N2 - 55 4-11 yr olds, in 5 age-groups, were observed for instances of immediate imitation of peers in a free-play setting. Imitation decreased with age, from an average of 14.82 to an average of 1.80 imitative acts per S per hour, with more verbal than motor acts being imitated for all age groups. Judges were not able to

discriminate between those acts imitated by the younger and those imitated by the older Ss. Dominant Ss (assessed by the amount of time an S was looked at and by teachers' ratings) were imitated more; in 4 of the 5 groups dominant Ss imitated more than nondominant ones. Among preschoolers, boys imitated more and were imitated more than girls. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Tested the hypothesis that crowded conditions increase aggressive behaviors. 10 male and 8 female elementary school students were observed twice weekly for 8 consecutive weeks during noon recreation on a crowded and an uncrowded day on the school playground. The 45-min recreation period was divided into 9 segments of 5 min each, and each S was observed once during each segment. Observed aggressive behaviors were coded into 5 categories: moderate verbal attack, menacing verbal attack, physical teasing, menacing gestures, and physical attack. Conditions of crowding in the home were reported from a parent questionnaire. No interaction effects were obtained between aggressive behaviors and density of crowding on the playground; however, Ss who displayed most aggressive behaviors tended to live in crowded home conditions. N2 - 2 sets of scales were developed designed to measure the strength of sex typing in children's play patterns in a naturalistic setting. Over a 12-week observational period, the scales based upon those activities showing a sex difference in play preferences appeared to be more stable than those scales based upon adult ratings of masculine and feminine activities. Masculine and feminine activity preferences, as measured by the more stable scales, were correlated with observational measures of other classroom behavior and performance on 3 cognitive tests. These results suggested that (a) many children have already learned to avoid opposite-sex activities by the time they enter nursery school; (b) sex-role learning during the preschool period appears to involve increasing attention to same-sex activities; and (c) the development of visual-spatial ability in boys is related to involvement in masculine activities. The advantages of a behaviorally based definition of masculine and feminine activity preference are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - In the 1st 2 classes of a pilot program for an integrated "Orientierungsstufe" (orientation classes for later choice of schools, Grades 5 and 6) in a Hamburg school, samples were taken for an "Ideal-Real" comparison of the extent of social integration in these classes. The following methods were used for verification: (a) a sociometric rating system: changes in sociometrical status during the 2-yr coeducational period (126 Ss); (b) behavioral observation: association frequency during recess (181 Ss); and (c) an attitude questionnaire: stereotype expectancies concerning members of the different social classes and their influence on the choice of friends (156 Ss). Certain classrooms showed class preferences when choosing a playmate. The expectancies regarding a doctor's son vs a dock worker's son differed significantly; these expectancies, however, were highly differentiated. On the whole, the extent of actual social integration in the school tested could be regarded as satisfactory. (34 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Observed 108 boys in Grades 3-6 for 12 wks during their recess hour on the school playground and videotaped incidents of fighting between 2 boys. Of 281 fights, 46 ended as a result of aid given by a 3rd boy. Analysis of the videotapes suggested that such acts of altruism had a high probability of occurrence when the aggressor failed to heed gestures communicating submission by the child under attack. In a 2nd study, 30 boys

and girls in Grades 4 and 5 were asked to predict whether a videotaped segment of a fight would be terminated by the intervention of a 3rd child or of its own accord. Although Ss had difficulty verbalizing the reasons for their judgments, the children could predict an act of altruism on the basis of nonverbal cues that took place between participants in a fight. Implications of the miscommunication of nonverbal cues between aggressor and the child under attack are discussed in terms of the "bystander effect." (PsycINFO Database Record (c) 2012

N2 - Describes a study of Chicano children 3-12 yrs old, of both sexes, living in 3 poverty areas in Colorado, 1 rural and 2 urban. Observations were made in early and late afternoon, 7 days/wk, in each of the 4 seasons.

Results are summarized briefly as they show differences according to site, sex, and ages of the Ss. A troublesome finding in the urban areas is that the girls do not get a fair share of outdoor activity. They are more closely supervised and learn a more passive role than boys. At all sites different children use different spaces, and for different activities. The implications of the study for the design of schools for children are outlined.

