly in the INT [USG: pre=1.031 A ñ 0.09, post=1.023 A ñ 0.012, P<0.05; urine osmolality (mOsm/kg water): pre=941 A ñ 30, post=782 A ñ 34, P<0.05], while no statistically significant changes were found in the CON [USG: pre=1.033 A ñ 0.011, post=1.032 A ñ 0.013, P>0.05; urine osmolality (mOsm/kg water) 970 A ñ 38 vs 961 A ñ 38, P>0.05]. Performance in an endurance run was improved significantly only in INT (time for 600 m: pre=189 A ñ 5 s, post=167 A ñ 4 s, P<0.05). Improving hydration status by ad libitum consumption of water can enhance performance in young children exercising in the heat. ABSTRACT FROM AUTHOR

N2 - This article focuses on the accomplishments of elementary and high school athletes in the United States. Javarris, a sophomore running back at Immokalee High, rushed for 1,151 yards on 175 carries and scored 14 touchdowns this season to lead the Indians to the state Class 2A playoffs. Huffman, a senior midfielder at Connecticut College, was named a National Field Hockey Coaches Association All-America for the second time. Davis, a fourth-grader at Center Hill Elementary, won gold medals in forms and sparring at the 2003 Junior Olympics & Masters Karate Championships in Myrtle Beach, S.C. It was his 28th gold medal in forms or sparring competitions this year. Adam, a senior at Quincy Senior High, won the Class AA state high school golf championship at The Den at Fox Creek in Bloomington. Bill, 17, a junior at the Oregon Episcopal School, won the men's sabre gold medal in the junior division (under-20) at the 2003 Junior & Cadet Pan American Fencing Championships in Guadeloupe

N2 - This article presents a list of sports players, teams, and entities which are designated as being either hot or not hot. When does a two-game average of 125 passing yards make you hot in these gunslingin' times? When those yards lead to back-to-back wins for a Jets QB who was abruptly released by the Cowboys in August and who rebounded after being knocked ga-ga and missing three series on Sunday. More fun-on-a-bun: Bills coach Mike Mularkey had his team eat cheeseburgers last Saturday to change its luck out West. Marty Schottenheimer

is the odds-on choice for coach of the year after his Chargers beat his former team, the Chiefs, 34-31 on Sunday. Son Brian Schottenheimer (San Diego's QB coach) missed the game but still helped deliver a winner: His wife, Gemmi, had the couple's first child on Saturday

N2 - This article presents several news briefs related to sports. Now that Billy Bob Thornton is out of the picture, Angelina Jolie is carrying a torch for someone else -- Juan Antonio Samaranch. Saying she would "consider it an honor to run with the Olympic torch as a gesture of hope for refugees and to express my active support for sport and world peace," the Oscar-winning actress will carry the flame for a few hundred yards in Athens on Aug. 12, the day before the Opening Ceremonies; In the March 9 "Queer Eye for the Straight Guy" the Fab Five will make over a guy who already has a wardrobe filled with sequined outfits: three-time national pairs figure skating champion John Zimmerman. The 30-year-old has been getting less than a perfect 6.0 from his new wife, Silvia Fontana, a former Italian women's figure-skating champion; For a man who's about to host a reality show, Mark Cuban is on a pretty unreal run. "In the span of seven months I will have enjoyed the birth of my first child, played against the Globetrotters, been KO'd in the World Wrestling Entertainment (WWE) and played in a baseball game with batting lessons from Steve Garvey," says the Mavericks' owner; Although he's never golfed with the Dalai Lama, Tiger Woods came close to reaching total consciousness by playing the role of Caddyshack's Carl Spackler in an American Express commercial that debuted Sunday; Skater Nancy Kerrigan recently recorded "Simply the Best" on a Tina Turner tribute album; Gatorade is planning to introduce an "ESPN-flavored" drink; Tracy McGrady, Orlando Magic guard, after being fined \$10,000 for kicking the ball into the stands twice during a game: "That's a lot of money. I'll have to get me another autograph-signing session to pay that."

N2 - Background: Asthma induced by house dust mites is a mayor health problem worldwide. Spider mites are outdoor phytophagous mites and they have the severest economic effect in the agricultural sector; they also have a worldwide distribution. Although predatory mites attack spider mites, the current predator complex does not afford adequate control, particularly when spray organic phosphate or sulfur spray programs upset the natural balance. Environmental changes may have played a key role in the newly discovered development of spider mite-induced allergic diseases, especially asthma

Methods/Data base: A review of the literature

Results: Epidemiological studies have demonstrated that spider mites such as citrus red mite (CRM), European red mite (ERM), and two-spotted spider mite (TSM) are important allergens in the development of work-related asthma in fruit- cultivating farmers. Moreover, outdoor spider mites are not only common sensitizing allergens, but are also associated with the prevalence of asthma among children and nonfarming adults living in rural areas

Conclusion: in conclusion, these findings provide a rationale for including outdoor spider mites in tests conducted to identify causative allergens in patients with asthma and other allergic diseases

VL - 101

IS - 10

N2 - The article looks at five football rookies who weren't first-round picks, but will still have impact. So which rookies chosen after the first round will rise quickly to the top? Last year angular wideout Anquan Boldin, who was taken 54th by the Cardinals, ranked third in the league with 101 catches. Picked 101st by the Texans, rugged running back Domanick Davis finished 15th in rushing yardage with 1,031. Here are five first-year players with a chance to have a similar impact. Chris Snee: G, Giants (second round, 34th pick). One NFL East scout says he is already the best offensive lineman on the team. The 6'3", 314-pound Snee--who married New York coach Tom Coughlin's daughter in July after the two had had a child while at Boston College--earned the starting right guard spot early in camp with his strong run blocking and skill at pulling. Dontarrious Thomas: OLB, Vikings (second, 48th). He'll start on the weak side of the defense behind end Kenechi Udeze, the first-round choice out of USC. Thomas had only 5 1/2 sacks in four years at Auburn, but Minnesota believes he's strong enough at 241 pounds to bust up pass blocking and get to quarterbacks. Keary Colbert: WR, Panthers (second, 62nd). He'll battle veteran Ricky Proehl for playing time as a third receiver. Darnell Dockett: DE, Cardinals (third, 64th). At 301 pounds he was chosen as a tackle, but because of his ability to pressure the quarterback and injuries on the line, Arizona shifted him to end midwaythrough the preseason. Bobby McCray: DE, Jaguars (seventh, 249th). The 6'6" 245-pounder from Florida was so impressive in training camp that Jacksonville cut former AllPro Hugh Douglas to ensure McCray playing time

N2 - Recently, more people are playing sports to improve their health, while children also actively take part in sports activities and other events. Here we report on the case of a patient who developed a buccal abscess through dental trauma caused by soccer. The patient's right upper lip was lacerated by a kick to his face after he fell over during a game of soccer. Two days after the injury, he visited our office because of swelling from the upper lip to the buccal region. We administered antiphlogistic treatment, and after 10 days he showed a healing tendency. Trauma in the outdoors caused by specific bacteria has the potential to become severe, so a rapid response is necessary. ABSTRACT FROM AUTHOR

N2 - Background: Little is known about how the type and context of physical activity behaviors varies among adolescents with differing activity levels. The aim of this study was to assess differences in the type and context of physical activity behaviors in adolescents by level of objectively measured physical activity. Methods: Cross-sectional analysis of 2728 adolescents (1299 males, 1429 females) participating in the Avon Longitudinal Study of Parents and Children (ALSPAC). The mean (SD) age was 13.8 (+0.1) years. Physical activity was measured using an Actigraph over 7 days. Adolescents were categorized into tertiles of activity (less, moderately, highly active) using counts/mm and min/d of moderate-to-vigorous activity (MVPA). Activity type was reported using the Previous Day Physical Activity Recall (PDPAR). Differences in the type and context of activity by activity level were analyzed using Chi squared. Results: Highly active boys reported more job, outside, and sports activities on school days ($P < .05$), and more sports activities on nonschool days ($P < .05$). Highly active girls reported more outside activities on school days ($P < .05$). Conclusions: Identifying the type and context of physical activity behaviors associated with more active adolescents, can help inform policy and physical activity interventions aimed at increasing activity levels in adolescents. N2 - STUDY DESIGN: The study used longitudinal data from the first and second cycles (1994-1995 and 1996-1997) of the Canadian National Population Health Survey. **OBJECTIVE:** Our objective was to derive prediction models for back pain in the general male and female household populations. **SUMMARY OF BACKGROUND DATA:** Little is known about the predictors of back pain in the general population. Most previous studies focused on specific occupational groups and used a cross-sectional or case-control design. **METHODS:** The study cohort consisted of all respondents aged 18+ years who reported no back problems in the 1994-1995 National Population Health Survey cycle (N = 11,063). Potential predictors of chronic back pain were classified into nine groups and entered into stepwise logistic regression models. Bootstrap methods were used to derive the final models and assess their predictive power. **RESULTS:** The overall incidence of back pain was 44.7 per 1,000 person-years and was higher in women (47.0 per 1,000 person-years) compared with men (42.2 per 1,000 person-years). In men, significant predictors of back pain were age (peak effect in 45-64 years), height, self-rated health, usual pattern of activity (especially heavy work), yard work or gardening (negative association), and general chronic stress. In women, significant factors were self-reported restrictions in activity, being diagnosed with arthritis, personal stress, and history of psychological trauma in childhood or adolescence. **CONCLUSIONS:** Overall health and psychosocial factors are important predictors of back pain in both men and women. Other risk factors differ between the two sexes

N2 - The objective was to analyse the utilization of health services and the costs of treatment of unintentional injuries by type of injuries according to the common Nordic classification of injuries. From prospective registration of all injuries seen at the only hospital and emergency clinic in Stavanger, Norway, we selected at random a stratified sample of 2,819 cases from 7,019 unintentional injuries that occurred in 1992 among the residents of Stavanger. From medical records, we obtained information about the utilization of health services and estimated medical costs during the first year after injury. Of the patients 70% required only a single out-patient visit, while an additional 20% completed their treatment within the first 30 days after injury. Fifty per cent of the total costs were due to injuries among persons aged 65 years and older. Home and leisure-time injuries accounted for 75% of the total costs. The cost per injury was NOK 3,807 (US\$ 614), NOK 24,831 per hospitalized patient and NOK 1,011 per non-hospitalized patient. The per-injury cost among people aged 65 years and older was NOK 15,428, compared with NOK 2,158 among people aged 0-64 years, the difference primarily due to the increase in the average severity of injury. The per-injury costs were ranked (in descending order): nursing home, undefined, street, home, other home and leisure, traffic, occupational, free nature, sports, school and day care centre/playground injuries. If health care costs are to be reduced by injury prevention,

priority should be given to injuries occurring at home and during leisure time and to injuries among elderly people

N2 - Until recently care settings for those with Alzheimer's disease have not focused on the outside environment and the need to encourage older adults to spend time outside in fresh air and sunshine. Safe, secure outside spaces encourage walking and other forms of exercise and, in addition, offer beneficial exposure to increased natural light levels. Gardens and other outdoor settings provide many opportunities for socialization, sensory stimulation, fun, and meaningful activities. Designing the outside environment has been an overlooked opportunity to create meaningful places that are rich in association, encourage good health and exercise, and are responsive to the magic of the changing seasons

N2 - Questions the extent to which school recess periods are contributing to the fitness needs of children.

Observes the extent of activity and types of behaviour engaged in by children (n=369) during unstructured play time at five elementary schools. Classifies the observed behaviours as either active (vigorous activity, moderate activity, or minimal activity) or passive (social interaction, independent behaviour, and waiting). Results indicate that the children are involved in some degree of physical play about 59% of the time. However, only 21% of recess time (i.e. about six minutes) is devoted to vigorous physical activity. Racial differences are minimal. Points out evidence which shows that the average elementary school child spends only two to three minutes in moderate to vigorous exercise during a physical education class. Suggests that the activity patterns during recess and physical education classes are the same, and that physical education programs do not provide the appropriate activities to adequately promote fitness, which could be carried over to recess

N2 - The purpose of this abstract is to present a preliminary grant proposal outline for a rural, low-income elementary school that was the recipient of a Carol M. White Physical Education Program (PEP) award. Since the mission of the elementary school is to provide high quality educational and service programs that support, empower, and build capacity in school learning communities, the school must ensure that its students achieve their highest academic, social, and emotional potential. Based on two years of physical activity (pedometry) and cardiovascular fitness (PACER test) improvements seen due to the implementation of a variety of health and fitness interventions, a new intervention to ensure the sustainability of health progress is being proposed. The mission of the "Outdoor Walking Trail" intervention is to provide the elementary school community with an

outdoor walking trail that allows families a safe place to play outside while developing an appreciation of a healthy, outdoor physically active lifestyle. The goals of the intervention are to increase children's outdoor physical activity frequency and duration, increase children's physical activity self-efficacy, and to promote the use of the safe, outdoor walking trail for children and their families. The intervention is framed within the Social Cognitive Theory and measurement of the effectiveness of the intervention will include subjective measures of physical activity knowledge and self-efficacy and perceived access to physical activity opportunities (via surveys) and objective measures of physical activity participation (via pedometry). The intervention grant proposal is being developed by students enrolled in the HSS 434: Public Health Education Methods course within the Public Health Education and Community Health Program at University of Louisville and will be offered to the elementary school by the students and faculty mentor as part of their university/community engagement partnership. N2 - Many of us fondly remember long, steamy summer days spent exploring the neighborhood, playing with friends, or spending time at the local swimming pool. Tim Esons, Director of School-Age Programs at South Shore Day Care Services, Weymouth, Massachusetts, shares similar memories. "During the summers, we spent our free time in the neighborhood with other kids and parents; but now, because parents are working or neighborhoods aren't safe. we are their neighborhood, he says, referring to the eight-week summer program offered by South Shore

The face of summer has changed across the country as the number of single-parent and dual-income families has increased. In 1996, 77% of married mothers with school-age children worked outside the home, compared with 40% in 1960. Mothers today are also more likely to work full time

An April 2000 report from the U.S. Departments of Education and Justice revealed that in 69% of all married-couple families with children ages 6-17, both parents work outside the home. The custodial parent works in 71% of single-mother families and 85% of single-father families. "It's hard to create a neighborhood now when no one is home in the afternoon," Esons says

N2 - The purpose of this study was 1) to test whether an orthosis, which provides postural stability of the trunk and guides the leg movements during walking (Norsk Funktion-walker orthosis [NFWO]), would enable nonambulant children with cerebral palsy with poor or no leg coordination and with little or no trunk control to walk on their own, 2) to investigate if there is an increase in motor function and activity while using a NFWO, and 3) defining requirements for a successful provision. Ninety-three children (39 girls, 54 boys; mean age 7.6 years; 67 with bilateral spastic, 10 with dyskinetic, 10 with mixed, 6 with ataxic cerebral palsy; Gross Motor Function classification System level 4: 45, level 5: 48) were provided with a NFWO. The following assessments were carried out immediately before and 3 months after using the NFWO: WeeFIM walking score; independence rating by parents or caregivers; aims or expectations of parents or caregivers; at a mean interval of 265 days after provision: mean daily walking distance (meters). With the NFWO, 78 children (84%) became ambulatory, 10 children (11%) used it exclusively as a dynamic standing frame only, and 5 children (5%) returned the NFWO. The mean daily walking distance was 99 m (2-463 m). The mean WeeFIM walking score of 1.99 (SD 0.83) without the NFWO increased to 4.42 (SD 1.00) with the NFWO indoors and to 3.71 (SD 1.24)

($p < 0.001$) outdoors. Independence rating by parents or caregivers reflected a highly significant increase in independent mobility with the NFWO compared with locomotion without ambulatory aides ($p < 0.001$) and of bilateral hand function ($p < 0.001$). No significant increase in the mobility was found when comparing former mobility aides (wheelchair, tricycle) with the NFWO. The ability to cross obstacles did neither significantly increase with the NFWO. Successful indication for a NFWO depends on 1) the child's motivation to walk and the support of the environment to achieve independent walking mobility through the use of this assistive tool, 2) the ability for selective reciprocal leg movements, and 3) no flexion contractures of hips and knees above 20[degrees] and a foot dorsiflexion of at least neutral-0[degrees]. The NFWO proved to be a useful ambulatory aid in the children with cerebral palsy with severe gait impairment to increase independent mobility

N2 - The Iwate Dental Association has made various efforts to establish how to maintain oral health care for children. This article reports an investigation into the conditions of maxillofacial and oral injuries in order to keep children safe when playing sports at elementary and junior high schools in Iwate Prefecture from 2003 to 2004. The results were as follows?? 1. In the one year which we examined, 746 cases of injury occurred at 62 elementary schools out of a total of 90, and 187 cases of injury at 47 junior high schools out of a total of 72. Boys sustained injuries more frequently than girls both at elementary schools and at junior high schools. 2. First?? t year pupils sustained injuries most frequently, and the risk frequencies of injury lowered with the progress in school year for elementary school pupils. For junior high school students of each school year, injuries occurred at similar frequencies. 3. The incidence of injury was high in June at elementary schools and in May at junior high schools. The period of time during the day when injuries happened most frequently was

12.00 to 14.00 at elementary schools and 16.00 to 18.00 at junior high schools. The places where injuries happened frequently were the school playground, gymnasium and classroom for elementary school pupils and the school playground and gymnasium for junior high school students. Injuries in elementary school pupils happened frequently at recess, and those in junior high school students happened frequently during extracurricular activities. 4. Frequently sustained injuries were face contusion, lip lesion, tooth fracture, tooth luxation and tooth displacement both for elementary school pupils and for junior high school students??for junior high school students, serious injuries such as brain concussion, cervical vertebrae injury, and mandibular fracture also occurred. When injured, junior high school students were more likely than elementary school pupils to go to hospital. ABSTRACT FROM AUTHOR

N2 - Presents a description of games and play activities which were prevalent among children and adults on Bellana, an island in the British Solomon Islands, before contact with the outside world in 1938. Data were collected through interviews and participant observation. Points to radical increase in population and change in residential form, plus the judgement of others, especially missionaries, of the Bellonese culture as inferior, as determinants of the gradual submergence of this part (i.e. games) of the Bellonese culture. Changes in game forms have also affected traditional patterns of settling political disputes. Net result has been a serious break in the continuity of the cultural tradition

N2 - The article provides information on the Harlem Hospital Playground Injury Prevention Program (HHPIPP), a project established by the Departments of Pediatric Surgery and Pediatrics at Harlem Hospital in New York City in 1988. The objectives of the program are to decrease the number of injuries to children in playgrounds in Central Harlem and to provide safe playgrounds. The article first explores the prevalence of playground injuries in the city predominantly of African American residents. The program's planning process, which is a multifaceted approach, is then discussed. The article also details how the HHPIPP teamed up with parents in the community to form the Safe Kids/Healthy Neighborhood Coalition

N2 - Concerns regarding the profound physical, social, and psychological problems associated with childhood nature deprivation have catalyzed extensive growth in nature-based education programs. Recent environmental education (EE) initiatives and legislative measures, such as the proposed No Child Left Inside Act, have stressed the importance of EE in the formal education sector. However, out-of-school EE programs remain an appealing alternative to in-class science education. Non-formal programs provide children with a unique opportunity to experience substantial outdoor immersion and often influence affective development. These benefits suggest that an expansion of the depth and scope of non-formal outdoor programs is necessary to achieve the long-term goal of an environmentally literate population. Efforts to develop strategies for implementing and evaluating affective changes associated with EE programs could place a greater emphasis on the environmental orientations of children from different backgrounds. This exploratory study employed a new instrument, the Children's Environmental Perceptions Scale, to investigate baseline differences in the environmental orientations of 133 six to thirteen-year-old children from different gender, age, and racial/ethnic groups in Athens-Clarke County, Georgia. This study used a mixed-method, pre-test, post-test approach to examine the effects of a one-week EE summer program sponsored by the State Botanical Garden of Georgia on children's eco-affinity, eco-awareness, and environmental knowledge. Responses of EE program participants were compared to a control group of students enrolled in local after-school programs. Brief personal interviews and open-ended evaluations supplemented quantitative survey data. Results did not reveal gender differences in baseline environmental orientations. However, eco-affinity levels were significantly lower in participants age ten or older. African

American children also displayed significantly lower eco-awareness and environmental knowledge scores than white children prior to the EE program. Interviews detailing children's unique interactions with nature yielded several possible explanations for these discrepancies. The EE program produced significantly higher adjusted mean eco-affinity and environmental knowledge post-test scores than the control group, regardless of gender, age, or race/ethnicity. The summer camp's influence on eco-affinity, an affective component of environmental orientations that is difficult to alter, was especially encouraging. Fun and exciting concepts expressed through physical activity appeared to be a key component of effective EE programming. Overall, results suggested that non-formal EE programs in public parks and other recreation areas provide an ideal forum for stimulating positive environmental orientations in a diverse group of children and may generate future support for outreach efforts in underserved communities. N2 - EXECUTIVE SUMMARY: A growing body of literature suggests that children today are spending less time outdoors than their predecessors. This assertion, however, is confounded by the absence of a baseline for detecting trends in children's activities and time spent outdoors. The U.S.D.A. Forest Service initiated the National Kids Survey to address this problem. This general population random digit dialing telephone survey reached 1,450 U.S. households with children from 2007-2009. A proxy household member (e.g. parent or guardian) age 20 or older spoke for children between the ages 6 and 15. Teens between ages 16 and 19 were interviewed directly. Participants were asked about a variety of topics including time children spend outdoors, common outdoor activities, and reasons for not spending time outdoors. Data showed that, in general, most children (> 62.5%) spent at least two hours outdoors daily. Results also indicated that children spent either more time (39.5%) or about the same amount of time (44.8%) outdoors this year as they did last year. Males, younger children, and Hispanics spent more time outside than other demographic groups. Playing or simply hanging out was the most common outdoor activity (84.0% of respondents). Other common activities included biking, jogging, or running (79.9%) and using electronic media outdoors (65.3%). Children participated in outdoor nature-based activities less frequently than many alternatives. Interest in other activities such as listening to

music, art, or reading (57.0%), watching TV, DVDs, or playing video games (48.1%), and using electronic media including internet and texting (47.8%) were the most common reasons for not spending time outside. African American and Hispanic respondents cited more reasons for not going outside than other racial/ethnic groups. Comparisons using contingency coefficients showed that children's outdoor time on weekdays, weekend days, and time spent outdoors relative to last year were strongly correlated with the amount of time their parents/guardians were spending outdoors. Results suggest that, contrary to popular beliefs, many children today are spending a substantial amount of time outdoors. However, the nature of children's outdoor time may be changing. For example, playing or hanging out, physical activities, and technology-centered activities are more popular than nature-based activities. Electronic media consumption and parental involvement in outdoor recreation activities seem to be important factors influencing children's time outdoors. Future research efforts should continue to monitor these trends and measure the frequency and type of children's outdoor activities across diverse recreation settings. To remain relevant in the lives of American youth, park and recreation professionals could use instruments such as the National Kids Survey to adapt current services and develop innovative outdoor recreation opportunities that appeal to multiple audiences. N2 - The author discusses the differences between running outdoors and running on a treadmill. She understands that people who work long hours prefer the treadmill to allow them to remain in a place that is safe and convenient. The treadmill also lets mothers work out while they keep an eye on their children. Speaking on the virtues of the treadmill, the author's coach Kevin McCarey states that aging runners need to keep their cardiovascular system and may need to achieve that in the gym

N2 - A year ago, as a freshman wideout at Pittsburgh, Larry Fitzgerald caught 69 passes for 1,005 yards and 12 touchdowns and was named All-Big East. He was a very good player, but well short of dominant. A year later he is one of the best college players in the country, a transcendent receiver who demands that defenses rewrite their game plans, fans remain anchored to their seats and Heisman voters write his name somewhere on their ballots. This ascent began in a most unlikely manner, with a heartbreaking telephone call. Early last April, Fitzgerald's mother, Carol, 47, lay in a Minneapolis hospital, racked with a cancer that had taken root in one of her breasts six years earlier, spread to her lungs and now reached her brain. Last Saturday night, as wintry winds sliced through Pittsburgh's Heinz Field, Fitzgerald's brilliant season ended with a thud in a 28-14 loss to Miami that cost the Panthers (8-4) a piece of the Big East championship and their first BCS bowl berth. In a demonstration of why it's so difficult for a receiver to control a game (and win the Heisman), Miami sacked Pitt senior quarterback Rod Rutherford nine times and draped two defenders on Fitzgerald all night, a cornerback in press man-to-man coverage and a safety sitting behind him. In the near future, Fitzgerald will decide whether to join former Ohio State running back Maurice Clarett in challenging the NFL's rule prohibiting college players from entering the draft until three years after graduating from high school

N2 - The article discusses the efforts of health experts and gym teachers to introduce children to the benefits of exercise, in light of the alarming rate of overweight school-age children. The kids got up long before sunrise and went to school early because some grown-ups had offered them a chance to play. The grown-ups rose in darkness because they had an opportunity to use sports and games to fight, in a small way, the obesity that is rampant among young Americans. The kids and the grown-ups arrived at Parker Memorial, a public school for third- and fourth-graders in Tolland, Conn., just as the early autumn fog was lifting off the nearby green hills. The students tossed their backpacks and jackets onto a table and stormed into the small gymnasium. The adults tightened the laces on their sneakers and cued up a boom box. This sweet convergence of problem and solution was born last winter when Jaci VanHeest, an associate professor of kinesiology at the University of Connecticut's Neag School of Education, was referred to Parker Memorial by representatives of a state health

district that had received a small federal grant. The most delicate task was inviting students who were overweight or at risk of becoming so. On the first day of Paw Pals, in March 2004, skeptical parents stood outside peering through the open gym doors. Children lined up against the wall, appearing terrified of the unfamiliar adults in their school. VanHeest asked them what they wanted to play. "Superman tag," said one pupil, breaking the silence. So they played Superman tag. For one hour every morning before school, through the end of May, the children played games that they themselves suggested. And something extraordinary happened: They discovered that they loved exercising. No statistics were kept, but parents reported to VanHeest that their children were losing weight. Teachers said the kids were more alert in the classroom

N2 - Background. Daily experiences are thought to play an important role in motor development during infancy. There are limited studies on the effect of postural and movement experiences on head control.

Objective. The purpose of this study was to quantify the effects of postural and movement experiences on head control through a comprehensive set of measurements beginning when infants were 1 month old. Design. This was a prospective, longitudinal, 2-cohort study. Methods. Twenty-two full-term infants who were healthy were randomly assigned to either a training group or a control group. Infants were observed every other week from 1 to 4 months of age. Head control was assessed using a standardized developmental assessment tool, the Test of Infant Motor Performance (TIMP), as well as behavioral coding and kinematics of infants' head postures and movements in a supported sitting position. Caregivers performed at least 20 minutes of daily postural and movement activities (training group), or social interaction (control group) for 4 weeks. Results. The training group had higher TIMP scores on head control-related items during the training period and after training stopped compared with the control group. Starting from the during training phase, the training group infants had their heads in a vertical and midline position longer compared with the control group infants. After training stopped, the training group infants actively moved their heads forward more often and for larger distances.

Limitations. The experiences outside daily training were not monitored, and the results may be specific to the experimental setup for infants with typical development. Conclusions. Young infants are able to take advantage of postural and movement experiences to rapidly advance their head control as early as 4 to 6 weeks of postnatal life. Infant positioning, caregiver handling, and caregiver-infant interactions were likely contributing factors.

This database of comprehensive measures may be useful in future trials focused on head control in infants with special needs. ABSTRACT FROM AUTHOR

N2 - Background: Many of the issues relating to game performance of students found in the physical education literature can be considered a failure of generalization from practices to games, and from games to games. However, no study in secondary physical education has examined generalization effects as a result of effective game pedagogy in the context of teaching games. Purpose: The purpose of this study was: (a) to examine the effects of technique-focused and tactic-focused instructional conditions on the learning of a tactic by students aged 12-14 years in physical education lessons participating in a tag rugby unit, and (b) to assess the extent to which the performance of this tactic generalized from instructional games to match games. Participants and setting: This study was conducted at an urban middle school (students between 12 and 14 years of age) in the Midwest of the USA. This study was conducted during a 20-day tag rugby instructional unit. Students in three classes participated in the study. Four students from each class were selected to be observed. Intervention: The tactic-focused instructional condition served as an intervention, while technique-focused instruction was used as a baseline. Research design: A multiple baseline design across two classes, with a third class serving as a control, was used to assess the performance of the participants. Data collection: The dependent variable was 'supporting movement', which occurred during instructional games and match games. Data were coded for each target student during instructional games and match games using event-recording procedures from observation of a digital-video of the lessons. Coding occurred for each episode for each target student. Each episode ended with any incidence of a pass, tag, score, a ball carrier's error, or if the ball went outside the field of play. When the 'supporting movements' met the decided criteria they were coded as correct. Data analysis: Each player's total number of correct 'supporting movements' was divided by the number of opportunities for supporting movement and then multiplied by 100 to calculate the percentage of correct supporting movements for each target student. Findings: Low-skilled, female and male students, and average-skilled female students improved their percentage of correct supporting movements after the tactic-focused instruction was implemented. Generalization from instructional games to match games occurred for all students except average-skilled males. Conclusions: Students who typically remain unaffected by instructional interventions improved their performance of supporting behavior during tactic-focused instruction. Furthermore, those students were able to apply a tactic from instructional settings to match games. This study presents an alternative analysis of the conceptualization of sports and tactics. N2 - Excessive load carrying by children and its resultant problems is not a new issue. Given the popularity of golf amongst youngsters, this study set out to examine the proportion of junior golfers who carried a bag; the weights junior golfers were carrying around the course in their bags; what type of bag and how they carried it; whether and where they experienced any pain or discomfort; and a number of other related factors. Seventy-five junior golfers responded to a questionnaire examining their carrying habits. The weight they carried was calculated using a balance and they self-reported any incidence of pain or discomfort felt and its location. Results showed that a significant proportion of juniors carried a bag, rather than pulled a trolley, that they carried an average of 18.7% of bodyweight in a bag, which falls outside acceptable recommendations, and 51% of bag carriers experienced some measure of pain or discomfort whilst carrying. The location of the discomfort was consistent with the manner in which the bag was carried. It is recommended that parents and professionals could take a greater interest in the problem and be more pro-active in encouraging youngsters to adopt alternative methods of club transport

N2 - Continuous research with regards to physical activity and physical fitness patterns of children is essential for the development and implementation of health promotion programmes. This study aimed to determine the physical fitness (PF) and physical activity (PA) status of 15-year-old adolescent learners from a low socio-economic, semi-urban community in the North-West province of South Africa, and the relationships between

PF, PA and distances the children walked to school. Grade 8 learners of two schools were selected for the study: School 1 (N=252), 116 boys; 136 girls, School 2 (N=66), 21 boys; 45 girls. The testing protocol included fitness tests for aerobic endurance, flexibility and body composition and the PDPAR questionnaire to determine PA levels. The results indicated that the boys and girls in School 1 and boys in School 2 were moderately active, while the girls in School 2 showed a significant lower PA level. Longer commuting distances and higher mean physical fitness values were found in School 1, while more hours of watching television were found among boys and girls ($p < 0.05$) in School 2. Poor strength levels, falling outside the healthy fitness zone, showed negative relationships with aerobic fitness and flexibility. Television viewing time and commuting distances to school appeared to have a moderate influence on the moderate to low PA levels of the total group, and physical activity showed a relationship with higher fitness values. It is recommended that activity intervention strategies must aim to empower adolescents with knowledge and skills to enable them to improve their PA levels and strength.

CY - ;

N2 - Examines play and games as situations in which important informal learning occurs. Attention is given to the social skills that emerge as a consequence of a particular play style. Observations of children at play during recess, gym, after school and competitive games indicated very distinct play patterns for boys and girls.

Attributes such as role differentiation, interdependence between players, size of the play group, explicitness of goals, number of rules and team formation, suggest that boys' play is more complex than girls' play. Sources and consequences of these sex differences are explored

N2 - This study explored the effects of parental monitoring, leisure boredom, and leisure activity on Internet addiction. The sample was 1,289 adolescents from eleven senior high schools in Taiwan. Participants were asked about their perception of being monitored by their parents, leisure boredom, leisure activities, and Internet addiction behavior. Results showed that leisure boredom and involvement in Internet and social activities increase the probability of Internet addiction; however, family and outdoor activities along with participative and supportive parental monitoring decrease these tendencies. Overall evidence suggests that parental monitoring is a major inhibitor of Internet addiction. Thus, adolescents should be supervised in their daily routines and encouraged to participate in family and outdoor activities. In addition, adolescents should develop a positive attitude toward leisure and the skills to prevent overdependence on online relationships with the assistance of parents. These findings suggest the preventive strategies regarding Internet addiction. ABSTRACT FROM AUTHOR

N2 - A random sample of 4,690 school children and youth from Primary grade 5 to Secondary grade 7 completed a questionnaire inquiring about the nature and extent of their sport and physical activity participation during the previous school year and their wishes for sport participation in the future. In terms of frequency of participation, the boys were fairly close to figures from western countries and showed little decline over age levels, whereas the girls had quite low participation frequencies and a sharp decline with age. Ninety percent of the school children and youth had engaged in at least one sport or activity in the past year. However, extent of participation based on frequency, duration and number of months per year was lower than western norms for the boys, and the girls were far below western girls in participation extent. There were some significant differences in participation patterns among the various districts of the Territory. The data showed that an overwhelming proportion of sport participation takes place in informal free-play settings as less than 3% of the sample indicated that they belonged to a sport club or similar activity organisation, and two-thirds of all participation occurred in a setting other than the school, a club, or in the form of formal lessons. There were substantial age and regional differences in the popularity of sports. More than 25% of the respondents had dropped out of an activity in which they had been involved the previous year. Hong Kong youngsters, if given a free choice, would give preference to familiar sports and physical activities, such as basketball, badminton, soccer (boys), and swimming (girls), but also show a remarkable interest in ice skating (girls). Dislikes for sport were different for males and females, the former avoiding dance, the latter mainly soccer and combative sports.

Recommendations emanating from this study included (1) targeting of the female population of children and youth in Hong Kong for sports participation promotion; (2) prioritization of encouragement and facilitation of sport participation for youngsters in particularly the Kowloon area, (3) finding ways to improve quality of sport performance in informal playground participation which is the prevalent mode of sport involvement for Hong Kong children and youth, and (4) finding ways to change the image of sport and physical activity and to make them more attractive to encourage entry into sport and diminish withdrawal

N2 - Abstract: Background/purpose: To investigate the month and day of the week of injury in common childhood activities using the National Electronic Injury Surveillance System database. Methods: All emergency department visits 2002-2006 from bicycles/tricycles, scooters, playground equipment, swimming/water activities, skiing/snowboarding, trampolines, and skating were analysed. The NEISS weighted and stratified data set was analysed using SUDAAN software. Weekday and month of injury, gender, race, anatomical location of the injury, geographical location of injury, and disposition were tabulated. Simple variation by month or weekday was analysed using cosinor analysis; combined variation for both month and weekday was analysed by topographical analysis. Results: There were an estimated 4.61 million emergency department visits for injuries from these activities in children in the United States. The average age was 9.5 years; there were 1.65 million girls (35.9%) and 2.97 boys (64.1%). Cosinor analysis demonstrated significant single peaks for month of injury for snow activities (January 27), trampolines (June 10), scooters (June 24), cycling (July 6), and water (July 12) activities. Double cosinor peaks were noted for skating (April 13 and September 12) and playground (April 22 and September 21) activities. Cosinor analyses demonstrated that the peak week days of injury were Monday for trampoline and snow activities, Saturday/Sunday for skating activities, Sunday for cycling, and Wednesday for playground equipment. There was no peak injury day for scooter or water activities. Topographical representation of paediatric injuries demonstrated that injuries from slides most frequently occurred April-May on Wednesdays and Saturdays, and those on swings April-May all days except Tuesday. Monkeybar injuries were bimodal, with the spring peak on Wednesday-Thursday in April/May and the fall peak Tuesday-Friday in September. Rollerblade injuries occurred Saturday-Sunday from March/April; rollerskates on Saturday-Sunday in January-April, and skateboards Saturday-Monday in August-October and Sundays in April. Conclusions: These findings can be used to further guide childhood injury prevention programmes/campaigns and especially track improvements after targeted prevention programmes. Public parks and schools should check/correct the status of playground landing surfaces just before the bimodal peaks. Education campaigns reinforcing the need for bicycle helmets could be concentrated immediately before the increase in cycling activity - March on weekends and April/May for weekdays.