N2 - The British Research Institute for Consumer Affairs conducted research on children's preferences, use, and accidents on different types of conventional play equipment. Methods included inspections of all playgrounds in 4 parliamentary constituencies, and surveys of parents, 7-12 yr old children, and hospital accident and emergency department reports in 3 additional communities. Preferences and use patterns ranged from high on flat swings and big combination slides to low for climbing frames, and various rocking horses and boats. All measures indicated that accidents were most pronounced on swings (23-51% of all accidents), then roundabouts (10-32%), slides (10-23%), and climbing frames (1-28%). The most common causes of injuries were (a) the surfaces on which the child fell, and (b) moving equipment. The Design Council of Great Britain estimates that at least 20,000 playground accidents a year need hospital treatment; the Research Institute for Consumer Affairs estimates that all accidents treated either by a doctor or a hospital approximate 150,000/yr. N2 - Tested the hypothesis that a child's displays of human submission involving diminished body stature have a higher probability of terminating attack by an aggressor than other behaviors exhibited by the child during an agonistic encounter. Groups of 28-34 8-12 yr old male elementary school students were observed in 24 40-min sessions over a 6-wk period. A videotape unit was activated whenever the initiation of agonistic interaction was observed. Results indicate that behaviors involving a diminution of body stature (kneeling, bowing, shoe tying) were found to precede the cessation of agonistic activity between the students significantly more frequently than other forms of behavior exhibited by the student under attack (e.g., threat displays, face-to-face interaction). It is suggested that to the extent that the aggressive encounters of children during play activity represent at least one form of human agonistic activity, a constellation of behaviors exist which serve an appeasement function.

N2 - Most behavior modification programs that have been used in an educational setting have been concerned primarily with classroom discipline. In an application of operant procedures to the instructional setting, the present study analyzed the effects of antecedent stimuli (e.g., prompts, instructions, lessons) and contingent positive reinforcers on pupils' use of prepositional phrases in their written compositions. Ss were 24 middle-class pupils in a combined 3rd-4th grade classroom. A simple point system was utilized in which extra points for written assignments could be exchanged for extra recess or activity time. Instructions and differential reinforcement were used singly and in combination to assess their effectiveness. The sequence of experimental manipulations, and a summary of ANOVA values are given in tabular form. Results indicate that the condition combining classical components of instruction with the operant reinforcement procedure was far superior to the other conditions. It is suggested that an integrated program involving both antecedent and consequent components will be more effective than programs using either component alone. N2 - Previous research has demonstrated that the connotations of the color white are positive and the connotations of the color black are negative. The present study investigated the relationship between children's response to these colors and their interracial behavior. 20 Black and White male and female 4-5 yr olds were observed in a free play situation on a school playground. Color preference and color attitudes were measured in 3 different ways. A correlation was found between playground behavior (i.e., positive or negative play with peers) and response to the colors black and white as measured in a situation in which Ss guessed the locus of origin of positive and negative self-evaluative statements broadcast simultaneously from black and white boxes. The correlation was substantially higher for females than for males. The high correlation for females is discussed in terms of a difference between the sexes in rate of perceptual and linguistic development.