N2 - It has been well evidenced that physical activity (PA) has a positive effect on human health. It is very likely that a physically active child will grow up to be a physically active adult. Growing older, there is evidence of decreasing PA in children and youth. In the period of adolescence, girls tend to be less physically active than boys and therefore they are understood to be a risk group in relation to PA. **OBJECTIVE:** The aim of the study was to characterize school related weekly PA in adolescent girls and to identify the influence of participation in physical education lessons (PE) on the structure of weekly PA. **METHODS:** The study was carried out using the ActiGraph monitor and record sheets in a period of five school days and two weekend days. **RESULTS:** The results have shown that girls participating in two or more PE lessons show higher overall PA performed at school and also spend more time performing intensive PA at school than girls participating only in one or no PE lessons during the week. At school, the girls spent on average 10 minutes performing moderate PA (3.1 f_ "6 MET) and 0.6 minutes intensive PA (> 6 MET). The girls spent most of the time at school in being physically inactive, on average 125 minutes. When we compare these results with health recommendations (seven times a week 60 minutes of moderate PA and 3 times a week 20 minutes of intensive PA), we can argue that PA in adolescent girls really needs to be examined in research. Moreover, the results show that school and PA performed there (physical education lessons) still plays its irreplaceable role in the education system regarding the total level of PA and healthy lifestyle in adolescent girls. **CONCLUSIONS:** The increase of total PA in adolescent girls can be secured by the increase in school related PA (more PE lessons, introducing at least one physically active recess for 30 minutes during a school day, enhancing active transport to and from school) and by the increase of girlsE - participation in organized PA outside of school and PA at weekends. **ABSTRACT FROM AUTHOR**

N2 - This study aimed to analyze the effects of an intervention strategy during the school recess on physical activity (PA) levels, by gender, age and body mass index (BMI). The sample comprises 158 Portuguese children aged 6 to 12 years. Weight and height were objectively measured. PA was assessed by accelerometry during the recess in pre-intervention and post-intervention periods. Introduction of extra outdoor play equipment was used as an intervention strategy. Significant interaction effects were found for the following areas: percentage of time spent in PA ($F(1,150)=70.157;p<0.001$), intervention X age group ($F(1,150)=24.416;p<0.001$) and gender X age group ($F(1,150)=6.919;p=0.009$); the time spent in Moderate PA for intervention X gender ($F(1,150)=15.290;p<0.001$) and BMI X gender ($F(1,150)=6.411;p=0.012$); the time spent in Vigorous and Very Vigorous PA ($F(1,150)=54.790;p=0.001$), intervention X age group ($F(1,150)=9.490;p=0.002$), intervention X gender ($F(1,150)=14.161;p<0.001$) and BMI X gender ($F(1,150)=5.049;p=0.026$). It appears that successful recess interventions to improve PA for children in elementary scholars are possible by providing relatively inexpensive play equipment

N2 - The aims of this study were to characterize the spontaneous physical activity of children during school recess, and to estimate variation in physical activity associated with gender and age. A MTI actigraph (Model 7164) was used with a sample of 140 boys and 131 girls, 6 to 10 years of age. MTI counts were converted to METs using a regression equation developed for children. The number and average duration of periods of activity by intensity were calculated for each child during a 30 minute recess: rest or mild physical activity (≤ 2.9 METs), moderate physical activity (3.0-5.9 METs), vigorous physical activity (6.0-8.9 METs) and very

vigorous physical activity (≥ 9.0 METs). Boys and girls spent about 50% of the recess in physical activity. Physical activity was characteristically done in very short bursts with intervals of rest or mild physical activity. The number of episodes of physical activity of all intensity levels was lower in older children while the inverse occurred at rest or mild physical activity. Boys engaged in higher intensity activity than girls and in general spent more recess time in physical activity

N2 - Background: The purpose of this study was to examine the association between pedometer-assessed physical activity and a number of individual, social, and environmental correlates among Cypriot elementary school children. Methods: School children in grades 5 and 6 (N = 104) and their parents (N = 70) wore pedometers for five consecutive weekdays and completed questionnaires assessing potential correlates of steps/d. Results: A hierarchical regression analysis indicated that gender, weekly frequency of sports club attendance, and hours playing outside accounted for 32% of the variance in steps/d. In addition, children with a body-mass index (BMI) above the 85th percentile (based on age and gender) scored significantly lower steps/d than children with a BMI below the 85th percentile. Conclusions: This study suggested that correlates of steps/d in children are similar to the findings of other studies using different measures of physical activity behavior. ABSTRACT FROM AUTHOR

N2 - The article focuses on the incidental learning of mechanical principles that occurs on playgrounds. Many children experience principles of mechanics long before their first formal exposure in a science class. On the playground, they experience translatory and rotary motion, forces such as gravity, and attempts to overcome gravity with muscular effort. These efforts result in work and the expenditure of energy. Playing on swings, merry-go-rounds, slides, and teeter-totters helps children understand concepts illustrated by Newton's laws of motion. Unknowingly, they learn about inertia, acceleration, ground reaction forces, and leverage

N2 - Each year over 200,000 children in the United States require emergency medical treatment for playground-related injuries, costing an estimated \$1.2 billion. Thus, the issue of playground safety is a topic of concern for many health care professionals. However, without a reasonable understanding of the scope and magnitude of the problem, any attempts to develop an injury prevention program will be limited. Therefore, this article reviews the data-based playground research so that suggestions can be made concerning the development of a comprehensive playground injury prevention program

N2 - The present study is aimed to perceive the different standards of physical activity in leisure time and the pattern of physical activity (regarding its manner, intensity, duration and frequency) of children within school context. A group of 120 children of both sexes, around the age of ten, attending Year 4 was selected amongst two Primary Schools in Vila Nova de Gaia. To assess the physical activity within their free time it was used Godin and Shephard's (21) questionnaire. Forty-nine children were asked to wear a portable accelerometer (Tritrac-R3D) for five days in order to assess their physical activity at school. The statistical procedures used were an average descriptive gauge, a standard deviation, unconditional and comparative occurrence; the independent measurement t-test and the Mann-Whitney non-parametric test. The results and conclusions obtained through this study suggest that: (1) boys show a greater rate of activity during free time in comparison to girls, specially in what concerns to high vigour physical activity; (2) children clearly manifest a pattern of physical activity which is fortuitous and it varies in its intensity and duration; (3) during school time children have physical activities of low intensity with less than 30 minutes per day of it being moderate/vigorous; (4) in

the playground boys are significantly more physically active than girls ($p < 0.05$); (5) even in planned PE sessions the standard of physical activity is of low intensity thus demonstrating children spend less than 50 % of lessons performing moderate/vigorous exercises; (6) a change of behaviour is neither reflected in planned PE sessions nor in playground activity regardless of the energy outlay

N2 - Background Concussion in sport typically recovers clinically within 10 days of injury. In some cases, however, symptoms may be prolonged or complications may develop. The objectives of the current paper are to review the literature regarding the difficult concussion and to provide recommendations for an approach to the investigation and management of patients with persistent symptoms. Methods A qualitative review of the literature on concussion in sport was conducted with a focus on prolonged recovery, long-term complications and management including investigation and treatment strategies. MEDLINE and Sports Discus databases were reviewed. Results Persistent symptoms (>10 days) are generally reported in 10-15% of concussions. This figure may be higher in certain sports (eg, ice hockey) and populations (eg, children). In general, symptoms are not specific to concussion and it is important to consider and manage coexistent pathologies. Investigations may include formal neuropsychological testing and conventional neuroimaging to exclude structural pathology. Currently, there is insufficient evidence to recommend routine clinical use of advanced neuroimaging techniques or genetics markers. Preliminary studies demonstrate the potential benefit of subsymptom threshold activity as part of a comprehensive rehabilitation programme. Limited research is available on pharmacological interventions. Conclusions Cases of concussion in sport where clinical recovery falls outside the expected window (ie, 10 days) should be managed in a multidisciplinary manner by healthcare providers with experience in sports-related concussion. Important components of management, after the initial period of physical and cognitive rest, include associated therapies such as cognitive, vestibular, physical and psychological therapy, assessment for other causes of prolonged symptoms and consideration of a graded exercise programme at a level that does not exacerbate symptoms. N2 - The case notes of all children, under the age of 16 years, who were admitted with alcohol intoxication to hospitals in the City of Aberdeen, during the 5-year period 1988-1992 were studied retrospectively. The circumstances in which the children took alcohol were noted and our hospitals' admission policy on children with alcohol intoxication was reviewed. A total of 154 children aged between 11 and 16 years (mean 14.4, SID 2.8) were admitted. The male to female ratio was 1:1. Most children consumed alcohol either at their own homes or at outdoors venues and about half of them drank in the company of their peers. 15% had a history of previous alcohol ingestion, drug poisoning or overdose, glue sniffing or attending hospital casualty department for accidental injuries. Ten children presented with coma and 2 children had associated physical injuries. 1 child required intensive care therapy due to multiple injuries. 142 children (93%) were admitted for overnight observation and in the majority of children no active treatment was required. None of the children in this age group had problems with hypoglycaemia or hypothermia and all children made a complete recovery. This study confirms that alcohol intoxication is common in children and complete recovery is always expected unless there were associated coma or other injuries at presentation. We conclude that children between 11 and 16 years of age with uncomplicated course of alcohol intoxication may be looked after at home safely under the supervision of the primary health services. Health education about the dangers of alcohol need to be addressed from an early age if reduction in teenage drinking is to be achieved

N2 - Presents findings from an interview survey study carried out in three separate districts in Norway on the types and frequencies of participation in leisure pursuits, and geographical patterns of the most popular activities. Relationships between predictor variables, participation frequencies, and satisfaction are examined in order to ascertain how to increase the level of engagement in outdoor leisure activities by passive groups. Results indicate that there is not a need to create new norms or expectations, but only to maintain the existing outdoor leisure cultures. Identifies old people, housewives with small children and those with physical handicaps as having lower levels of engagement in outdoor leisure activities

N2 - Purpose: This article is an accessible material, well-structured and easy to use by educators, teachers of physical education and sports, coaches in physical education classes, namely during the performance sport activities. Prepared in accordance with current modern bibliographical needs, this article aims to support the

theoretical and practical- methodological knowledge in whose possession to be able to respond to social and motor orders related with the skill development, namely with the balance in children of preschool age. Methods: Research methods used in this research are part of private methods and of those processed, analysis and interpretation of data collected by the study. Measurements and records method consisted of applying and recording the "Flamingo" and Matorin test results. Results: Knowledge level of manifestation of the equilibrium capacity (coordination) in pre-school children in independent motor activity, by use of specific means to physical education and sport, is subject to the manifestation of motor skills, functional and psychological characteristics of each individual. Independent physical education activities will ensure the continuity of motor preparation, since at this age, by establishing a proper proportion between the individual physical condition and learning motor skills specific to physical education and sport, but also a gradual scaling of the physical exercise. Conclusions: Programming the physical education and sports activities shall be in conformity with the geographical environment, the material conditions of the school curriculum and with the analytical curriculum of the field. At the preparation and organization of physical education classes and sports, should be taken into account the number of children, the ratio number of girls and boys, health, level of physical development, psychological differences, the place that the physical education and sport occupies at the group's daily schedule, the conditions in which it is carried on (in room or outdoor), the provision of school material, etc.. The use of the most efficient means and methods specific to physical education and sports can provide an improvement in health, harmonious physical development, an individual optimal physical condition, along with training and development of mental skills necessary to integrate children into society. N2 - Research is scarce in relation to using social-cognitive theory inclusive of social-cognitive, affective and environmental constructs to predict physical activity (PA) and fitness with hearing impaired (HI) children. Hence, the purpose of our investigation was to evaluate the ability of social cognitive variables (e.g., self-efficacy and social support), environmental (i.e., time outside) and affective constructs (e.g., physical activity enjoyment) to predict PA. Children from the Czech Republic and the USA (N = 64, M age = 14.1) with hearing impairments completed questionnaires assessing predictor variables and PA. Using multiple regression analyses we accounted for 29% of the variance in PA. Based on standardized beta-weights, the best predictors of PA were gender, country, and a block of social-cognitive constructs. Compared to males and females from the

Czech Republic and to females in the USA, American males receiving social support from their friends and who enjoyed physical education were the children most likely to be physically active. Future research examining environmental influences more fully (e.g., school settings, after school programs) both within the USA and cross-culturally and adult influences beyond parents (e.g., teachers, coaches) are encouraged. N2 - The author reflects on the rationale of active participation in sport and outdoors which is fundamentally a value-based attitude absorbed from strong influences. He indicated that family not school or clubs facilitates the strongest, most sustained outdoor experiences that children can ever get. He noted that parents and grandparents send children to schools with outdoor ethos and provide outdoor opportunities. A noted challenge to outdoor educators is how to reach less advantaged families

N2 - In 2001, the Welsh Assembly Government announced proposals for a Foundation Phase for children aged three to seven years. The Foundation Phase framework promotes a play-based approach to children's learning in both indoor and outdoor contexts and places children's wellbeing and their personal and social development at its core. While the framework is currently being piloted across Wales, full implementation will not take place until 2010; for many schools, then, this is a time of transition. This paper discusses the findings of a research project that aimed to

document the current use of the outdoors by a group of early years teachers working in South Wales. Drawing on data from interviews and observations conducted in four schools, it is suggested that the teachers missed many of the opportunities afforded by the outdoor environment to enhance children's learning. The paper considers the reasons why this might be the case and comments on the distinction, apparent in two schools, between what was seen as 'normal' and 'special' outdoor activity.

N2 - This article reports on a study in which eight Foundation Phase teachers were supported in exploring Reggio-inspired projects in the outdoor environments of their settings. The study found that the teachers did adopt more child-initiated/centred approaches although it is maintained that in part this was related to the outdoor context in which the explorations took place. However, supporting such approaches was not easy for the teachers while many did not make regular use of their outdoor spaces. It appeared that 'real work' was seen to take place within classrooms and was focused on the learning of subject content.

N2 - Investigated how mentally handicapped adults spend their leisure time. Parents or care-givers of mentally handicapped adults, living at home, were interviewed as to how their son or daughter spent their leisure time. Findings showed that these handicapped adults lead a sheltered existence within the community. Activities were passive and solitary in nature. Nearly half of the sample did not take part in any activity outside of the family, only one third took part in any community activity and only one fifth had non-handicapped friends. Parents seemed willing for this leisure pattern to continue and few had suggestions for different activities. Parents

believed their children were not interested in other activities and felt recreational activities should be well supervised

N2 - OBJECTIVES: To characterize prospective agricultural injury experience among rural California Central Valley public high school students enrolled in agricultural sciences curriculum. METHODS: The University of California, Davis Youth Agricultural Injury Study (UCD-YAIS) examined prospective farm-work injury among

students from 10 California Central Valley public high schools. RESULTS: Of eligible subjects, 882 (62.5%) completed at least one annual follow-up survey. Of these, 489 reported farm work in the previous year, including 40 (8.2%) with at least one farm work-related injury. Fractures were the most common injury, especially among girls. Girls were more likely to suffer animal-related injury and boys injury from motor vehicles, machinery, or tool use. Prospective injury risk was strongly associated with prior-year farm injury (OR 8.53; 95% CI 4.02, 18.1) and farm work hours. After adjustment for farm work hours, grade level, and sex, risk was significantly associated with machinery operation, applying chemicals, number of hazardous tasks performed, riding motorcycles or mopeds, riding in back of an uncovered pick-up truck, and smoking. Risky attitude toward farm safety was associated prospectively with injury in stepwise fashion. CONCLUSIONS: Adolescents are at risk for serious farm-work injuries. Although limitations on hazardous tasks and farm work hours are likely to be the most efficacious means for reducing injury, education will play an important role. Education should include inculcating safety-related attitudes and habits and focus on hazardous tasks, such as those involving animals (for girls) and motor vehicles and machinery (for boys), especially among youth with prior farm injury

N2 - An investigation was initiated to determine if challenge/initiative games, conducted in an existing recreation setting for one hour daily, could be an effective treatment to enhance the self-concept of abused children living in a residential care facility. Over 28 consecutive days, a treatment group of 18 abused children received one hour of challenge/initiative games ("New," cooperative, or adventure games inclusive of a debriefing segment). A control group of 20 abused children participated for one hour daily in a traditional recreational (playground, diversionary, or competitive) games program. The results indicated that challenge/initiative games significantly enhanced four out of six components of self-concept in abused children, as measured by the Piers-Harris children's Self Concept Scale. Based on the results of this study, recreation professionals should consider incorporating challenge/initiative games as a part of their structured programs.(JLR)

N2 - Determines and compares the socio-economic background parental occupations, incomes, type of education) of white male athletes participating in four sports (football, basketball, wrestling, gymnastics) at the Pennsylvania State University. Hypotheses were 1) differences in socio-economic levels are characteristic of persons engaging in various types of sports, and 2) individuals who participate in contact or combative type sports, such as football and wrestling, are more likely to have been brought up in a lower social setting than those athletes who participate primarily in non-combative sports. Data partially supported hypothesis (1) while no support was found for hypothesis (2). Football players were characterized by socio-economic factors which are not typical of other athletes: formal schooling of parents, a higher proportion of mothers working outside the home, and a larger number of children in the family

VL - 31

IS - 4

N2 - Physical activity is important for children's development and their current and future health; national recommendations are for them to engage in at least 60 minutes of moderate to vigorous physical activity daily. Most of children's physical activity occurs outside of school hours; thus, access to and the quality of community recreation facilities and programming are particularly relevant. Researchers have identified strong links among socioeconomic disparities, physical inactivity, and poor health, but a limited number of studies have examined how access to community recreation facilities and physical activity programming are affected by local socioeconomic conditions. In many low-income communities, park and recreation facilities may be the only place for children to be physically active outside of school; thus, it is important to understand the connection between community environmental characteristics and child use of facilities. We were interested in determining whether the characteristics of community recreation center environments would be associated with neighborhood income and children's use of the centers. To do this we designed a study to identify whether neighborhood income disparities were associated with recreation center environmental characteristics and whether those characteristics were associated with young children's use of the center. We believed that findings to these questions could inform policy decisions within recreation centers and recreation departments to improve equity, facility use, and levels of physical activity. Thirty community recreation centers and 541 nearby families with children aged 5-8 years in five cities in Southern California participated in the study. To generate data we used multiple research instrumentation including (a) a structured physical activity survey of program offerings and barriers to children's participation in physical activity at the center [completed by recreation center supervisors], (b) direct observation of the presence and condition of recreation center facilities and amenities by trained assessors, and (c) a parent questionnaire on child use of the center. Results indicated that the condition of the community center facilities and amenities, but not their number, was positively related to neighborhood income ($p < .05$). As well, the number of cost-free, but not total, youth physical activity programs was inversely associated with neighborhood income ($p < .05$). Parent's report of their children using centers was positively associated with the number of amenities observed there ($p < .05$). The results suggest that policy makers and community recreation center staff should consider both neighborhood economic issues and environmental characteristics in their efforts to promote children's physical activity at recreation centers. N2 - The article reports on the playground renovations being carried out by the Playground Task Force comprising various representative organizations from Baltimore, Maryland, to provide safe playgrounds to children in the state. The task force recommended the development of a city-wide playground network. Elementary schools would have playground areas, which included structures and spaces that encouraged interaction with nature. The second network of playgrounds would be established in parks to provide clusters of outdoor. The task force was committed to competing for grants and raising public and private funds from city, state, local businesses and non-profit foundations

N2 - This article presents an interview with football player Randy McMichael, tight end with the Miami Dolphins. What was your welcome-to-the-NFL moment? When I got that phone call on draft day in '02, it was real exciting, but it didn't really hit me until I got to the Fort Lauderdale airport. Favorite off-day activity? I buy new clothes for me and my two kids, and I try to keep everybody clean. If I weren't in the NFL, I'd be... A kindergarten teacher. You've got to mold children when they're young, because when they get to high school, they get a little out of control. McMichael, the Dolphins' top pass catcher, had four receptions for 62 yards versus the Pats. Week 6 has been good for McMichael: In '02 he had a team-high five catches

JA - American Journal on Addictions

VL - 19

IS - 4

N2 - We are very pleased that The American Journal on Addictions (AJA) has committed to continuing to publish all abstracts from poster presentations made at the 2009 annual meeting of the American Academy of Addiction Psychiatry (AAAP). Scientific presentations made at the meeting play a vital and important role in the content of the meeting, and AAAP has been committed to fostering this aspect of the program. Prior to the

2005 meeting, AJA published a small number of abstracts based upon ratings made by members of the Research Committee as a means for acknowledging the work presented. After discussion, the Board of Directors recommended publishing all abstracts from poster presentations, and recent changes in the Journal and consensus by the Board have resulted in this new initiative. By publishing these abstracts, AAAP completes what may be viewed as a three-step process. The first step is the submission of abstracts for a poster presentation at the meeting; these abstracts undergo peer review and critique by the Program Committee, and those that do not fulfill a minimal standard of quality are not accepted. The second step is then the actual presentation at the meeting. This new, final step is the publication of the abstract in a citable journal that is well established and respected in the field of addictions. Our hope is that the opportunity to have an abstract published in the Journal will capture the attention of, and be attractive to, researchers in the field. The AAAP annual meeting provides a unique opportunity for researchers and clinicians to interact, and the AAAP and AJA are taking this step in an effort to reach out to members of the research community who may not traditionally attend and present at the meeting. Other steps taken by AAAP, such as major presentations at the meeting centered on NIDA's Clinical Trials Network (CTN), also seek to capitalize upon this unique opportunity for the research and treatment communities to interact and learn from each other. It is the intent of AAAP and AJA that publication of all poster abstracts will occur following annual meetings into the future. We hope you will consider submitting a presentation for the 2010 annual meeting. The process is simple, the meeting is collegial and enjoyable, and there is now the additional bonus of a citable reference for your work. Finally, congratulations to the authors of these abstracts.

Poster 1: Buprenorphine-Medication Assisted Treatment: A Retrospective Analysis of Health Plan Data Charles Ruetsch, PhD, Health Analytics LLC, Columbia, Maryland; J Tkacz
Background/Objective: Buprenorphine-medication assisted therapy (B-MAT) is an effective treatment for opioid dependence (OD), but its cost benefit is unclear. This study estimated cost benefit of B-MAT from the payor perspective. **Methods:** A pre-post case matched time series analysis of 2 groups (1. B-MAT fill and, 2. no B-MAT fills) were analyzed over time. Data were claims (Q4 2005 to Q3 2008) from a large MCO of members with a diagnosis of OD. A within subjects Poisson model was used to regress patient characteristics onto six service utilization count measures and a within subjects MANCOVA was used to analyze service cost measures. **Results:** After controlling for demographics, Medicaid status, and health status, Group 1 had more Rx fills (5.21) and physician and outpatient visits (.88), but fewer hospital days (1.46) and ER visits (.22; p 's < .05). Group 1 had higher Rx (\$1,208) and physician and outpatient costs (\$160), but lower inpatient hospital costs (\$1,986; p 's < .05). Overall, Group 1 had lower total healthcare costs (\$11,200, p < .001). Utilization of costly services and costs decreased over time and the interaction terms indicate that B-MAT patients drive most of the decreases. **Conclusions:** Though B-MAT patients incur higher pharmacy and office visit costs, they use fewer expensive health care services in other areas, resulting in an overall positive cost-benefit conclusion. Further, the longer that patients are on B-MAT the lower their cost is overall compared to non-B-MAT patients. **Source of Funding:** Reckitt Benckiser Pharmaceuticals.

Poster 2: Compliance with Buprenorphine- Medication Assisted Treatment Decreases Drug Use among Opioid Addicts Joseph Tkacz, MS, Health Analytics LLC, Columbia, Maryland; C Ruetsch
Background/Objective: Among those who are opioid dependent (OD), there is also a risk for poly-substance abuse. Follow-up substance abuse was examined on a national sample of OD patients during treatment with buprenorphine-medication assisted therapy (B-MAT). **Methods:** Subjects ($N = 1,426$) were new B-MAT patients who were randomly assigned to an intervention arm (B-MAT + telephonic patient support medication compliance program) or control arm (B-MAT alone) as part of a larger RCT. Measures included the Addiction Severity Index collected at baseline, 1, 2, 3, and 6 months. Difference in use of a variety of substances at 6 months was compared between subjects who were compliant (C) with B-MAT and subjects who were noncompliant (NC). Compliance was defined as taking medication on at least 22 of the previous 28 days. Chi-square tests of equality of proportions were used to compare groups. **Results:** Compared to C subjects, NC subjects were significantly more likely to use: alcohol (44% vs. 33%), heroin (11% vs. 3%), methadone (5% vs. 1%), other opiates (22% vs. 7%), cocaine (6% vs. 2%), and cannabis (23% vs. 15%); p 's < .05. **Conclusions:** Results indicate that, in addition to less opioid use, C Ss used additional licit and illicit substances less often than did NC Ss. These results are particularly important given the number of OD patients who abuse multiple substances, and the high costs associated with drug dependence (eg, treatment, prison, crime, etc.). Future studies should compare the effectiveness of other treatment modalities on subsequent drug use patterns in opioid-dependent patients. **Source of Funding:** Reckitt Benckiser Pharmaceuticals.

Poster 3: Predictors of Buprenorphine-Medication Assisted Treatment Compliance among Opioid-Dependent Patients: Results at Month Six Charles Ruetsch, PhD, Health Analytics LLC, Columbia, Maryland; J Tkacz
Background/Objective: Compliance with buprenorphine medication assisted therapy (B-MAT) drives early treatment outcomes among opioid-dependent (OD) patients. This study examines the relationship between patient behavior, participation in a compliance program, and 3-month treatment compliance. **Methods:** Treatment (B-MAT) seeking patients (N

= 1,426), were randomly assigned to an intervention group (B-MAT plus patient support program) or control group (B-MAT as usual). Measures included the Addiction Severity Index and Treatment Services Review collected at baseline, 1, 2, 3, and 6 months. Chi-square tests of equality of proportions were used to compare compliance between groups at each measurement period. Month six compliance was regressed onto group, demographic indicators, and baseline indicators. Subjects who were assigned to the intervention, but did not choose to participate, were excluded from analyses. Results: Subjects assigned to the intervention were significantly more likely to be compliant with B-MAT at all 4 follow-up measurement periods (months 1, 2, 3, and 6; p 's < .001). Baseline heroin and barbiturate use, the number of days receiving treatment for psychological problems, and the number of days experiencing medical problems were significant inverse predictors of B-MAT compliance. Older subjects who were paid for more days of work were more likely to be compliant with B-MAT. Conclusions: Baseline drug use, medical and psychiatric issues, and a variety of demographic indicators were all predictive of B-MAT compliance at month 6. Future research should focus on developing methods that allow or facilitate application of compliance programs, such as Here-ToHelp[®], among these more vulnerable populations. Source of Funding: Reckitt Benckiser Pharmaceuticals. Poster 4: Differences in Opioid Dependence Severity by Health Insurance Ameliorated by Month Six of Buprenorphine Treatment Charles Ruetsch, PhD, Health Analytics LLC, Columbia, Maryland; J Tkacz Background/Objective: Few studies have examined the effect of patient insurance coverage on outcomes among opioid-dependent (OD) patients in buprenorphine-medication assisted therapy (B-MAT). Vital to payors, both commercial and government, the purpose of this study was to understand differences in treatment outcomes between commercially insured B-MAT patients and those with public sector coverage (ie, Medicare or Medicaid) or no insurance coverage. Methods: Subjects (N = 1,426) were new B-MAT patients who were randomly assigned to an intervention arm (B-MAT + telephonic patient support medication compliance program) or control arm (B-MAT alone) as part of a larger RCT. Measures included the Addiction Severity Index collected at baseline, 1, 2, 3, and 6 months. Results: At baseline, subjects with Medicaid/Medicare or no coverage (n = 606) had significantly higher legal, psychiatric, and employment composite scores, indicative of greater problem severity in these areas, compared to the commercially insured (p 's < .05). The commercially insured group had a significantly higher alcohol composite score (p < .05). By month 6, there were no longer any differences between the two groups on the legal and psychiatric composite scores, yet the differences on employment and alcohol composites remained. Conclusions: B-MAT appears to have a positive impact on many areas of the OD patient's life. Future research is needed to elucidate why only certain differences between insurance groups disappeared after 6 months of treatment while others remained, and to investigate whether the sequela of other types of substance abuse (eg, alcohol) differ based on one's health insurance type. Source of Funding: Reckitt Benckiser Pharmaceuticals. Poster 5: Cytochrome P450 Abnormalities in Patients Who Require High-Dose Opioids Forest Tennant, MD, Dr PH, Veract Intractable Pain Clinic, West Covina, California Background: For unclear reasons, some chronic pain patients require very high-dose opioid therapy to adequately control pain. Recently, it has become possible to test for some genetic cytochrome P450 enzyme abnormalities. Methods: Fifteen (15) chronic pain patients who required 100 mg or more of morphine equivalence a day to control pain were tested for one or both the cytochrome P450, 2C9 or 2D6, genotypes. Their opioid serum concentrations were determined approximately 1 hour after their usual opioid dosage. Results: One of 11 (9.0%) patients tested for genotype 2D6 was abnormal. This patient is of Asian extraction. Serum concentrations of oxycodone and its metabolite, oxymorphone, were undetectable 1 hour after dosing. Two (2) of 8 (25%) patients tested for 2C9 genotype were abnormal, and both had very high serum concentrations of fentanyl (8.1 and 16.4 mg/ml) 1 hour after dosing. All three patients with cytochrome P450 genotype abnormalities stated that opioids provided pain relief for a very short time, usually only 1 to 2 hours, after administration. Conclusions: This preliminary investigation shows that genetic, cytochrome P450 abnormalities exist, in at least some high-dose opioid patients, even though only two of many genotypes were tested here. Cytochrome P450 abnormalities may require high serum opioid concentrations to stimulate ('force') enzyme activity and/or the abnormality may result in ultrafast metabolism. High-dose opioid patients are often stigmatized as abusers or addicts, and this preliminary study compels further study and possibly a new clinical perception of these patients. Source of Funding: None. Poster 6: Outcomes of Chronic Pain Patients Treated with Opioids for Over 10 Years Forest Tennant, MD, Dr PH, Veract Intractable Pain Clinic, West Covina, California Background: Recent epidemiologic studies indicate that about 10 million Americans now take opioid drugs for pain control. This relatively recent and dramatic occurrence has had little outcome study. The author recently reported 24 Southern California chronic pain patients who were treated with opioids over 10 years and who had positive social, physical, and functional results. Methods: Physicians who have long-term opioid-treated pain patients were recruited by advertising in a trade journal for physicians. Once identified, physicians completed a questionnaire for each 10-year patient. Information consisted of opioid use, dosage, underlying cause of pain, length of opioid therapy, stability of dosage, complications, and functional

abilities. Results: To date 50 total patients from six geographic sites have been identified. The majority of patients have remained on a stable opioid dosage for long periods and maintain good function in activities of daily living including dressing, reading, work, care for family, attendance at social functions, driving a car, and ambulation without assistance. Conclusions: This survey study leaves out patients who may have experienced severe side effects or found opioids to be an impairment to normal activities of daily living and discontinued their use. Although the percentage of patients who fall in the 'poor outcome' category is unknown, it is clear that long-term opioid use is associated with a positive outcome in some chronic pain patients. Given the findings here, there is no obvious reason to discourage opioid use or encourage pain patients to cease opioids. Source of Funding: None. Poster 7: Implementation of an Electronic Information System to Enhance Practice at an Opioid Treatment Program Steven Kritz, MD, Addiction Research and Treatment Corporation, Brooklyn, New York; LS Brown, Jr, M Chu, R Zavala Background: Adoption of electronic health systems (EHS) is commonly discussed in healthcare reform, especially in addiction treatment. We report the design and pre-implementation quality and patient and staff satisfaction results of an integrated EHS in an outpatient opioid agonist treatment program, consisting of seven clinics and providing primary medical and HIV-related care for approximately 3,000 predominantly minority adults in New York City. Methods: Besides quality and satisfaction, three other aims (productivity, financial performance, and risk management) were in the parent study, using a pre-post, prospective comparative design. Quality measures included: (1) viral load assessment in hepatitis C virus (HCV) infected patients, and (2) timely assessment of patients' medical and addiction status at various intervals. Using an anonymous survey, patient and staff satisfaction were assessed. Associations were assessed with staff and patient variables. Results: HCV viral load was appropriately performed in 92% of cases; annual medical assessments were timely for 83% of cases; annual addiction assessments were timely at 30 days, 90 days, and annually for 81%, 46%, and 70% of cases, respectively. Seventy-four percent of patients were satisfied/very satisfied with their care, while 33% of clinicians and managers were satisfied/very satisfied with the pre-EHS system for providing care. Conclusions: These results provide insight into primary care and addiction treatment delivery in one large program and provide the basis of assessing the impact of an integrated EHS, further informing healthcare reform discussions. Source of Funding: This R01 study is funded by the National Institute on Drug Abuse: DA022030. Poster 8: Design of a Novel Relapse Prevention Videogame as an Adjunct to Treatment for Alcoholic Patients Marcia L Verduin, MD, University of Central Florida, Orlando, Florida and Orlando VA Medical Center, Orlando, Florida; S LaRowe, C Bowers, R Joyce, P Smith, H Myrick, J Salazar, B Stabile Background: Relapse prevention (RP) therapy is well supported in the treatment of alcoholism. However, current delivery of RP therapy provides little opportunity to practice skills in a safe, realistic environment. Innovative approaches are needed to develop alternative settings for RP skill practice and maintenance. Methods: Addiction specialists collaborating with serious games programmers developed an interactive videogame grounded in RP theory for alcoholics to play as an adjunct to standard treatment. The game is currently being evaluated in a randomized prospective clinical trial. Results: The game concept for 'Guardian Angel' is based on lifestyle management-type games. The group developed four minigames housed within an overarching core game. In the core game, patients go about their daily lives while managing emotions, cravings, finances, and relationships. During each 'day' of the game, patients must play one of the minigames-Route Planner (navigating home while avoiding potential triggers), Clean House (ridding their home of hidden alcohol and other triggers), Drink Refusal (practicing drink refusal skills), and Balance Out ('therapy' sessions to reinforce key RP skills). Feedback from focus groups has been uniformly positive. A laptop will be provided for attendees to play the game during the poster session. Conclusions: An interactive videogame based on RP theory may provide a motivating, safe, realistic environment for alcoholics to practice their RP skills, in addition to standard treatment. Preliminary focus groups indicate that patients find the videogame acceptable and engaging. A clinical trial is underway to determine the efficacy of the game as an adjunct to treatment. Source of Funding: Robert Wood Johnson Foundation. Poster 9: Cross-Cultural Adaptations and Physician Training Integrating Alcohol Interventions into Routine Tuberculosis Care in Tomsk, Russia Hilary Smith Connery, MD, PhD, McLean Hospital, Belmont, Massachusetts and Harvard Medical School, Boston, Massachusetts; V Livchits, A Shields, L McGrady, N Patrick, CS Lastimoso, A Grishkina, JE Hart, SS Shin, SF Greenfield Background: IMPACT (Integrated Management of Physician-delivered Alcohol Care for Tuberculosis patients) is a randomized controlled trial to assess the effectiveness of alcohol interventions as an integrated component of TB care provided to patients with co-occurring TB and alcohol use disorders (AUD) in Tomsk, Russia. We discuss cross-cultural adaptations and physician training to provide an alcohol brief counseling intervention (BCI) and medical management with naltrexone (NTX). Methods: Alcohol interventions were delivered monthly by TB physicians as part of a 6-month directly observed therapy, short-course ('DOTS') protocol for TB treatment. Patients with TB meeting CIDI-SAM criteria for AUD provided informed consent for random assignment to receive BCI, NTX, BCI + NTX, or TAU (treatment as usual) adjunct to DOTS. Eighteen TB

physicians were certified to perform all adjunct interventions through a series of trainings by a US-Russian multidisciplinary team using in-person and teleconferenced didactics, role-plays, feedback, and mock interviews. AUD interventions were audiotaped, translated, and reviewed weekly by a bilingual United States-Russian fidelity team consisting of expert AUD supervisors and trained bilingual coders and Russian supervisors. TB physicians received ongoing corrective feedback and training for adherence to each intervention. Results: Financial incentives and personalized training positively affected physician attitudes toward AUD intervention delivery and adherence to protocol. Cross-cultural challenges include linguistic adaptations, altering cultural norms of physician-patient dialogue, and limited referral support services for AUDs. Conclusions: Frequent dialogue and performance feedback with TB specialists by a multidisciplinary United States-Russian AUD training team resulted in cross-culturally acceptable and feasible AUD interventions integrated into TB care. Source of Funding: Supported in part by a grant from the National Institute on Alcohol Abuse and Alcoholism R01AA016318 (SS) and from the National Institute on Drug Abuse K24DA019855 (SFG). Poster 10: Ethics and Addiction: Moving Beyond Mistrust in Individual and Collective Care Relationship Aymeric Reyre, MD, Avicenne Hospital, Paris, France and WHO Collaborative Center for Ethics, Paris, France; O TaA_eb, JF Rouchon, G Broder, E Hirsch, MR Moro, T Baubet Background: Data from the literature as well as the daily care of addict patients stress the importance of pejorative representations they are carrying. These representations lead to a climate of mistrust responsible for major difficulties in establishing an authentic care relationship. Methods: Our phenomenological analysis of mistrust is based on Georges Devereux's complementarist epistemology. It allows us to link anthropological, philosophical, and clinical viewpoints and opens tracks for the medical person's ethical positioning. Results: The pragmatic approach based on the analysis of interactions in the economic field and on game theory, calls to bet on trust to maximize systemic efficiency. On the other hand, a philosophy of action lead to Michel Foucault's ethics of the 'Care of the Self': the medical staff, in an environment of mistrust, must develop a thinking and an aesthetic of its action. Finally, Paul Ricoeur and Hannah Arendt's moral philosophy calls for an ethics of mutual recognition and leads to rethinking the role of the promise in the care relationship. Conclusions: It is possible to remove the care relationship from the stranglehold of mistrust: (1) by taking the risk of trust, (2) by reflecting on our action in the field of care and exposing this action to the opinions of the others, (3) by using promise wisely, without limitation or excess, (4) by forming 'islets of trust' in our care institutions, spaces free from the need to promise, which could guarantee their democratic nature. Source of Funding: None. Poster 12: Maternal Cigarette Smoking and Substance Use Disorders during Pregnancy and Offspring Bipolar Disorder Timothy E Wilens, MD, Massachusetts General Hospital, Boston, Massachusetts; M Martelon, J Wozniak, M Monuteaux, M Evans, T Parcell, J Biederman Objectives: Recent work has suggested a positive relationship between prenatal exposure to cigarettes and substances (alcohol or illicit drugs) and offspring psychiatric disorders. No study to date, however, has primarily examined these exposures with offspring bipolar disorder (BPD). We looked to replicate previous work from our group that reported a positive association between maternal use of cigarettes during pregnancy and offspring BPD using a separate sample. Methods: As part of two family studies of BPD, 322 families, including 225 BPD subjects (mean age $A \pm SD$: 11.60 $A \pm 3.50$) and 97 controls (mean age $A \pm SD$: 13.70 $A \pm 2.10$), were comprehensively assessed with a structured psychiatric diagnostic interview for psychopathology and substance use. Maternal use of nicotine and substances during pregnancy were captured using two methods derived from structured psychiatric interviews. Results: BPD offspring were more likely to be exposed to prenatal maternal smoking than control offspring (odds ratio (95% CI) = 2.48 (1.15, 5.32)). However, this association lost significance when adjusted for comorbidity with conduct and attention deficit hyperactivity disorders (odds ratio (95% CI) = 1.17 (.47, 2.94)). There was no association between substance use disorders (SUD; including drug or alcohol abuse or dependence) during pregnancy and offspring BPD. There were notable differences in the clinical characteristics of youth with BPD exposed to prenatal maternal smoking and alcohol use disorders. Conclusions: We partially replicated previous findings showing that comorbid BPD is associated with maternal use of nicotine during pregnancy. Our results warrant further replication in larger, less comorbid, prospective samples. Source of Funding: NIH R01 DA12945 (TW), K24 DA016264 (TW), and NIH R01 MH066237 (JW). Poster 13: Does Conduct Disorder Mediate the Development of Substance Use Disorders in Adolescents with Bipolar Disorder? A Case-Control Family Study Timothy E Wilens, MD, Massachusetts General Hospital, Boston, Massachusetts; MK Martelon, MJP Kruesi, T Parcell, D Westerberg, M Schillinger, M Gignac, J Biederman Background: Recent work has highlighted important relationships among conduct disorder (CD), substance use disorders (SUD), and bipolar disorder (BPD) in youth. However because BPD and CD are frequently comorbid in the young, the impact of CD in mediating SUD in BPD youth remains unclear. Methods: A total of 105 adolescents with DSM-IV bipolar disorder (mean $A \pm SD$ = 13.6 $A \pm 2.50$ years) and 98 controls (13.7 $A \pm 2.10$ years) were comprehensively assessed with a structured psychiatric diagnostic interview for psychopathology and SUD. The study was conducted from January 2000 through December 2004. Results:

Among bipolar disorder youth, those with CD were more likely to report cigarette smoking and/or SUD than youth without CD. However, CD preceding SUD or cigarette smoking did not significantly increase the subsequent risk of SUD or cigarette smoking. Adolescents with bipolar disorder and CD were significantly more likely to manifest a combined alcohol plus drug use disorder compared to subjects with bipolar disorder without CD ($\chi^2 = 11.99, p < .001$). Conclusions: While bipolar disorder is a risk factor for SUD and cigarette smoking in a sample of adolescents with BPD, comorbidity with CD in adolescents, comorbidity with preexisting CD does not increase the risk for SUD. Further follow-up of this sample through the full risk of SUD into adulthood is necessary to confirm these findings. Source of Funding: National Institutes of Health grants RO1 DA12945 and K24 DA016264. Poster 14: Open Trial of Sustained Release Bupropion in Adults with ADHD plus Substance Use Disorders Timothy E Wilens, MD, Massachusetts General Hospital, Boston, Massachusetts; JB Prince, J Waxmonsky, R Doyle, T Spencer, MK Martelon, M Evans Objective: To evaluate the effectiveness and tolerability of bupropion in adults with Attention-Deficit/Hyperactivity Disorder (ADHD) and comorbid active Substance Use Disorders (SUD). Methods: This was a 6-week open trial of sustained-release (SR) bupropion in adults aged 18 to 55 years diagnosed with both ADHD and SUD. Bupropion-SR was initiated at 100 mg SR and increased weekly to a target dose of 200 mg SR twice daily. Subjects were assessed on multiple outcomes including ADHD, SUD, and adverse effects. All analyses were intent to treat, with last observation carried forward. Results: Thirty-two subjects were treated with bupropion, with 19 subjects completing the entire protocol (59%). At end point there were clinically significant reductions in the ADHD RS (34.1 \pm 8.2 to 19.4 \pm 11.4, $f^2 = .43$, $t = 6.49, p < 0.0001$) and the Clinical Global Impression (CGI) of ADHD severity (baseline = 5.0, endpoint = 3.8, $f^2 = .24$, $t = 6.16, p < 0.0001$). In contrast, there were clinically negligible effects on the self-report of substance use (p 's > 0.05) and on the overall CGI of SUD severity ($f^2 = .23$, $t = 4.95, p < 0.0001$). Conclusions: Results from this open trial suggest that in adults with ADHD and SUD, treatment with bupropion-SR is associated with clinically significant reductions in ADHD, but not SUD. Source of Funding: NIH K24DA016264, Departmental funds for clinical trial. Poster 15: Addiction Psychiatry Service: A Specialty Addiction Consultation-Liaison Service in an Academic Medical Center Joji Suzuki, MD, Brigham and Women's Hospital/Harvard Medical School, Boston, Massachusetts; J Kauffman, M Renaud, S Brenner, E Margetson, J Peteet, D Curtiss, A Fife Background: Substance use disorders contribute significantly to the morbidity and mortality of hospitalized medical patients. To better manage medical/surgical patients with substance use disorders in the general hospital setting, a specialized multidisciplinary addiction consultation-liaison team (Addiction Psychiatry Service) has been providing expert diagnostic, management, interventional, and referral services. Methods: Consultations received by the Addiction Psychiatry Service during the period of January 2008 through December 2008 were reviewed for demographic and clinical characteristics. The history, development, composition of the service, as well as the integration with the existing psychiatric consultation-liaison service were also examined. Results: A total of 996 patients were referred to Addiction Psychiatry Service in the year 2008, with the following demographic and clinical characteristics: mean age 51.6 (range 17-87), male 63.9%, ethnicity (White 47.7%, African-American 31.8%, Latino 20.5%), consulting service (medicine 56.8%, surgery 17.8%, ICU 15.1%, OB/GYN 6.2%, ED 2.1%, neurology 2.1%), reason for consultation (withdrawal management 61.3%, counseling/referral to treatment 44.9%, delirium 11.4%, pain vs. addiction 10.2%, transfer to detoxification treatment 5.1%), substances used (alcohol 59.1%, opioids 26.1%, cocaine 22.1%, cannabis 7.6%, benzodiazepines 3.6%, amphetamines .4%, barbiturates .4%), and referrals accepted by patient (outpatient individual 37.1%, intensive outpatient 23.6%, methadone maintenance 11.2%, outpatient dual diagnosis 7.9%, inpatient detoxification 5.6%, residential and partial hospital 3.4%). Conclusions: Hospitalized patients in an academic medical setting have high rates of substance use disorders. A multidisciplinary addiction consultation-liaison service may be a useful model for supporting the medical/surgical staff to better care for patients with substance use disorders. Source of Funding: None. Poster 16: Ethnographic Survey of Hispanic Adolescent Heroin Users in Dallas County Carlos F Tirado, MD, MPH, University of Texas Southwestern Medical Center, Dallas, Texas; C Coton, KR Williams, JC Maxwell, B Adinoff Background: Since 2005, Dallas County has seen an unprecedented rise in the rate of intranasal and intravenous heroin use among Hispanic children and adolescents. There are documented cases of children as young as nine seeking opioid detoxification and there have been at least 26 heroin-related deaths in children under age 18 since 2005. Statewide, Hispanics represent the largest proportion of heroin users entering treatment under age 25. Methods: Seventy-two ($N = 72$) consecutive English speaking/reading respondents of Mexican and Mexican-American origin between age 13 and 18 with a primary diagnosis of heroin dependence were recruited from three participating drug rehab programs over a 7-month period. Subjects participated in a 90-minute self-report and structured interview session to obtain data on intranasal heroin use patterns, psychiatric comorbidity, high-risk sexual behaviors, and cultural and familial factors related to level of acculturation and intergenerational drug and alcohol use. Results: Sixty percent of respondents were female.

Roughly one-third of respondents were born in Mexico versus 85% of parents reported as Mexican born. Average age at interview was 15.7 years with average age of first use of heroin 13.5 years and age of initiation of daily use 14.1 years. One in six respondents had used heroin IV and one in four reported at least one certain heroin-related overdose. Nearly half (46%) of respondents reported they first tried heroin on school grounds. A third of respondents reported greater than four lifetime sexual partners. Fifty-one percent reported sometimes or rarely/never using a condom. Seventy-four percent of respondents reported at least one prior 30+ day residential treatment episode. One in five reported prior psychiatric treatment for depression. The most common secondary drugs of abuse were marijuana (46%), cocaine (22%), and alcohol (21%). One in six reported some form of physical, sexual, or psychological trauma. Forty-percent reported having used alcohol to the point of intoxication with a first or second degree relative and 46% reported using drugs to get high with a first- or second-degree relative. Preliminary hypothesis testing revealed no statistically significant relationship between level of acculturation and IV drug use or frequency of treatment entry. Conclusions: There are clear and concerning trends signaling the disproportionate and increasing use of intranasal heroin among young Hispanics in North Texas. Adolescent Hispanics who are in treatment centers have well-established heroin dependence and problem use of several other drugs. The use of heroin in area schools is troubling, but provides opportunity for assertive preventive measures. The presence of a psychiatri

N2 - Epileptic encephalopathy is defined as a condition where the epileptic activity itself may contribute to the severe neurological and cognitive impairment seen, over and above that which would be expected from the underlying pathology alone. The epilepsy syndromes at high risk of this are a disparate group of conditions characterized by epileptic seizures that are difficult to treat and developmental delay. In this review, we discuss the ongoing debate regarding the significance of inter-ictal discharges and the impact of the seizures themselves on the cognitive delay or regression that is a common feature of these syndromes. The syndromes also differ in many ways and we provide a summary of the key features of the earlyonset epileptic encephalopathies including Ohtahara and West syndromes in addition to later childhood-onset syndromes such as Lennox Gastaut and Doose syndromes. An understanding of the various severe epilepsy syndromes is vital to understanding the rationale for treatment. For example, the resolution of hypsarrhythmia in West syndrome is associated with an improvement in cognitive outcome and drives treatment choice, but the same cannot be applied to frequent inter-ictal discharges in Lennox Gastaut syndrome. We discuss the evidence base for treatment where it is available and describe current practice where it is not. For example, in West syndrome there is some evidence for preference of hormonal treatments over vigabatrin, although the choice and duration of hormonal treatment remains unclear. We describe the use of conventional and newer anti-epileptic medications in the various

syndromes and discuss which medications should be avoided. Older possibly forgotten treatments such as salthiame and potassium bromide also have a role in the severe epilepsies of childhood. We discuss hormonal treatment with particular focus on the treatment of West syndrome, continuous spike wave in slow wave sleep (CSWS)/electrical status epilepticus in slow wave sleep (ESES) and Landau Kleffner syndrome. The role of the ketogenic diet has in recent years come to the fore of the management of these severe epilepsies and we describe successful use in myoclonic astatic epilepsy, Lennox Gastaut syndrome and Dravet syndrome. It is important that resective epilepsy surgery is not ignored in the management of these children, particularly those with hemipathology who may present with ESES and respond well to hemispheric disconnection. Adjunctive and symptomatic surgical treatments such as vagal nerve stimulation and corpus callosotomy may improve seizure burden. Finally, it is vital that the identification and treatment of developmental, behavioural and psychiatric co-morbidities are not neglected and that a rational, holistic approach is taken to the management of epileptic encephalopathies. N2 - School and community based physical activity programs aim to increase the involvement of children through providing more comprehensive and extended access to opportunities to be active. This research project was initially devised to compare physical activity levels and practices of children at an 'Active Australia' school and at a school utilizing a school based Health and Physical Education program. The framework involved primary school children in grades 4-7 (girls, n=259; boys, n=232) wearing a pedometer and completing a physical activity survey each day for four days. The results of a One-way ANOVA indicated the daily step means of two schools differed significantly [F(1,489)=7.36, p=.007]. Irrespective of school, boys' means were significantly higher than girls [F(1,489)=53.04, p<.0001]. Sport was the most frequent outside of school activity cited. A significant difference for boys [F(3,284)=8.81, p<.0001] and girls [F(3,318)=13.92, p<.0001] respectively was found for mode of transport to school. Children who walked to school averaged significantly more steps per day than those who travelled by bus or car. Chi-square indicated that those who walked to school were also significantly more likely to play sport. The Effect Size for walking versus all other forms of transport to school was 12.3, which is very large

N2 - The main aim of this study was to assess potential differences between groups of pre-school children meeting and not meeting health recommendations for physical activity (PA) from the aspect of so called indicators of physical activity (active energy expenditure, number of steps). The number of steps was measured by Yamax Digi-Walker SW-200 pedometers (Yamax Corporation, Tokyo, Japan) and the active energy expenditure was measured by Caltrac (Muscle Dynamics Fitness Network, Torrance, California) accelerometers. Evaluation of PA from the aspect of so called health criteria was realized following the criteria of Frámel, Novosad and Svozil (1999), who recommend values of so called health criteria of PA. Meeting these criteria, it is possible to suppose that PA positively affects the healthy development of an individual. The sample consisted of 200 pre-school children. Forty nine of these children (30 boys and 19 girls) were labeled as group A (children who did not meet the recommended values at least in one of the health criteria of PA). Group B (children who met the recommended values at least in one of the mentioned criteria of PA) consisted of 151 children (74 boys and 77 girls). The Mann-Whitney U test was used to test the statistical significance of possible differences between groups A and B and also between boys and girls within these groups as well. In all monitored parts of a week, as well as in both monitored parts of a day, a significant difference ($p < .001$) was found between groups A and B in both indicators of PA. Regarding these variables, the smallest differences ($p < .02$) were observed within the time spent at school. Our results confirm that a stay at kindergarten belongs among the relevant parts of a day from the aspect of children's physical activity in the sense of a very "problematic" part of a day, when the values of active energy expenditure and steps are decreased almost by 50% even in children physically active outside the school. On the other hand, a kindergarten is a proper place

for children with hypokinetic behavior, who can be activated by an adequate incidence of school physical regimen. ABSTRACT FROM AUTHOR

N2 - Ecotherapy is an intervention that improves mental and physical health and wellbeing by supporting people to be active outdoors: doing gardening, food growing or environmental conservation work.

This report shows how ecotherapy is being used to help people maintain good mental wellbeing - and how the same intervention is increasingly being used as treatment to help people recover from a range of mental health problems.

N2 - The objective of the dissertation was to differentiate the influence of strength changes and, separately, of the motorial frequency on the energetical cost of physical work. The examinations were carried out on the group of twenty one 12-14 year old boys who had practiced swimming for 3-5 years. They underwent a 6 min effort test on a Jaeger bicycle cycloergometer. In all the tests, during a rest, work and restitution, the following factor was measured of oxygen inhaled (VO₂). In all cases examined in my work differences essential for statistics characterize the changes of energetical cost more significantly during the work with a small or even without outside resistance, than during efforts with greater outside resistance

N2 - Purpose. Lack of physical activity is associated with increased risk of overweight and cardiovascular disease, conditions associated with lower socioeconomic status (SES). Associations between activity levels of urban youth and limited access to safe recreation areas in their neighborhoods of residence were investigated. Design. Analyses of data from the Project on Human Development in Chicago Neighborhoods, a multilevel longitudinal study of families and communities, are reported. Setting. Chicago, Illinois. Subjects. Individual-level data were obtained from 1378 youth 11 to 16 years old and caregivers living in 80 neighborhood clusters. Neighborhood-level data were collected from 8782 community residents and videotapes of 15,141 block faces. Measures. Parental estimates of hours youth spent in recreational programming were used to estimate physical activity. A scale of residents' assessment of neighborhood safety for children's play was created; disorder measures came from videotaped observations. Results. Physical activity averaged 2.7 hours/week (SD = 5.0), varying significantly across neighborhoods. Using hierarchical linear regression, SES, age, and male gender, but

not body mass index, were independently associated with physical activity. Lower neighborhood safety and social disorder were significantly associated with less activity, controlling for demographics. Conclusions. One mechanism for reduced physical activity among youth may be the influence of unsafe neighborhoods. Neighborhood interventions to increase safety and reduce disorder may be efficacious in increasing physical activity, thereby reducing risk of overweight and cardiovascular disease. CY - New York;

PB - Macfadden Book Co.

N2 - The authors describe the events that lead to forty Italian physical culture student instructors being brought to the United States for a six-month study program under physical culturist, Bernarr Macfadden. In 1930 Macfadden went to Europe to study health conditions as a member of US President Hoover's Committee on Child Health and Welfare. In Italy he met with Signor Renato Ricci, Italian Under-Secretary of State for Physical Education who described and showed Macfadden physical training facilities, classes, and programs. He also met with Benito Mussolini, and after many conferences with Ricci and others, he invited Mussolini to send 40 students to the United States to work with him and learn Macfadden's physical fitness program. Other chapters describe the introduction of the students to New York City, and the various cultural activities shown to them upon their arrival. The focus of the physical training program included exercises which strengthened the spine and muscles, the participation in sports of basketball, baseball, tennis, wrestling, boxing and track, and a diet of "eating only a sufficient amount of good food to nourish the body and no more." During the experiment, the diet included some fruit and meat, with emphasis on freshly ground wheat, rye and corn. The latter portion of the book has text and photographs of the exercises used and the forty individual records of each man's physique measurements at the beginning and the end of the training program. Also included in the individual records is the outcome of tests at the beginning and end of the program including, two hand press, back lift, arm pull ups, abdominal lift, deep knee bend, 100 yard dash, one mile run

N2 - The purpose of this study was to measure the effectiveness of integrated anatomy and physiology lessons on fifth grade students taught in their physical education class. Knowledge base, attitudes, and participation level changes were the targeted areas during the study. This quasi-experimental study looked at the changes that took place in the control group and the experimental group over the eight week study. The evaluations of this project were obtained through analyzing the test scores of the control and experimental groups; a pre-test and a post-test were administered. There was an attitude survey to identify changes in attitudes before and after the lessons were taught. Other evaluations came from teacher observations, recorded in journal entries, and from looking at student journal entries throughout the unit. The results showed a dramatic increase in the content knowledge of the experimental group. The control group showed little improvement; very few made dramatic increases in scores. Another very noticeable difference was in the attitude and behavior of the two classes. The control group, who were exposed only to the standard physical education curriculum, were very negative about the test and general information, even when being covered in the class. They could not connect the information with activities, because there was never enough taught to them. The experimental group were eager to take the post-test and had confidence in what they were being tested on. They referred to the information and used the terms in general conversation outside of the classes where the material was covered. The things they were learning had a purpose. The learning became part of their physical education class and connections between the material and physical activities were made by many students

N2 - OBJECTIVES: To draw on empirical findings of the psychological factors that cause elementary-school children to engage in risky play behaviors that can lead to injury, with the aim of developing an integrative model that can support intervention-program planning. METHODS: An extensive review of literature on this topic was conducted, determinants of risk taking for which there was empirical support were identified, and results were synthesized to create an integrative model of children's risk taking. RESULTS: Research on risk taking in children is limited, but the findings support the importance of examining child, family and socio-environmental factors to understand children's risk-taking behaviors. CONCLUSIONS: Development of a model outlining the determinants of risk behaviors can provide a foundation for initiatives that aim to reduce such behaviors and prevent childhood injuries

N2 - The purpose of this study was to determine the effects of a 12-week interval fitness training program on pre-pubertal, elite-level male soccer players. Thirteen 10 and 11 year old soccer players served as the experimental group while 11 age-matched players from a team in the same league acted as controls. All subjects

were tested prior to and following a 12-week training programme. The tests included: an anaerobic speed test (SAT) in which subjects performed a treadmill run at 7 m.p.h. and an 18 percent grade, until volitional fatigue; 7 repeats of 40 yds. every 20 seconds, and a timed 1-mile endurance run. The 12 week anaerobic training programme for the experimental group consisted of 4 different high speed activities performed over 15-20 minutes 3 times weekly at a work: rest ratio of between 1:2 and 1:3. Analysis of variance for a 2 by 2 (Exp-Count, Pre-Post) factorial design revealed a significant Groups by Pre-Post interaction on all variables except the 40 yard speed measure. It was concluded that the 12-week interval training programme significantly increased the anaerobic and aerobic fitness of pre-pubertal, elite-level male soccer players (HERACLES) Etude des effets d' un programme d' entraînement d' interval training, axe sur le developpement du metabolisme anaerobie lactique et alactique, sur les capacites aerobie et anaerobie d' enfants ages de 10 a 11 ans, joueurs de football de competition; les tests anaerobie consistent en une epreuve de vitesse sur tapis roulant (7 mph) avec pente de 18 % et une course de vitesse de 40 yards; le test aerobie en course d' endurance de 1 mile

N2 - The investigation was performed in order to establish the effect of the social status on taking up kinesiological activities. The data obtained in the questionnaire for assessment of the social status and scales for establishing the intensity of kinesiological activity were processed by means of the factor and regression analysis. The results show: (1) there are relatively low but statistically significant relations between the social status and taking up kinesiological activities. (2) the greatest positive effect on taking up kinesiological activities is the dimension named as the socio-political status, to a certain extent also the so called life style, political orientation and the basic residential status. The negative effect, although statistically smaller is the educational status of the mother and the basic economic status. Besides the statistical reasons there are some objective ones of the obtained results. A greater participation of women in sports is related with the status of the parents in society and at work, but also with the nature of influence of the social environment on the individual, particularly in childhood, as well as with the political orientation and a higher standard of living, while the educational status of the mother is on the margins of positive social power, at least in the case of women who participated in this investigation. A few hypotheses have been postulated for these results that should be checked since they differ from some investigations carried out so far

VL - 16

N2 - Objective Determining the knowledge and attitudes towards injury prevention/safety promotion (IPSP) for pre-school children among Croatian parents of newborn babies. Participants 351 parents (285 mothers, 66 fathers). Methods Anonymous self-administered questionnaire containing demographic items and items on knowledge and attitudes regarding IPSP for pre-school children. Main Outcome Measures Knowledge and attitudes towards IPSP for pre-school children. Results The answers the parents gave varied greatly for the 40 questions asked. For example: almost all parents showed correct attitudes and knowledge regarding leaving an infant unsupervised in water (99.3% mothers, 100% fathers answered correctly), having pre-school child sitting at the front seat if held by an adult (99.3% mothers, 100% fathers answered correctly) and playground safety (98.2% mothers, 100% fathers answered correctly). An adequate number (73.9% mothers, 76.9% fathers) chose the correct answer on the question related to the storage of chemicals and a similar number (77.5% mothers,

65.6% fathers) said they indeed did store them in the proper manner. It was shocking to see how low they scored on some very important questions: 35.9% mothers and 23.1% fathers recognise child-walkers as dangerous and only 12.7 fathers and 20.0% mothers knew that the safest position for sleeping for an infant is on the back. Conclusions Parents play a crucial role in injury prevention/safety promotion as models for their children, their educators and persons in the position to intervene within environment making it safer. Therein lays the importance of their sufficient knowledge and positive attitudes. Our results show a need for further public health education of the parents. ABSTRACT FROM PUBLISHER

N2 - The validity of the Caltrac movement sensor for use with preschool children was assessed. Caltrac-derived values for energy expenditure were compared with those derived via laborious coding of direct observation that involved classification of the child's videotaped activity every other 5 seconds for an hour in the day-care center or on the playground. Both Caltrac and direct observation values were expressed in kilocalories. The subjects were 20 children with a mean age of 35 months. The correlation coefficient for the total of indoor and outdoor activity was $r=.62$ (p is less than .01). The separate correlations for indoor and outdoor activity were $r=.56$ (p is less than .05) and $r=.48$ (p is less than .05), respectively. However, when the children's weight, height, age, and sex were factored out of both the Caltrac and direct observation scores, the correlations fell to $r=.25$ (n.s.), $r=.47$ (p is less than .05), and $r=.16$ (n.s.) for the total, indoor and outdoor activity, respectively. Thus the Caltrac seemed to record indoor activity (mainly walking) more accurately than it recorded the more varied playground movements, casting doubt on its value as a means of measuring physical activity in children 2-3 years of age

N2 - This study explored whether children differentiate between their physical capabilities at play activities, informal recreational activities, and formal competitive activities. Harter's (11) six-item Athletic Competence subscale from the Self-Perception Profile for Children was administered to 578 children and adolescents (ages 7-15 years). The items were modified to refer to three different categories of physical activity instead of sport or outdoor games as used in the original subscale. Repeated measures ANOVA revealed that children differentiated between the three categories of physical activity, and that the competitive sport category was their area of lowest perceived competence. Males had higher levels of perceived competence than females in each category

N2 - It's not just baseball players who know that the third strike is a bitter pill. Michael Pittman, 27, the Buccaneers' running back you last saw celebrating his 124-yard performance in the Super Bowl, may have a long wait before he plays his next down. Pittman was arrested on May 31 outside his Phoenix home and charged with two counts of felony assault on his wife, Melissa, who on Mother's Day had given birth to their second child, a daughter. According to police reports Pittman and Melissa, who have been married for four years, began arguing after Melissa found phone numbers belonging to other women on Pittman's cellphone bill. Police say the argument unfolded outside the house, where Pittman berated Melissa with profanities and then rammed his Hummer into the passenger side of Melissa's Mercedes as she tried to drive away

N2 - The aim of this study was to analyze the quality of life related to health (QLRH) and physical activity (PA) patterns of adolescents with overweight or obesity and adolescents with normal weight. A total of 106 subjects (12.06 A ñ 0.9 years of age) from a school in the city of Granada (Spain) participated in the study. The Kid-Kindl version of the Kindl questionnaire (adapted and validated to Spanish) was used to measure QLRH by means of the dimensions of physical well-being, emotional well-being, self-esteem, family, friends, and school. Results demonstrate that the percentage of active boys (those that practice 2 or more hours of moderate to vigorous PA outside of school) is significantly greater than the percentage of active girls. When comparing the PA done by subjects with normal weight and those with obesity/overweight, it is observed that subjects with normal weight are significantly more active. For the points obtained in the questionnaire about quality of life, it is shown that subjects with normal weight obtain significantly better scores in general. This difference is also observed in all other dimensions of the questionnaire, except in the "Family" dimension where there are no differences; however, statistically significant differences are seen only in the "Self-esteem", and "School" dimensions. Given these results, it is necessary to develop intervention plans to generate healthy habits in children and adolescents, so they can maintain them in the future, and in this way reverse the tendency toward being obese adults. ABSTRACT FROM AUTHOR

El estudio pretende analizar la calidad de vida relacionada con la salud (CVRS) y la realizaci3n de actividad fA-sica entre adolescentes con sobrepeso u obesidad y adolescentes con normopeso. Participaron en el estudio un total de 106 alumnos (12,06 A ñ 0,9 aA ñ os) de un centro educativo ubicado en Granada capital. Como herramienta de recogida de datos se utilizA3 el cuestionario Kindl en su versi3n Kid-Kindl (adaptado y validado al espaA ñ ol) para medir la CVRS a travAcs de las dimensiones de bienestar fA-sico, bienestar emocional, autoestima, familia, amigos y colegio. Los resultados muestran cA3mo el porcentaje de sujetos masculinos activos (realizan 2 o mA s horas de actividad fA-sica extraescolar de intensidad moderada o vigorosa) es bastante superior al de alumnas activas, siendo estas diferencias estadA-sticamente significativas. Al comparar la actividad fA-sica realizada por alumnos con normopeso y sobrepeso/ obesidad, observamos cA3mo los alumnos con normopeso son mA s activos, siendo estas diferencias estadA-sticamente significativas. En cuanto a las puntuaciones obtenidas en el cuestionario de calidad de vida, se puede comprobar que los alumnos con normopeso obtienen mejores puntuaciones en la puntuaci3n global del cuestionario, siendo esta diferencia estadA-sticamente significativa. Lo mismo ocurre en todas las dimensiones del cuestionario, exceptuando la dimensi3n "Familia", donde no existen diferencias, aunque la significatividad estadA-stica sA3lo se da en las dimensiones de "Autoestima" y "Colegio". A la vista de los resultados se hace imprescindible crear planes de intervenci3n para generar hA -bitos de vida saludables en niA ñ os, para que Acstos los puedan mantener en un futuro, y podamos invertir la tendencia de ser adultos obesos. N2 - Abstract Unintentional Childhood Injury burden, outcomes and risks are assessed in Kampala. Proportional incidence rates, percentages and injury odds are computed; risk trends are constructed. Five hundred and fifty-six childhood injuries were recorded between January and May 2008. Male: female ratio was 15:10. Parents transported most patients to hospital using mini-buses, private cars and motorcycles. Median injury location was 5km. Homes, roads, schools were lead locations. Play and daily living activities are commonest injury time activities. Falls, burns and traffic constitute 70.5% of injuries. Burns, open wounds, fractures are commonest. Motorcycles, buses and passenger cars caused most crashes. Play grounds, furniture, stairs and trees were commonest fall sources. Liquids, fires and hot objects cause most burn. 43.8% of cases were admitted. 30% were not disabled; 10%, disabled; 1%, fatal. Injury odds varied with age, place and cause. We failed to capture poisoning and drowning. Local paediatric injury priorities should include home, road and school safety. ABSTRACT FROM PUBLISHER

N2 - Forty-five typically-developing children and 19 children with special needs, ages 3 to 5 years, were observed interacting on the playground. Observers recorded three types of play engaged in by the children. These included: (1) playing alone, (2) playing with a teacher, or (3) playing cooperatively with peer(s). Scan-sampling was the observational technique used by the observers. This technique required a snapshot observation of a child at play for 10 seconds. Results indicated that children with special needs engaged in less cooperative play and were observed playing alone or with a teacher more often than their typically-developing peers. Furthermore, children with special needs often arrived on the playground later than their typically-developing classmates; consequently, they had fewer opportunities to be involved in play with peers. Field notes made by observers indicated that in some instances teachers used effective strategies to facilitate the inclusion of children with special needs in cooperative interactions. Results and observations are discussed and recommendations for practice and future research are provided

N2 - Background: Team pentathlon (TP) is designed to increase physical activity (PA) among children. Every day for eight weeks students register each PA episode completed outside of physical education classes.

Depending upon the type and intensity of the activity, a correction factor is applied to the duration of each episode; a total of 60 corrected minutes represents one pentathlon hour (PH). The study intended to characterize elementary and secondary school students' patterns of PA in relation with grade level, sex and season. Methods: The study considered a total of 1496 students from grade five and six and secondary first students of both sexes who had completed TP either during fall or winter. The students' PA pattern considered weekly number of PA episodes, average duration of episodes, uncorrected weekly PA volume, average correction factor, and average number of PHs per week. Results: Activities selected by boys were significantly more intense than those selected by girls and their overall average number of PHs per week was slightly higher. Winter PA lasted longer than during fall but was less intense, resulting in a significant but meaningless difference between winter and fall in terms of weekly PHs. Overall, grade five students were more active than older students both in terms of uncorrected and corrected PA volume per week. Conclusion: Results of the study suggest that sex and season differences usually reported in the literature are not present when students engage in TP. ABSTRACT FROM AUTHOR

N2 - Gender and ethnic trends were examined in 351 Mexican American and Anglo American children between the ages of four and seven. Four physiologic variables, seven observed and reported variables related to diet, and eight observed and reported variables related to physical activity were periodically assessed. Children were observed at home at meal times and at school (or a day care center) at lunch and recess. A linear regression model was used. Of the four physiologic variables, two variables (height and total skinfolds) showed significant

ethnic differences, with Mexican American children showing greater skinfolds over time and the tendency to be shorter than Anglo American children. Of the variables related to diet, five of the seven variables showed gender or ethnic differences; percent of calories from fat and food preparation behaviors tended to place Mexican American children at greater risk. When examining physical activity, four of the eight variables showed gender and/or ethnic differences in trend. As children age, they get less active at home and more active and are prompted more often to be active. They also participated in more organized physical activities as they get older

N2 - These days, civic participation has been popularized in various fields of public service. It is well known that civic participation improves the quality of public service. In the area of medical service, civic participation has not been popular compared with other fields. For the staff of medical facilities, especially in hospitals, it is very important to protect the safety of patients. As a result they are not receptive to civic assistance from outside their realm. We can find some civic activities in children's ward in a few facilities offering children amusement and mental support. In this paper I would like to report one of such activities in a children's ward. It could be considered a model case of civic participation in medical service. The substance of this report is comprised of the "life story" of a woman who has managed it

CY - ;

N2 - Discusses how small children learn through play. Proposes that play teaches them essential social and physical skills. Suggests that children who do not have a chance to develop their skills will be distinctly handicapped in approaching the world around them. Examines how children need a large amount of time exploring their physical world in order to enhance muscle development and make sense of the universe. Play is the way children communicate their ideas to themselves and is therefore of tremendous importance toward their overall intellectual development

N2 - Context: Ankle injuries are the most common sport-related injuries. To date, no studies have been published that use national data to present a cross-sport, cross-sex analysis of ankle injuries among US high school athletes. Objective: To investigate the incidence rates of ankle injuries by sex, type of exposure, and sport. Design: Descriptive epidemiologic study. Setting: One hundred US high schools. Patients or Other Participants: United States high school athletes. Main Outcome Measure(s): We reviewed ankle injury data collected over the 2005-2006 school year from a nationally representative sample obtained by High School RIO, an injury surveillance system. Specific sports studied were boys' football, boys' and girls' soccer, girls' volleyball, boys' and girls' basketball, boys' wrestling, boys' baseball, and girls' softball. Results: An estimated 326 396 ankle injuries occurred nationally in 2005-2006, yielding an injury rate of 5.23 ankle injuries per 10 000 athlete-exposures. Ankle injuries occurred at a significantly higher rate during competition (9.35 per 10 000 athlete-exposures) than during practice (3.63) (risk ratio = 2.58; 95% confidence interval = 2.26, 2.94; P < .001). Boys' basketball had the highest rate of ankle injury (7.74 per 10 000 athlete-exposures), followed by girls' basketball (6.93) and boys' football (6.52). In all sports except girls' volleyball, rates of ankle injury were higher in competition than in practice. Overall, most ankle injuries were diagnosed as ligament sprains with incomplete tears (83.4%). Ankle injuries most commonly caused athletes to miss less than 7 days of activity (51.7%), followed by 7 to 21 days of activity loss (33.9%) and more than 22 days of activity loss (10.5%). Conclusions:

Sports that combine jumping in close proximity to other players and swift changes of direction while running are most often associated with ankle injuries. Future research on ankle injuries is needed to drive the development and implementation of more effective preventive interventions. ABSTRACT FROM AUTHOR

N2 - Background: Injury research on mountain biking has been mostly limited to examining professional riders and off-road biking. Mountain bikes represent the largest segment of bike sales in the United States.

Recreational mountain bike use is popular and understudied.Purpose: To describe the scope, distribution, and trends of mountain bikef_ "related injuries treated in US emergency departments.Study Design: Descriptive epidemiologic study.Methods: A retrospective analysis was conducted with data from the National Electronic Injury Surveillance System of the US Consumer Product Safety Commission for patients aged f% • 8 years from 1994 through 2007. Sample weights provided by the system were used to calculate national estimates of

mountain bike *f*_"related injuries based on 4624 cases. Bivariate comparisons between categorical variables were assessed with injury proportion ratios and 95% confidence intervals. Results: Nationwide, an estimated 217 433 patients were treated for mountain bike *f*_"related injuries in US emergency departments from 1994 to 2007, an average of 15 531 injuries per year. The annual number of injuries decreased 56%, from a high of 23 177 in 1995 to 10 267 in 2007 ($P < .001$). The most common injuries were upper extremity fractures (10.6%) and shoulder fractures (8.3%). Patients aged 14 to 19 years sustained a greater proportion of traumatic brain injuries (8.4%) than did patients aged 8 to 13 years and *f*% • 20 years combined (4.3%). A greater proportion of female riders (6.1%) than male riders (4.5%) were hospitalized. Conclusion: Mountain bike *f*_"related injuries decreased from 1994 to 2007. Upper extremity fractures were the most common injury. Girls and women may be more likely than boys and men to sustain more severe injuries requiring hospitalization. Despite the decline over the past decade, more can be done to improve safety and reduce injuries in this popular recreational activity. ABSTRACT FROM AUTHOR

N2 - Aim of this study is the investigation of significance of the functional parameters that Greek Parents take into consideration for the qualitative' camps evaluation in our country. The sample constituted 9026 parents which had sent their children in various camps in Southern Greece, during one of the three camping periods, and who have filled in a questionnaire of closed questions considering functional subjects of the camp, i.e. facilities, level of education, specialization of executives (group leaders, etc), program of activities, etc. Results showed that the basic camp's evaluation factors are in order of evaluation, executives, program of activities of the camps, and are followed by, infrastructures - facilities while in smaller percentage diet and the natural environment of camps are evaluated. Moreover according to parents' opinions on the way of compensation that should be differentiated depending on the level of services given. The majority of the respondents would like their children to be involved mainly with sport environmental activities, while with regard to executives' level of

education priority is given in the graduates or students of higher education institutions and more concrete in professors or students of Physical Education. Parents prefer the energetic entertainment and involvement (active participation in the activities) of their children, which is realised in an optional and not in an obligatory base. This fact dictates the need for capable executives to correspond in the necessary process of encouragement and incentive of the campers. ABSTRACT FROM AUTHOR

N2 - This study presents behaviour-model-based product design as a new approach to safe product design for children. Ubiquitous sensing technology and statistical modelling technology allows us to quantitatively observe and record children behaviour and thus acquire children behaviour model from the large-scale sensory data. This study proposes a system for modelling children behaviour and designing consumer product based on the developed behaviour model. The proposed system consists of a wearable sensor for spatially and temporally measuring children behaviour in an everyday setting together with Bayesian network modelling technology to acquire a children behaviour model. We consider this system from both the theoretical and practical viewpoints. The theoretical framework describes a behavioural model in terms of spatial statistics. The practical aspect of this paper is concerned with a case study in which the proposed system is used to create a new type of playground equipment that is safer for children, in order to demonstrate the practical effectiveness of the system. In this case study, we conducted in situ measurement of 47 children playing with equipment by a wireless wearable location f_{-} electromyography sensor that the authors developed in cooperation with a kindergarten. A model on children's climbing behaviour was created from the measured data. By cooperating with a playground equipment maker, a new climbing wall type of equipment was developed and the developed equipment was installed at a kindergarten. This study also evaluates the performance of the model statistically by observing children playing with the developed equipment using cameras for over 1 year. ABSTRACT FROM

N2 - The purpose of this study was to explore children's everyday outdoor occupations in context. A naturalistic observational approach was employed to record the observed outdoor occupations of children in Mbarara, Uganda. Thematic analysis, through pattern formation and constant comparative analysis, was used to uncover categories and themes in the data. Patterns emerged from the data revealing two overarching categories containing three themes: 1) types of occupations: play, work and nothing in particular and 2) characteristics of occupational engagement: being in peer groups, having fun and using materials in the environment. The themes reveal that children's occupations are both similar and different across minority and majority world cultures and that children's occupations are contextually situated and flexible in nature. A limitation of the study was that the observational approach made identification of children's ages subjective. Subsequent studies should explore children's experiences of occupational engagement using interviews and focus groups. Copyright Ac 2010 John Wiley & Sons, Ltd

 N2 - The school setting provides a unique opportunity to promote physical activity in children by ensuring adequate time, appropriate facilities and education guidance is offered. However school uniform design could also limit physical activity. A repeated measures crossover design was used to compare school recess and lunchtime physical activity over four weeks in 64 primary school children (M = 10.48 yrs) when wearing winter uniform or sports uniform. Pedometers recorded step counts during each school recess and lunch break. Perception of the level of intensity of physical activity was also measured using a self-report log book. Mixed model analyses found that girls, but not boys, were significantly more active at recess ($p = .03$), lunch ($p = .04$) and overall ($p = .006$) when wearing their sports uniform compared to their winter uniform. School uniform did not impact the boy's physical activity levels. Perceived intensity of physical activity increased slightly among both girls and boys. A physically restrictive school uniform has the potential to inhibit physical activity among primary-school-aged girls. ABSTRACT FROM AUTHOR

N2 - With the prevalence of overweight and obesity in the under 18 s on the rise, there are increasing numbers of weight management programmes offering treatment within and outside of the NHS, however only a few are formally evaluated (Aicken et al., 2008). Activ8 is a 6-week community based group intervention targeting overweight and obese children aged between 5 and 18 years. The course consists of weekly 1-h sessions that combine game based physical activities and nutritional education sessions. The aim of this study was to evaluate the effect of the Activ8 intervention on anthropometry and body composition. Routinely collected data was pooled from all children attending Activ8 during 2009. Information recorded included gender, date of birth and measurements for weight, height and body fat percentage (%BF), measured using bioelectrical impedance analysis. Patients with only a single measurement, missing birth date and attending siblings under the 91st percentile for BMI for age were excluded. The prevalence of co-morbidities such as type 2 diabetes and sleep apnoea were not assessed. Statistical analysis was carried out using SPSS comparing anthropometric and body compositional variables before and after attendance and examining the effect of age and gender on outcomes. Ethical approval was received from the Research Ethics Review Panel of the London Metropolitan University prior to the commencement of data collection. In 2009, 15 courses were organised. Of the 133 children starting, 70 completed the course. All but two of the participants were clinically obese at the start of the course (mean BMI centile = 99.69 (0.60). Mean age was 10.62 (2.97) years. Girls represented 52.9% of the sample, whilst 86.7% were from ethnic minority backgrounds. The results indicated that at the end of the intervention average absolute BMI decreased by $f^{0.29}$ kg m (SD = 0.49, P = 0.000, CI = 95%), which remained significant when converted to z-scores and percentiles. Whilst %BF decreased on average by $f^{0.79}$ %, this did not reach statistical significance (SD = 2.43, P = 0.080, CI = 95%). Reduction in z-BMI, but not absolute BMI or BMI centile, was significantly greater (P = 0.046) in boys compared with girls. Some differences in outcomes stratified by age were also observed with the younger age groups achieving significantly greater reductions in absolute BMI (P = 0.003), z-BMI (P = 0.000) and BMI centile (P = 0.009). No significant differences were observed according to age group or gender in the reduction of %BF. The results are in line with the findings of other, similar interventions (Oude Luttikhuis et al., 2009). In line with NICE guidelines, the results indicate that Activ8 appears to be successful in achieving a decrease in adiposity as indicated by BMI, at least in the short term. Whether these results are sustained should be examined in a longer-term follow up study. It is recommended that the reasons behind the relatively high drop out and low uptake rates should be investigated through the adoption of a robust evaluation process. This audit of Activ8 has shown that it compares favourably to similar interventions, however further studies are required to evaluate long term efficacy, to eliminate the possible confounding effect of factors such as ethnicity and co morbidities and to strengthen the quality of the evidence by the use of randomisation and a control group. Aicken, C., Arai, L. & Roberts, H. (2008) Schemes to Promote Healthy Weight Amongst Obese and Overweight Children in England. N2 - The article focuses on one study which examines the differences in patterns of objectively measured physical activity (PA) when done weekdays and weekend days and whether age and gender play integral roles in the existence of these differences. A number of children were asked to participate in a randomized school-based obesity prevention program or Stockholm Obesity Prevention Project. They were asked to spend a great deal of time outdoors or in a stimulating environment where their PA will be measured using the accelerometer. Collected data were then analyzed using Statistica. After data analysis, it was revealed that it is at the age of six when children's PA starts to decline. It added that PA levels are disproportionately low in both girls and boys during weekends

N2 - Increased numbers of children who are technology-dependent are now being cared for at home by parents and other caregivers. However, there is inadequate understanding of the daily lives of families who care for technology-dependent children at home and how these families manage over time. The purpose of this descriptive, naturalistic study was to explore the meaning of and factors involved in the long-term home care of a child who is technology-dependent from the family's point of view using an interpretive interactionist approach (Denzin, 1989). The sensitizing theoretical framework for the study was Kazak's (1986, 1989, 1992) systems and social-ecological model. The purposive sample consisted of 15 families which included at least one child aged 3-12 years who: (a) had been technology-dependent and living at home for at least one year, and (b) was medically stable at the time of the study. Family experiences with childhood technology dependence were explored using unstructured parental interviews and home observations of family members engaged in usual routines and activities of daily living. Demographic data were also obtained. Four themes emerged from the

interpretive interactionist data analysis: (a) managing daily life with technology, (b) negotiating with outside entities, (c) maintaining a functioning family, and (d) making sense of life. The potential for frequent and unexpected change, unpredictability, and limited parental control inherent in each of these major thematic areas contributed to families' perceptions of the fragility and instability of family life with technology. The contextualization of the phenomenon of family experience with long-term childhood technology dependence revealed that families felt as if they were "living in a house of cards." Major strategies used to increase stability were vigilance, advocacy, and reframing. Based on the results of the study, recommendations for nursing are made

N2 - The lack of physical activity (PA) in children is an important health risk factor. Previous studies have shown that some environmental features may be associated with PA levels. Objectives: Find and comprehend which environmental features were mostly positively associated with children's physical activity. Methods: Twenty-eight studies were systematically reviewed. This research was used to assess the association between environmental features and physical activity among children (ages 3 to 12) who fulfilled the selection criteria. Results: Results across the various studies showed that facilities and parks/playgrounds are mostly positively associated with children's PA. Sidewalks and bike lanes were positively associated to PA in all studies. Safety, traffic and weather showed inconsistent associations with children's PA. Conclusions: Beginning to understand which environmental features contribute more to PA in children can lead to increased levels of PA.