N2 - Attempted to answer the question, "Can a preschool classroom be designed in which children function at a high level of involvement without being directed and restricted by adults?" The 2-fold approach to this question involved studying 5 private nursery school classrooms and measuring the degree of involvement exhibited by the children in those rooms during free play. The classrooms were rated for quality through the use of a modified form of an instrument designed by Prescott, Jones, and Kritchevsky for studying playgrounds. The rooms with the higher ratings for space quality had fewer uninvolved children. The findings indicate a relationship between the quality of a play area, as defined and measured by the instrument, and young children's involvement there during free play. It is concluded that the instrument used is potentially useful for designing and evaluating classrooms. (19 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Time-sampled observations were made of the free-play fantasy behavior of 4 groups of 10 3-5 yr olds in a preschool setting. Males displayed more, and more active, fantasy play than females; older Ss engaged in more make-believe than younger ones. Increases in fantasy play over the year depended on age, sex, and the nature of the activity. Males and older Ss performed more make-believe play outdoors than females and younger Ss. Whereas interactive fantasy play was shown more often by males and older Ss, cooperative role taking was more common among females. The greater role-taking fantasy play of females as compared with males was not simply a function of the females greater use of a "homemaking" play area. The opportunity for outdoor play may be related to the greater overall fantasy play of males. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Tested the hypothesis that less aggression would be observed on the playground of a pluralistic school than on the playground of a traditional school. This hypothesis is based on the notion that the pluralistic school environment would be less frustrating to the student, and therefore students would be less likely to aggress during recess. Two undergraduates, naive to the purpose of the study, observed and tabulated 1st-3rd graders' aggressive verbalizations and behaviors during morning recesses at a pluralistic and a traditional school. The majority of pupils at each school were lower class. The traditional school was 30% Chicano, 5% Black, and 63% White, while the pluralistic school was 31% Chicano, 27% Black, and 38% White. Results indicate that significantly less physical and verbal aggression occurred on the playground at the pluralistic school. It is suggested that the implications of these results may be particularly valuable to the education of lower class and minority children. N2 - Suggests that spelling and penmanship are done well by children who wish to conform and are done poorly by rebels and "free spirits," and that when poor performance is attributed to such things as perceptual difficulties rather than attitudes, the children use it as an excuse in future troubles. Problem-solving subjects, such as mathematics and grammar, are done well by self-reliant children. The social myth that girls are not gifted in mathematics discourages them. Poor reading may be the result of rebellion against the entire educational and social system, of the poor reading material used in classes, or of social attitudes (e.g., reading is a "sissy" activity). Children who have recess as their favorite subject indicate that they have no use for schooling at all and find little enjoyment or excitement in it. After having eliminated medical and other factors, personality should be considered as a source of failure in various school subjects. N2 - Data on peer relations were obtained when 35 males and 27 females were 21/2 yrs old and again when they were 71/2 yrs old. Ss who at age 21/2 were friendly, involved with their peers, and able to cope with aggressive peers were likely, at age 71/2, to spend many hours outside school with peers, to be socially at ease, and to be the ones who decided with whom they would play and what they would play. In other words, sociability at 21/2 was positively related to sociability at 71/2. Social behavior at 71/2 had very different meanings for males than for females. The highly social males, when with peers, tended to have extensive peer relations; that is, they usually played with groups of males. The highly social females, when with peers, tended to have intensive peer relations; that is, they usually played with only 1 other female. N2 - Evaluated a strategy designed to maintain behavior after withdrawing a token reinforcement program. In a special education classroom, 4 6-8 yr old educable retarded children received token reinforcement for attentive classroom behavior throughout the day. Using a multiple-baseline design across morning and afternoon class sessions, the following phases were presented: Baseline, Token Reinforcement, Tokens plus Peer Praise and Delayed Reinforcement, and Teacher and Peer Praise with a Group Contingency. Phases after the initial token program were designed to gradually fade tokens and substitute "natural" reinforcers (peer praise and activities available in the setting) without a loss of behavior gains. In the last phase, tokens were no longer used in the classroom. 2 follow-up phases, conducted 2 and 9 wks after all contingencies had been withdrawn, showed that inappropriate behavior had been maintained at the low levels achieved during the initial program. Data at the end of the last follow-up phase (approximately 12 wks after any contingency had been in effect) failed to show recovery of inappropriate behavior. N2 - Compared 72 children who attended 8 preschool playgrounds for disadvantaged children in Belfast with 72 who attended the same playgrounds exactly twelve months later and with a control group of 72 nonattenders. Retests 6 mo after initial testing on the Peabody Picture Vocabulary Test and the Columbia Mental Maturity Scale, when the mean ages of the 3 groups were 50, 49, and 49 mo respectively, revealed significant differences between attenders and nonattenders on both measures. Between-playgroup and between-cohort differences were not significant. These effects, which occurred in the context of a traditional nursery curriculum, are attributed to the variety of activities in which the children were encouraged to engage and the warmth, interest, and participation of the playgroup leaders. N2 - Reported relations between data from a simple and reliable activity recorder, O data of vigorous play in outdoor and indoor settings, and teachers' ratings of 58 21/2-yr-old children. The recorder consists of 3 small manual wristwatches placed in a small packet so that each watch records movement in 1 of 3 dimensions (horizontal, vertical, or lateral). Any movement across 1 dimension results in a movement of the sweep-hand of the appropriate watch. Data from the recorder were highly related to other objective data for both sexes outdoors, but only males showed generality of play across situations. Recorder data showed males more active than females and were related to nearly all teachers' ratings for both sexes. (15 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Presents some of the constructive approaches used to assess more adequately than do standard tests the status of disadvantaged minority group children. Most standard tests exhibit both racial and socioeconomic bias in their questions. Research supporting this contention is described. It is suggested that tests biased in favor of disadvantaged minorities could give useful information about what might be expected of these children.