N2 - Preventing injuries to children, especially debilitating and life threatening, requires an awareness of where these types of injuries occur during the school days. This review examines falls from playground equipment, events that have been identified as the leading causes of nonfatal unintentional injuries for children. Thus, the issue of playground safety is a topic of concern for health educators. School health educators play an essential role in developing safe and healthy outdoor play environments for children. This paper highlights the importance of injury prevention awareness and outlines different strategies that health educators can take for preventing playground injuries. In addition, this paper examines a project that was conducted in the state of Iowa in relation to what effects playground surfacing materials and staff training may have on injury prevention on school playgrounds. The results of the project concluded that with the addition of proper surfacing material and staff training, playground injuries could be reduced. Health educators need to investigate the types of playground injuries in current programs and develop a strategy to keep children healthy and active

N2 - Modern lifestyles are characterized by excessive sitting. People who are aware of this problem try to engage in various recreational activities in their leisure time so as to diminish the negative impact of their sedentary lifestyle. All well-informed parents want their children to spend quality leisure time. This is where the first problem occurs: older children are usually well taken care of since sports activities in urban centres are relatively readily available. The youngest children are not so fortunate: sport activities are scarce, playgrounds are uncared for, the green areas of parks are in a state of disrepair, and similar. Hence, our research focused on the Slovenian legislation governing children's playgrounds. [ABSTRACT FROM AUTHOR]

N2 - The purpose of physical education is to guide youngsters to become and remain physically active for life. Research on correlates and determinants of physical activity has shown the importance of developing intrinsic motivation in students so that they will choose to be physically active in their leisure time. When the physical education curriculum is considered a physical activity intervention, learning outcomes, instructional tasks, and activities then target known correlates of physical activity. This article presents teaching strategies and curriculum outcomes that specifically target six correlates of physical activity among children and adolescents. By directing efforts toward known correlates of physical activity during physical education, teachers can help youth become more physically active outside of school. ABSTRACT FROM PUBLISHER

 N2 - This study compared moderate-to-vigorous physical activity (MVPA) of students with autism spectrum disorders (ASD) and students without disabilities during inclusive physical education and recess. Students (7-12 years) wore a uniaxial accelerometer in school for 5 consecutive school days. Results indicated a significant difference between settings, $F(1,46) = 15.94$, $p < .01$, partial $\eta^2 = 0.26$, observed power = 0.97. Students with and without ASD spent a higher proportion of time in MVPA during physical education than during recess, relative to the amount of time spent in those settings. In addition, structured physical education offers opportunities to increase students' MVPA engagement

N2 - The aim of the work was to compare effects of outdoor and indoor physical education lessons with the main focus on the health aspects. Indoor activities are usually lower in intensity because of the less space available. Also, physical exercises performed mostly in a gym lead to certain limitation of children's skills to adaptation to external (environmental and climatic) conditions. That is why outdoor lessons seem to be more effective. During one- year experiment, conducted on a school-children sample (n = 227, aged 10-14 years), indoor and outdoor lessons were compared, using heart-rate (HR) monitors , movement counters and personal opinions of the participants about the intensity of the workout. Also out-of-school physical activity (leisure time), endurance level and number of classes skipped due to health problems were compared. Outdoor lessons proved to be better in every compared aspect. The HR during outdoor lessons averaged around 159,1 beats/min., and only 142,1 during indoor activities. Over 50 % of the outdoor class time was conducted in high HR (HR160), while only 26,4 % duration of the indoor lessons demanded that intensity. All these results were supported by the high percentage of the HR-max used and personal opinion of the participants about the intensity of the workout, and also by almost 20 % greater number of movements during outdoor lessons. Percentage representation of the endurance improvement in outdoor groups was 11 % and in indoor ones only 1 %. During the period of this experiment, amount of leisure time devoted to extracurricular recreation activities in outdoor groups increased almost twice as much as before the experimentation, and number of absences decreased considerably

N2 - Background: Declining levels of children's physical activity may contribute to Australia's increasing childhood obesity epidemic. School recess is an underutilized opportunity to increase children's physical activity. Methods: Thirteen regional Australian public primary schools participated in the study (2946 children). The Children's Activity Scanning Tool 2 (CAST2) collected observational playground physical activity data. The research also addressed: length of break, socioeconomic status (SES), gender, number of scanning days, and instrument calibration. Results: The proportions of Moderate or Vigorous Physically Activity (MVPA) children at the observed schools ranged from 0.4 to 0.7. The odds ratio of boys being MVPA relative to girls ranged from 0.8581 to 2.137. There were significant differences between the mean proportions of 3 days of activity (range $P = .001$ to $P = .015$) and no association between SES school groupings (deviance ratio: 0.48; $P = .503$). Interrater reliability for instrument calibration using Spearman correlations coefficients ranged from $r = .71$ to $r = .99$. Conclusions: There were significant differences between proportions of MVPA children at the 13 schools and between male and female populations. There was no association between playground physical activity and SES. The monitoring period for CAST2 should be at least 3 days. Interrater reliability indicates that correlations between observers were consistently high. ABSTRACT FROM AUTHOR

N2 - Background: The benefits of physical activity to maintain optimal health and well-being in children and adolescents are undisputed. The school environment offers opportunities for children to be physically active. Objective: The aim of this review is to systematically examine the effects of recess-based interventions on the physical activity (PA) levels of school-aged children and adolescents. Data Sources: A systematic literature search was conducted to identify papers reporting interventions to promote PA during school recess and/or lunchtime periods. The search was conducted in six databases (PubMed, SPORTDiscus^{f, >}, Web of Science, Proquest, Cochrane and Scopus) for papers published between January 2000 and April 2011. Study Selection: Articles were included in the review if (i) they reported the findings of an intervention targeting PA levels of children and/or adolescents during school recess and/or lunchtime; (ii) have a measure of PA as an outcome variable; (iii) participants were aged between 5 and 18 years; and (iv) were published in English. Methods: Two authors independently searched the literature using the same search strategies to identify papers reporting interventions that promote PA during school recess and lunchtime periods. Methodological quality was assessed using an adapted eight item assessment scale. The effects of the interventions were assessed with a rating system used in a recent review of interventions in youth. Results: The search originally retrieved 2,265 articles. Nine published peer-reviewed journal articles met the inclusion criteria for this review. Eight studies used randomized controlled trials and one was a controlled trial. Three studies demonstrated high methodological quality (33%). None of the studies adequately reported the randomization procedure or used power calculations. Few studies reported potential confounders and three studies had less than a 6 week follow-up. Five studies demonstrated a positive intervention effect on children's PA levels, with four reporting statistically significant increases and two reporting significant decreases in recess PA. The summary of the levels of evidence for intervention effects found inconclusive results for all intervention types, though promising strategies that require

further investigation were identified. Limitations: Whilst every effort was made to ensure that this review was as encompassing as possible, it may be limited by its search terms especially if there were studies with unclear titles or abstracts. In addition, only manuscripts published in English were considered, eliminating any possible studies published in other languages. Conclusions: All of the studies used an objective measure to assess PA outcomes, although several criteria were consistently absent from the studies. The levels of evidence were not sufficient to establish conclusive intervention effects on children's recess PA. This could be due to the small number of published studies. There is a need for higher-quality intervention research to strengthen published findings to inform recess PA interventions. Intervention research is needed in adolescents due to the absence of school recess intervention research in this population. ABSTRACT FROM AUTHOR

N2 - Background: It is known that children are more physically active outdoors than indoors. However, few previous studies have observed the time course for physical activity as young children transition from indoor to outdoor activities. Methods: Participants were 3- to 5-year-old children enrolled in the Children's Activity and Movement in Preschool Study (CHAMPS). Trained observers used the Observational System for Recording Physical Activity in Children-Preschool Version (OSRAC-P) to record children's physical activity levels over 20 minutes in outdoor settings. The 20-minute outdoor observational period began immediately following the transition from indoors to outdoors. Results: Children's activity levels were moderately high at the time of transition and declined over the 20-minute observation period. Different patterns, however, were observed for boys and girls. Overall, boys were more active than girls. Boys' activity levels declined in a linear fashion over the 20-minute period, while girls' activity levels increased slightly, decreased, and then increased slightly again. Conclusions: These data indicate that physical activity levels decline with increased duration of outdoor play. The frequency and duration of outdoor play should be investigated for the purpose of optimizing physical activity levels.. ABSTRACT FROM AUTHOR

N2 - A certain stereotyped picture of the feminine office-holder is shared alike by the housewives, the male executives, and even the women executives, which many times conflicts with what they know of themselves and their own personal experience. According to this general opinion, the feminine -executive most often attains her office through influential friends. She goes into politics, because she wants to earn a living and likes that sort of career. She has many firm convictions of good government and advocates equality of laws. The woman office-holder is conscientious about her work. She may admit her mistakes and the truth of opponents' arguments, and is able to see the humor in unpleasant details. She has about the same number of outside interests as men. The female executive is often termed conservative, and is not considered to have much general interest in politics that do not concern her personally. She places more emphasis on matters of social welfare than on those of financial and international importance. Her efficiency is affected by worry over social relations. The care of the home is a big handicap to her profession and, conversely, the profession interferes greatly with the home and marriage. The woman executive has difficulty deciding on committees and methods of procedure for meetings; and in persuading others to accept her point of view. She makes judgments in government matters quickly and occasionally wishes to change decisions after making them. She is not easily approached by employees, although she is apt to criticize them for errors. Inconsistency in statements and actions and the tendency to sit back and let the men lead the discussions are often characteristics. She is jealous of her fellow workers and they of her. She acts from intuition and permits feelings of irritation and depression to affect her work. She gives excessive attention to details, which annoy her when they go wrong. She is inhibited in her work by fear of criticism and is too much influenced by what other people say. In comparison with this attitude, it is interesting to note the actual characteristics of the woman executive, as determined from the self-ratings and facts about the lives of 120 of them. She is well educated and has had 10 years or more experience in holding executive offices. Her activities may have been along party lines and her career may have been hindered by prejudice against women, although not necessarily so. She has received the cooperation and support of feminine organizations both before and after obtaining office. The chief factors contributing to her success were excessive work and the ability to speak in public, rather than such factors as influential friends. She is motivated to seek office by the wish to carry out the ideals of good government and the desire for that sort of career. She is liberal, with many firm convictions of good government and much interest in general politics. She may or may not advocate equal laws for men and women. She puts as much emphasis on financial and international matters as on those of social welfare. She has probably been married sometime in her life and is frequently married at the present time. If she is married, the years of matrimony and number of children in the family average about the same as those of the non-professional woman of the same age and educational background. These facts, as well as her own assertions, indicate that her profession has not interfered with her marriage or management of her home. Nor has the care of the home or worry over social matters interfered with her profession as re-elections indicate. Of the present married women legislators, 46 per cent have been re-elected, which is about the same proportion as that of the total group of feminine legislators. The feminine executive's husband does not support her, although he may or may not contribute to some extent. She is apt to maintain her children and also other relatives, either partly or entirely. During the year she has missed less than a week's work on account of illness. In regard to her

executive ability, she does not have difficulty deciding on committees and plans, persuading others, or enforcing orders on men below her in rank. She makes judgments in government matters quickly. She may or may not be ambitious and is apt to give excessive attention to details. While the woman executive occasionally may wish to change decisions, she is on the whole consistent in statements and actions. She is approachable to her employees and does not criticize them. She may or may not sit back and let the men carry on discussions at meetings. The feminine office-holder does not experience jealousy or feel it towards her fellow workers. She is not inhibited in her profession by fear of criticism, and does not let feelings of irritation or depression affect her efficiency. She is not apt to be frequently annoyed by details which go wrong. The woman executive is somewhat influenced by others' viewpoints, but does not have difficulty resisting majority opinion in committee meetings. She does not often act from intuition and frequently sees humor in unpleasant details. She is conscientious about her work, and admits her own mistakes and the truth of opponents' arguments. She has about the same number of outside interests as the male office-holder. A marked discrepancy exists between the stereotyped opinion of the woman executive (which is even held by women office-holders themselves) and the personal characteristics manifested by this group. The percentages of re-election, which are similar to those of men executives, are evidence of the efficiency of the woman office-holder. The 1937 survey of the National League of Women Voters (5) showed that 44 per cent of the feminine legislators were serving re-election terms. Similarly, 39 per cent of the feminine legislators of the present study have previously held the same office. Of several states representing different sections of the country, the present Legislative Directory of Vermont (8) shows that 27 per cent of the feminine members of the House of Representatives have held seats there before; 50 per cent of those in Maryland (4) in 1939 have done the same. The record for Nebraska (7) over a period of 74 years from 1866-1940 shows that 33 per cent of the women members of the legislature in that period have been re-elected. These figures are similar to those for the men; 33 per cent of the male legislators of the present study are serving re-election terms. For the state of Vermont, the Legislative Directory (8) indicates that 49 per cent of the present male members of the Senate and 31 per cent of the House of Representatives have held the same office previously. In Maryland (4), 28 per cent of the male members of the Senate and 27 per cent of the House of Representatives were serving re-election terms in 1939. The record of Nebraska (7) over a period of 74 years shows that 28 per cent of the male members of the legislature served more than one term. The record for both men and women is higher in the present U. S. Congress (1). All of the present feminine members have held office previously. Two-thirds of the male members of the Senate and 85 per cent of the House have held office formerly. In both the state legislatures and the U. S. Congress, the percentages of re-election are similar for men and women. As large a proportion of the women are re-elected as the men, even though the former have to face prejudices which the latter do not. If re-election can be taken as an adequate criterion of efficiency, then we may conclude that, on the whole, women office-holders are as efficient as the men. The disparity between stereotyped opinions of the lack of efficiency of the woman executive and her actual ability become apparent. Such attitudes are partly developed by men to maintain the present system of employment, from which they benefit, and by the home-makers, because they profit from that economic system. The strength of these opinions is indicated by the fact that the women executives continue to hold similar ideas, although they are contrary to their own personal experience. Such opinions have hindered many women from ever obtaining office, but once they have obtained them, they have proved as efficient as the men, as re-election indicates. If an educational program is to be started to remove the discrepancy between the general opinion of the woman executive and her actual qualifications, it should be directed not only toward men and non-professional women, but also toward the women executives themselves. They also reflect the general attitudes about women office-holders, which do not accord with the facts of their own lives. ABSTRACT FROM AUTHOR

N2 - Over the last century a visible change has taken place in the relationship between children and their living environment in Warsaw. In many Polish cities increased road traffic, pollution and crime, fragmentation of urban fabric, and reduction of public green areas have resulted in the creation of a 'children-unfriendly' environment. The present paper is based on a research project carried out in the Institute of Tourism and Recreation of the Józef Piłsudski University of Physical Education in Warsaw between 2008 and 2010 regarding children's playgrounds in Warsaw. The project consisted of case studies on specific themes such as playground facilities, safety, pressures for change, popularity of play sites, and proposed renewal strategies. The authors studied diverse preferences of children and their caregivers as well as their expectations of outdoor recreation infrastructure and management improvements. The emphasis was also placed on disabled children and constraints on the use of playgrounds by these groups. A good playground means safety, fun, delight and excitement. However, there are still many problems connected with small, local playgrounds with poor facilities, situated mostly on communal or co-operative housing estates. Built from cheap and flimsy materials, many playgrounds are not safe for children as they often do not meet the most fundamental safety requirements. Moreover, in any playground design it is important to realize that children's needs are likely to change over time, but due to rather tough budgets of communal or co-operative housing, refurbishments may be too expensive. There is no doubt that the openness of outdoor recreation areas, following the 'space for all' principle, with unlimited public use in mind (for the disabled and the able bodied alike), is a crucial condition of an integrated healthy environment. N2 - The purpose of this article was to describe the phases of planning of an intervention study in nursing. The phases were selecting an appropriate intervention, developing and testing the intervention, planning the study design and educating the nursing staff involved in the study. As an example, a research project concerning children's postoperative pain relief is described

Intervention research was a method for investigating the effectiveness of a nursing action in a natural setting. In the process of planning, it was important to choose and develop an intervention that was effective, innovative, practical enough to be implemented in the patient's care and ethically correct. The study requires an experimental or quasi-experimental study design, which was still rarely used in nursing research. One of the most significant phases in an intervention study was to educate the interveners, as the nursing staffs were responsible for collecting the data in practice

When assessing validity, it was important to ensure that the outcome was produced by the treatment rather than by extraneous factors. The outcome was influenced by the patient, the intervener and characteristics of the setting

Evidence-based nursing requires that intervention studies are taken into more active use in nursing science. This kind of research was time-consuming and requires the researcher to collaborate with representatives of different professions and disciplines

N2 - Commentary on Asthma in exercising children exposed to ozone: a cohort study by McConnell, R., Berhane, K., Gilliland, F., London, S.J., Islam, T., Gauderman, W.J., Avol, E., Margolis, H.G., Peters, J.M. The aim of this study is to investigate the relation between the first time diagnosis of asthma and team sports in children exposed to air pollutants. Results indicate that there is a relationship between a new diagnoses of asthma in children and heavy exercise in communities with high concentrations of ozone which may lead to the conclusion that outdoor exercise in an area of air pollution could contribute to the development of asthma in children

N2 - Outlines the extent to which research addresses the issue of whether or not elementary schoolchildren need recess. Examines the anti-recess argument: 1) the current climate in schools stresses academic achievement, and recess is viewed as taking away from academic instructional time, and 2) recess results in aggression and fights, particularly for boys. Presents counterarguments and makes a case for recess. Concludes that children are better and happier students and citizens as a result of recess

N2 - This study considered the growth status and physical fitness of primary school children in a rural and an urban community in the Valley of Oaxaca, southern Mexico, in 1999-2000. The prevalence of growth stunting, wasting, and overweight and obesity were also considered. The sample included 700 school children 6 to 13 years of age, 361 from the rural community (177 males, 184 females) and 339 from the urban community (173 males, 166 females). Anthropometric dimensions included body size, segment lengths, skeletal breadths, limb circumferences and skinfolds. The body mass index (BMI), leg length, arm and calf muscle circumferences, sum of skinfolds, and a trunk/extremity skinfold ratio were derived. Physical fitness items included motor- and health-related tests: right and left grip strength (muscular strength), 35-yard dash (32.3 meters, speed), standing long jump (explosive power), sit- and-reach (flexibility), timed sit-ups (30 seconds, abdominal strength and endurance), and a distance run (8 minutes in grades 1-3 and 12 minutes in grades 4-6, cardiovascular endurance). Height, weight, sitting height, estimated leg length and skeletal breadths on the trunk were significantly larger in urban than in rural school children. The BMI, sitting height/stature ratio, skeletal breadths on the extremities, limb and estimated limb muscle circumferences, subcutaneous fatness and relative fat distribution did not consistently differ by age group and sex between urban and rural children. Urban children tended to perform better in the sit and reach, sit-ups and standing long jump, but results were not consistently significant. Rural children 6-9 years tended to perform better in the dash. There were no urban-rural differences in grip strength, but strength per unit body mass was greater in rural children. Rural children in grades 1-3 performed better in the distance run, but results in older children were not consistent. The prevalence of stunting was about twice as great in rural than in urban children, but the prevalence of wasting was very low in both communities. The prevalence of overweight was significantly greater in urban than in rural children, but the prevalence of obesity was low. Rural children, boys more than girls, reported more frequent daily participation in household-related activities classified as moderate and moderate-to vigorous in intensity compared to urban children. Urban boys reported more household-related activities of light or very light intensity. Urban and rural girls did not differ in reported frequencies of daily household activities classified of light and very light intensity. Urban children reported more diversity in diet, specifically at breakfast and dinner, than rural children. Animal protein represented in meats and meat derivatives were rather limited in the diets of rural children. The results of the comparisons of growth status, physical fitness, daily activities and diet of urban and rural primary school children reflect, to a large extent, the contrast of living conditions and access to resources in the urban and rural communities

N2 - The main purpose of the present study was to assess usual physical activity (PA) patterns of school children. The study was carried out with 49 boys and girls (mean age of 10 years) in 4th grade of two schools in Vila Nova de Gaia/Portugal. Children wore a portable accelerometer device (Tritrac-R3D) on the waist for 5 days. Statistical procedures included descriptives (means, standard deviation, frequency) and independent t-test. The main results were as follows: (1) during the school period, PA level was low, with children not doing the daily minimum of 30 minutes of moderate to vigorous PA; (2) boys showed a higher pattern of moderate to vigorous PA than girls during recess period; (3) children, even in organized physical education (PE) classes, demonstrated a low PA pattern, with less of 50 % of the total PE class time in moderate at vigorous PA; (4) there was no difference in energy expenditure when comparing PE class and school recess. N2 - With the growing significance of sedentary activities, such as television-watching, playgrounds remain important leisure facilities for children, since physical play activities have an important role in supporting children's motor, social and emotional development. When children have the opportunity to play in a playground they are promoting healthy lifestyles. In Portugal children are required to attend school until the age of 16 years and are provided with education, which is regulated by national government standards, but in regard to leisure opportunities, there is considerable inequality of provision from locality to locality. Seeking to promote the principles of play and health in the open air, a project was developed to discover the pattern of provision of children's playgrounds in different regions of the North of Portugal and to examine their physical characteristics. A questionnaire was developed and sent to Town Halls, seeking information on playground provision in each district and on the characteristics of the equipment provided in the playgrounds. This study includes four sub-regions - Ave, Cavado, Minho-Lima, Alto Tras-os-Montes - that include 38 districts. The north region of Portugal covers 21.194 km² and is occupied by more than 3.600.000 inhabitants. The region has one of European youngest populations. It was found that almost half of the districts surveyed provided less than

5 playgrounds in their area. Children in general therefore have few opportunities to play in playgrounds because of lack of provision and have very few opportunities to choose the activities they like to engage in because of the lack of attractive equipment. Playgrounds are located mostly in areas without heavy traffic and the majority of playgrounds have minimal equipment - typically four or less items. The paper discusses the implications of these findings for policy-makers in the region

N2 - This study examined the level of caregiver supervision when children were engaged in active play at public pools. A six-hour unobtrusive observation period was conducted at six different indoor aquatic venues with caregivers accompanying children aged < 10 years eligible to be monitored. Child behavior, corresponding caregiver supervision, and the willingness of parents to intervene when children exhibited unsafe behaviors all

were considered. Environmental factors and pool conditions were also recorded. Chi-square tests illustrated that increased supervision was associated with decreased incidents and lower risk behaviors. Supervision was significantly affected by child and caregiver age, number of children for whom caregivers were responsible, and child swimming ability. The nature of caregiver supervision in aquatic settings requires further investigation to enable the development of effective programs to address poor supervision practices. ABSTRACT FROM

N2 - This study aimed to determine and compare the nature of supervision children received in two settings that have different levels of environmental risk, an aquatic setting (public pools) and a nonaquatic setting (playgrounds). An observational design was implemented to examine caregiver and child behaviors at six indoor public pools and four playgrounds. Chi-square tests of homogeneity were conducted to determine associations between caregiver and child variables. Preschool children received significantly higher levels of supervision than school-aged children in both settings. For school-aged children the level of supervision varied between settings, with children significantly more likely to be unsupervised in public pools and poorly supervised on playgrounds. Reasons for the lack of supervision in aquatic settings remain unclear, particularly as this setting was considered to present higher environmental risk, because drowning rates are high for young children. Because evidence indicates inadequate supervision is common in aquatic settings, further investigations are required to identify ways to promote closer supervision practices and determine caregiver perceptions regarding their responsibilities when supervising young children in aquatic settings. N2 - The purpose of this line of research was to describe how agency is manifested in preschool children with disabilities, and to analyze how manifestations of agency are influenced by natural environmental contexts of home, therapy settings, and peer settings. An additional purpose was to describe an eleven week parent-oriented intervention based on the construct of agency and document changes in parents and children that occurred during the course of this intervention

Three related studies addressed these issues. Three studies were conducted using naturalistic methods of field observation and ethnography. The first study included six children with disabilities and their families. The participants were observed a minimum of five times and no more than nine times in home, therapy settings, and peer settings. The data from Study One were used to analyze children with disabilities in terms of occupational roles and as active participants in different environments. Study Two was a secondary analysis of the data gathered in Study One. The data were examined with a focus on the environmental settings. The researcher analyzed themes of agency or active participation across settings. Additionally, the data were used to examine aspects or qualities of different settings that enhance agency. These qualities may be in the social, cultural, and physical environment that each setting offers. Study Three examined an ongoing parent-oriented treatment setting that utilized the construct of agency and the environment as treatment modalities for children with disabilities. The data analysis revealed aspects of treatment, such as parent education, complexity of play objects, and environmental elements such as peer interaction and classroom routines, that help produce change and lasting adaptation in children with disabilities

The potential significance of these studies is twofold. The first is the addition of basic knowledge to the field of occupational therapy about agency, a theoretical construct. The information gathered from this research will add to the knowledge base of the profession by moving the construct of agency from the philosophical to the practical. The practical knowledge is expected to include ways of observing agency as it is manifested in different roles, activities, and environments of children with disabilities. The second area of potential significance is learning to view therapy with children differently and children with disabilities as action agents. It is hoped that the results of these studies will help practitioners view children with disabilities in ecologically valid domains. The results indicate that children with disabilities have a variety of behaviors that indicate their active involvement with the environment that is not reflected in standard assessments. These may be related to functional activities required in the roles and in the environments in which they participate

CY - ;

N2 - In the western world women, if they are interested in sport at all, are mostly engaged in physical activities which allow an aesthetic presentation and/or a modelling of the body. They are relatively seldom active in types of sport in which the body is employed as an instrument in trails of strength with others or with the environment. At the same time women do not claim much space in many respects - their presence does not fill a room, they do not prowl the streets, they seldom appropriate and use the natural environment for sport. The differences between men and women in sport orientation and the use of physical space begins in childhood. The results of the research can be summed up as follows: 1. The space used by boys was much larger than the space used by girls. 2. Girls are underrepresented on public sporting grounds. 3. Boys and girls differ in the way they use play grounds and other areas appropriated for free movement. 4. Boys' activities tend to contain sporting elements while girls' leisure time activities are more sedentary. The causes for these different play and motor preferences lay in different areas: the family, peer-groups, sporting facilities and so on. Here are the possible sites for change

Les femmes qui vivent en Occident, si elles sont généralement intéressées par le sport en général, s'orientent dans la plupart des cas vers des activités sportives qui permettent une présentation esthétique et/ou un modelage du corps. Elles se consacrent relativement peu à des activités sportives dans le cadre desquelles le corps est utilisé en tant qu'instrument dans des épreuves de force nécessitant un affrontement avec d'autres personnes ou avec l'environnement. En même temps, les femmes ne revendiquent pas énormément d'espace, et ce, à bien des égards - elles ne remplissent pas les salles, n'envahissent pas les rues, ne s'approprient et n'utilisent que rarement leur environnement naturel pour exercer leur sport. Les différences existant entre les hommes et les femmes, en matière d'orientation sportive et d'utilisation de l'espace physique s'observent dès l'enfance. Les conclusions de l'étude réalisée en ce sens peuvent être résumées de la manière suivante: 1. L'espace utilisé par les garçons est beaucoup plus important que l'espace utilisé par les filles. 2. Les filles sont sous-représentées sur les terrains de sport publics. 3. On constate de nettes différences dans la manière dont les garçons et les filles utilisent les terrains de sport et les autres espaces permettant une certaine liberté de mouvement. 4. Les activités pratiquées par les garçons affichent une réelle tendance à comporter des éléments sportifs, alors que les activités de loisir préférées des filles affichent un caractère plus sédentaire. Les raisons de ces différences entre les préférences des filles et des garçons en matière de jeu et de mouvement sont de divers ordres: la famille, le groupe des semblables, l'infrastructure sportive, etc. Ce sont là les domaines possibles d'intervention. (HERACLES)

Differences existant entre les hommes et les femmes en matière d'orientation sportive et d'utilisation de l'espace physique

N2 - Changes, slowly but persistently occurring in human development, adjustments that are required during the life and work of the modern man, which nature cannot follow at the pace, and the decrease of basic human functional competences are some of the undamental reasons, due to which profound attention should be dedicated to the sustainability of complete human development. The discussion on sustainable development and ecological awareness should not gnore the efforts to create an environment promoting health maintenance. History shows that human ntervention in the natural environment enabled man, motivated by the hunger for development and progress, which considerably simplified his daily life, however, concomitantly made him, neglect the very thing that throughout the millennia not only preserved, but also enabled him to evolve as a species -- that is physical activity. Human development that reflects in changes in humans that occur over time, are usually presented and described as a complex system of constant, reciprocal exchanges in basic domains: the physical domain (body size, body proportions, brain development, motor development, etc.); the cognitive domain (thought processes and ntellectual abilities including attention, memory, problem solving, creativity, academic and everyday knowledge, etc.) and the social/emotional domain (self-knowledge, self-esteem, expression of emotions, temperament, interpersonal skills, etc.). Motor development is a process that in the individual's life, through different life periods enables the transition to a higher level of motor competences -- the development of motor abilities and acquiring more demanding and upgraded motor skills in constant interaction and correlation with the environment. Among these competencies motor skill is the basis or human motor capital, which in the complete unctioning of humans and in the process of preserving and ensuring health presents the fundamental lever and one of the needed skills that significantly contribute to the individual's quality of life and development through all life periods. Consequently, the period that is devoted today to monitoring and studying motor development of the individual, by considering the role of sustainability and ecological perspective, can be named competence- oriented period, an approach that from the start and continuingly by following the set goals of the problem discussion defines motor competencies, the lifelong competency model of motor development. Among three periods of the presented model; i.e. the acquisition of motor competence, the utilization of motor competences and the decline of motor competences; the period of childhood is of substantial importance in the scope of lifelong functional competences as motor competences. Inadequately acquired fundamental motor patterns negatively affect the process of upgrading motor stereotypes, leading to the lack of motor competences, and consequently also result in inadequate and irregular physical/sports activity in adulthood. On the basis of different research findings, the importance of fundamental motor patterns as the foundation for lifelong functional competences will be presented. ABSTRACT FROM AUTHOR

CY - ;

N2 - Podlasie is a historical region situated along the middle stretch of the Bug River and the upper Narew River in Eastern Poland. Throughout the centuries it underwent various alterations often changing borders and the national status. The former Podlasie was the land of primeval forests, woods and marshlands cut by the rivers Biebrza, Narew, Bug and Krzna. For a long time the immemorial Podlasie was an object of contentions and fights, and that is why over the centuries it went under Polish, Russian and Lithuanian rule respectively. On numerous occasions throughout its existence it was also burnt and devastated by the Tartars, the Swedes, and the Teutonic Knights. Apart from the mentioned incursions the peoples of Podlasie successfully resented the marching of troops during the wars. Podlasie is a historical region situated along the Bug River and the upper Narew River in eastern Poland. The ethnic and religious diversity of southern Podlasie has vastly contributed to the mingling of cultures and the introduction or formation of various customs and traditions in the area. The latter also include plays and games which along with the settlement of different ethnic groups have enriched the lives of inhabitants of the region. Traditional folk plays and games are disappearing in southern Podlasie. Old-time pastimes traditionally passed on from generation to generation have been replaced with modern sports already known in other regions, or by passive forms of leisure such as computer games or television. The plays and games described in the article were collected from habitants of numerous towns and villages of southern Podlasie. They are divided into games played on village paths, playgrounds and in households as well as holiday games and winter games. They all bear witness to the richness of life of children and youngsters in the area in the past. [ABSTRACT FROM AUTHOR]

N2 - The problem of the study was to determine the differences in early-life outdoor experiences (individually, with family, environmental education, etc.) between individuals who have adopted an anthropocentric view of the environment and individuals who have adopted a bio-centric or eco-centric view of the environment. To test this difference, three phases of the study were performed. The subjects for the first phase were five historical figures (John Muir, Aldo Leopold, Rachel Carson, Theodore Roosevelt, and Henry David Thoreau) determined by the use of a Delphi study (using various Indiana University faculty) as America's greatest conservationists/environmentalists. The second phase involved ten modern day individuals (four men and six women) who were identified by various Monroe County agencies as being actively involved in the environmental movement. The early life of each historical figure was examined, and the modern day individuals were interviewed to determine which factors (using constant comparison) were consistent in causing them to become active in the conservation movement. Those influential factors, consistent in causing the historical figures and modern day conservationists to become actively involved in the environmental movement, were appreciative early-life outdoor experiences (alone and with friends), reading, and family (influence and vacations). The third phase involved a quantitative survey of 583 (resulting in 537 usable surveys) Indiana University students from a variety of major areas of study. A Discriminant Analysis was performed on the independent (17 variables based on previous research) and dependent variables (individuals were classified as eco-centric or anthropocentric). The results showed that the 17 independent variables explain 7.62% ($R_c=276$, $r^2=.762$) of the group variance. In addition, the confusion matrix for classification procedure shows that 75.6% of the respondents were correctly classified as either eco-centric or anthropocentric individuals. Those independent variables that are the most significant in discriminating between eco-centric and anthropocentric individuals include appreciative early-life outdoor experiences (alone and with friends), family early-life outdoor experiences, media (television and reading), and negative experiences. This study provides evidence that encouraging and providing opportunities for interaction with natural environments during an individual's early-life is important in developing environmental attitudes

N2 - It is well established in athletic adult individuals that specialization to an aerobic or anaerobic phenotype can occur. Less is known about this specialization in children. While childhood participation in organized sports is increasing, still very little is known about the physiological potential of young athletes. For example, the development of the aerobic and anaerobic energy systems in relation to each other in children is not well known. Many children are being put on training programs before puberty without any knowledge as to whether or not this can influence specialization to an aerobic or anaerobic phenotype. Early authors basing their results on twin studies, suggested a strong genetic component to aerobic or anaerobic phenotypes (Klissouras et al., 1973). This was not confirmed by muscle biopsy studies in children (Bell et al., 1980) and in fact Bouchard et al. (1992) have proposed a strong environmental or training influence to athletic performance. The purpose of this study was to look at the question of metabolic specialization in pre pubertal children before they had any influence of growth or maturation or training effects. The hypothesis was that if specialization exists, then those children with the better anaerobic capacity would have the lower aerobic capacity and vice versa. An attempt was made to screen out the better sprint and endurance performers with field tests, as it was felt that if specialization was occurring it would most likely be present in this group of individuals. A total of 42 pre-pubertal children from one school completed the study. Mean age was 9.31 years (range 8-11 years). All children initially completed field tests of 50 yard run and 1600 yard run to determine the best sprint and endurance performers. The sprint group (S) performed the 50 yard run under 8.50 seconds, while the endurance group (E) ran 1600 yards under 8 minutes. A questionnaire was filled out to exclude subjects who were involved with a track club or regular training program. On a separate day laboratory tests and anthropometric measures were performed. The laboratory tests performed in random order consisted of a Wingate protocol for anaerobic parameters on one day and a Quinton cycle ergometer for aerobic parameters on another day. Statistical analysis consisted of a zero order correlational analysis for the dependent variables of age, sex, height, weight, sum of skinfolds, sprint run time, endurance run time, anaerobic capacity, peak and mean anaerobic power, and aerobic capacity. In addition a Hotelling's T2 test was performed to determine significant differences between the sprint and endurance groups. The results showed no significant differences between sprint or endurance groups with respect to anthropometric or laboratory measures. There was a trend for the sprint group to have higher peak anaerobic power 9.43 plus/minus 0.87 W/kg (S) versus 8.67 plus/minus 1.25 W/kg (E). However, they also showed a trend towards higher aerobic power 52.03 plus/minus 7.97 ml/kg/min (S) versus 47.73 plus/minus 9.25 ml/kg/min (E). This suggests no specialization. In addition the correlational analysis showed high positive correlations between mean anaerobic power and VO₂max (r is 0.88) and peak anaerobic power and VO₂max (r is 0.82) suggesting that those children who do best aerobically also do best anaerobically in the pre-pubertal age group. The evidence provided from this study suggests that pre-pubertal children are metabolic non-specialists. Therefore rigorous training programs trying to implement aerobic or anaerobic specialization in this age group are likely not beneficial. The specialization seen in adolescents and adults may be secondary to growth or maturational changes after puberty and this would most likely be the better stage to begin regular training programs in children

 N2 - Playgrounds are an important outdoor environment for children. Yet few playgrounds are designed to be accessible to children with restricted mobility. In this study the child with restricted mobility is defined as one who is unable to move around without the aid of a wheelchair, walking-frame, walking-stick or other walking device. The purpose of the study was to explore the attitudes to accessibility problems in playgrounds among two groups of key persons: "creators" and "users of playgrounds" in a medium-sized municipality in northern Sweden. Eleven key persons (5 "creators of playgrounds" and 6 "users of playgrounds") were interviewed in a semi-structured interview. The interviews were analysed according to content analysis and could be coded under different themes. The results showed that those who created playgrounds had (i) a fragmented organization, (ii) insufficient knowledge of disabilities, (iii) poor economy, and (iv) attitudes as an obstacle. Interviews with the users of the playgrounds were coded under two themes (i) the playground is not for me (i.e. for children with restricted mobility) and (ii) assistance is a precondition for accessibility. The results were discussed in the light of how the inaccessibility of play environments can affect the development of children with restricted mobility, and affect their possibilities of a life on a par with that of other children

N2 - To meet their family's needs, parents must create and maintain daily routines that are sustainable, meaningful, provide opportunities to shape their children's development, and meet the often conflicting and competing needs of individual family members. As the number of women participating in paid work outside of the home continues to increase, parents are faced with the dilemma of how to create and maintain routines that facilitate their accomplishment of the work required to meet their family's needs for both economic support and physical and psychological nurturance of their children. This article tells the stories of three families with traditional and non-traditional divisions of household work in order to demonstrate various methods that they used to divide the work within their family. These stories are followed by a discussion of differences in routines and patterns of engagement in child care occupations found in families with non-traditional and traditional divisions of household work. This article contributes to a growing body of knowledge in occupational science

that captures the complexity of occupation through its description, exploration of its meaning, and portrayal of its storied nature in people's lives

N2 - Objective: Identifying community physical activity interventions that facilitate increases in moderate physical activity (MPA) is important in meeting targets set in government health policy. This study evaluated community interventions that aimed to increase levels of MPA. Intervention themes included exercise referral, classes and groups, peermentoring, motivational interviewing, campaigns and directories, outdoor activity and training physical activity leaders. Design: Longitudinal, pre-intervention and intervention assessments occurred between 2004 and 2006. Setting: Recruitment of 10,433 people from ten sites located in areas of high health need across England. Method: Demographic data were collected by questionnaire, with seven-day, population-

specific self-reports assessing pre-intervention and intervention MPA. Using guidelines for young people and adults, MPA MET-minutes/week were used to assign participants to four MPA categories (sedentary, lightly, moderately and highly active) at pre-intervention and intervention phases. Cross-tabulation established movement between three change categories (reversal, stability and progression). Results: From nine sites, 5324 people engaged in the evaluation, and a sub-sample of 998 provided demographic and 1022 self-report baseline and intervention data (i.e. completers) for a typical week's physical activity participation. Of completers who were sedentary or lightly active at pre-intervention, 58.5 per cent achieved recommended physical activity guidelines. 80.9 per cent who were sedentary at pre-intervention reported as lightly, moderately or highly active at intervention. Conclusions Completers increased overall activity levels, including those sedentary and lightly active at pre-intervention who increased levels to recommended guidelines

N2 - ISSUE ADDRESSED: The increase in mental health disorders worldwide makes it important to recognise health promotion interventions that are effective, accessible and affordable. Although natural spaces are coming to be recognised as health-promoting settings for general populations, little is understood about the use of nature-contact in treatment and care for individuals experiencing ill-health. METHODS: This paper provides a summary of key research findings and presents a case study examining the self-reported health and well-being benefits of nature contact for a small clinical sample. The 'Spectrum of Interventions for Mental Health Problems and Mental Disorders' provides a conceptual framework for ordering current and future information relating to nature-based interventions. RESULTS: Evidence demonstrates that separately, physical activity, social connection, and contact with nature enhance human health and well-being. The case example illustrates how 'active', 'social' and 'adventurous' contact with nature may be combined within a treatment intervention to protect and enhance the health of individuals experiencing chronic mental, emotional and physical health difficulties. CONCLUSIONS: 'Contact with nature' constitutes a health promotion strategy with potential application in prevention, early intervention, treatment and care. Recommendations include further research to investigate the benefits of nature contact within existing interventions, and the impacts of 'active' and 'social' nature contact within tailored interventions for targeted individuals and communities

N2 - The purpose of this study was to examine the relationship between physical activity, physical fitness and somatic characteristics in 27 prepubertal girls aged 9 years. Somatic measurements included body height, body mass and 5 skinfolds. Physical activity was recorded using the parental 7-day recall. Physical fitness was evaluated using the EUROFIT test battery. The sum of 5 skinfolds was negatively correlated with endurance shuttle run and bent arm hang. Physical fitness tests - where functional strength, flexibility, speed of limb

movement or agility are required - were not significantly correlated with somatic features and physical activity scores. The results of stepwise multiple correlation revealed that somatic characteristics accounted for 32 per cent of variance, and in combination with moderate-to-vigorous physical activity - for 41 per cent of variance in endurance shuttle run. These findings indicate that in pubertal girls the body mass, body fatness and moderate-to-vigorous physical activity were significantly, negatively correlated with those physical fitness tests where the body mass was moved or projected. In summary, the results of present investigation strongly support the theoretical standpoints of motor development according to which the fitness level of a growing child is influenced by biological and environmental factors. However, the magnitude and nature of associations between fitness, biological variables and environmental factors are not so clear

N2 - This project has two main aims - (1) expose intellectually gifted and talented students to scientific aspects of physical education and sport to connect theory and practice in physical education activity; and (2) offer an interesting and enjoyable multi-disciplinary enrichment program outside of regular learning hours in a unique domain not included in school curricula to help change student attitudes toward physical education as a subject matter, and part of the daily routine. Participating in the project were 15 boys (N = 7) and girls (N = 8) (CA = 10-13) from eighth grade classes in Israel. The program consisted of 24 double lessons applied in three laboratories of sport and physical education sciences - psychomotor, biomechanics, and physiology laboratories; eight double lessons were held in each of the three laboratories. Every theme or study unit taught in this program included three components - theoretical subject, laboratory experiences, and applications during movement and physical activity. The project was evaluated by three means - a group task to examine academic achievement, a feed back questionnaire, and a post-program gathering of students and parents. From knowledge students demonstrated, as well as from their written evaluations, their positive attitudes towards physical education, their perseverance in studies, and their performances of optimal tasks, it was concluded the project attained its aims

Ce projet avait deux objectifs principaux: (1) exposer les étudiants intellectuellement surdoués et talentueux à l'aspect scientifique de l'éducation physique et du sport afin de permettre un lien entre la théorie et la pratique au niveau d'activités d'éducation physique, et (2) offrir un programme extracurriculaire multidisciplinaire et enrichi qui se voulait à la fois intéressant et plaisant. Ce programme était centré sur un domaine unique ne faisant pas partie du programme d'étude afin de permettre à chaque participant de modifier son attitude envers l'éducation physique autant en tant que matière académique que d'activité journalière. Au total 15 élèves de huitième année en Israël prirent part à l'étude, 7 garçons et 8 filles, âgés entre 10-13. Le programme consistait en 24 leçons doubles, dans trois laboratoires de sciences du sport et d'éducation physique, appliquées aux domaines de la

psychomotricite, la biomecanique et la physiologie. Huit lecons doubles eurent lieu dans chacun de ces laboratoires. Chaque theme, ou unite d'apprentissage, enseigne dans le cadre de ce programme comprenait trois composantes; les sujets theoriques, les experiences de laboratoire et l'application durant l'execution de mouvements et activites physiques. Le projet a ete evalue a partir de trois moyens: un projet de groupe afin d'evaluer le cheminement academique, un questionnaire de feedback et une rencontre post programme avec les parents et les eleves. A partir des connaissances acquises par les eleves, leurs evaluations ecrites, leurs attitudes positives envers l'education physique, leur perseverance dans leurs etudes et leur performance optimale des taches, il semble que les objectifs du programme ont ete rencontres

N2 - Context: More than 7 million US high school students play sports. Objective: To compare practice and competition injury rates and patterns in 5 boys' sports (football, soccer, basketball, wrestling, and baseball) and 4 girls' sports (soccer, volleyball, basketball, and softball) during the 2005-2006 school year. Design: Prospective injury surveillance study. Setting: Injury data were collected from 100 nationally representative United States high schools via High School RIO (Reporting Information Online). Patients or Other Participants: Athletes from participating high schools injured while participating in a school-sanctioned practice or competition in one of the above sports. Main Outcome Measure(s): Practice and competition injury rates, body site, diagnosis, and severity. Results: High school athletes participating in these 9 sports at participating schools sustained 4350 injuries during the 2005-2006 school year, which corresponds to an estimated 1 442 533 injuries nationally. The rate of injury per 1000 athlete-exposures was higher in competition (4.63) than in practice (1.69) (rate ratio [RR] = 2.73, 95% confidence interval [CI] = 2.58, 2.90). Of all sports, football had the highest competition (12.09) and practice (2.54) injury rates per 1000 athlete-exposures. Compared with injuries sustained during practice, higher proportions of competition injuries were head/face/neck injuries (proportion ratio [PR] = 1.61, 95% CI = 1.34, 1.94), particularly in boys' soccer (PR = 7.74, 95% CI = 2.53, 23.65) and girls' basketball (PR = 6.03, 95% CI = 2.39, 15.22). Competition injuries were more likely to be concussions (PR = 2.02, 95% CI = 1.56, 2.62), especially in boys' soccer (PR = 6.94, 95% CI = 2.01, 23.95) and girls' basketball (PR = 5.83, 95% CI = 2.06, 16.49). Higher proportions of competition injuries caused the athlete to miss more

than 3 weeks of play (PR = 1.28, 95% CI = 1.08, 1.52), particularly in baseball (PR = 3.47, 95% CI = 1.48, 8.11) and volleyball (PR = 2.88, 95% CI = 1.01, 8.24). Conclusions: Rates and patterns of high school sport injuries differed between practice and competition. Providing athletic trainers with this information is a crucial step in developing the targeted, evidence-based interventions required to effectively reduce injury rates among the millions of high school student-athletes. N2 - Background: Prospective studies on physical activity (PA), diet, and body composition in adolescents are lacking, particularly outside high-income countries. Goals: To describe the methods used to assess these variables in the 1993 Pelotas (Brazil) Birth Cohort and to discuss the fieldwork challenges faced and alternatives to overcome them. Methods: In 2006-07 a subsample of the 1993 Pelotas cohort was revisited. PA was estimated using questionnaires, a combined heart-rate and motion sensor (Acti-Heart), and the ActiGraph GT1M accelerometer. Diet was investigated by questionnaire. Total body water was determined by stable isotopes. Thirty individuals had their total energy expenditure assessed by doubly labeled water. All data were collected at participants' home. Results: The logistics of the fieldwork and the difficulties in undertaking the study and alternatives to overcome them are presented. Preliminary analyses show that 511 individuals were traced (response rate = 90.0%). Compliance of both adolescents and their families for the motion sensors and body-composition measurements was excellent. Conclusions: The authors conclude that it is feasible to carry out high-quality studies on PA in developing countries. They hope the article will be useful to other researchers interested in carrying out similar studies. ABSTRACT FROM AUTHOR

N2 - The relationship between junior boys' tennis success, as measured by a top 20 International Tennis Federation's Junior Circuit (ITFJC) ranking, and subsequent ranking accomplishments in professional men's tennis is discussed. The names, countries, and birthdates of all players to achieve a top 20 ITFJC boys' year-end ranking from 1992 to 1998 were recorded. The progress of these players through the professional ranks was then tracked to the end of 2004. Results indicate that 91% of top 20-ranked boys achieved a professional men's ranking, while a stepwise regression analysis revealed junior ranking (JR) to be a predictor of future, professional ranking ($\hat{Y} = 0.232$, $r^2 = 0.054$, $p < 0.05$). A regression equation [predicted professional rank = $78.17 + 6.31*(JR)$] accounted for a significant amount of variance in professional ranking. For male players, therefore, the achievement of a top 20 junior ranking appears to be a reasonable yardstick for future, professional success. The type of surface upon which junior players develop their games was also shown to influence professional ranking highs, with play on clay courts or a combination of clay and hard courts helping to produce higher, professionally ranked players than hard court play alone ($p < 0.01$). N2 - Overweight children are increasing in the United States. Is your Little Leaguer so fat his blood type is Chee-tos? Americans have the fattest kids on earth. Over the last 20 years the number of overweight children in this country has doubled. Soon, if that trend continues, one of every three kids will be obese. We only have each other to blame. It's you, Mr. Dad, pumping your bike madly while you let your triple-chinned five-year-old lie in the back of his little vinyl bike caboose. It's you, Mrs. Elementary School P.E. Instructor, letting policy wonks talk you into replacing sports that actually make a kid sweat -- dodgeball, kickball, tag -- with "activities" like competitive cup-stacking. It's you, Mr. School Board Member, cutting gym classes to supposedly focus on "literacy." Or reducing gym to one or two times a week. It's you, Mrs. U.S. Senator, spending hundreds of billions of dollars to check grandmothers for shoe bombs while letting funding for schools shrink to the size of Uday Hussein's heart. According to the Centers for Disease Control, one in three kids born in 2000 will contract type 2 diabetes -- and potentially the heart disease, blindness, asthma, sleep apnea, gall bladder disease and depression that may come with it -- because they are obese. At least there's one person who wants to do something about it, and you won't believe who it is -- LeBron James. The Cleveland Cavaliers rookie is fast-

breaking a campaign, sponsored by Nike, to get kids off the PlayStation and back on the playground. He's visiting 47 schools in seven cities and donating sports equipment, getting courts and school yards resurfaced, and paying for instructors who think kids ought to play something other than Capture the Flab. The average kid spends 5 1/2 hours per day in front of a TV, a video-game monitor or a computer

N2 - The article focuses on football player Adrian Peterson, a running back for the Minnesota Vikings team of the National Football League (NFL). An autograph Peterson signed for a child shortly after suffering a torn anterior cruciate ligament in a game on December 24, 2011 is used to illustrate his determination to recover from the injury. Peterson's rapid recovery from the injury in time to play the entire 2012 season is considered, as are his very high levels of muscle strength and physical fitness. Peterson's performance in the 2012 season, in which he rushed for over 1800 yards in the Vikings' first 14 games, is discussed

 N2 - Background: The aim of the European Youth Heart Study (EYHS) is to establish the nature, strength, and interactions between personal, environmental, and lifestyle influences on cardiovascular disease (CVD) risk factors in European children. Methods: The EYHS is an international study measuring CVD risk factors, and their associated influences, in children. Relationships between these independent factors and risk of disease will inform the design of CVD interventions in children. A minimum of 1000 boys and girls ages 9 and 15 y were recruited from four European countries f_ "Denmark, Estonia, Norway, and Portugal. Variables measured included physical, biochemical, lifestyle, psychosocial, and sociodemographic data. Results: Of the 5664 children invited to participate, 4169 (74%) accepted. Response rates for most individual tests were moderate to high. All test protocols were well received by the children. Conclusions: EYHS protocols are valid, reliable, acceptable to children, and feasible for use in large, field-based studies. ABSTRACT FROM AUTHOR

N2 - Physical activity is an integral component of a healthy lifestyle, with relationships documented between physical activity, chronic diseases, and disease risk factors. There is increasing concern that many people are not sufficiently active to benefit their health. Consequently, there is a need to determine the prevalence of physical activity engagement, identify active and inactive segments of the population, and evaluate the effectiveness of interventions. The aim of the present study was to identify and explain a number of methodological and decision-making processes associated with accelerometry, which is the most commonly used objective measure of physical activity in child and adult research. Specifically, this review addresses: (a) pre-data collection decisions, (b) data collection procedures, (c) processing of accelerometer data, and (d) outcome variables in relation to the research questions posed. An appraisal of the literature is provided to help researchers and practitioners begin field-based research, with recommendations offered for best practice. In addition, issues that require further investigation are identified and discussed to inform researchers and practitioners of the surrounding debates. Overall, the review is intended as a starting point for field-based physical activity research using accelerometers and as an introduction to key issues that should be considered and are likely to be encountered at this time. N2 - The article discusses summer camp employment for college students in the U.S. Summer camp employment provides excellent pre-service opportunities for college students who are majoring in physical education and recreation management. Through these experiences they can develop and enhance their teaching, leadership, and communication skills that will be beneficial in future employment. Many camp directors have expressed that a camp employee should possess certain personality traits in order to be effective. An effective employee is a hard worker, possesses the hard skills related to specific camps, has a good work ethic, is a role model, and has prior related work experience. Another important personality essential for the camp employee is to be child-centered and compassionate of children attending the camp. According to the American Camping Association, there are more than 10,000 day and resident camps in the United States where more than half a million people work as counselors, activity leaders, and program directors

VL - 27

IS - 4

N2 - Parents and caregivers generally believe that the camp experiences they purchase for their children will not only yield transient pleasure and lasting memories of fun encounters, but significant developmental outcomes as well. Camp professionals serving over 11 million youths each year embrace such outcomes and commonly advance mission statements that point to the development of friendship skills, self-confidence, competence, self-reliance, independence, citizenship, and many other developmental outcomes. Empirical evidence of how these outcomes might be facilitated through specific recreation leadership strategies (e.g., activity staging) is lacking. The Self-Determination Theory (SDT) would suggest that youth leaders (e.g., camp counselors, recreation activity specialists) could attend to competence, relatedness, and autonomy in staging experiences for the outcome of intrinsic motivation. Such evidence is essential if immediate conscious experiences of campers are to be optimized and stable outcomes to campers are to be expected. Thus, this study examined the effect of three strategies for staging a recreation encounter on intrinsic motivation of youth attending a residential summer camp. Youth participated in a storytelling activity on three occasions, with each occasion staged differently by leaders. One of the staging strategies included a technique intended to elicit high degrees of autonomy, along with competence. A second strategy was designed to evoke autonomy and relatedness, and a third condition represented a traditional model (i.e., competent tutor) for staging encounters in organized recreation settings. A significant effect was found for the contrast of the combined autonomy conditions (representing autonomy support) vs. the competent tutor condition. This finding is particularly important to camp practitioners. This applied test of Self-Determination Theory-based conditions presents evidence to practitioners that providing recreation encounters that foster the three basic psychological needs of competence, relatedness, and autonomy are more likely to increase intrinsic motivation compared to a traditional method (i.e., competent tutor). Accordingly, staff of youth serving programs might implement strategies derived from Self-Determination Theory in the stream of daily recreation activities to facilitate camper acquisition of intrinsic motivation. For instance, the detailed scripts in this study are a model of how to stage recreation encounters (i.e., storytelling activity) to increase intrinsic motivation of campers. Specifically during the storytelling activity, the autonomy-supportive leaders 1) paused to allow time for responses, 2) provided specific, meaningful feedback to encourage effort, and 3) verbally acknowledged campers' perspectives. N2 - Children from poor, urban, and disadvantaged environments often demonstrate poor motor skill competence in both object control (OC) and locomotor skills (Goodway & Rudisill, 1996; Hamilton et al., 1999). This study examined the motor skill competence of disadvantaged, African American preschoolers. Further, it investigated the effects of a 9-week OC intervention on OC competence. Two instructional approaches were compared: low autonomy (LA) consisting of direct-instruction and a mastery motivational climate (MMC). Participants were randomly assigned to a LA (n = 36), MMC (n = 38), or comparison (no motor intervention) group (n = 39). The LA and MMC groups participated in 18 30-min OC sessions and the comparison group participated in the same amount of unstructured recess. All children were pre- and posttested on the OC subscale of the TGMD-2 (Ulrich, 2001). Preintervention OC competence was low based on percentile ranks (LA = 23%, MMC = 20%, comparison = 20%). A 3 (Group) x 2 (Sex) ANOVA on pre-OC scores revealed no significant group differences (p = .90) or Group x Sex interaction (p = .60). However, a significant sex main effect was found with boys having greater OC competence than girls, $F(1, 107) = 29.34$, $p < .001$. A 3 (Group) x 2 Time x 2 (Sex) ANOVA with repeated measures revealed a significant Group x Time interaction, $F(2, 107) = 210.97$, $p < .001$, indicating the OC intervention was effective. Post hoc Tukey HSD analysis reported the LA ($p f\% \square = < .001$) and MMC ($p f\% \square = < .001$) groups had significantly better OC competence than the Comparison group from pre- to postintervention. There was no difference between the LA

and MMC groups ($p = .88$). A nonsignificant Group x Time x Sex interaction ($p = .94$) showed that there were no sex differences within groups from pre- to postintervention. Clearly, disadvantaged preschoolers had low OC competence and needed motor intervention. When instruction was provided by either LA or MMC, preschool children improved their OC skills. N2 - Outlines the theoretical, social and educational considerations and goals of physical activity for school-age children. States that activity is the real objective of life including organic vigor and vitality. Suggests how to measure and assess these goals in the three areas of physical conditioning, physical fitness, and athletic ability. The implications of these goals are important for every teacher as each is a physical educator. Suggests also the optimum classroom environment, importance of recess, the importance of the diversity of the program, and the increasing differentiation of activities between boys and girls as they mature

N2 - The article discusses a study on the relationship between happiness and children's health in Ohio. Health care providers have recognized the importance of amusement activities for ill or hospitalized children. The study

assesses whether counties with more art, entertainment and recreational activities have healthier children. The results showed that 62% of the children were in excellent health, 23.34% were in very good health, while only 3.81% were in fair or poor health. It was also noted that the population-adjusted dollar volume received for arts, recreation and entertainment increased with higher health status. It was concluded that the communities that offer amusements are more likely to have healthier children

N2 - Athletic ability is highly valued by a majority of children and youth. Comparison processes in the athletic domain occur in physical education and organized sport as well as in the unstructured contexts of play and games. Children with movement difficulties are more likely to face failure or exclusion in sport and on the playground. Yet we know little of the processes underlying their self-esteem. These children struggle in physical

education, and on sports days are likely to experience humiliation before their peers, teachers, and parents. Therefore, it seems likely that the social, psychological, and physical experiences of these children impact on the relative contribution of domain-specific perceptions of competence and importance to global self-worth (GSW). In this study, we employed Harter's Importance Rating Scale (IRS) and Self-Perception Profile for Children (SPPC) to examine importance ratings, discrepancy scores, and domain-specific perceptions of competence as predictors of GSW. Children (N = 130, 62 boys and 68 girls) aged 8-12 years were categorized into high (HMC; n = 62) and low motor coordination (LMC; n = 68) groups according to their scores on a motor proficiency battery. Regression analyses using domain-specific perceptions of competence, importance, and discrepancy scores confirmed that self-perception ratings were the best predictors of GSW. For both groups, perceptions of physical appearance, social acceptance, and behavioral conduct contributed significantly to prediction of GSW. By contrast, perceived athletic competence increased prediction of GSW for the HMC group but not the LMC group

N2 - The purpose of this study was to compare daily, physical education, recess, and after school moderate to vigorous physical activity (MVPA) levels between children with and without autistic spectrum disorders (ASD). Children ages 5 to 12 years wore a uniaxial accelerometer for five days (four weekdays, one weekend day).

There were no differences between children with and without ASD at any physical activity setting. Both groups were more active during recess compared to after school, and children with ASD were similarly active in recess and physical education. Although many children with ASD acquired 60 min of physical education per day, this may decrease with age as opportunities for recess and physical education are eliminated. [ABSTRACT FROM AUTHOR]

N2 - This study investigated the potential of a classification procedure to determine type, duration, and frequency of children's physical activity (PA) during 7 days based on accelerometer data. Hip and wrist accelerometer data (1-second epoch) were collected over a week in 41 children (age: 10.7 \pm 0.9 years). The classification procedure was used to assign each second into one of the following four categories: stationary activities, walking, running, and jumping. A diary was used to assess the simultaneous activity setting. Children spent 75.5% of the time (600.9 \pm 80.1 minutes/day) on stationary activities, 15.6% (124.6 \pm 33.6 minutes/day) on walking, 2% (16.1 \pm 8.6 minutes/day) on running, and 1% (4.7 \pm 5.2 minutes/day) on jumping. The median duration of stationary activities, walking, running, and jumping was 4, 2, 1, and 1 seconds, respectively. The largest proportion of running and jumping occurred during outdoor sport training (10.7%), physical education classes (6.7%), and vigorous outdoor activity (6.1%). The classification procedure used in this study shows the potential for analyzing children's PA in free- living conditions. The study results revealed that children's PA is characterized by very short activity bouts and that providing the possibility for children to participate in structured or unstructured outdoor activities might increase their PA. Therefore, the classification procedure enhanced the analysis of the transitory nature of children's PA and the understanding of their PA behavior during different activity settings. N2 - The article presents descriptions of some of the worst moments in the history of sports according to Sports Illustrated magazine. In the third-worst trade in history, behind beads-for-Manhattan and Ruth-for-cash, the Super Bowl--contending Minnesota Vikings exchange five players and eight draft choices for one man with two bad wheels and a penchant for speaking in the third person. Herschel Walker, newly acquired from the Dallas Cowboys, runs 47 yards on his first play as a Viking. Another bad moment was when the night before Super Bowl XXXIII, Atlanta Falcons free safety Eugene Robinson leaves his wife and two children in a Miami hotel and propositions an undercover cop posing as a prostitute. He does so 100 yards from a police sub-station. With 5,000 sportswriters in town. Hours after accepting the Bart Starr Award from Athletes in Action for exhibiting "high moral character." Another bad moment in sports occurred when by holding a 10-Cent Beer Night, the Cleveland Indians give new meaning to bad hops. Some 25,000 fans come and--to be fair--they don't all streak

across the diamond or sprint into centerfield to moon the bleacherites. But many do. With the game tied 5-5 and the Indians at bat in the ninth, the bases weren't loaded but the crowd was. Umpire Nestor Chylak and Cleveland reliever Tom Hilgendorf are both hit over the head with chairs by fans. When order proves impossible to restore, the Indians, having forfeited their dignity, also forfeit the game

N2 - The article examines the issue of how much focus should be placed on the elimination of physical risk or danger from a child's environment, particularly in the area of sports or physical recreation are concerned. It is suggested in the article that the complete elimination of risk and danger from a child's environment could be a bad thing. The article explores whether physical risk or danger contributes positively in any way to a child's development or life in general. The article also discusses how many U.S. schools have eliminated such games as touch football and tag from their playgrounds and physical education programs

N2 - Background: The audibility of teachers and peers is an essential factor in determining the academic performance of school children. However, acoustic conditions in most classrooms are less than optimal and have been viewed as 'hostile listening environments' that undermine the learning of children in school. While research has shown that typical classrooms may be acoustically challenging, the acoustic conditions in physical education settings are without a doubt more challenging than in the typical classroom. To date, researchers in physical education have sparingly focused on the way acoustics affect physical education settings. Aims: The focus of this research effort was to measure noise levels in elementary-, middle- and high-school physical education settings and compare them to the American Speech-Language-Hearing Association (ASHA) guidelines (30 dBA) and American National Standards Institute (ANSI) standards (40 dBA). Documentation of these ambient noise levels may give greater understanding to the effect of background noise on student learning in physical education. Methods: Acoustic environments were measured in indoor and outdoor settings in 12 elementary, 4 middle, and 6 high schools in northwest Florida. Nine outdoor, seven gymnasium, and six covered area settings were evaluated. Ambient noise levels were recorded for each unoccupied physical education setting. A sound decibel digital meter which met American National Standard Specification for Sound Level Meters set on the 'A'-weighted scale and on slow response was used to record the noise levels for each setting. Two-tailed t-tests were used for comparison of the overall mean noise levels in outdoor, gymnasium, and covered physical education settings to the standards established by ANSI and ASHA. Results: The findings showed that all of the settings were significantly ($p < .05$) higher than the established standards and only 1 of the 22 physical education settings studied had background noise levels at or below 40 dBA. These results also indicate that the physical education settings investigated exhibit ambient noise levels at 10-15 dB higher than recommended levels. Conclusions: In light of the acoustics standards and prior research, these results are discouraging if not alarming. These results also suggest that the background noise in physical education settings is likely detrimental to student learning. These findings indicate an immediate need for administrators to support future research and determine the most appropriate, cost-effective procedures to reduce noise in existing physical education settings. Strategies for reducing high noise levels in physical education settings include sound amplification devices, acoustical modifications, and future construction strategies. ABSTRACT FROM AUTHOR

N2 - In order to resolve the theme "Are younger children lacking exercise?", the relationships among the quantity of exercise, lifestyle, home environment and parents' thoughts were studied in 204 preschoolers aged 4-5 years old. Lifestyle and parents' thoughts affected the activity and quantity of exercise of kids. Early rising, the presence of siblings, attending kindergarten and the mother not working allowed younger children to exercise more than late risers, those without siblings, holidays, and with both parents working. Moreover, parents' opinion on sport affected the quantity of the child's exercise. In order to increase the amount of exercise in younger children, it is advisable for parents to wake up earlier and play with their kids outside. ABSTRACT

N2 - Background: Reliable and comprehensive measurement of physical activity settings is needed to examine environment-behavior relations. Methods: Surveyed park professionals (n = 34) and users (n = 29) identified park and playground elements (e.g., trail) and qualities (e.g., condition). Responses guided observational instrument development for environmental assessment of public recreation spaces (EAPRS). Item inter-rater reliability was evaluated following observations in 92 parks and playgrounds. Instrument revision and further reliability testing were conducted with observations in 21 parks and 20 playgrounds. Results: EAPRS evaluates trailpath, specific use (e.g., picnic), water-related, amenity (e.g., benches), and play elements, and their qualities. Most EAPRS items had good-excellent reliability, particularly presence/number items. Reliability improved from the original (n = 1088 items) to revised (n = 646 items) instrument for condition, coverage/shade, and openness/visibility items. Reliability was especially good for play features, but cleanliness items were generally unreliable. Conclusions: The EAPRS instrument provides comprehensive assessment of parks' and playgrounds' physical environment, with generally high reliability. ABSTRACT FROM AUTHOR

N2 - The objective of this study is to analyze the different role that efficacy beliefs play in the prediction of learning, innovative and risky performances. We hypothesize that high levels of efficacy beliefs in learning and innovative performances have positive consequences (i.e., better academic and innovative performance, respectively), whereas in risky performances they have negative consequences (i.e., less safety performance). To achieve this objective, three studies were conducted, 1) a two-wave longitudinal field study among 527 undergraduate students (learning setting), 2) a three-wave longitudinal lab study among 165 participants performing innovative group tasks (innovative setting), and 3) a field study among 228 construction workers (risky setting). As expected, high levels of efficacy beliefs have positive or negative consequences on performance depending on the specific settings. Unexpectedly, however, we found no time x self-efficacy interaction effect over time in learning and innovative settings. Theoretical and practical implications within the social cognitive theory of A. Bandura framework are discussed

N2 - This study identified and described participation roles kindergarten and second grade children took on during partner tasks in physical education. Over a period of one year four participation roles were identified: (1) initiating partner, (2) responding partner, (3) collaborating partner, and (4) non-compliant partner. Data suggested a shift from kindergarten to second grade in roles students assumed during partner activities and that this change may be related to egocentrism as a developmental characteristic of young. A class of 24 kindergarten children eagerly wait at the door of the gymnasium to enter and begin 30-minutes of physical education. As they enter, the teacher instructs them to find and sit on one of the two-dozen (four-inch diameter) colored dots which have been painted on the gym floor. The dots are a variety of different colors, spaced six feet apart, and are used by the teacher to assist in spacing the young children evenly on one half of the gym. The 24 dots have been painted on the floor in a rectangular pattern. As the teacher views her class she sees four lines of children with equal space between each line. She asks the children in the two middle lines to turn and face the children in the outside lines. Children have been asked to turn and face a classmate before. The children's voices can now be heard, whispering, and they appear ready to burst into movement at any time. Children do not know if they will be throwing, catching, kicking or striking, but they do know that the classmate they are facing is to be their partner. On the other end of the gym two classes of second grade students, taught by a different teacher, are sitting on 48 colored dots, involved in a similar routine

N2 - Boys are typically more physically active than girls, but schools have the potential to promote health-related physical activity for all children. This study investigated gender differences in children's physical activity levels during physical education (PE) classes and unstructured recess periods. The activity levels of 91 fifth-grade children were assessed by accelerometer (Caltrac) on 3 days. Results indicated that children's activity levels were low to moderately stable from day to day in both environments. Boys and girls had similar activity levels during PE, $t(89) = 1.49$, $p = .140$, but boys were significantly more active than girls during recess, $t(89) = 3.27$, $p = .002$. Girls were significantly more active during PE than they were at recess, $t(51) = 2.08$, $p = .043$. The results suggest that structured PE classes may provide similar amounts of physical activity for both genders

N2 - The article discusses a report which revealed that kids who stay inside the house too much may suffer "nature deficit disorder" which can add to a range of behavioral problems like attention disorders, depression and declining creativity. Another report showed that U.S. children spend more than 53 hours a week engaged with entertainment media, only about six percent of the children play. Researchers also found that kids who play outside are less aggressive, in better shape and more creative

N2 - The article presents a study exploring the affinity among children towards nature as it not only develop environmental values and attitude but also foster positive social development. However, it highlights the advancing technological culture as one of the factors that separate children from nature as it introduced them the sedentary lifestyle that are spent indoors. Researchers have depicted a decline by 50 percent from 1997 to 2003 on time spent in outdoor activities

N2 - Background and purpose: Skills that are important for both social interaction on the playground and performance in physical education are ball handling skills because they are the cornerstones of many games. Unlike motor skills that develop naturally with general movement experiences, even children without disabilities need to be taught and to practice ball handling skills to become proficient. The purpose of this study was to compare ball skill performance of children with and without DCD in a one-to-one testing situation. Subjects: We recruited a sample of 116 children, 51 girls and 65 boys, aged between 7 and 11 years ($M = 8.82$ years, $SD = 0.80$). In total, 30 (25.9%) met criteria for DCD, and 86 (74.1%) did not. Method: Motor ability was assessed using the Movement Assessment Battery (M-ABC). Each participant was required to complete 10 overhand throws and to catch a ball adjusted to their hand size with two hands 10 times. Video analysis was used to determine the developmental level of throwing and catching (Roberton & Konczak, 2001). Results: A MANOVA with the factors DCD-group and age band on throwing (foot action, trunk action, backswing, humerus action, forearm action) and catching (arm action, hand action, body action) revealed a significant main effect of DCD for the developmental sequences of throwing ($p < .05$) as well as for catching ($p < .01$). Furthermore, children without DCD caught more balls than did the DCD children, $F(3, 99) = 10.13$, $p < .001$, $\eta^2 = .235$, and their throwing accuracy was significantly superior to that of the DCD children, $F(3, 101) = 3.59$, $p = .016$, $\eta^2 = .096$. Conclusions: The findings from this study clearly showed that children with DCD are at a disadvantage in controlling a ball. Without a tailored intervention, these children will not be able to participate properly in physical activities. ABSTRACT FROM AUTHOR

N2 - Background: A lack of physical activity (PA) and the occurrence of overweight and obesity among school-aged youth have become a major societal problem. Arising from the general concern about the future generations' health, schools have been found to be potentially important settings to promote positive health behaviour, since all pupils can be reached spending large amounts of time in the school environment. Moreover, it is beyond doubt that physical education (PE) has a key role to play. As in other European countries, the Flemish PE goals identify the importance of PA in the development and maintenance of good health. However, the discrepancy between the important role attributed to PE with regard to the development of a healthy and physically active lifestyle and the currently observed increasing sedentary and unhealthy behaviour of children and youth, is one of the reasons to question the efficiency of the current PE curricula. Aims: Within the framework of the Flemish education system, this paper aims to document on the pathways by which PE and schools can contribute to establish lifetime adherence to sport and physical activity in order to enhance and maintain young people's health later in life. From a public health perspective, this is one of the main challenges for PE in the forthcoming decades. Methods: The current PE curriculum requirements and implementation in Flemish schools are described as a starting point. Then, evidence-based recommendations are formulated in order to optimise the content and delivery of the PE curriculum towards its health-related goals. Conclusions: School PE has been recognised as the foundation base of the PA participation pyramid. Nevertheless, there is a need to move beyond the PE and school curriculum. Especially, schools, parents and the community should work together to encourage children and youth to be physically active. As a consequence, the PE teachers' role should not be restricted to the education of pupils during PE lessons, but should be expanded to include guiding youths in the process of becoming physically active both inside and outside school and for life. PE teachers have

to accept this responsibility and this effort has to be recognised by the school board. ABSTRACT FROM AUTHOR

N2 - This study analyzed the 1999 to 2003 database of the Center for Disease Control and Prevention (CDC) for seasonal and longer-term time trends in the sexually transmitted diseases (STDs) of chlamydia, gonorrhea, and syphilis in the United States. Linear regression was used to ascertain time trends, and a linear mixed auto-regression model was applied to determine the statistical significance of the major peaks relative to the annualized time series mean. A statistically significant increasing trend during the 5 yr span was documented only in the incidence of chlamydia. No clear annual periodicity was detected in any of the STDs; instead, significant three-month cycles were documented in all the STDs, with prominent peaks evident in March, May, August, and November. The March and May peaks could be associated with the sexual activities of young adults during spring break, which for different colleges and universities, commences as early as mid- to late-February and concludes as late as early- to mid-April, when huge numbers of sexually active youth congregate at beach resort settings. We propose the August peak is representative of summer sexual activity, in particular, of youths during school recess when adult supervision is poor. Finally, the autumn peak seems to be an expression of an endogenous annual rhythm in human reproductive biology, exemplified by elevated levels of testosterone in young males and sexual activity at this time of the year. N2 - Many nonprofit organizations needing volunteers struggle to find individuals who can provide the hours of support their programs, services, and events need (Urban Institute, 2004). Researchers have recognized the contribution of youth volunteers and have examined various aspects of youth volunteer experiences to better understand them (e.g., Hall, McKeown, & Roberts, 2001). Much of the research has focus on those 13 and older, however, youth between the ages of 8 and 12 (younger youth) have been overlooked. Research shows that younger youth do volunteer (Grimm, Dietz, Spring, Arey, & Foster-Bey, 2005), but little is known about the experiences they have. The purpose of this study was to explore constraints younger youth face and ways in which these constraints are negotiated. Using semi-structured, face-to-face interviews, data were collected from 73 youth volunteers (31 males; 42 females) ages 8 to 12 and 7 Executive Directors from Boys and Girls Clubs (BGC) in Atlantic Canada. The findings indicated that attitudes of adults in the community toward younger youth can limit the volunteer opportunities that are welcoming for this age group, affect younger youths' perception of their abilities, and influence their enjoyment of the volunteer experience. The important roles facilitators played in younger youths' access to and enjoyment of volunteer experiences was evident. Youth leaders can help younger youth overcome constraints by ensuring that youth are matched with volunteer tasks that are appropriate for their skill set, are adequately prepared for the tasks and situations that may arise while performing their tasks, participate in tasks with friends, and have chances to discuss their volunteer experiences. Parents can also support involvement through preparing their child for, and debriefing volunteer experiences. Forming partnerships with organizations that need volunteers may be helpful in lessening some of the challenges youth leaders encounter when trying to facilitate volunteering experiences for younger youth. Efforts to educate the public about the abilities of younger youth to contribute to their community may be important in shifting attitudes and increasing the welcoming opportunities available. N2 - Context: Although playground surfaces have been investigated for fall impact attenuation, the surfaces that cheerleaders use have received little attention. Objective: To determine (1) the critical height for selected surfaces used by cheerleaders at or below which a serious head impact injury from a fall is unlikely to occur, (2) the critical heights for non-impact-absorbing surfaces for comparison purposes, and (3) the effect of soil moisture and grass height on gmax (which is defined as the multiple of g [acceleration due to gravity at the earth's surface at sea level: ie, 32.2 feetA²s⁻²-1A²s⁻²-1] that represents the maximum deceleration experienced during an impact) and the Head Injury Criterion (HIC) at the critical height for a dry grass surface. Design: Observational study. Settings: A local cheerleading gym, indoor locations within the authors' institution, and various outdoor locations. Main Outcome Measure(s): gmax, HIC, and critical height. Results: Critical heights for the surfaces tested ranged from 0.5 ft (0.15 m) for concrete and vinyl tile installed over concrete to more than 11 ft (3.35 m) for a spring floor. Increases in grass height and soil moisture resulted in an increase in the critical height for grass surfaces. Only spring floors and 4-in (0.10-m)-thick landing mats placed on traditional foam floors had critical heights greater than 10.5 ft (3.20 m), thus providing enough impact-absorbing capacity for performance of 2-level stunts. Conclusions: The potential for serious head impact injuries can be minimized by increasing the shock-absorbing capacity of the surface, decreasing the height from which the person falls, or both. Cheerleaders and cheerleading coaches should use the critical heights reported in this study to compare the relative impact-absorbing capacities of the various surfaces tested, with critical height as an indicator of the impact-absorption capacity of the surface. The findings of this study can be used to select the most appropriate surface for the type of maneuver to be performed, based on the maximum height expected to be achieved by the cheerleader(s) during execution of the maneuver. Cheerleaders should not perform maneuvers at heights that exceed the critical height for the surface on which they are performing. ABSTRACT FROM AUTHOR

N2 - [Purpose] In this study, we examined physical contact with obstacles by children with and without developmental disorders (DD). [Subjects] Participants were nine children with DD and nine normal children. [Methods] All participants went through a course with seven pieces of playground equipment and six bars at different heights under three conditions: the first trial was with no instruction, the second trial was with an instruction to avoid collision, and the third trial was with an instruction to avoid collision and go through as fast as possible. [Results] The children with DD had more physical contact with the bars than normal children, indicating that attention deficit was not the cause of the increased contact in the children with DD. They also showed a significantly higher number of waist-contacts when compared to the normal children. This suggests that the children with DD had more contact when concurrent visual-feedback could not be used during avoidance movements. [Conclusion] It is possible that incorrect estimation based on body-characteristic information is the cause of the increased contact in the children with DD. ABSTRACT FROM AUTHOR

N2 - The article presents a study showing the positive relationship between academic achievement and physical activity or participation in sports conducted by Coe, Pivarnik, Womack, Reeves, and Malina. The group reveals that the students involved in regular physical activity outside of school have higher academic achievement scores. This result implies that sports participation meets threshold level for physical activity that is essential to produce potentially desirable effects. Physical education classes need to offer greater number of healthy activities because the students are found to be inactive in physical activities in school