Attempts to create such instruments are detailed. Other alternatives suggested are improved test administration and nontest kinds of assessment, e.g., observations made in the classroom or playground. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Determined whether preference scaling techniques could be used to aid engineering system design. Children's play equipment was selected as the design area. Paired comparison and rank-order methods were used to determine whether 48 3rd-4th graders had preferences for different types of play equipment; whether these preferences were reliable over time; and whether actual use of play equipment was predictable from the preference scales developed. Photographic stimuli were used for the scaling and were presented to Ss. The frequency of use of play equipment was also determined using time-lapse photography. Results indicate that (a) Ss did have stable and reliable preferences for play equipment and (b) these preferences were correlated with actual usage of the equipment. N2 - Compared play activities of children in nursery and primary school in terms of social participation and play content. 12 boys and 12 girls were observed in upper nursery school and 5 boys and 5 girls in primary school. 6 boys and 6 girls were followed from nursery to primary school, and 20 boys and 20 girls through the 1st 3 mo of primary school. Nursery school play was characterized by greater variety, less structure, and a greater proportion of nonplay activity than primary school play (37% vs 14%). In the transition from nursery to primary school, differences in amount of structured play were more marked in girls than in boys. In semidirective interviews with 30 children, nursery children described their play without giving it a label. Primary school children would simply name the game, implying a commonly understood play culture. (English summary) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated the play preferences of 68 junior, senior nursery, and kindergarten school children in Delhi. Ages ranged from 4 yrs, 2 mo to 5 yrs, 3 mo. Ss were drawn from all socioeconomic status categories. Each child was observed 45 min daily for 5 days continuously by the classroom teacher during play situations. Ranks based on total preference scores were used to indicate the preference of the group for different play equipments. Slide, sound pit, nesting frames, and crayon drawing were found to be the preferred play activities. No relationship was seen in the play preference between boys and girls in kindergarten for outdoor games. The trend for indoor games at the junior nursery level was similar. Girls showed contrasting play preferences across educational levels. Results are interpreted in terms of maturational factors. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Filmed 54 kindergartners while at play on the school playground. Space utilization was assessed by 10-min film segments taken on each of 6 randomly selected days covering a 7-wk period. Ss were also given the Bender Visual-Motor Gestalt Test, 3 performance subtests of the Wechsler Preschool Primary Scale of Intelligence, a body image test, a body-size concept test, and a self-drawing task (to measure space utilization in graphic production). Results lend support to the concept that young children can be differentiated by the amount of space each uses while engaged in self-initiated nonstructured locomotor movement. Also, relationships were found between space utilization by children and selected aspects of behavior. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Presents a model for counseling groups of elementary school children which synthesizes theory and practice derived from T-group theory, developmental psychology, perceptual psychology, client-centered counseling, behaviorism, and the humanistic-existential orientation. The rationale for the use of this model in an educational setting is discussed. Group structure and guidelines for counselor behavior are described.