N2 - The article presents information on the study done to determine the total moderate-to-vigorous physical activity (MVPA) that can be attributed to sports involvement in the youth. The article also assesses the contributions to MVPA from recess and physical education. The method of research is also disclosed along with the results. It is revealed that the researchers selected and observed a group of boys between the ages of six and 12 who participated in soccer, basketball, and football. It is pointed out that there is a need to consider the unique characteristics of the youth in regard to sports, physical education, and recess. The limitations of the study are also acknowledged by its proponents along with suggestions for future studies

N2 - An apparent increase of childhood obesity along with observed low physical activity (PA), initiates searching for effective strategies and verification of programs enhancing an increase of PA in children and reduction of their excessive weight. School environment offers apt opportunities to carry out physical and nutrition intervention programs because children spend a significant part of the day at school. The main goal was to identify the effect of a two-year longitudinal school-based PA intervention program aimed at the reduction of obesity in children after two years since the program was finished. 84 girls and 92 boys aged 10-11 participated in the study who participated in the survey in 2006-2008 as 6-9 year-olds and were included in the intervention group (43 girls and 45 boys) and the control group (41 girls and 47 boys). PA was monitored using Yamax pedometer and obesity was estimated using the percentile graph of Body Mass Index of World Health Organization (WHO) for girls and boys aged 5-19. At the beginning of the intervention program, there were no

significant differences found between the proportion of obese girls and boys in the intervention and the control groups - (girls 6.9% x 7.3 %, boys 11.1 % x 6.4 %, intervention x control groups resp.). At the end of the intervention program, there was no occurrence of obesity in the intervention group whereas there were 21.9 % girls and 23.4 % boys obese in the control group. After two years since the intervention program finished, there was a significantly lower ($p = 0.0124$) occurrence of obesity (girls 2.3 %, boys 6.7 %) and higher ($p < 0.0001$) number of school steps (girls 3099, boys 3368) in the intervention group than in the control group (girls 17.1 %, boys 23.4 %; girls 1751, boys 1799). A long-term increase of PA performed at school environment can significantly enhance the prevention of childhood obesity. ABSTRACT FROM AUTHOR

N2 - Introduction: This study had two main purposes: i) to identify the incidence rate of physical activity practice and some other health related parameters (alcohol ingestion; obesity tobacco and drugs) in school age students from Vila Real; ii) to verify the impact of physical activity and sports practice in these health related parameters. Materials and Methods: A sample of 376 school age students with age ranged from 16 to 20 years was used. To evaluate the physical activity practice and alcohol, tobacco and drugs abuse the Health Behavior in School-Aged Children inquiry was used. For the Quetelet Index the height and weight of each one of the students was evaluated. The cut of points proposed by Cole (2000) to determine overweight and obesity was used. The χ^2 was used in the comparison between the categorical variables and the Mann-Whitney test in the ordinal variables. Results: The all evaluated sample had practice in physical education discipline, and 34.6% of student had also extra school physical activity (clubs).The incidence rate of overweight and obesity in the sample was 11.2% and 2.1% respectively. In what concerns the illicit abuse ingestion 34.8% on inquired students had normal alcohol consumption, 20% tobacco consumption and 22% drugs consumption. Discussion: The results

pointed showed also significant statistical differences comparing the groups with and without extra physical activity outside the school yard. In beer consumption ($p=0.004$). These results are in accordance with previous results Matos (2003) which refer that young child who does not practice physical activity have higher alcohol consumption values. In what refers to the other variables in spite of non statistical significant, it was observed for more obesity, more alcohol and tobacco consumption in non active students. These results agreed with the specific consulted literature. ABSTRACT FROM AUTHOR

Introducción: Este estudio tiene dos objetivos: i) verificar la incidencia de la práctica de actividad física y de algunos indicadores de salud (obesidad, consumo de alcohol, tabaco y drogas) en alumnos del 2º y 3º Ciclo de la Enseñanza Básica y Secundaria de Vila Real; ii) verificar el impacto de la práctica de actividad física y deportiva en estos indicadores de salud. Materiales y Métodos: La muestra fue constituida por 376 jóvenes con edades comprendidas entre los 16 y los 20 años. Para evaluar la práctica de actividad física y el uso de sustancias ilícitas fue utilizado el cuestionario "Comportamiento y Salud en Jóvenes en Edad Escolar", adaptado del estudio europeo Health Behavior in School-Aged Children. Para el cálculo del Índice de Masa Corporal, fue recogido el peso y la altura, siendo utilizados los valores de corte propuestos por Cole (2000) para definir sobrecarga u obesidad. En la comparación de grupos se usó a X² en las variables categóricas y el test de Mann-Whitney en las ordinales. Resultados: La totalidad de la muestra participaba de las clases de educación física escolar y 36,4% de los jóvenes practicaban deporte extraescolar. La incidencia de sobrecarga ponderal y obesidad fue de 11,2% y 2,1%, respectivamente. Cuanto al consumo de sustancias ilícitas, 34,8% de los inquiridos consumían alcohol, 20% de los alumnos fumaban y 22% afirmaron ya tener experto drogas. Discusión: Los resultados demostraron haber diferencias significativas cuando se comparó jóvenes que practicaban educación física escolar y otra modalidad deportiva extraescolar en el consumo de cerveza ($p=0.004$), presentando, los primeros, consumos superiores. Estos resultados están de acuerdo con Matos (2003), indicando que los jóvenes que no practican actividad física afirman, más frecuentemente, consumir alcohol. Relativamente a las otras variables dependientes, a pesar de las diferencias no sean estadísticamente significativas, se verifica una tendencia para los jóvenes que sólo practican educación física escolar sean más obesos, consuman más vino y bebidas blancas. Estos resultados están en consonancia con la literatura de la especialidad. ABSTRACT FROM AUTHOR

N2 - The article discusses free time physical activity to fight obesity in children. The Recess Activity of the Week (RAW) program is presented as an effective way to motivate children to join physical activities. Sample activities were developed to help teachers develop their own programs in school. The U.S. Centers for Disease Control and Prevention states that 18.8 percent of children between 6-11 years old are overweight

N2 - This article assesses the usefulness of the Parent Attitude Research Instrument (PARI) as a means of distinguishing the maternal child-rearing attitudes in groups with high and low levels of fear of failure (FF). In

an achievement-oriented culture, a negative approach to achievement could lead to poor adjustment. The purpose of the study conducted by the author was to assess the usefulness of the PARI as a means of distinguishing the maternal child-rearing attitudes in groups with high and low levels of FF. The study showed that mothers of the highest FF scorers tended to show more marital conflict and more irritability than mothers of the lowest FF scorers. They believed more in avoidance of communication and suppression of sexuality. They exhibited more inconsideration of the husband, showed more ascendancy, and fostered more dependency. On the other hand, mothers of the lowest FF scorers appeared to foster more martyrdom, show more interest in excluding outside influence, and were very permissive in approving the child's activity

N2 - Series books, although "by no means literary masterpieces" (Inness, 1997, p. 96), serve as windows onto the popular culture of the time. Vintage juvenile fiction that focuses on the "new" leisure activities of camping and hiking provides valuable insights into the construction of race, class, gender and sexuality at the turn of the century. Not just representations of the modern historical period, these books provide insights into the "ideological density" of the era and as such broaden and strengthen our understanding about the role of leisure in our lives. The focus of this paper is on the "ideological density" of both series and single-issue books for boys and girls featuring the leisure activities of camping and hiking. [ABSTRACT FROM AUTHOR]

"En aucun cas" se trouve dans les livres de series "un chef-d'oeuvre litteraire" (Inness, 1997, P. 96), mais ils permettent d'obtenir de l'information aupres de la culture pop de cette periode. La fiction juvenile typique qui se fixe aupres des "nouveaux" activites loisirs de camping et d'excursion offre des apercus precieux dans la construction de race, classe, sexe et sexualite a la tournure du siecle. Non seulement est-ce que ces livres offrent une representation de la periode historique moderne, mais aussi des apercus dans la "densite ideologique" de cette epoque et comme tel, elargissent et renforcent notre comprehension du role des loisirs dans nos vies. Cet article se fixe sur la "densite ideologique" des livres de series et de simple edition pour les garcons et filles qui incluent les activites loisirs de camping et d'excursion. N2 - Continuous observation of 34 girls and 30 boys aged between 5 and 10 years was undertaken as part of an ongoing investigation of children's activity levels. Observations were carried out during school break times, lunch times and physical education lessons and during free time outside of school. Children engaged in moderate to vigorous physical activity (MVPA) for 28 percent of total time. Twenty four children (37.5 percent) recorded at least one sustained 20-min period of MVPA and 31 children (48 percent) recorded at least one 15-min period of sustained MVPA. Sixty four physical education lessons were observed. During these lessons 28 children (44 percent) participated in MVPA for a sustained 5-min period and 10 children (16 percent) engaged in MVPA for a sustained 10-min period. There is evidence that some preadolescents are engaging in sustained MVPA. Whether the findings could be considered satisfactory or otherwise, in terms of heart health, depends on the length of sustained activity deemed appropriate for preadolescents. There are also many young children who take part in minimal physical activity and therefore widespread efforts to promote physical activity among children need to be maintained

N2 - Objective. A comprehensive understanding of individual differences in maternal parenting behaviors cannot be realized without consideration of multiple determinants of parenting within the same study. The goal of the present study was to examine the association of 3 categories of determinants of parenting (i.e., parent personality, contextual sources of stress and support, and child effects) to individual differences in maternal parenting behaviors. Design. Supportive and controlling parenting and child social responsiveness were observed during 2 free-play sessions when toddlers (N = 140) were 30 to 36 months old. Mothers completed questionnaires measuring personality and contextual sources of stress and support. Results. More maternal supportive behaviors were predicted by higher levels of child social responsiveness. More maternal control was associated with lower socioeconomic status, more work outside of the home, more extraversion, and more neuroticism. Conclusions. Because the determinants of parenting that predicted maternal controlling behaviors were different from those that predicted supportive parenting behaviors, examining how multiple determinants of parenting relate to different aspects of parenting behavior is necessary to more fully understand individual difference in parenting behaviors

N2 - Purpose : To ascertain how well health services in Lusaka, Zambia currently meet the safe motherhood and reproductive health care needs of women who have physical impairment leading to disability. Methods : A qualitative study was conducted in Lusaka, Zambia. In-depth tape-recorded interviews were conducted with 24 purposively selected women with disabilities and with 25 safe motherhood/reproductive public sector health service providers. Qualitative analysis was conducted using NVivo software. Results : Women with disabilities encounter various social, attitudinal and physical barriers to accessing safe motherhood and reproductive health (RH) services in this particular setting. The strong desire for children and affection can increase vulnerability to sexual exploitation. At the same time, a generalized assumption among reproductive health service providers that women with disabilities will not be sexually active, and not require RH services, leads to increased vulnerability to sexually transmitted infection including HIV. Once pregnant, traditional beliefs about transmission of disabilities can create barriers to integration in ante-natal clinics. Nurse-midwives' fear of delivery complications in women with physical impairments can also result in routine over-referral to a tertiary maternity facility which is outside the locality and harder for women with mobility limitations to get to. Conclusion : Greater understanding of the influences underpinning societal attitudes towards sexuality and disability in this setting, and more extensive communication between health care staff and women with disabilities would facilitate positive action towards improving safe motherhood and reproductive health services for women with disabilities. N2 - The article reports on research which was conducted to determine the amount of physical activity in which children engage during physical education classes and factors that mediate their participation. Third and 4th grade students wore pedometers during each 30-minute physical education class for one school year. Researchers found that third and fourth grade boys took significantly more steps than third and fourth grade girls, and those involved in youth sports accumulated more steps during a 30-minute physical education class

compared to those who were not involved in youth sports. They also found that steps accumulated during classes held outside were significantly greater compared to those accumulated during classes held inside, and steps accumulated on free (recess) days were significantly greater compared to those accumulated on structured days. They concluded that their results highlight the need for recognition of the contexts of gender and youth sport participation when planning and implementing an appropriate physical education experience for children

N2 - This paper examines the influence of some childhood background factors on adult levels of participation in hunting and fishing activities. The study, based on data collected from hunters and fishermen in Pennsylvania, offers some insights into the effect early experiences with two types of outdoor recreational activities have on participation in adult life. The data show that residence in youth and source of introduction to hunting and fishing, although significantly related to extent of participation as a youth, are not related to higher levels of adult participation. However, for hunters, and to a limited extent for fishermen, frequency of participation as a youth is positively related to current level of participation. It is suggested that intervening factors occurring in the time interval between youth and adulthood serve to reduce or eliminate the influence of childhood residence and source of introduction, and that at different points of the life and work cycles certain variables recede and others emerge as influences on participation. Work-related influences on level of adult participation are presented as one such "intervening" variable. ABSTRACT FROM AUTHOR

N2 - Conditions and realisation of physical education in youngest children of primary schools at the Włocławek province (202 schools) were analysed. Only 19,31% of schools had an appropriate gymnasium, sports area and recreation area. 72 schools (35,64%) had a full-size gymnasium, 69,31% of schools had a full-size sports area, and 57,43% of schools had a full-size recreation area of surface at least 450 m². Overall weekly physical exercises organised by schools were 3 hours or more in 99.5% of schools, 4 hours at least in 73.77% of schools, and 5 hours at least in 18.32% of schools. The majority of schools realised program of 4-5 hours or more per week (55,45%). Equipment with recreation area was a significant determinant of number of hours of physical exercises provided by schools ($\chi^2=6,76$; $p=0,03$), while equipment with gymnasium ($\chi^2=2,31$; $p=0,52$) or sports area ($\chi^2=1,33$; $p=0,51$) were not

CY - ;

N2 - The impact of children on cultural heritage places is a phenomenon dreaded by parks managers. Children's means of exploring and comprehending the world around them is much more direct and less abstract than that of adults. By understanding children's learning behavior, the processes leading to a detrimental impact cannot only be avoided, but moreover be turned into a positive experience for children and parents alike. Parks management can be informed by experiences garnered in the fields of museum interpretation and education in zoological and marine parks. The mere provision of textual and pictorial information is limiting the learning experience of children, as well as that of many adults. Showcased specimens of artifacts are illustrative to an adult audience; they are "remote" for children. Management needs to provide for controlled environments in which children can satisfy their needs of examining artifacts and sensitive items on their terms through touch tables and other interactive displays, forcing the adoption of different postures, etc. If well done, this satisfies children's need for physical exploration and reduces impact in the open space setting. For geographically remote parks, there is a need to provide an outlet for children to "let off steam" after a long trip in the car. The establishment of an adventure playground would be desirable, preferably designed with thematic reference to the specific park

visited. Park infrastructure must address children's learning and energy dissipation needs through the provision of interpretation centers and (outside) activity areas appropriate to children of various ages. This needs to be coupled with information and guidelines for parents visiting parks, including strategies to control and channel children's actions and energy through (i) careful planning of the trip and the approaches to the park, (ii) planning of activities at arrival, and (iii) guidelines for appropriate parental control during the visit. Parents will have a better visitor experience if their children are engaged in a captivating learning experience. Such children will be less demanding of parental control and their parents will have more time to follow their own interests. It follows that such parents will also be more responsive to issues of nature and cultural conservation

N2 - Abstract: Objectives: To explore children's perceptions of the factors influencing their engagement in physical activity during the *f_ocrITICALf__* lunchtime period, using a *socialf_*"ecological framework. Design: This study was an in-depth descriptive qualitative design. Methods: Fifty-four South Australian children aged 10*f_*"13 years participated in same-gender focus groups. Transcripts, field notes and activity documents were analysed using content analysis. Using an inductive thematic approach, data were coded and categorised into perceived barriers and facilitators according to a *socialf_*"ecological model. Results: Children identified a range of environmental, social and intrapersonal barriers and facilitators. Bullying/teasing, the school uniform and school rules were exposed as explicit barriers to lunchtime play. Other important barriers included lack of access to, and poor suitability of, space, lack of access to programs/facilities and equipment, and lack of peer and teacher support. Perceived facilitators of lunchtime physical activity centred on access to equipment, enjoyment, motivation to improve skills, and peer support and acceptance. The freedom to make up or modify rules for games was also perceived to be a facilitator of lunchtime play. Conclusions: Communicating with children has been an effective approach in uncovering perceived barriers and facilitators to lunchtime play that may not have been previously considered in the quantitative correlate literature. Lunchtime interventions targeting children's physical activity should focus on addressing the barriers perceived to be important to lunchtime play. Copyright &y& Elsevier

N2 - This study examined the relations between specific adherence variables and child outcomes among a sample of 60 families participating in a family-based pediatric obesity program. Adherence was measured using both objective and self-report methods. Family adherence to the treatment protocol significantly predicted child outcomes. However, parent self-report measures of adherence were better predictors of child outcome than objective measures. The importance of including parent self-report measures of adherence for behaviors outside of the treatment setting was demonstrated in this study. Pediatric obesity treatment should emphasize the importance of modifying parent behaviors as a means for improving child outcomes

N2 - The article focuses on the lack of physical activity among children during recess. According to the findings from a research conducted by M. L. Babkes and C. D. Sinclair, elementary school children appear to rarely reach very active intensity levels during recess while fifth-grade children took the most steps and were most physically active than any other children in elementary. The research also reveals that male children were more physically active in terms of duration, intensity and frequency during recess as compared to female counterparts

N2 - As our society becomes more technologically advanced, people are spending more time indoors in artificial environments and less time in natural settings. Richard Louv coined the phrase "Nature Deficit Disorder" to describe some of the social, psychological, and ecological struggles that have arisen as members of society become less in tune with the natural world. Physical Education teachers are in a unique position to get children outside into natural environments while still meeting necessary educational requirements. This article will also address a case study of a child with ADHD. Nature Deficit Disorder (NDD) is a term developed by Richard Louv, author of "Last Child in the Woods: Saving our children from Nature Deficit Disorder," which refers to the recent trend of children spending less time outdoors in natural environments. Louv suggested that the detachment from nature has contributed to a wide range of behavioral problems including depression, childhood obesity and an increase in the symptoms of Attention Deficit Hyperactivity Disorder (ADHD). His research has shown that children who get regular, daily doses of green spaces tend to perform better in school, are more physically active, and are more content (Louv, 2005). Physical Education by its nature gets children active and helps them burn excess energy. When Physical Education moves outside, children benefit even more.

N2 - The article highlights on an after-school program in a middle school and youth development strategies that can also be embedded in the physical education curriculum and can serve a wide age range. It typifies a number of programs that use physical activity to tap children's developmental potential Project Effort and Project Lead. Today's youths face many obstacles as they move toward adulthood. Regardless of their life circumstances, all young people need ample choices for supervised growth!promoting activities both inside and outside of school. The goal is for youths to become productively independent and to be able to survive and thrive in a society that needs their contribution. Many youths, however, are learning negative, habit-forming, life-altering behaviors that will inhibit them from finding success in the adult society and that will lead to a pattern of personal failure throughout life. The after-school leadership program is designed to provide positive growth experiences to middle school youngsters. Participants in this program include students who are recommended by school staff because they are at or below the academic average of the school. Physical activities, especially adventure activities, constitute the primary means for achieving program goals

N2 - The goals of this study were to compare visitation patterns and recreation participation among Latino men and women at three different urban outdoor recreation environments and to examine the types of physical activities that took place at each of the three environments. Ecological model was employed as a theoretical framework in this study. Data were collected with the use of questionnaire surveys distributed to 917 visitors at 1) two community parks in Elgin, Illinois, 2) a section of the Lincoln Park in Chicago that contains an extensive trail system, and 3) an outdoor sports complex in Aurora, Illinois. The results showed significant variations in the recreation use of these three environments and, in particular, in their suitability to foster physically active leisure among Latino men and women. Walking was more common at the community parks and trails, whereas soccer was more popular at the sports complex. Trails were also conducive to jogging/running and bicycling. Latino users of all environments showed significant gender variations in recreation participation, with women more likely to be involved in walking and all passive activities other than barbecuing/picnicking, and men more likely to be involved in all active pastimes (other than walking). The implications of the study's findings are explored. Park managers are encouraged to consider the family-focused nature of the Latino culture when programming and/or planning for this particular subgroup of the population. Providing programs and services that allow Latino parents to be physically active with their children should be encouraged. Examples include family field trips, family soccer games, dances, and mother-children walks. Informational campaigns that clearly explain the health benefits associated with physical activity (for both adults and children) are also encouraged. In summary, organizing family-oriented events that promote various physical activities in parks, trails, and sports complexes may be an effective strategy for improving the activity levels of Latino men, women, and children. N2 - The article focuses on International Play Association that aims to protect, preserve, and promote play as a fundamental right for all humans. Legislative and advocacy activities of IPA/USA are based on the United Nations' Declaration of the Rights of the Child. IPA/USA rationalizes the importance and relevance of play by noting that children are the foundation of the world's future. Play helps children develop physically, mentally, emotionally, and socially. IPA/USA is a strong advocate for recess. For more information about membership and the many facets of IPA/USA, one can see their web page at <http://www.ipausa.org/>

N2 - The physical activity levels of 47, 5- to 7-year-old children were assessed before and after a school playground was painted with fluorescent markings. Children's physical activity was measured using heart rate telemetry during three playtimes before and after the markings were laid down. Children in the experimental and control groups spent 27 and 29 min, respectively, in moderate to vigorous physical activity (MVPA) before the intervention, increasing to 45 and 36 min, respectively, during the intervention period. MVPA, vigorous physical activity (VPA) and mean heart rate remained relatively stable in the control group compared to respective increases of 10 and 5% of playtime and 6 beats min⁻¹ in the experimental group during the intervention period. The ANCOVA analysis revealed significant interactions and main effects for the intervention for MVPA, VPA and mean heart rate. Conversely there were no main effect differences between groups. These results suggest that while playground markings had a significant and positive influence on children's physical activity, factors other than playground markings may also influence children's physically active play.

N2 - The article focuses the life of Bode Miller, a skier and his wife Morgan Beck, a volleyball player, who faced rough time in the year 2013. It informs that Miller lost his brother on April 7, 2013 which is one of the saddest parts of his life. It further informs that Miller and Beck also fought a battle for the custody of a child from his ex-girlfriend in 2013. It also mentions that despite of these odd things both of them love each other very much and understands each others feelings

N2 - The purpose of this study was to investigate the perceived impact of outdoor residential camp experience on the spirituality of youth. This research focused on 11 participants in month long leadership programs at two YMCA residential camps in Ontario, Canada. After conducting an in-depth interview at the beginning and end of each of the participant's leadership experience, it was found that the participants did feel camp had an affect on their spirituality. The camp setting played a role by providing a natural setting and an opportunity for the participants to get away from their everyday lives in an urban environment. In this environment, experiencing structured and unstructured time alone influenced their spirituality, by providing them with opportunities to reflect on their lives. Social experiences also had an impact on the participants' spirituality by allowing them to develop relationships through formal and informal activities. Finally, the majority of the participants expressed that the camp experience provided them with positive feelings that they associated with their spirituality. This study found that the four themes of the camp setting, alone time, social experiences, and positive feelings played an interrelated role in the participant's camp experience and spirituality

N2 - Background: High school sports participants sustain millions of injuries annually; many are recurrent injuries that can be more severe than new injuries. Hypothesis: Recurrent injury patterns differ from new injury patterns by sport and gender. Study Design: Descriptive epidemiology study. Methods: High school sports injury data for the 2005 through 2008 academic years were collected via High School Reporting Information Online (RIO) from a nationally representative sample of 100 US high schools. Results: From 2005 through 2008, certified athletic trainers reported 13 755 injuries during 5 627 921 athlete exposures (24.4 injuries per 10 000 athlete exposures). Recurrent injuries accounted for 10.5% of all injuries. Football players had the highest rate of recurrent injury (4.36 per 10 000 athlete exposures). Girls had higher rates of recurrent injuries than boys in soccer (injury rate ratio = 1.39; 95% confidence interval, 1.07-1.82). Recurrent injuries most often involved the ankle (28.3%), knee (16.8%), head/ face (12.1%), and shoulder (12.0%), and were most often ligament sprains (incomplete tears) (34.9%), muscle strains (incomplete tears) (13.3%), and concussions (11.6%). A greater proportion of recurrent injuries than new injuries resulted in the student choosing to end participation (recurrent = 2.4%, new = 0.7%). Recurrent shoulder injuries were more likely to require surgery than new shoulder injuries (injury proportion ratio = 4.51; 95% confidence interval, 2.82-7.20). Conclusion: Recurrent injury rates and patterns differed by sport. Because recurrent injuries can have severe consequences on an athlete's health and future sports participation, injury prevention must be a priority. Knowledge of injury patterns can drive targeted preventive efforts. ABSTRACT FROM AUTHOR

N2 - The article discusses how obesity is even more pronounced among black and Mexican children than among whites. Obesity among all children in the U.S. has reached alarming levels, but according to a Centers for Disease Control and Prevention study (chart, below) the problem is considerably worse for minority

populations than for Caucasians. "If you think about all the environmental risk factors that contribute to this childhood obesity, many are worse in minority and low-income communities," says Shiriki Kumanyika, associate dean for health promotion and disease prevention at the University of Pennsylvania School of Medicine, who has studied obesity in minority populations for more than two decades. "You often have poorer availability of healthy food. Cultural and regional food preferences also may be contributors. Schools in lower-income communities often do not have adequate outside play areas, and there are built-in environmental issues like safety and street lighting [that inhibit exercise]. Two other factors: First, obesity rates are also higher in minority adults than in Caucasians, and the children of obese adults are more likely to be overweight than the children of normal-weight adults. Second, Kumanyika says, "a high rate of obesity is a longstanding situation in several minority populations: Mexicans, Native Americans and adult black women." But among young African-Americans, she says, "it's a more recent trend."

N2 - The article discusses reasons why children in the United States are heavier than ever before, as of 2004. Geography. In the latter half of the 20th century Americans increasingly moved from city neighborhoods to suburbs. Kids stopped walking and riding their bicycles and got into cars. Routine forms of exercise were lost. Fear. Children who were inclined to leave their homes to play were discouraged by parents who were fearful of abduction. Hardworking Parents. The increase in the number of two-income households has left kids stranded in after-school and extended day-care programs. Before, children were outdoors burning calories. The Soccer Myth. Organized youth teams have exploded--particularly in soccer--but youngsters who join them play only a couple of days a week and get a fraction of the exercise they need, often standing around awaiting their turns in static drills. Emphasis on Test Scores. Cash strapped schools, frightened by No Child Left Behind mandates, have shifted resources and class time from phys ed to prepping students for standardized tests. Fast Food. Mom's baked potato has been replaced by a supersized order of fries cooked in beef fat. Soft-drink machines have been lodged in high school hallways. Technology. First came television, followed by cable and digital and hi-def. Video games evolved from Pong to Tomb Raider. Finally came the Internet and the IM monster. Children sit and click. A Family Trait. The children of overweight people are often overweight themselves, and more than 64% of U.S. adults are overweight

N2 - Recently research has shown that many children are not developing competence in fundamental movement skills. For example, it has been suggested that Victorian children in Grade 2 have major developmental deficits in throwing, catching, striking and kicking. It is clear that early schooling experiences must provide equitable and outcome producing play experiences for children if they are to develop fundamental movement skills that form that basis of future participation in physical activity. Three comparative case studies examined the opportunities that pre-primary children (5 year-olds) have to engage in fundamental movement skills in an outdoor play settings. Direct observation of individuals and small groups allowed for the analysis of the fundamental movement skills performed by children. Results indicated that many children are not engaging in the manipulative skills of throwing, catching, hitting and kicking while running, jumping and climbing were the predominant skills performed. Further findings indicate the variability in the practice of fundamental movement skills at the different centres relate to time allocation, teacher/adult presence in the play setting, playground design and equipment usage/availability

N2 - Introduction: This study examined the differences between boys and girls in relation to activity levels during play and sensory preferences for activity level, body position and movement. A review of the literature revealed no evidence to explain if boys and girls prefer different body positions while playing or if body position might be used to measure their activity levels. Method: This retrospective study used data from demographic forms, children's Sensory Profiles and observations of children's play in classroom settings. The sample consisted of 53 typically developing children between ages 3-5 years from a suburban preschool in Kansas in the United States. Results: Analysis of data from play observations revealed no significant differences between boys and girls in relation to body position mean ($p = 0.33$), body position standard deviation ($p = 0.19$) and total number of change position times ($p = 0.28$). Analysis of data from children's Sensory Profiles showed no significant differences ($p = 0.97$) between boys' and girls' seeking preferences reflected by activity level, body position and movement items in the Sensory Profile. Conclusion: Future research should investigate children's play in outdoor playgrounds and implement more rigorous methods in rating activity levels

N2 - This study tested the effect of a short-term coordination program focused on improving the agility of school children ages 7 to 8 years. Healthy Japanese children were placed in an experimental group of 26 children (10 girls, 16 boys) and a control group of 20 children (9 girls, 11 boys). The experimental group participated in 10 coordination program sessions during recesses; each session was performed 1 to 3 times per week, for 26 days. No differences were observed between the groups in repeated side-step scores prior to the program, although an interaction was observed after the completion of the treatment. The short-term coordination program was effective in increasing the agility of elementary school children aged 7 to 8 years.

N2 - **PURPOSE:** Although girls are generally less physically active than boys, some girls regularly engage in high levels of physical activity (PA); however, very little is known about these girls and how they differ from those who are less physically active. This study examined the PA behavior and related characteristics of highly active adolescent girls and compared them with those who are less active. **METHODS:** Data from 1,866 eighth-grade girls from six field centers across the United States participating in the Trial of Activity for Adolescent Girls (TAAG) were included in the present analysis. Mixed-model analysis of variance examined differences in sociodemographic, anthropometric, psychosocial, and physical activity (accelerometry and self-report) variables between high- and low-active girls; effect sizes were calculated for the differences. **RESULTS:** High-active girls were taller, had lower body mass indices and body fat, and were less sedentary. High-active girls scored higher on self-efficacy, enjoyment of PA, self-management strategies, outcome-expectancy value, and support from family and friends than low-active girls. Low-active girls participated in more leisure time and educational sedentary activities than high-active girls. High-active girls participated in more PA classes/lessons outside of school, team sports, and individual sports. They were also more likely to participate in sports in an organized setting in the community or at school than low-active girls. **CONCLUSIONS:** Health promotion efforts should focus on decreasing the amount of time girls spend in sedentary activities and replacing that time with organized PA opportunities; such efforts should seek to minimize perceived barriers and increase self-efficacy and support for PA

VL - 12

IS - 1

N2 - The purpose of this study was to investigate the relationships of physical activity and physical fitness with educational achievement in rural South African school children aged 7 to 14 years (n= 212). All boys and girls underwent the following physical fitness tests: standing long jump, bent arm hang, sit ups, 10 x 5m shuttle run, 50 meter run, 1,600 meter run, flamingo balance, sit and reach, and plate tapping. All tests were performed in accordance with the European Tests of Physical Fitness (EUROFIT) and American Alliance for Health, Physical Education, Recreation and Dance (AAHPERD) protocols. A questionnaire was used to gather physical activity information concerning indoor and outdoor household activities, games and sports performed during the week days and weekend days. Educational achievement was assessed by means of the Educational Achievement Tests in Mathematics and English designed by South African Human Sciences Research Council. In contrast to what has been found in developed countries, the results of the present study did not show strong evidence for the hypothesis that physical activity and physical fitness are positively associated with educational achievement. Explanations for this finding may be that: first, the children in this population are confronted by a number of educational problems that may have confounded the relationship. Second, because all these children have high levels of physical activity it may be difficult to measure its influence on educational achievement, and third, the cross-sectional nature of this study. N2 - Increasingly sedentary lifestyles are contributing to overweight and other health concerns as children spend less and less time outside engaged in active play. Outdoor play provides important opportunities to explore the natural world, interact with peers, engage in vigorous physical activity, and learn about our environment. However, out-door environments often fall short of providing infants and toddlers with comfortable, engaging, and challenging activities needed for optimal physical development. This article provides suggestions for creating satisfying and developmentally appropriate outdoor play spaces for infants and toddlers

N2 - Data for the analysis were the health related fitness scores, anthropometric measures, and physical activity information from the National Children and Youth Fitness Study. The subjects were 6,800 boys and 6,523 girls, ages 6 through 18. Multiple regression produced linear composites that were used as covariates to evaluate physical and environmental characteristics that relate to gender differences. The distance runs, chin-ups, and sit-ups displayed similar patterns in gender differences across age. Before puberty the important covariates are

mainly physical, namely skinfolds. Following puberty the major factors that reduce gender differences are skinfolds and the amount of exercise done outside of school time

N2 - The purpose of this dissertation was to examine usual mobility methods of children with cerebral palsy (CP) in the home, school, and outdoors/community settings. Mobility is needed in activities of daily living and limitations in mobility may impact participation in society. Even though interventions are often provided in natural environments, knowledge of the impact of environmental setting on mobility is limited

The subjects were 307 children with CP, ages 6-14 years who participated in a longitudinal study, randomly selected from 19 centers, and stratified by age and Gross Motor Function Classification System (GANEFS) level. Measures included the GANEFS, parent-completed questionnaire on children's usual mobility methods, and the Gross Motor Function Measure

The first study indicated differences in gross motor capability and parent report of performance of mobility methods in children with CP. Among children with CP who have similar capability, there were differences in performance across settings. The second study demonstrated among children within the same GANEFS level, the variability of mobility methods across settings. Children performed higher-ranked mobility methods at home (requiring the most gross motor control), lower-ranked mobility methods at school, and the lowest-ranked mobility methods (requiring the least gross motor control) in the outdoors/community. The third study provides evidence for nonlinear changes in mobility over time in children with CP. During the first 1 1/2_ "2 1/2 years, mobility methods increased to higher-ranked methods, while in the second 1 1/2_f_ "2 years, mobility methods were unchanged or decreased to lower-ranked methods. The changes in mobility methods over time did not differ across settings

The findings indicate that environmental setting has an impact on the usual mobility methods of children with CP. The examination of children with CP should include capability and/or performance measures, depending on the purposes of examination. Performance should be measured specific to settings where children function, including the contextual features and personal factors that may influence mobility. Intervention should address the factors contributing to mobility, such as environmental adaptations and child-related factors. Screening of children with CP should occur at regular intervals so that interventions can address the changes in mobility

N2 - In the elective course of Basic games and swimming it has been realized a seven days practical training program as a part of undergraduate studies for the following courses: classroom teacher, the preschool teacher and educator in children's homes. The purpose of this course is to enable students to track, Organize, -and continuously upgrade the teaching process in the field of outdoor activities and swimming techniques, as well as the elementary games on the water. With a good organization, under the existing conditions (indoor Olympic swimming pool), the methodological procedures that have so far proved as most effective in a very short time, non-swimmer students have mastered the basic elements of swimming. In the beginning they were practicing on the ground through a game and then through specific movements in the water. The participant s sample consisted of students of the Faculty of Pedagogy in Jagodina. A total of 116 students followed the curriculum, 44 of who were non-swimmers, 14 were swimmers and 58 were only swimmer beginners. After having the results at the final measuring, after carrying out the plan and program, we were been able to determine that a large number of students were able to learn the techniques properly and that the number of floaters decreased significantly, while the number of swimmers increased. N2 - In March of 1995, the Ministry of Sport presented the Government's first attempt at a new sport policy by submitting the 'White Paper on Sport' to the nation. The White Paper, aptly titled 'Getting the Nation to Play' represented the Government's broad vision of how South African sport could be developed. Though touching on all aspects of sport, it emphasizes that the focus is to be at the bottom end of the sport development continuum(South Africa, Ministry of Sport, 1995:87). This is crucial because the goal is to reverse the low levels of participation among the Black population, especially those in the rural areas. The changes that have taken place in the political arena in South Africa since 1990, have not only impacted on the political, social and economic spheres of South Africa but have also permanently changed the face of South African sport inside and outside the country. South Africans as citizens of the global sports village however now have to deal with tremendous challenges facing the administrators, managers, coaches and participants. One of these challenges is to improve the participation levels of the youth in South Africa. The expression a child in sport is a child out of courthas special relevance in this regard. The purpose of this research is inter alia to: shortly discuss the inception and development of Technikon Pretoria with specific relevance to the Witbank Campus; describe the management of sport in South Africa; document the practical execution of a needs assessment for the management and development of sport at the Witbank Campus of Technikon Pretoria; and process the raw data into understandable and interpreted units. These units will then be used as a basis from which mechanisms will follow to ensure that the management and development of sport at the Witbank Campus of Technikon Pretoria be done in a holistic manner but at the same time with practical application. The main aim is to improve the participation levels in sport of all students at the Witbank Campus of Technikon Pretoria

N2 - Investigates the types of games played by successful women outside of school during the ages of 6-12 years. Hypothesis that successful women might not necessarily conform to the game involvement for women in general was supported. Investigates differences between academic and administrative women in terms of factors which would have the greatest predictive power as related to success in each role. Questionnaires were received from 194 full-time professional academic and non-academic women. Found that the success of female administrators was related to number of team games, but not to the number of male games

N2 - The article discusses a study which examines the risk factors for physical inactivity among adolescents in Ho Chi Minh City (HCMC), Vietnam. Using multistage cluster sampling, a cross-sectional survey was performed among 2684 junior high school students in 2004. Hierarchical multivariate logistic regression was used to identify potential risk factors associated with physical inactivity. The study has found that overweight status, passive transportation, absence of recess exercises, and availability of a nearby game shop were among the factors associated with physical inactivity among adolescents. Findings indicate that physical activity among adolescent is associated with household, school, and community factors

N2 - (we have the PDF of the full report)

Executive Summary

Our health and well-being are intricately interconnected with the health of our natural environment. Trees and forests are integral components of healthy ecosystems that support healthy human populations. Trees help to reduce smog and pollution in our cities by filtering out many airborne pollutants that have negative impacts on our health, such as carbon dioxide, carbon monoxide, lead, nitrogen dioxide, ozone, sulphur dioxide and particulates. These pollutants have been linked to heart disease, respiratory illnesses, diabetes and cancer.

Forests and green spaces have also been linked to a significant decline in stress, improved rehabilitation, faster hospital recovery rates, and a decrease in the severity of symptoms in attention deficit disorders.

Experts have determined that a minimum 30 per cent forest cover is required to maintain a healthy, sustainable ecosystem. Currently, forest cover is as low as five per cent in some regions of Ontario's settled landscape, compromising the health of our ecosystems and their inhabitants.

The decline in forest cover is evident in both rural and urban landscapes in Ontario. In the settled regions, rural forests have been diminished as a result of increased population density, agricultural land uses and a rapid growth in residential and commercial development. Trees and forests in urban areas face their share of challenges including pollution, climate change, introduced pests, competing demand for root space, disease and old age. Ontario now has severely fragmented forests in both rural and urban areas, threatening species migration, wildlife habitats, water cycles and climate regulation.

Efforts to enrich our

N2 - Canadian public health messages relating to physical activity have historically focused on the prescription of purposeful exercise, most often assessing leisure-time physical activity (LTPA). Although LTPA contributes to total energy expenditure (TEE), a large part of the day remains neglected unless one also considers the energy expended outside of purposeful exercise. This paper reviews the potential impact of incidental (non-exercise or non-purposeful) physical activity and lifestyle-embedded activities (chores and incidental walking) upon TEE and indicators of health. Given that incidental movement occurs sporadically throughout the day, this form of energy expenditure is perhaps most vulnerable to increasingly ubiquitous mechanization and automation. The paper also explores the relationship of physical inactivity, including sleep, to physical activity, TEE, and health outcomes. Suggestions are provided for a more comprehensive physical activity recommendation that includes all components of TEE. Objective physical activity monitors with time stamps are considered as a better means to capture and examine human movements over the entire day. ABSTRACT FROM AUTHOR

Les messages de santAc publique en matiA"re de l'activitAc physique au Canada ont mis traditionnellement l'accent sur la prescription de l'exercice physique utile, principalement pratiquAc pendant les pAcriodes de loisir (LTPA). MA me si les LTPA contribuent A la dAcpanse AcnergActique totale (TEE), une grande partie des activitAc faites pendant la journAc sont nAcgligAc es A mo ins de porter une attention A la dAcpanse d'Acnergie en plus des activitAc utiles. Cet article analyse l'impact des activitAc physiques dites accessoires (ne constituant pas de l'exercice physique en soi ou n'Acquant pas utiles) et des activitAc physiques intAcgrAc es dans le mode de vie (les tAcches journaliA"res et la marche concomitante) sur la TEE et les indicateurs de santAc. Comme les mouvements accessoires s'Acaccomplissent de faA on intermittente dans le quotidien, cette forme de dAcpanse d'Acnergie devrait diminuer face A la gAcnAcralisation de la mAcnAcnisation et de l'automatisation des tAcches. Cet article analyse aussi la relation entre l'inactivitAc physique, y compris le sommeil, et l'activitAc physique, la TEE et les rAcpercussions sur la santAc. On y trouve Acgalement des propositions visant A la prescription de l'activitAc physique plus d'AcnAcnisation incluant toutes les composantes de la TEE. Le monitoring objectif des activitAc physiques selon les pAcriodes de la journAc constitue le meilleur moyen de d'Acvaluer et de l'analyser les mouvements humains pendant toute la journAc. N2 - Abstract: Objective: To investigate the psychometric properties of the Physical Abilities and Mobility Scale (PAMS) in children receiving inpatient rehabilitation for acquired brain injury (ABI). Design: Admission and discharge PAMS item and total scores were evaluated. The WeeFIM was used as the criterion standard. A case study was used to illustrate the complementary nature of the PAMS and WeeFIM. Setting: A single, free-standing, academically affiliated pediatric rehabilitation hospital. Participants: Children (N=107) aged 2 through 18 years receiving inpatient rehabilitation for ABI between March 2009 and March 2012. Forty-two additional children treated during this time were excluded because of missing PAMS data. Interventions: Not applicable. Main Outcome Measures: Internal consistency was evaluated using Cronbach alpha. Interrater reliability was

evaluated through overall agreement, Pearson correlations, and intraclass correlations. Construct validity was examined through exploratory factor analysis. Criterion validity was explored through correlations of PAMS overall and factor scores with WeeFIM total and subscale scores. Sensitivity to recovery was examined using paired t tests, examining differences between admission and discharge scores for each item and for the total score. Results: Internal consistency and interrater reliability were high. Factor analysis revealed 2 factors: lower-level skills and higher-level mobility skills. Correlations with the WeeFIM ranged from moderate to very strong; total PAMS score most strongly correlated with the WeeFIM mobility subscore. Total PAMS score and each item score significantly increased between admission and discharge. Conclusions: The PAMS is a reliable and valid measure of progress during inpatient rehabilitation for children with ABI. By capturing fine-grain progress toward both lower-level and higher-level mobility skills, the PAMS complements the WeeFIM in assessing functional gains during the rehabilitation stay. N2 - The purpose of this study was to report the eating behavior inside and outside the school environment, of the prepubescent children. Also, to discover any relation between their physical characteristics, and their every day eating behavior. 60 Greek children (M = 10.5 years old, SD = 1.5 years), participated in this research. The sample consisted of 31 boys and 29 girls from the 5th and 6th grade of the 2nd Primary Public School of Komotini. Children's weight and height were recorded. A skinfold caliper was used for the assessment of the percentage of the body fat, according to the equation of Slaughter et al. (1988). For the evaluation of children's eating behaviors in every day life, special cards adopted from Baranowski et al. (1986) were used for a one-week period. The special food cards were then evaluated with Diet food analysis software (Strength & Conditioning, 1997). The results have shown that: food intake effects the concentration of all food ingredients, like calories, proteins, carbohydrates, fats etc. According the body fat results of the subjects, boys belong to

obese group and girls tend to obesity. Results also revealed that the Physical characteristics like weight, height, % of body fat and obesity could be predicted by the estimation of the rest Physical characteristics and by selected nutrients

N2 - Despite the great importance given by the government to improve the conditions of children's living through fitness and activities, there aren't many researches attempting to record prepubescent physical activity as a means of improving health. It is unlikely that children's amount of range physical activity, of which develops in their social environment, has never been studied in Greece. In an attempt to overcome this, the purposes of this research were to record physical activity inside and outside the school environment, and discover a possible relationship between the motor activity of children and their physical characteristics. Sixty Greek children (10 years of age, SD 0.5 years) participated in this research. The sample consisted of 31 boys and 29 girls from 5th and 6th grade of Primary Public School. Physical activity was recorded with the use of a questionnaire (Sallis, et al., 1993), and a questionnaire for the assessment of parents' opinion about physical activity of their children was also distributed (Rose et al., 1987). Children's weight and height were recorded and a skin fold caliper was used for the assessment of the percentage of body fat, according to the equation of Slaughter, et al., 1988. The statistical analysis of the data included linear correlation, stepwise regression analysis, frequencies and ANOVA. Results showed: Children's physical activity was not correlated with the physical characteristics. Physical characteristics like weight, height, percent body fat and obesity could be anticipated by the values of one or more physical characteristics and, there was a significant difference between parent's estimates and children's personal opinion

N2 - Objective: Record the injury incidence in all age categories in male volleyball players and clarify the role of age in injury occurrence. Design and Setting: The injury incidence rate, severity, diagnosis and the anatomical location of the injuries, which occurred during practice and competition in all the championship period, were recorded prospectively during the period 2005-2006. Participants: A total of 407 Greek male volleyball players participating in all Volleyball Championships in Greece according the Greek Volleyball Federation have been observed on weekly basis for the period 2005-06. Main Outcome Measurements: The injury incidence rate recorded as number of injured players and also number of injuries per player/year (total exposure time). Results: Injury occurrence is age related and junior volleyball players have lower injury rate than the senior ones. Acute injuries were significantly more in comparison to overuse syndrome and the ankle was the most common injured anatomical location. Finally, outside hitters, universals and setters presented different injury rate than the other players and the "incorrect sprawls" & "step on others' foot" were the most common injury factors. Conclusions: Findings in injury occurrence rate must be interpreted in relation to the total exposure time in order to have more realistic conclusions. [ABSTRACT FROM AUTHOR]

N2 - ABSTRACT BACKGROUND Recess is a key aspect of a healthy elementary school environment and helps to keep students physically active during the school day. Although national organizations recommend that students not be withheld from recess, this practice occurs in schools. This study examined whether district policies were associated with school practices regarding the withholding of recess for behavior management or academic reasons, as well as the use of physical activity (eg, running laps) for behavior management.

METHODS Data were gathered from administrators at US public elementary schools by mail-back surveys conducted during the spring of the 2008-2009, 2009-2010, and 2010-2011 school years. Corresponding school district policies were gathered and coded. Each year's sample was nationally representative and data were analyzed as a stacked cross-sectional sample. A total of 1,919 surveys were received (61.2% response rate).

RESULTS Averaged over the 3 years, students were not withheld from recess for poor behavior or academic reasons at 28.3% and 26.7% of elementary schools, respectively. Strong district policy was associated with an increased odds of not withholding students from recess for poor behavior (adjusted odds ratio [OR] = 2.27, $p < .001$) or completing schoolwork (adjusted OR = 1.99, $p < .001$). Withholding recess was less common in the South versus the West, Midwest, and Northeast. Use of physical activity for behavior management was rare and not associated with district policy. CONCLUSIONS Strengthening district policies may be an effective strategy for changing school practices pertaining to withholding of recess, and to ensure that all students have opportunities to be physically active during the school day. N2 - This study examined changes occurring in the physical activity pattern of college-educated men and women during the adult life cycle. Participation was measured both in terms of the variety of activities and the number of participation days across a spectrum of 30 activities, and for three categories of activities within that spectrum (individual/dual activities, outdoor activities, and team sports). The results indicate lower participation of females than males in team sports and outdoor activities, but not in individual/dual sports. A decline in participation was noted with increasing age and this effect differed between males and females. Marital status and presence of children did not differentially affect participation of males and females. Participation was found to decrease faster with age for single persons as opposed to married persons or those with children. Implications for physical education curriculum planning are discussed

N2 - Objective: To examine the psychometric properties of an objective method for assessing real-world arm activity in a large sample with subacute stroke. Design: Validation study. Setting: Community. Participants: Persons 3 to 9 months poststroke (N = 169) with mild to moderate motor impairment of their hemiparetic arm enrolled in a multisite, randomized clinical trial of constraint-induced movement therapy. Interventions: Not applicable. Main Outcome Measures: Participants wore an accelerometer on each arm outside the laboratory for 3 days before and after treatment or an equivalent no-treatment period. They also completed the Actual Amount of Use Test (AAUT), which is an observational measure of spontaneous more-impaired arm use, and the Motor Activity Log (MAL), which is an interview assessing more-impaired arm use in daily life. Results: Low-pass-filtered accelerometer recordings were reliable (r range, > .8) and stable (P range, > .48). Their validity was also supported. Correlations calculated across all participants at baseline between the ratio of more-impaired to less-impaired arm accelerometer recordings and AAUT and MAL scores were .60 and .52, respectively. Conclusions: Accelerometry provides an objective, real-world index of more-impaired arm activity with good psychometric properties. [ABSTRACT FROM AUTHOR]

N2 - This article discusses a need by children to enjoy the joys of playing outdoors. According to the article, the growing trend of shifting away from outdoor play can be attributed to societal trends, including urbanization, changing family structures and technology. Several ways parents can enhance the play experiences of their children include making time for play, providing play materials and offering a variety of play experiences

N2 - The effects of the redevelopment of an elementary school playground were evaluated by comparing the situation before and after physical transformation. Observations produced data on the actual use during play time. Interviews were held with all the pupils on their perception and evaluation of the change. A group of adult experts judged the environment before and after the change on aspects like complexity, 'manipulability' and 'affordance' for different activities. An interview with the designer of the plan gave information about his intentions and expectations, especially regarding behavioural aspects. Data from these different sources are presented and related to each other

N2 - The article focuses on "Can You Dig It?" party before the John Deere Classic. This is no ordinary tractor pull that one can see on cable TV at weird hours. Last year's debut of "Can You Dig It?" was well-attended. This year, the number of players, wives, children, friends and caddies doubled, although there is no such thing as overflow on this massive stretch of real estate. It's turned into a company picnic, with golfers interacting with each other and its staff. The John Deere test site is basically an outdoor office that serves as a summer venue for customers and dealers

N2 - Cross-country skiing has become an increasingly popular outdoor sport activity of adults in winter time. Due to the many positive effects of this type of sport on a human being it is only reasonable that children should also become familiar with it. Teaching of this sport must first and foremost follow the golden rule: children must find cross-country walking and skiing fun! It is only in this way that a seed of desire and need for a pleasant and healthy winter recreational activity will be planted in children, so that it will continue developing also at an older age. N2 - In the modern civilized world children's play has become increasingly static, resulting in a higher number of contemporary diseases. Given that the need for movement and playing are a child's basic needs, children should be offered opportunities for active and healthy leisure time. One such possibility is the children's playground which has to be expertly designed in terms of safety, usability and comfort. A quality playground must consist of play structures that meet all applicable standards, be properly maintained and interesting and appealing to children. Well-designed and adequately equipped children's playgrounds near kindergartens, schools and in residential areas may play an important role in the physical, motor, cognitive, emotional and social development of children. VL - 32

IS - 1

CY - ;

N2 - The amount of sport and physically active leisure undertaken by 1518, five to seventeen year-old New Zealanders was surveyed. The percentage of participants who met the recommended physical activity guideline that they undertake at least thirty minutes of moderate intensity physical activity on most days of the week was determined. Sixty nine percent of the children and adolescents met this guideline; this percentage is comparable to other international studies. Children and adolescents undertook, on average, 6.2 hours per week of sport and active leisure with boys undertaking significantly ($p < .01$) more hours of activity compared with girls. Similarly, significantly more Maori (75 % - $p < .05$) and young people from a European background (69 % - $p < .10$) achieved the recommended guidelines compared with young people of other cultures (58 %). Physical activity declined with increasing age, with the most dramatic decrease in activity seen in the 16-17 year-old age group. Seventy three percent of those surveyed participated in sport or active leisure at school (during school hours), with 24 % taking part in activities organised by the school outside normal school hours. Thirty four percent of young people took part in sports and activities organised by non-school based clubs, with significantly more boys involved in club sports and activities than girls. The most popular activities undertaken with clubs with swimming and ball sports like soccer, netball and rugby. Sixty five percent of young people took part in sports and activities with family and/or friends. Informal activities like swimming, cycling and walking were among the top five activities for both boys and girls. A number of policies and programmes are in place aimed at activating the approximately 30 % of young people who are insufficiently active

N2 - Background: Studies suggest that expert performance in sport is the result of long-term engagement in a highly specialized form of training termed deliberate practice. The relationship between accumulated deliberate practice and performance predicts that those who begin deliberate practice at a young age accumulate more practice hours over time and would, therefore, have a significant performance advantage. However, qualitative studies have shown that a large amount of sport-specific practice at a young age may lead to negative consequences, such as dropout, and is not necessarily the only path to expert performance in sport. Studies have yet to investigate the activity context, such as the amount of early sport participation, deliberate play and deliberate practice within which dropout occurs. Purpose: To determine whether the nature and amount of

childhood-organized sport, deliberate play and deliberate practice participation influence athletes' subsequent decisions to drop out or invest in organized sport. It was hypothesized that young athletes who drop out will have sampled fewer sports, spent less time in deliberate play activities and spent more time in deliberate practice activities during childhood sport involvement. Participants: The parents of eight current, high-level, male, minor ice hockey players formed an active group. The parents of four high-level, male, minor ice hockey players who had recently withdrawn from competitive hockey formed a dropout group. Data collection: Parents completed a structured retrospective survey designed to assess their sons' involvement in organized sport, deliberate play and deliberate practice activities from ages 6 to 13. Data analysis: A complete data-set was available for ages 6 through 13, resulting in a longitudinal data-set spanning eight years. This eight-year range was divided into three levels of development corresponding to the players' progress through the youth ice hockey system. Level one encompassed ages 6f_ "9, level two included ages 10f_ "11 and level three covered ages 12f_ "13. Descriptive statistics were used to report the ages at which the active and dropout players first engaged in select hockey activities. ANOVA with repeated measures across the three levels of development was used to compare the number of sports the active and dropout players were involved in outside of hockey, the number of hours spent in these sports, and involvement in various hockey-related activities. Findings: Results indicated that both the active and dropout players enjoyed a diverse and playful introduction to sport. Furthermore, the active and dropout players invested similar amounts of time in organized hockey games, organized hockey practices, specialized hockey training activities (e.g. hockey camps) and hockey play. However, analysis revealed that the dropout players began off-ice training at a younger age and invested significantly more hours/year in off-ice training at ages 12f_ "13, indicating that engaging in off-ice training activities at a younger age may have negative implications for long-term ice hockey participation. Conclusion: These results are consistent with previous research that has found that early diversification does not hinder sport-specific skill development and it may, in fact, be preferable to early specialization. The active and dropout players differed in one important aspect of deliberate practice: off-ice training activities. The dropout players began off-ice training at a younger age, and participated in more off-ice training at ages 12 and 13 than their active counterparts. This indicates a form of early specialization and supports the postulate that early involvement in practice activities that are not enjoyable may ultimately undermine the intrinsic motivation to continue in sport. Youth sport programs should not focus on developing athletic fitness through intense and routine training, but rather on sport-specific practice... ABSTRACT FROM AUTHOR

N2 - The article provides information on how physical education teachers can make physical activities enjoyable for students to help them combat obesity in the U.S. The author inferred that the instructor can accomplish this through two mechanisms such as the effective use of lesson time to promote more moderate-to-vigorous physical activity and making the physical education experience motivating for overweight students to choose to be active outside of lesson time. Furthermore, information on how teachers can convince overweight students to participate in exercises after class is also provided

N2 - Guidelines for the maintenance of health and wellbeing in children recommend at least 60 minutes of moderate-to-vigorous physical activity (MVPA) daily. In South Africa, community sport and recreation facilities and opportunities are meagre in areas previously disadvantaged by apartheid, so schools should be

primary sites for enabling children to meet these recommendations. However, physical education has been marginalized in the curriculum and extra-curricular sports provision has declined. The purpose of this study was to investigate children's school day physical activity patterns in relation to meeting daily recommended guidelines. A total of 112 children (boys n=53; girls n=59), from Grades 3 to 6 (aged 8 to 12 years) from 3 disadvantaged schools participated in the study. Physical activity, representing the whole school day and recess, was measured over 5 days using ActiGraph accelerometers. Qualitative interviews were conducted on a subsample of 20 learners. The results indicated that children accumulated 35 minutes of in-school MVPA, contributing 58% of the 60 minutes of MVPA a day recommendation. Recess accounted for 37% of in-school MVPA. Boys participated in significantly more in-school MVPA than girls (boys=38.47 A ñ 16.10 mm, girls=32.59 A ñ 14.03 mm). Almost 90% of Grade 6 children failed to accumulate 30 minutes of MVPA. Low levels of in-school MVPA among girls and the marked decline at Grade 6 are disturbing. Schools should be pivotal in the provision of physical activity to combat the health risks associated with increasingly sedentary lifestyles. Schools need to increase PA through the provision of quality physical education and find cost effective ways of promoting school-day PA. ABSTRACT FROM AUTHOR

 N2 - Recommendations for increasing children's daily physical activity (PA) call on classroom teachers to assume an activist role at school. This study examined relationships among preservice classroom teachers' (PCT; n = 247) biographical characteristics, perceptions and attitudes regarding school PA promotion (SPAP). Results indicated participants who completed SPAP-related college coursework and had PA-related teaching/coaching experiences reported higher SPAP competence. Significant relationships were found among BMI, personal PA competence and SPAP competence in the contexts of PE and extracurricular settings. Personal PA competence and SPAP competence at recess and in the classroom predicted 19% of the variance in SPAP attitudes. Experiences in PA settings and preservice training may have important implications for the overall success of efforts to enhance school PA promotion. ABSTRACT FROM AUTHOR

N2 - The article focuses on the significance of sports for youth development in the U.S. It says that physical activity contexts primarily include organized sport, school physical education, recreational activities, motor skill development programs, dance, recess, and active transport. It notes of these contexts, organized sport is particularly salient for children and adolescents. Despite its potential to promote social, psychological, and physical development and health-related outcomes, it stresses that the youth sport context is often neglected in the physical activity literature. The author also shares his most important experience as a youth sports coach for a parks and recreation department during his undergraduate and graduate years in California

IS - 1

N2 - Poor sportsmanship is a serious and growing problem in youth sports. Unpleasant experiences that follow from incidents involving poor sportsmanship can lead children to limit their physical activity, thereby increasing their risk of developing health problems such as obesity and limiting the quality of their lives. In contrast, creating sport experiences that promote sportsmanship can heighten the fun in the activity and encourage children to adopt physical activity as part of their lifestyles. The "Play Hard, Play Fair, Play Fun" (PHPFPF) youth basketball program incorporated elements of prosocial behavior theory to shift the focus from competition to an atmosphere of sportsmanship. Specific techniques were implemented to facilitate sportsmanship behavior among participants and spectators in a youth basketball program, to enhance feelings of cooperation, and to help form relationships among participants on competing teams. Examples of these techniques included pre-game introductions among the players and referees, a signed petition on a large poster board in support of sportsmanship posted prominently outside the gym, large banners and posters promoting sportsmanship on display in the gym, awards to players for good sportsmanship, re-setting the score to zero when the score discrepancy between the two teams became too large, a post-game social event for the players and coaches, and a league website featuring photographs of each team's weekly sportsmanship award winner. Evaluation data showed that such techniques led to positive feelings from the parents about their children's sportsmanship attitudes and provided insight into relationships among fun, age, game outcome, and similarity of ability levels of opposing teams. Overall, participants reported higher levels of fun when the game was close (as opposed to a "blow-out"). The negative impact of a blow-out game on fun levels of participants was most severe for the oldest participants who, statistically, are those on the cusp of dropping-out. This suggests that making efforts to

promote sportsmanship and to balance the skill and ability levels of teams may be critical components to fun and, thus, continued participation. More generally, results demonstrate the effectiveness of the PHPFPF program in enhancing fun and sportsmanship in youth sports. ABSTRACT FROM AUTHOR

N2 - We look for, from the lines of the Cultural and Gender Studies that approach the post-structuralism of Foucault, to understand how the gender and the sexuality establish different ways of being boys/girls inside the break time play. Considering that these actions take place through relations of power, we look for sought to map and identify them through an ethnographically inspired methodology. We focused on groups of 2nd and 3rd grades. We argue that, in the space of break time a non-official and non-intentional learning takes place, from which or through which the children learn how to be boys and girls. [ABSTRACT FROM AUTHOR]

Procuramos, a partir de las vertientes de los Estudios Culturales y de Genero que se aproximan del pos-estructuralismo de Foucault, entender como el genero instituye modos diferenciados de ser nino/a en el recreo escolar. Considerando que ese es un proceso permeado de relaciones de poder, procuramos mapearlas e identificarlas a travez de una metodologia de inspiracion etnografica. (observacion participante y entrevistas) realizada, durante un ano, en una escuela publica de Porto Alegre, RS. Focalizamos un segundo y un tercer grado. Argumentamos que, a traves de los juegos, sucede un aprendizaje no-oficial y no-intencional, a partir del cual los/las ninios/ as apre(e)enden determinadas formas de fememilidade e de masculinidad. N2 - This article profiles former tennis player, Roscoe Tanner. Rock bottom? That's tough to pinpoint, he says, sighing. So many lows to choose from. Rock bottom might have come when he walked into that Stygian cell in a German prison and realized that for the length of his stay he would be defecating in front of his cellmate. "Man," he says, "that was humiliating." The time he was arrested in front of all those fans at a senior tennis event, that was pretty embarrassing, too. And when his father, once his most ardent supporter, turned uncommunicative, that one really stung. No, wait, I've got it, he says. Here's the lowest moment of his odyssey: Immediately after he finished serving four months in a maximum security county jail in Florida on a grand theft charge, he was transferred to a New Jersey jail where he would serve five months for willfully withholding child support. For two weeks he sat on a bus that zigzagged along the Eastern Seaboard picking up other criminals who were being reassigned from one jail to another. At night the convicts either slept in their seats or, if they were lucky, bunked down at a county jail. They were allotted three meals a day, but there was a catch: Their hands never came out of restraints. Ever try eating McDonald's with your wrists locked at your waist? It's not real pleasant. This is what it came to recently for Tanner. The tennis star who once shared drinks with Prince Rainier on the French Riviera and dined with the Reagans in the White House was sitting on a bus near an exit ramp, positioning his chin at just the right angle so he could eat a Big Mac. It's hard to imagine a less likely candidate to make an absolute mess of things. Tennis players just don't fall into the abyss--especially not a player born to the manor, with a Stanford diploma, a thick Rolodex of connections and, if that weren't endowment enough, movie-star looks and boundless reserves of charm

N2 - The purpose of this study was to determine preferences for assessment and treatment strategies used by pediatric physical therapists (PTs) for balance dysfunction in children. Sixty-seven percent (566 of 843) of a random sample of PTs, stratified by region of the United States, who belonged to the Section on Pediatrics of the American Physical Therapy Association in 1994, and who had agreed to receive outside mailings, returned a mail survey. The respondents were either currently practicing physical therapy or had practiced within the last five years at the time of the survey. In the questionnaire, two case studies were presented, a child with mild balance dysfunction and a child with moderate balance dysfunction. Therapists rated from listed choices: 1) assessments and treatment techniques they would use for these two children, 2) frequency of treatment, and 3) philosophy of therapy. Respondents indicated that they would: 1) most often use nonstandardized balance assessments, 2) use a combination of functional and more traditional treatment activities, 3) adjust frequency of treatment based on treatment setting and the child's severity of dysfunction, and 4) most often identify with the neurodevelopmental (NDT) philosophy of treatment. No relationships were found between geographical region and treatment philosophy. A significant relationship was found between treatment philosophy and years of pediatric PT experience. PTs with more experience indicated a preference for the NDT philosophy as compared with a motor learning philosophy ($\chi^2 = 15.4, p < 0.05$). These results can be used to understand pediatric PTs' current practice related to assessment and treatment of balance dysfunction in children and to design studies that compare the effectiveness of traditional assessment and treatment strategies for balance deficits with newly proposed strategies

N2 - One objective of Healthy People 2000 is to increase physical education class time by at least 50% to allow students to spend more time in physical activity. In addition, the Council on Physical Education for Children

(1992) indicated that children should be provided recurrent and meaningful age-appropriate practice times to develop understanding of movement concepts. This study consisted of 97 Arkansas superintendents and 91 Mississippi superintendents who volunteered to participate and were given the Superintendents' Attitudes Toward Physical Education questionnaire (SATPE) which asked about their attitudes toward K-6 physical education in the public school. Both Arkansas and Mississippi are considered to be rural states and were found to be similar in size according to the mean number of students enrolled in each school and a compatible match was assumed. This allowed for a comparison between Arkansas, which has state mandates requiring elementary physical education, and Mississippi which has no state mandates for the offering of elementary physical education programs. A Pearson's correlation, t-test, regression, and factorial analysis were performed on the data. The factor structure of 28 questionnaire items yielded five factor components. These factor components were named implementation of programs, barriers to implementation, requirements for implementation, benefits of physical education programs, and physical education curriculum concerns. The results indicated that a greater number of Arkansas superintendents held bachelor's degrees in physical education and a greater number of Mississippi superintendents held bachelor's degrees in social studies. Although a greater number of Arkansas superintendents held degrees in physical education, it was revealed that they are less likely to support any aspect of elementary physical education. In addition, the longer Arkansas superintendents were in education the less likely they were to support K-6 physical education. On the other hand, Mississippi superintendents were more likely to support elementary physical education programs the longer they were in education, even though most did not have a physical education background. Mississippi superintendents were also more likely to purchase equipment, books, and workbooks for schools, teachers, and students. Mississippi superintendents were also interested in paying a certified physical education specialist from outside the district to train classroom teachers in physical education curriculum. The SATPE, Appendixes, and references are included

N2 - Background: Postpartum weight retention is a risk factor for long-term weight gain. Encouraging new mothers to consume a healthy diet may result in weight loss. Objective: To assess predictors of diet quality during the early postpartum period; to determine whether diet quality, energy intake, and lactation status predicted weight change from 5 to 15 months postpartum; and to determine whether an intervention improved diet quality, reduced energy intake, and achieved greater weight loss compared with usual care. Design: Randomized clinical trial (KAN-DO: Kids and Adults Now *f* "Defeat Obesity), a family- and home-based, 10-month, behavioral intervention to prevent childhood obesity, with secondary aims to improve diet and physical activity habits of mothers to promote postpartum weight loss. Participants: Overweight/obese, postpartum women (n=400), recruited from 14 counties in the Piedmont region of North Carolina. Intervention: Eight education kits, each mailed monthly; motivational counseling; and one group class. Methods: Anthropometric measurements and 24-hour dietary recalls collected at baseline (approximately 5 months postpartum) and follow-up (approximately 10 months later). Diet quality was determined using the Healthy Eating Index-2005 (HEI-2005). Statistical analyses: Descriptive statistics, IØ2, analysis of variance, bi- and multivariate analyses were used. Results: At baseline, mothers consumed a low-quality diet (HEI-2005 score=64.4A ñl 1.4). Breastfeeding and income were positive, significant predictors of diet quality, whereas body mass index was a negative predictor. Diet quality did not predict weight change. However, total energy intake, not working

outside of the home, and breastfeeding duration/intensity were negative predictors of weight loss. There were no significant differences in changes in diet quality, decreases in energy intake, or weight loss between the intervention (2.3A ñ5.4 kg) and control (1.5A ñ4.7 kg) arms. Conclusions: The family-based intervention did not promote postpartum weight loss. Reducing energy intake, rather than improving diet quality, should be the focus of weight-loss interventions for overweight/obese postpartum women. Copyright &y& Elsevier

N2 - Explores the significance of leisure in the lives of women with young children in Edinburgh, Scotland. States that across all ethnic groups, it is the mother, rather than the father, who makes extensive changes to her life when children are born. Reports that many mothers with young children have no energy left at the end of a day for activities outside the home, and that many women rely on contacts with other mothers during the day for socializing and support. Identifies exit routes' which provide a break from children and domestic routines a day off to shop, a night out with girlfriends, a part-time job - and addresses the constraints to enjoying these activities. Focuses on the role that other women play in providing support. Concludes that for mothers, time off from work goes hand in hand with the struggle for improved childcare provisions and renegotiating the division of this labour

N2 - Good sports results are determined by many factors of which most essential is perfect health. In order to enjoy it, it is necessary that, among others, the way of life should meet hygiene requirements. The questionnaire investigation covered 142 elementary and secondary school students practising sport, and a control group of 257 subjects. Investigated were items selected from a day routine: sleep, outdoor stay, number of meals, time of school and homework as well as after-class activities. In groups under investigation there was discerned an incorrect way of life manifesting in: sleep and movement deficiency and too small a number of meals. In the elementary school group those shortcomings were more frequent among sports students than in the control group. This dependence has not been noticed in the investigated group of secondary school students. The conclusion points at organizational possibilities to improve the way of life of children and the youth practising sport

N2 - Ecopsychological theory and practice underscore the vital importance of realizing the interdependence between human beings and the diverse living universes that they inhabit. This article focuses on the mental health implications of the shift toward a more ecologically rooted identity by examining relationships between psychological well-being and the personal experience of connection with nature. Three separate surveys conducted with undergraduate and community samples assessed relationships between the Connectedness to Nature Scale (CNS), psychological well-being, mindfulness, and outdoor recreation. Higher CNS scores were consistently associated with greater trait mindfulness, more participation in appreciative outdoor activities, and higher scores on multiple measures of both hedonic and eudaimonic aspects of psychological well-being. Discussion focuses on informing optimal strategies for nature-based interventions. the diverse living universes that they inhabit. N2 - To probe into the rehabilitation effects of "children's playground" style hospitalization environment acted on, 163 cases of hospitalized children were investigated on their psychological and behavioral problems and medical indexes changes of these children before and after the hospitalization environmental changes were compared with each other. Results: after the hospitalization environment being changed, among the investigated 12 items of psychological and behavioral questions, the fractional value rate of often happening was 2.3% . The fractional value rate of at times happening accounted for 12.5%. The fractional value rate of not happening accounted for 85.2%. The numbers of admissions increased by 318.4%. The rate of satisfaction in patients increased 4% The average hospitalization day of patients were 2.82 days shortened. And the average hospitalization expenses of patients were 45.84 Yuan decreased. Suggested that "children's playground" style of hospitalization environment may help the pediatric patients to recover from their illness. N2 - Background: United States high school soccer participation increased 5 fold over the last 30 years. With increased participation comes increased injury incidence. Hypothesis: High school soccer injury patterns will vary by gender and type of exposure. Study Design: Descriptive epidemiologic study. Methods: Soccer-related injury data were collected over the 2005-2006 and 2006-2007 school years from 100 nationally representative United States high schools via Reporting Information Online (RIO, an Internet-based sports-related injury surveillance system). Results: Participating certified athletic trainers reported 1524 soccer injuries during 637 446 athlete exposures (AEs), for an injury rate of 2.39 per 1000 AEs, corresponding to a nationally estimated

807 492 soccer-related injuries during the 2005-2006 and 2006-2007 seasons. The injury rate per 1000 AEs was greater during competition (4.77) than practice (1.37) (rate ratio [RR] = 3.49; 95% confidence interval [CI], 3.15-3.87). Overall, the most frequent diagnoses were incomplete ligament sprains (26.8%), incomplete muscle strains (17.9%), contusions (13.8%), and concussions (10.8%). The most commonly injured body sites were the ankle (23.4%), knee (18.7%), head/face (13.7%), and thigh/upper leg (13.1%). Similar proportions of boys (57.9%) and girls (53.9%) returned to activity in <1 week. During competition, girls sustained complete knee ligament sprains requiring surgery at a rate of 26.4 per 100 000 AEs, higher than the rate among boys during competition (1.98 per 100 000 AEs) (RR = 13.3; 95% CI, 3.15-56.35) and among girls during practice (2.34 per 100 000 AEs) (RR = 11.3; 95% CI, 4.31-29.58). Player-to-player contact was more common among competition injuries (injury proportion ratio [IPR] = 2.42; 95% CI, 2.01-2.92), while noncontact mechanisms were more common among practice injuries (IPR = 2.39; 95% CI, 1.90-3.01). Conclusions: High school soccer injury patterns vary by gender and type of exposure. Identifying such differences in injury patterns is the important first step in the development of evidence-based, targeted injury prevention efforts. ABSTRACT FROM

N2 - This study evaluated the effects of competitive intensity, represented by the variables time in competition, phase of play, and field location, on injury severity in U.S. high school football. The injury rate was higher in competition than practice (RR = 4.75, 95% CI: 4.34-5.20). Mild and moderate injuries were frequently lower leg/foot/ankle sprains/strains and concussions. Severe injuries were frequently knee sprains/strains and arm fractures. Severe injuries composed a greater proportion of injuries sustained during the beginning and middle of competition compared with injuries sustained during the end/overtime (IPR = 1.83, 95% CI: 1.25-2.69). Compared with injuries sustained during general play, a greater proportion of kickoff/punt injuries were severe (IPR = 1.69, 95% CI: 1.07-2.68) or were concussions (IPR = 1.86, 95% CI: 1.05-3.30). Identifying factors contributing to severe injury is a crucial first step toward developing targeted evidence-based interventions aimed at reducing the incidence of severe injuries among the millions of high school football players.

N2 - Context: Ice hockey, lacrosse, and field hockey are increasingly popular sports among US youth athletes, but no authors to date have compared injuries in male and female pediatric (ages 2 through 18 years) participants. Objective: To compare patterns of injury among pediatric ice hockey, lacrosse, and field hockey players. Design: A descriptive analysis of all pediatric (ages 2 through 18 years) ice hockey, lacrosse, and field hockey injuries captured by the US Consumer Product Safety Commission's National Electronic Injury Surveillance System. Setting: US Consumer Product Safety Commission's National Electronic Injury Surveillance System. Patients or Other Participants: Children with ice hockey, lacrosse, or field hockey injuries presenting to emergency departments participating in the National Electronic Injury Surveillance System. Main Outcome Measure(s): We reviewed all ice hockey, lacrosse, and field hockey injuries captured by the National Electronic Injury Surveillance System and categorized them by sex, age, injury site, and injury diagnosis. Results: An estimated 321 237 pediatric participants in ice hockey, lacrosse, and field hockey presented to US emergency departments from 1990 through 2003. The injured were primarily male (74.4%) and aged 10 through 18 years (95.4%). Ice hockey accounted for more injuries (53.6%) than lacrosse (26.5%) or field hockey (19.9%). Children aged 2 through 9 years sustained twice the proportion of head and face injuries (53.1%) as children aged 10 through 18 years (23.2%) (incidence rate ratio [IRR] = 2.25, 95% confidence interval [CI] = 1.94 to 2.62). Males incurred a higher proportion of shoulder and upper arm injuries (14.1%) than females (3.1%) (IRR = 4.51, 95% CI = 3.07 to 6.62). The proportion of concussion was higher in ice hockey players (3.9%) than in field hockey players (1.4%) (IRR = 2.75, 95% CI = 1.17 to 6.46). Females in lacrosse had twice the proportion of facial injuries (20.9%) as males (10.5%) (IRR = 1.95, 95% CI = 1.46 to 2.60). In all sports, the ball or puck caused a greater proportion of face injuries in females than in males (IRR = 2.48, 95% CI = 2.03 to 3.05). Facial injuries from falls occurred in higher proportions in ice hockey players (10.6%) than in lacrosse (2.4%) (IRR = 4.32, 95% CI = 1.53 to 12.18) and field hockey (0.4%) players (IRR = 28.38, 95% CI = 6.71 to 120.01). Conclusions: Pediatric ice hockey, lacrosse, and field hockey injuries differed by age and sport and, within each sport, by sex. An understanding of sport-specific patterns of injury should assist coaches and certified athletic trainers in developing targeted preventive interventions. ABSTRACT FROM AUTHOR

N2 - This study examined the impact of a short-time coordination program conducted during recess periods on improving agility in elementary school students. The subjects consisted of 62 third grade students, who were randomly assigned to an experimental group (n = 31) and a control group (n = 31). The experimental group completed a coordination program intended to improve agility during 20-minute recesses, three times a week for four weeks, whereas the control group participated in usual activities such as mini soccer games and tag games during the recess. Repetitive side steps, an indicator of agility, were measured for both groups at the beginning and end of the intervention period. While the test scores indicated no difference between the two groups in the pretest, the posttest indicated a significant difference in the test scores in favor of the experimental group, $t(60) = 2.27$ and $p < .027$. The results indicated that the short-time coordination program can be effective in improving agility in elementary school students. ABSTRACT FROM AUTHOR

N2 - Until recently, studies into juveniles' leisure activities concentrated mainly on adolescents. In this study, the leisure activities of both pre-adolescents and adolescents are studied. Departing from sociological debates on the busyness of contemporary young adolescents' leisure diaries and of an advanced onset of the transition from childhood into the youth phase, a questionnaire was designed for 10 to 15 year-olds. 927 Dutch youngsters were studied. By means of CATPCA, it was found that 10-12 year-old girls mainly engage in reading and in creative activities, whereas the boys spend most time playing outside. Fourteen and fifteen year-olds, on the other hand, showed a clear interest in youth-cultural activities, which did not support theoretical notions about the advancement of adolescence at the expense of childhood. Questions on organized activities showed that the market of leisure opportunities is not equally accessible to everyone: higher class kids are in an advantageous position compared to lower class kids, which affects the degree to which these subgroups have the opportunity to develop important leisure capital through informal learning

Jusqu'a recemment, l'etude des activites de loisir chez les jeunes etait centree principalement sur les adolescents. Dans la presente etude, nous examinons les activites de loisir tant chez les preadolescents que chez les adolescents. A partir de debats sociologiques sur l'importance qu'occupent les loisirs dans l'emploi du temps des jeunes adolescents d'aujourd'hui et sur la precocite de la transition de l'enfance a l'adolescence, un questionnaire a ete elabore a l'intention des jeunes de 10 a 15 ans. Ainsi, 927 jeunes Hollandais ont fait l'objet de cette etude.

Une analyse CATPCA (analyse categorique des composantes principales) a revele que les fillettes de 10 a 12 ans s'adonnaient principalement a la lecture et aux activites creatrices dans leurs moments de loisir, tandis que les garcons du meme age passaient le plus gros de leur temps a jouer dehors. Toutefois, chez les 14 et 15 ans, on a decele un interet marque pour les activites culturelles pour les jeunes, ce qui allait a l'encontre de la theorie voulant que l'adolescence precoce s'installe au detriment de l'enfance. Les questions portant sur les activites organisees ont permis de constater que le marche des loisirs n'etait pas egalement accessible a tous. En effet, les enfants des classes superieures sont avantages, compares a ceux des classes moins bien nanties, ce qui a un effet sur la mesure dans laquelle ces sous-groupes ont la chance d'accumuler un capital-loisir significatif par le biais d'un apprentissage non structure

Hasta hace recientemente el estudio de las actividades de ocio en los jovenes estaba enfocado principalmente sobre los adolescente. En el presente estudio, examinamos las actividades de ocio tanto en los preadolescentes que en los adolescentes. A partir de debates sociologicos sobre la importancia que ocupan las diversiones en el empleo de tiempo de los jovenes adolescentes de hoy en dia y sobre la precocidad de la transicion de la infancia a la adolescencia, un cuestionario dirigido a jovenes de 10 a 15 anos fue elaborado. Asi, 927 jovenes holandeses formaron parte de este estudio. Un analisis CATPCA (analisis de categorias de componentes principales no lineal) revelo que las ninos de 10 a 12 anos se consagran principalmente a la lectura y a las actividades creativas en sus momentos de ocio, mientras que los ninos de la misma edad pasan la mayor parte del tiempo a jugar fuera. Sin embargo, en los jovenes de 14 y 15 anos, se descubrio un interes destacado por las actividades culturales para los jovenes, lo que va en contra de la teoria que preconiza que la adolescencia precoz se instala en detrimento de la ninez. Las preguntas referentes a las actividades organizadas, permitieron de constatar que el mercado de las diversiones no es igualmente accesible a todos. En efecto, los ninos de clases sociales altas son favorecidos, comparados a los de las clases menos pudientes, lo que tiene un efecto en la medida que estos subgroups denen la suerte de acumular un capital-ocio significativo por medio de un aprendizaje no estructurado

N2 - Because the community lacked counseling services for whole families experiencing separation and divorce, The Boomerang Bunch was conceived, designed and implemented by six school counselors to identify and therapeutically address changes impacting the participant families as they attempted to "bounce back" from separation and divorce. Building on the strengths and resilience of these families, school counselors met with students and their families at the community public school outside of school hours for 8 weeks. The rationale, group process, techniques, therapeutic activities, and outcome are outlined providing school counselors with the specifics to replicate The Boomerang Bunch in their school setting

N2 - Conducting physical activity research with young children with special needs presents unique challenges that researchers working with other groups may not encounter. Children with special needs may include children with diagnosed disabilities and/or children experiencing developmental delays. When possible, research should be conducted in the natural play or school environment so the young child's typical behavior is viewed, however, equipment constraints may necessitate that a clinical or laboratory setting be used to collect accurate data. Best practice in early childhood research will require consideration of the following: subject recruitment, researcher experience, data collection environments, assistants in data collection, child interaction patterns and task persistence, and trials to be analyzed. While these topics may relate to collecting research data with children of all abilities, this paper will emphasize specific concerns related to young children with special needs

N2 - Background: School experiences of children with cystic fibrosis (CF) have not been documented in great detail before. The survival and the quality of life of children with CIF have considerably improved in the last decade. Whether CF affects their school performance and what information about CIF is available to their teachers is unknown. Method: A questionnaire was designed in two parts: 1) to ascertain academic progress, practical difficulties, attendance, coping at school and restrictions imposed: 2) to identify teachers' perceived level of information and their actual knowledge of CF. Subjects were 41 children--21 boys and 20 girls with a mean age of 11.5 years. Mann-Whitney tests were used to look at association between variables. Correlation was estimated using Spearman rank correlation test on SPSSPC+ package, Results: The majority of children were making good progress at school, regardless of clinical status, A minority (22%) had sports restrictions, most commonly in outdoor games, The median number of days absent from school in the previous year was 1 (range 0-90). 48% of children had special arrangements organized in the school, usually for medication and physiotherapy. 68% of the teachers felt they were not well informed about CF and this was confirmed by the knowledge questionnaire. Conclusion: Overall, children with CF appear well adjusted to school life. General information on CF should be provided to teachers with more specific and sensitive information given for selected individuals with parental consent. Implication for practice: School health services should have better liaison with the teams caring for children with CF Although well adjusted at school in general, some children with CF are restricted from certain activities and have difficulties with homework and continuous assessment related to their time consuming treatment. In addition, they might benefit from increased use of ambulatory treatment of chest infections, which includes not only IV therapy but also chest physiotherapy, both of which can be given in the school setting to minimize school absence

N2 - Abstract Number : 4185 | ID : O-4-09-04 Use of Green Spaces and Behavioral Indicators of Neurodevelopment in Schoolchildren. Exposure: green spaces Background: Contact to green spaces has been associated with improved mental health and well-being; however, available evidence on the impact of green spaces on child behavioral development is scarce. Aim: To study the association between use of green spaces and behavioral indicators of neurodevelopment in primary school children. Methods: This study was based on a sample of 2407 schoolchildren (6-8 years) from 39 schools across Barcelona (2012) under the framework of BREATHE study. Parents were asked to fill a questionnaire including sociodemographic and household characteristics and child's frequency of green space use. Annual total time spent in green spaces was abstracted by multiplying the number of days and hours per day that children spent in green spaces during school days, weekends, and holidays. To evaluate the behavioral patterns we utilized Strengths and Difficulties Questionnaire (SDQ) filled by parents. We applied linear regression models to estimate the association between quartiles of the annual total time spent in green spaces and SDQ total and subscale scores, adjusted for parental education, occupation, marital status, and smoking, breastfeeding, child's sex, ethnicity, school level, and preterm birth. Results: Comparing the fourth quartile with the first quartile of annual total time spent in green spaces, we found a 0.9 (95% CI: 1.5, 0.3), 0.3 (95% CI: 0.5, 0.1), and 0.4 (95% CI: 0.5, 0.2) reduction in SDQ total, emotion, and peer scores respectively. For these associations we observed dose-response relationship across quartiles of annual time spent in green spaces. For hyperactivity, there was a dose-response relationship; however, the association for the fourth quartile was not statistically significant. For prosocial and conduct subscales the results were not conclusive. Conclusion: We found a moderate beneficial impact of contact to green spaces on behavioral development in schoolchildren, though adjustment for social context has not yet been completed

N2 - Abstract Number : 3819 | ID : O-4-09-02 Buffering Effect of Residential Surrounding Greenness and Roadside Trees on the Association between Residential Proximity to Roads and Term Low Birth Weight. Exposure: green spaces BACKGROUND: Maternal residential proximity to major roads has been associated to a range of adverse pregnancy outcomes; however, there is no available report on buffering effect of residential surrounding greenness or roadside trees on such an association. AIMS: To investigate the buffering effect of residential surrounding greenness and roadside trees on the association between maternal residential proximity to major roads and term low birth weight (LBW). METHODS: This study was based on 6487 singleton term births occurring in Barcelona (2001-05). We utilized satellite-derived Vegetation Continuous Fields (VCF) and Normalized Difference Vegetation Index (NDVI) to respectively abstract the averages of percent tree cover in a 30m buffer around major roads and NDVI in a 500m buffer around each home. We generated an indicator with three categories: 1) those women residing further than 200m of a major road (reference category), 2) those residing within 200m of greenest major roads (i.e. third tertile of roadside tree percentages) and 3) those residing within 200m from a less green major road (i.e. the first and second tertiles). We developed similar indicator for residential surrounding greenness based on NDVI tertiles. RESULTS: Compared to the reference category, there was a non-significant increase in the adjusted risk of term LBW for those women living within 200m of greenest major roads (OR=1.32 (0.85, 2.06)) or having highest surrounding greenness (OR=1.31 (0.81, 2.11)). This association became stronger and attained statistical significance for those living within 200m of major roads with lower roadside tree coverage (OR=1.52 (1.07, 2.16)) or homes with less surrounding greenness (OR=1.51 (1.07, 2.12)). Stratified analyses according to tertiles of roadside tree percentage or NDVI showed similar patterns. CONCLUSION: Roadside trees and residential surrounding greenness could buffer the association between residential proximity to major roads and term LBW

N2 - Abstract Number : 3710 | ID : P-2-17-05 Association between city parks and risk of hypertension amongst reproductive age women. Cardiology Clinic, Lithuanian University of Health Sciences, Lithuania; Tomas, Grazulevicius, Vytauto Didziojo Universitetas, Lithuania; Sandra, Andrusaityte, Vytauto Didziojo Universitetas, Lithuania Exposure: green spaces Background There is some evidence that exposure to green environments is associated with health benefits, including lower blood pressure, although little research has been reported using exposure measures at the personal level. Aims We examined the association between city parks and hypertension amongst reproductive aged women. Methods This study included 3,416 women 20-45 year old Kaunas city residents. We used a geographic information system (GIS) to assess the ambient NO2 exposure and surrounding greenness in buffers of 300 m, 700 m and 1000 m around each women place of residence. Green space exposure effects on doctor-diagnosed hypertension were estimated by multiple logistic regressions with adjustments for potential confounders and NO2 exposure. Results An increase in the distance from city parks across 20-45 years old women was associated with an increase in odds ratio (OR) for high normal blood pressure group and an exposure-response relation was indicated (OR=1.10, 95% CI 0.80-1.50 and OR=2.01, 95% CI 1.31-3.11, moderate vs. lowest and highest vs. lowest exposure, respectively). The effect was less pronounced amongst women of hypertension group (OR=1.22, 95% CI 0.80-1.86, highest vs. lowest exposure). Conclusions The present study findings suggest a beneficial effect of exposure to green spaces on hypertension risk amongst 20-45 years old women. Neighbourhood greenness may have an impact in prevention hypertension and reducing related morbidity

N2 - Abstract Number : 3511 | ID : O-4-09-03 The influence of urban green space on mental health in Auckland, New Zealand. Exposure: green spaces Background As urbanization is escalating globally, urban features which improve or hinder physical and, more recently, mental health are of growing importance. One area of investigation entails the health benefits of urban green spaces. This study examined the relationship between six different measures of green space access and anxiety/mood disorders in Auckland, the largest and fastest-growing city in New Zealand. Methods Anxiety/mood disorder treatment counts by three age groups were aggregated to 3149 small area units in Auckland. Six measures of green space access were derived using GIS techniques involving total green spaces and useable green spaces. We fitted negative binomial regression models to test the relationship between access to green space and area-level anxiety/mood disorder, adjusted for age and area-level deprivation. Results Anxiety/mood disorders were associated with three green space measures. Access to total and useable green space within 300 meters did not exhibit significant associations, however access measures within 3km and distance to nearest useable green space both indicated a protective effect of increased access on decreased anxiety/mood disorders. Conclusion This study found that proximity to useable green space and the proportion of green space within the larger neighbourhood was positively associated with decreased anxiety/mood disorders in an urban environment. This suggests the benefits of green space on mental health may relate both to the ability to participate in activities in parks near to the home and to visualization of green space in the neighbourhood environment

N2 - Abstract Number : 3444 | ID : P-2-17-10 Contribution of the physical environment to socioeconomic gradients in walking in the Whitehall II study. Exposure: green spaces Background: Socioeconomic gradients in walking are well documented, but evidence on the extent to which these may be attributed to the physical environment (PE) is limited. Aims: To examine the contribution of objective measures of PE to socioeconomic gradients in minutes walked per week in participants living in London, UK. Methods: Analysis included 3363 participants (50-74 years) from the Whitehall II study (2002-4) who provided data on self-reported walking, socio-demographic characteristics, and whose postcode of residence could be linked to objective measures of PE. Individual-level socioeconomic position (SEP) was measured as most recent employment grade (six groups). Area-level SEP included quintiles of the income score from the Index of Multiple Deprivation. Attributes of PE included crime, land use, air pollution, road safety, road density, green space, access to services, access to public transport, and population density. Data on walking was log transformed prior to regression modelling. Results: In models adjusted for age, sex, ethnicity and labour market status, average minutes walked were 15.1% (95% CI: 4%-27.5%, $p[\text{trend}] < 0.001$) higher in the lowest employment grade compared to the highest. Similarly, adjusted average minutes walked were 12% (95% CI: 2.5%-22.1%, $p[\text{trend}] = 0.041$) higher in the lowest quintile of area-level SEP compared to the highest. Objective measures of PE attenuated to some extent the gradient for individual-level SEP (13.8%; 95% CI: 2.6%-26.0%, $p[\text{trend}] < 0.001$ for lowest vs highest employment grade) and substantially reduced the area-level SEP gradient in walking (4.6%; 95% CI: -5.9%-16.3%, $p[\text{trend}] = 0.691$ for lowest vs highest quintile). Of PE variables, only road safety was found to be predictive of walking. Conclusions : The contribution of PE on individual-level SEP gradients in walking appears to have a small effect in this relatively affluent population of older adults living in

greater London. Whether these results are generalizable to the general UK population and outer-London areas requires further research

N2 - Abstract Number : 3103 | ID : P-2-17-17 Green space and spatial analysis of social inequalities in infant mortality in France. Exposure: green spaces Background- Few studies considered environmental benefits to explain social health inequalities. Natural environments that contribute to good health might have an effect on socioeconomic health inequalities. In developed countries, the evidence that green spaces have health benefits for urban population is now strong. Recent studies suggest such positive effects on pregnancy outcomes. Aims- To investigate the relationships between green spaces and the spatial distribution of infant mortality taking into account neighborhood deprivation levels. Methods- The study took place in the Lyon metropolitan area, France (1340 155 in 2009). All infant deaths cases aged <1 year that occurred between 2000 and 2009 were geocoded at the census block level (n= 715). Each census block was assigned greenness and socioeconomic deprivation levels. Using a spatial “scan statistic, we examined whether there were significant clusters of high risk of infant mortality according to these neighborhood characteristics. Results- Our results highlight that infant mortality is not randomly spatially distributed, with clusters of high risk in the southwest of the Lyon metropolitan area (53 census blocks; RR:1.70; p<0.003). After adjustment on greenness levels and socioeconomic deprivation, this cluster disappears, suggesting that these factors explain in great part the spatial distribution of infant mortality. No interaction was found between the two factors. Conclusions - We propose 3 hypotheticals not exclusive pathways by which green space may have a beneficial effect on adverse pregnancy outcomes: (i) a psychological pathway, (ii) a physiological disruption process and (iii) an environmental pathway. This work adds some evidence to the link between access to green space and pregnancy outcomes but requires further research for confirmation

Additional File 4: Summary of Study by Study Results

Table S2. Associations between outdoor time and habitual physical activity.

First Author, Year	Study Results
Baranowski, 1993	(+) A model including gender, month and outdoor/indoor location accounted for 75% of the variance in preschoolers' observed physical activity. F (11, 624) = 1.94, $p < 0.03$
Boldemann, 2006	(+) Children who spent more than 45.88 % (the median outdoor time for all children in the study) of their time outdoors achieved more steps/min than children who spent less time outdoors (20.2 vs. 19.2 steps/min). <i>Outdoor stay above vs. below median value</i> <i>Boys and girls:</i> 20.2 steps/min; CI: 19.2–21.2 vs. 19.2 steps/min; CI: 19.2–20.2 <i>Boys:</i> 21.2 steps/min; CI: 19.8–22.7 vs. 20.6 steps/min; CI: 19.1–22.0 <i>Girls:</i> 18.7 steps/min; CI: 17.4–19.9 vs. 17.4 steps/min; CI: 16.2–18.7
Burdette, 2005	(+) Parent reported outdoor time checklist and recall of a typical day in the last month were significantly positively correlated with VPM. <i>Parent reported outdoor play time assessed by:</i> <i>Checklist:</i> $r = 0.33, p = 0.001$ <i>Recall:</i> $r = 0.20, p = 0.003^b$

Table S2. Cont.

First Author, Year	Study Results
Cleland, 2008	<p>(+) At T1, each additional h outdoors on weekdays in cooler months associated with an extra 11.6 min/week (1.6%) of MVPA for older (10–12 y/o) boys and an extra 17.0 min/week (2.8%) for older girls. At T2 (3 y follow-up), each additional h outdoors on weekdays in warmer and cooler months was associated with an extra 12.7 min/week (2.5%) and 13.6 min/week (2.6%) of MVPA for older boys. At T1, each additional h outdoors on weekends was associated with an additional 6.1 min/week (2.4%) and 4.7 min/week (2.2%) of MVPA for older boys and older girls in warmer months, and an additional 9.4 min/week (3.7%) and 9.5 min/week (4.4%) of MVPA for older boys and older girls in cooler months. Each additional h outdoors on weekends during warmer months at T1 was prospectively associated with an additional 4.5 min/week (1.7%) of MVPA at T2 for older boys. At T1, each additional h outdoors on weekends during cooler months associated with an additional 9.4 and 9.5 min/week (3.7% and 4.4%) for older boys and girls. Each additional h outdoors on weekends during cooler months at T1 was prospectively associated with an additional 4.8 min/week (1.9%) of MVPA at T2 for older boys. Cross-sectional associations at T2 showed outdoors time was associated with 4.5 additional min/week (1.7%) during warmer months and 4.8 additional min/week (1.9%) during cooler months for older boys. Linear regressions adjusted for maternal education and SEs adjusted for school attended at T1.</p> <p>(≠) On weekends at T1 there were no cross-sectional associations between outdoor time and MVPA during warmer months, for younger children (5–6 y/o) during cooler months, or prospectively; At T2 outdoor time was not related to MVPA during warmer or cooler months for younger boys, younger girls, or older girls. On weekends there were no relationships between outdoor time and MVPA for younger boys or girls; no prospective relationships for older girls or younger children; At T2 there were no cross-sectional associations for older girls or younger children.</p> <p><u>Weekdays</u></p> <p><i>T1 cooler months, older boys:</i> $b = 11.6$; CI: 4.9–18.3</p> <p><i>T1 cooler months, older girls:</i> $b = 17.0$; CI: 3.3–30.7</p> <p><i>T2 warmer months, older boys:</i> $b = 12.7$; CI: 0.7–24.7</p> <p><i>T2 cooler months, older boys:</i> $b = 13.6$; CI: 2.5–24.6</p> <p><u>Weekends</u></p> <p><i>T1 cooler months, older boys:</i> $b = 9.4$; CI: 3.1–15.7</p> <p><i>T1 cooler months, older girls:</i> $b = 9.5$; CI: 4.3–14.8</p> <p><i>T1 warmer months, older boys:</i> $b = 6.1$; CI: 1.5–10.7</p> <p><i>T1 warmer months, older girls:</i> $b = 4.7$; CI: 0.7–8.7</p> <p><i>Prospective, warmer months, older boys:</i> $b = 4.5$; CI: 0.6–8.4</p> <p><i>Prospective, cooler months, older boys:</i> $b = 4.8$; CI: 0.8–8.9</p> <p><i>T2 warmer months, older boys:</i> $b = 4.5$; CI: 0.6–8.4</p> <p><i>T2 cooler months, older boys:</i> $b = 4.8$; CI: 0.8–8.9</p> <p>P's < 0.05</p>
Conrad, 2013	<p>(+) There was a positive association between PA status and outdoor time ($p < 0.001$). The association remained significant ($p < 0.001$) when age and gender were included as a covariate – values were not reported.</p> <p>Low PA status:</p> <p>$\bar{x}_{\text{outdoor time}} = 3:32$ hours/day; CI: 3:24–3:40</p> <p>Medium PA status:</p> <p>$\bar{x}_{\text{outdoor time}} = 3:43$ h/day; CI: 3:36–3:49</p> <p>High PA status:</p> <p>$\bar{x}_{\text{outdoor time}} = 3:53$ h/day; CI: 3:45–4:01</p> <p>$p < 0.001$</p>

Table S2. Cont.

First Author, Year	Study Results
Danner, 1991	(+) There was a significant positive relationship between “accelerometer readings” and parent-reported outdoor time (for each of 4h, mothers indicated if their child spent the majority of the hour indoors = 0 or outdoors = 1). R = 0.43, $p = 0.002$
Dolinsky, 2011	(+) Children who spent more time outdoors had 33.8% more min/day MVPA ($p = 0.001$) than children who spent less time outdoors (adjusted for group and h monitoring). $\bar{x}_{\text{outdoor time}} = 2.0 (\pm 1.6)$ h/day $\bar{x}_{\text{MVPA}} = 14.9 (9.5)$ min/day % difference = 33.8; CI: 18.7–50.7
Jones, 2009	(+) Children (total sample, boys, girls) who spent an above average amount of time outside the home had higher \bar{x} min/day spent in bouts of MVPA ($p = 0.002$) Total sample: Above average outdoor time, $\bar{x}_{\text{MVPA}} = 45.1 (38.8)$ min/day vs. Below average outdoor time, $\bar{x}_{\text{MVPA}} = 27.7 (38.3)$ min/day $p = 0.002$ Boys: Above average outdoor time, $\bar{x}_{\text{MVPA}} = 57.1 (39.9)$ min/day vs. below average outdoor time, $\bar{x}_{\text{MVPA}} = 47.6 (51.1)$ min/day $p < 0.05$ Girls: above average outdoor time, $\bar{x}_{\text{MVPA}} = 28.8 (31.3)$ min/day vs. below average outdoor time, $\bar{x}_{\text{MVPA}} = 17.0 (24.4)$ min/day $p < 0.05$
Klesges, 1990	(+) A model that include environment (% of time the child spent outdoors vs. indoors) and also sex, relative weight, family risk of obesity, familial interaction, parental encouragements to be active, parental discouragements to be active, and environment x family risk interaction accounted for 25% of the variance in physical activity. Standardized B = 0.34, $p = 0.000$
Ludvigsson, 2007	(+) Playing outdoors was associated with a higher degree of physical exercise. $R^2 = 0.082$, $p < 0.05$
Loucaides, 2006	(+) Hours per day playing outside was significantly correlated with steps/day. Outside time was significant predictor of steps/day in a model that also included gender (entered at step one), self-efficacy (step two), social variables (step three) and hours playing outside and sports club attendance at (step four). Sports club attendance and time playing outside contributed 7% unique variance in steps/day [$F(2, 93) = 6.10$, $p < 0.01$] when entered at step 4. $r = 0.40$ $p < 0.001$. Standardized B = 0.261, $p < 0.05$
McKenzie, 1992	(+) Percent time outdoors was significantly and positively correlated with estimated caloric expenditure at home ($r = 0.65$) and at recess ($r = 0.29$) (p value not reported). $r = 0.65$
McKenzie, 2008	(+) Indoor time was negatively correlated with % time children spent in MVPA, and EER (estimated energy expenditure rate), respectively. Media viewing, PA motivated (% time PA was being prompted), other adult present, sibling present, other children present, and number of children living in household, and being indoors significantly predicted % time in MVPA (square root) in a regression model ($R^2 = .599$). Being indoors independently predicted reduced MVPA % in the model. $r = -0.73$. $r = -0.74$, p 's < 0.01 . B = -0.341, SE = 0.040, $t = -8.47$, $p < 0.01$

Table S2. Cont.

First Author, Year	Study Results
	<p>(+) During summer parents reported their children engaged in $\bar{x} = 12.7$ h (± 11.0) LPA; 8.2 h (± 6.1) MPA; 5.5 h (± 4.5) VPA per week. During winter parents reported their children engaged in 9.5 h (± 8.9) LPA, 5.2 h (± 4.3) MPA, and 5.0 h (± 3.3) VPA per week. An average amount of outdoor time in the summer (3–5 h/week) is associated with accumulating 5–9 h/week and >9 h/week of MPA. A high amount of outdoor time in the summer (>5 h/week) is associated with accumulating 5–9 h/week and >9 h/week of MPA. An average and high amount of outdoor time in the summer are both associated with accumulating 4–6 h/week and >6 h/week of VPA, respectively. An average (2–3 h/week) and high (>3 h/week) amount of outdoor time in winter are associated with accumulating 3–6 h/week and >6 h/week of MPA, respectively. An average and high amount of outdoor time in winter are associated with accumulating 3–4 h/week and >4 h/week of VPA, respectively.</p> <p><i>MPA in summer</i></p> <p><i>Average outdoor time</i></p> <p>5–9 h/week of MPA, OR = 2.38; CI: 1.18–3.14</p> <p>>9 h/week of MPA, OR = 5.75; CI: 3.89–8.49</p> <p><i>High outdoor time</i></p> <p>5–9 h/week of MPA, OR = 3.27; CI: 2.26–4.74</p> <p>>9 h/week of MPA, OR = 12.41; CI: 7.92–19.43</p> <p><i>VPA in summer</i></p> <p><i>Average outdoor time</i></p> <p>4–6 h/week of VPA, OR = 1.72; CI: 1.29–2.28</p> <p>>6 h/week of VPA, OR = 3.71; CI: 2.50–5.52</p> <p><i>High outdoor time</i></p> <p>4–6 h/week of VPA, OR = 2.21; CI: 1.55–3.17</p> <p><i>Winter</i></p> <p>>6 h/week of VPA, OR = 7.55; CI: 4.81–11.84</p> <p><i>Average outdoor time</i></p> <p>3–6 h/week of MPA, OR = 1.70; CI: 1.39–2.06</p> <p>>6 h/week of MPA, OR = 4.33; CI: 3.35–5.59</p> <p><i>High outdoor time</i></p> <p>3–6 h/week of MPA, OR = 2.50; CI: 1.61–3.90</p> <p>>6 h/week of MPA, OR = 9.39; CI: 5.92–14.90</p> <p><i>Winter</i></p> <p><i>Average outdoor time</i></p> <p>3–4 h/week of VPA, OR = 1.31; CI: 1.06–1.60</p> <p>>4 h/week of VPA, OR = 2.06; CI: 1.64–2.58</p> <p>3–4 h/week of VPA, OR = 1.96; CI: 1.29–2.98</p> <p>>4 h/week of VPA, OR = 4.35; CI: 2.87–6.60</p>
Ortlieb, 2013	
Sallis, 1993	<p>(+) Percentage of observed intervals spent outdoors (15.5% (± 15.5)) was correlated with observed PA (0.060 (± 0.008) kcal/kg/min) kcal/kg/min).</p> <p>$r = 0.74, p < 0.001$</p>
Wickel, 2013	<p>(+) The percentage of MVPA was low inside the home (3.3%), inside another home (8.4%) and inside at school (10%), compared with outside a home (70%), within the neighborhood (84.1%), and outside during an after-school program (72.9%). Time outside at home (3–6PM) increased the odds of exceeding M MVPA levels 2.56 times. Time outside at another home increased the odds of exceeding M MVPA levels 2.42 times.</p> <p>$\beta = 0.94, p < 0.001, OR = 2.56; CI: 2.06–3.17$</p> <p>$\beta = 0.88, p < 0.001, OR = 2.42; CI: 1.87–3.13$</p>

Table S3. Associations between outdoor time and acute physical activity.

First Author, Year	Study Results
Cooper, 2010	<p>(+) Children recorded $\bar{x} = 41.7(\pm 46.1)$ min outdoor time after school each day. PA was more than 2.5 times higher outdoors than indoors. This difference was consistent in each h of measurement from 3:30pm until 8:30 pm. Each min outdoors was associated with an increase of 1018.1 (CI: 875.4–1160.7) CPM in the unadjusted model, and 1000.6 (CI: 850.0–1151.2) in a model adjusted for gender, age, BMI SD scores, IMD, daylight, pubertal status.</p> <p>$\bar{x}_{\text{outdoors}} = 1345.8 \pm 907.3$ CPM vs. $\bar{x}_{\text{indoors}} = 508.9 \pm 282.9$ CPM</p> <p>$F = 783.2, p < 0.001$</p> <p>$\beta = 1018.1$ (unadjusted model)</p> <p>CI: 875.4–1160.7</p> <p>$t = 14.8, p < 0.001, R^2 = 0.137$</p> <p>$B = 1000.6$ (adjusted model)</p> <p>CI: 850.0–1151.2</p> <p>$t = 13.78, p < 0.001, R^2 = 0.144$</p>
Dunton, 2011	<p>(+) Total steps were significantly greater when children were outdoors at home (PMM = 448.58 steps) and outdoors away from home (PMM = 462.79 steps) than in any other location. The likelihood of attaining at least 5 min of MVPA during the 30 min before the EMA survey was significantly greater for entries occurring outdoors (23%) compared with at home indoors (5%), at someone else's house (9%), or in other locations (8%), all p's < 0.05.</p> <p><i>Step counts</i></p> <p><i>Outdoors not at home:</i> PMM (SE) = 462.79 steps (42.22)</p> <p><i>Outdoors in yard:</i> PMM (SE) = 448.58 steps (80.83)</p> <p><i>At other house:</i> PMM (SE) = 274.88 steps (49.29)</p> <p><i>indoors at home:</i> PMM (SE) = 210.61 steps (12.50)</p> <p><i>Other locations:</i> PMM (SE) = 354.16 steps (25.94)</p> <p>P's < 0.05</p> <p><i>5 minute MVPA bouts</i></p> <p><i>Outdoors:</i> PMM (SE) = 0.23 (0.04)</p> <p><i>Indoors at home:</i> PMM (SE) = 0.05 (0.01)</p> <p><i>Someone else's house:</i> PMM (SE) = 0.09 (0.04)</p> <p><i>Other locations:</i> PMM (SE) = 0.08 (0.02)</p> <p>P's < 0.05</p>
Klinker, 2014	<p>(+) Boys had 7.7% more of their daily MVPA outdoors than girls (adjusted). Boys had 24.3 more minutes of MVPA outdoors than girls did (adjusted). During the course of the whole day, a 1 hour increase in outdoor time was associated with an increase of $\bar{x} = 9.8$ min MVPA (adjusted model controlling for age, BMI, number of valid days, and time in domain. School was included as fixed effect to account for clustering of students within school).</p> <p>Daily median (IQR) proportion of MVPA spent outdoors</p> <p>Children = 70.0 (63.5–76.5)</p> <p>Boys = 73.8 (68.6–78.4)</p> <p>Girls = 65.3 (55.9–71.4)</p> <p>Adjusted difference = 7.7%, $p = 0.000$</p> <p>Daily outdoor median (IQR) min of MVPA</p> <p>Children = 50.1 (36.5–65.5)</p> <p>Boys = 61.8 (41.0–76.0)</p> <p>Girls = 42.3 (25.3–52.3)</p> <p>Adjusted difference = 24.3 min, $p = 0.000$</p> <p>Coefficient = 9.8, $p < 0.001$; CI: 6.9–12.8</p>

Table S3. Cont.

First Author, Year	Study Results
Raustorp, 2012	<p>(+) CPM of total activity were significantly higher for outdoor than indoor activity (1098 vs. 493 CPM, $P < 0.001$) in both boys (1134 vs. 530 CPM, $P < 0.001$) and girls (1064 vs. 459 CPM, $P < 0.001$). A greater percentage of MVPA and light PA occurred outdoors than indoors for the total sample, for boys, and for girls.</p> <p><i>Overall total CPM</i></p> <p><i>Total sample</i></p> <p>Outdoor = 1098 CPM vs. Indoor = 493 CPM; $p < 0.001$</p> <p><i>Boys</i></p> <p>Outdoor = 1134 CPM vs. Indoor = 530 CPM; $p < 0.001$</p> <p><i>Girls</i></p> <p>Outdoor 1064 CPM vs. Indoor = 459 CPM; $p < 0.001$</p> <p>~25% of outdoor (65 min), 10% of indoor (75 min) time spent non-sedentary</p> <p><i>Overall MVPA</i></p> <p><i>Total sample</i></p> <p>Outdoor % = 7.3 ± 5.7 vs. Indoor % = 2.3 ± 1.7; $p < 0.001$</p> <p><i>Boys</i></p> <p>7.5% vs. 2.0%; $p < 0.001$</p> <p><i>Girls</i></p> <p>7.0% vs. 2.7%; $p < 0.001$</p> <p><i>Light PA total sample</i></p> <p>Outdoor % = 17.6 ± 6.1 vs. Indoor % = 8.5 ± 2.6</p>
Smith, 2009	<p>(+) A one-way within-subjects ANOVA indicated a significant effect of inside vs. outside classes on average steps per class. Average steps/class during classes held outside ($\bar{x} = 1,874$, $SD = 220$) were significantly greater than average steps/class during classes held inside ($\bar{x} = 1,393$, $SD = 197$).</p> <p>Pillai's Trace = 0.96, $F(2, 136) = 1718.41$, $p < 0.001$, partial $\eta^2 = 0.96$.</p> <p>$t(135) = 58.76$, $p < 0.001$, $\eta^2 = 0.96$</p>
Skala, 2012	<p>(+) Children spent 5.36% more time standing, 4.42% more time walking, and 5.29% more time in MVPA in outdoor PE classes compared with indoor classes. MVPA was significantly associated with outdoor class vs. indoor class location.</p> <p><i>PE class % time standing</i></p> <p>Outdoor = 41.40 ± 13.98; Indoor = 36.04 ± 12.06; \bar{x} difference = -5.36, $p < 0.05$</p> <p><i>PE class % time walking</i></p> <p>outdoor = 26.60 ± 14.23; indoor = 22.18 ± 9.73; \bar{x} difference = -4.42, $p < 0.05$</p> <p><i>PE class % time MVPA</i></p> <p>outdoor = 41.42 ± 16.75; indoor = 36.13 ± 11.93; \bar{x} difference = -5.29, $p = 0.037$</p> <p>Unstandardized $\beta = 5.794$, SE = 2.817, $p = 0.041$, CI: 0.233–11.354</p>

Table S3. Cont.

First Author, Year	Study Results
Vanderloo, 2013	<p>(+) Preschoolers had higher average min/h MVPA outdoors than indoors. Preschools had higher average total min/h outdoors than indoors. Boys participated in more min/h MVPA outdoors vs. indoors. Both boys and girls displayed a statistically significant increase in TPA during outdoor playtime compared with indoor play time.</p> <p>(≠) There was not a significant difference for the % of class time that was very active outdoors (\bar{x} = 14.83, SD = 8.04) vs. indoors (\bar{x} = 13.96, SD = 7.46). There was not a significant \bar{x} difference in minutes of PA for standing, walking, being very active, or engaging in MVPA during an indoor vs. outdoor lesson.</p> <p><i>Average min/h of MVPA</i> Indoor \bar{x} = 0.54 (0.59) Outdoor \bar{x} = 5.03(4.92) $z = -4.41, p < 0.017$</p> <p><i>Average min/h of TPA</i> Indoor \bar{x} = 14.42 (6.78) Outdoor \bar{x} = 31.68 (10.83) $z = -4.70, p < .017$</p> <p><i>Boys MVPA</i> indoor \bar{x} = 0.63 (0.63) outdoor \bar{x} = 6.42 (4.97) $z = 3.62, p < .0083$</p> <p><i>Boys' TPA</i> indoor \bar{x} = 16.91 (7.22) outdoor \bar{x} = 35.71 (7.65) boys, $z = 3.57, p < 0.0083$</p> <p><i>Girls TPA</i> indoor \bar{x} = 11.40 (4.92) outdoor \bar{x} = 26.79 (12.32) $z = 3.12, p < 0.0083^1$</p>
Wheeler, 2010	<p>(+) Compared with indoors, boys and girls had a greater odds of an epoch of PA being MVPA outdoors in greenspace, outdoors not in greenspace, and outdoors out of the neighbourhood area. Relative odds of an epoch exceeding MVPA threshold remained significantly higher outdoors than indoors after adjusting for confounders (BMI, age, pubertal stage, deprivation index, season, minutes of daylight).</p> <p>(≠) Preschool girls' MVPA not significantly different indoors from outdoors.</p> <p>Boys <i>in green space:</i> OR = 6.02; CI: 5.32–6.81, $p < 0.01$ <i>not in green space:</i> OR = 4.28; CI: 3.87–4.73, $p < 0.01$ <i>Outdoors out of area:</i> OR = 1.84; CI: 1.54–2.19, $p < 0.01$</p> <p>Girls <i>in green space:</i> OR = 5.22; CI: 4.61–5.91, $p < 0.01$ <i>Not in green space:</i> OR = 4.76; CI: 4.31–5.26, $p < 0.01$ <i>Outdoors out of area:</i> OR = 1.92; CI: 1.63–2.27, $p < 0.01$</p> <p>Boys <i>Green space:</i> OR = 5.77; CI: 5.08–6.54, $p < 0.01$ <i>Not green space:</i> OR = 4.22; CI: 3.81–4.66, $p < 0.01$ <i>Outdoors out of area:</i> OR = 1.81; CI: 1.52–2.15, $p < 0.01$</p> <p>Girls <i>Green space:</i> OR = 5.12; CI: 4.52–5.79, $p < 0.01$ <i>Not green space:</i> OR = 4.75; CI: 4.29–5.24, $p < 0.01$ <i>Outdoors out of area:</i> OR = 1.93; CI: 1.63–2.29, $p < 0.01^m$</p>

Notes: (+), positive relationship; (≠), no relationship; ANOVA, analysis of variance; BMI, body mass index; CI, 95% confidence interval; CPM, counts per minute; EMA, electronic momentary assessment; h, hour; IMD, index of multiple deprivation; IQR, inter quartile range; \bar{x} , mean; min, minute; MVPA, moderate-to-vigorous physical activity; OR, odds ratio; PA, physical activity; PE, physical education; PMM, predicted marginal mean; SD, standard deviation; SE, standard error; TPA, total physical activity.

Table S4. Associations between outdoor time and habitual sedentary behaviour.

First Author, Year	Study Results
Dolinsky, 2011	(+) Children's mean sedentary time was 6.1 (1.3) h/day. Children who spent 1 h \leq outdoors had 4.4% less sedentary time than children who spent less than 1 h/day outdoors. (Adjusted for group and h of monitoring).
	<i>Boys and girls</i>
	% difference = -4.4; CI: -7.3--1.4, $p = 0.005$

Notes: (+), positive relationship; CI, confidence interval; h, hour.

Table S5. Associations between outdoor time and acute sedentary behaviour.

First Author, Year	Study Results
Raustorp, 2012	(+) Significantly more sedentary behavior was accumulated indoors than outdoors for the total sample, for boys and for girls.
	<i>Total sample</i>
	89.1% vs. 75.2%, $p < 0.001$
	<i>boys</i>
	89.2% vs. 73.8%, $p < 0.001$
Skala, 2012	<i>girls</i>
	89.1% vs. 76.8%, $p < 0.001$
	(+) Children spent significantly greater portion of indoor PE classes being sedentary than outdoor PE classes. 16.76 \pm 14.83 vs. 26.81 \pm 13.52, \bar{x} difference = 10.05, $p < 0.001$
Vanderloo, 2013	(+) Preschoolers engaged in fewer min/h of sedentary activity outdoors vs. indoors. Boys had significantly higher sedentary levels indoors vs. outdoors.
	<i>Boys and girls</i>
	<i>Outdoors</i> , $\bar{x} = 25.33 \pm 10.78$ min/h vs. <i>indoors</i> , $\bar{x} = 50.21 \pm 19.98$ min/h
	$z = -4.25$, $p < 0.017$
	<i>Boys</i>
	<i>Outdoors</i> $\bar{x} = 23.11 \pm 8.39$ min/h vs. <i>Indoors</i> $\bar{x} = 53.14 \pm 22.84$
	$z = 3.57$, $p < 0.0083$

Notes: (+), positive relationship; (\neq), no relationship; CI, 95% confidence interval; \bar{x} , mean; min/h, minutes per hour; PE, physical education; SE, standard error.

Table S6. Associations between outdoor time and motor skills.

First Author, Year	Study Results
Saakslahti, 1999	(+) More time playing outdoors was correlated with faster completion of 10 m run.
	(\neq) Total time playing outdoors was not related to the following motor skills: walking, standing broad jump, agility, throwing at a target from 2 or 3 m, throwing-catching combination, clapping, galloping, somersault, kicking a ball.
	<i>10 m run time</i>
	<i>Outdoor playing time</i>
	$r = -0.29$, $p = 0.42$

Notes: (+), positive relationship; (\neq), no relationship; m, metre.

Table S7. Associations between outdoor time and cardiovascular fitness.

First Author, Year	Study Results
	(+) Children in the highest tertile of outdoor activity had a significantly lower diastolic and systolic BP than children in the lowest tertile of outdoor activity. Indoor activities were associated with an increased likelihood of having an elevated BP.
Gopinath, 2011	<i>highest vs. lowest tertile of outdoor PA (≥ 0.57 hours/day vs. ≤ 0.14 hours/day) diastolic BP $\bar{x} = 61.5$ (59.5–63.5) vs. $\bar{x} = 63.0$ (60.8–65.2); $p = 0.01$</i>
	<i>highest vs. lowest tertile of indoor PA (≥ 0.18 h/day vs. ≤ 0.06 h/day) systolic BP $\bar{x} = 98.9$ (97.7–100.1) vs. $\bar{x} = 101.2$ (99.6–102.8); $p = 0.03$</i>
	<i>indoor physical activity and elevated BP OR = 0.50; CI: 0.27–0.92; $p = 0.03$</i>
	(-) Systolic BP was positively correlated with playing outdoors.
Saakslanti, 1999	(\neq) Systolic BP was not correlated with playing indoors. Diastolic BP was not correlated with playing indoors or outdoors.

Notes: (+), positive relationship; (\neq), no relationship; (–), negative relationship; BP, blood pressure, CI, Confidence Interval; h/day, hours per day; \bar{x} , mean; OR, odds ratio; PA, physical activity.