Descriptions and interpretations of 4 sessions with 1 female and 2 male 5-6 yr. olds are presented. It is concluded that the activity-interaction model allows for the arrangement of conditions required for learning and functioning both within and outside of the school. N2 - Studied how to help children incorporate more original ideas into their art production. Ss were 30 6th graders. The instructional material was a series of problem-solving tasks presented in detective stories with cartoon illustrations in booklet form. There were 16 lessons with an average of 35 pages each. An opaque projector was used in order for the trainer to read to the entire class at 1 time and was followed up by oral discussions of the problems. The test was a framed 6" * 9 1/2" paper on which the S drew a picture appropriate to children playing in a school yard. Ss' drawings were evaluated by 4 art teachers as to whether they were stimulus-free or stimulus-bound, and on originality. Results indicate that the experimental group of 15 did significantly better on these variables than did the 15 controls. Findings suggest that schoolchildren are trained to give responses similar to teachers' directions. Training by projecting the lessons on a screen to the entire class encouraged oral discussion and produced enthusiasm and involvement. Further study is needed to see if this creative expression remains with these Ss or if continuous training is necessary. The study indicates that creative expression can be stifled or developed in accord with atmosphere and curriculum variables. (34 ref.) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Conducted structured doll-play interviews with 40 Mexican-American 4- and 5-yr-olds, to explore where and when skin color discrimination and the evaluation of color differences occur. The study attempted to determine whether discrimination and evaluation occur simultaneously and whether they were functions of the S's age and sex, or exposure to group participation outside the home. The Ss tended to group the dolls by sex and size before grouping them by skin color. Evaluation on the basis of skin color occurred at the same time the discrimination was made, "good" dolls being white and "bad" dolls dark. After exposure to school the doll with which the child identified was white, with a tendency for boys to perceive the white adult male doll as larger than the dark one of the same size. Major dimensions of good and bad parents and good and bad children were inferred from the S's descriptions of their behavior. Results have been related to comparable studies with regard to Negro and Oriental children and the similarities and differences discussed. N2 - The following report is a summary of what the Mountainside system has been attempting by way of early identification of a child's developmental level and needs, readiness for learning, and the ways learning can be fostered. In the spring of 1963, on reviewing the number of underachievers in the upper grades who were recognized as early as 1955-1957, but for whom no recommendation was made, and in recognizing the large number of immature and/or anxious children in the kindergarten and considering the competitive situation which such children encounter at the first grade level, it was decided by the administration to form a special first grade, which for want of a better term was named the Transitional First Grade. The major purpose of this transitional first grade was to allow children who needed extra growing and learning time to have the opportunity for a more individualized program, extra and special materials, a specialist teacher who has worked with nursery and kindergarten level children, plus the socialization opportunities of playground, music, special programs with the other children in more formal first grades. Twenty children were found to be eligible for the transitional first grade. The twenty sets of parents were then separately interviewed by the psychologist and the principal of the school the child attended. Of the twenty sets of parents interviewed, four elected to send the child to a private school first grade, and one family was so emotionally disturbed by the whole situation that its child was placed in a formal first grade. The transitional class was thus started in September 1963 with fifteen pupils. Advantages and disadvantages of the transitional first grade are discussed. N2 - (from the chapter) Since we need a starting point, let us start with observing a child at tasks and behavior that make up so much a part of a young child's life--the routines. At school we generally think of these as clean-up, toileting, snack-time, lunch, rest, etc. These are the "uncreative" but necessary aspects of the program that are repeated day after day, the activities around which many a program revolves. Let us look at a child about to become involved in a routine--for example, getting dressed for outdoors. Although this seems to be a simple and obvious activity, let us look at a child with the following questions in mind: What is the stimulus for the activity? What is the setting? What seem to be the child's reactions? It sounds as though each of these questions requires an answer, as in a questionnaire. On the contrary, the questions are only reminders of things to be aware of as you are observing. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Two types of leaders have been contrasted in the child study literature since the early 1930's, one group-oriented, the other, self-oriented. In the present research, systematic observations of boys of each type are made on the school playground, where these patterns have been observed in the past, and in the more intimate, less competitive situation of the back yard. Six group-oriented leaders and six self-oriented leaders were selected from the third grades of four New England public schools on the basis of a teacher's rating and ratings by two previous observers of the boys. During the winter and spring of 1954 these twelve nine-year-old boys were observed on the playground during a free play period and in the neighborhood, using the set of categories for interaction process analysis developed by Bales. The clinical judgments of teachers and social scientists are not entirely validated since boys of both leader types show the same amount of aggression on the school playground, although the self-oriented leader is more aggressive in the neighborhood. Other expected differences appear since the self-oriented leader gives fewer suggestions and shows more tension in both situations. The major finding of this research is that there are more differences between situations than between the two leader styles. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - For a number of years one of the primary concerns of those interested in the children who make up what is known as the Nursery Group at the Clinic of Child Development has been objectification of the records of observations of the spontaneous behavior of these young children during free play periods. The important question of method in the study of the social behavior of young children has recently been summarized and evaluated elsewhere. In this study, the 15 subjects were drawn from a group of normal, healthy children between the ages of 2 and 5 years. Three of the 15 children were in daily attendance in the Nursery during the academic year. Seventy-five observations were made, 5 observations of the activity patterns of each child. At least 2 of the 5 observations were outdoors. Each observation was 5 min. in length. The records obtained by the use of the device not only enable one to account relatively accurately for each second of time during which a child is under observation, but they also have a cinematographic quality. It is increasingly evident that this recording device can be used in making observations of many categories of behavior. It tends to increase the observer's objectivity and to decrease the tendency to interpret observations. The results show that if several observers, each one interested in a different behavior category, could make their observations of a child's behavior during the same 5-min. period, and then "pool" their observations, a relatively complete picture might result. N2 - The question as to whether differences in personality distinguish individuals of one profession from those of another has received considerable attention in both popular and psychological thought. In the present study the following questions were considered: (a) is there a difference in the reaction patterns of an artistically superior group of children as compared to an artistically inferior group of children; (b) is there a difference in the amount of progressive activity of this artistically superior group as compared to the amount of progressive activity of this artistically inferior group. The subjects used for this comparison were children selected from the Preschool of the Iowa Child Welfare Research Station and the Iowa University Elementary School. We find that the Z group, both boys and girl, excel the X group in progressive activity on equipped playgrounds. The boys of the Z group are considerably more active than the girl, but the Z girl is considerably more active than the X boys. In general we conclude that probably the primary difference between artistic and inartistic groups is revealed in the greater interest of the artistic group and the correspondingly greater response to play materials. According to the above results because of their greater inactivity, girls may devote more time to play with materials of which art materials are a part. N2 - Two boys between six and seven years of age were observed for a total of 500 minutes in periods of approximately five minutes' duration. The observations were made in the playroom and on the playground of a child placing institution during regular play periods. The material on each child was analyzed and classified into 42 categories in such a manner as to have mutually exclusive groupings of 50 minutes each for intercorrelations. The instances of occurrence of certain types of behavior, such as facial movements, contact with others, walking, etc., were counted. Examination of data indicates that large samples of observed behavior show a higher reliability than small samples. However, even in 50-minute groupings, when conditions of observation are carefully controlled and short periodic observations are made, the mean reliability is well above .80, while 100-minute groupings are slightly below .90 and 150-min-minute groupings are about .92. N2 - (from the chapter) The entire youth of a human being falls quite naturally into three periods, each of six to seven years, and everyone of these periods may be looked upon as a whole, complete in itself. The distinguishing feature of the first period is its character of play. The human being develops his natural powers by play; by it the child, through his senses, comes to a realisation of the world outside himself, gains control over his own movements, and learns to express and communicate his ideas in speech. The student of the first period has to do with the child whose world is the nursery and the kindergarten, and the difference between the

psychology of early childhood and the psychology of school-age is no less marked than that between first education and school pedagogics. The problems of the first period are, primarily, of a genetic order concerned with the gradual unfolding of the mental powers from their very earliest beginning, whilst in school-psychology, the all-important point of interest is the existent psychic condition at fixed stages of childhood. And this difference makes itself felt even in the methods of scientific research; in early childhood by far the most important point is the continuous observation of as many sides as possible of the individual child, whilst at school-age we have to combine a wide observation of the child with experimental testing of separate powers and with statistic results of examination of great numbers. We will now attempt to give a short resume of the work done in child-psychology up to the present time, and, in so doing, follow first the main-trend development and then two remarkable off-shoots, viz. psychoanalysis and the Montessori movement. N2 - (from the chapter) The years from about eight to twelve constitute a unique period of human life. The acute stage of teething is passing, the brain has acquired nearly its adult size and weight, health is almost at its best, activity is greater and more varied than it ever was before or ever will be again, and there is peculiar endurance, vitality, and resistance to fatigue. The child develops a life of its own outside the home circle, and its natural interests are never so independent of adult influence. Perception is very acute, and there is great immunity to exposure, danger, accident, as well as to temptation. Reason, true morality, religion, sympathy, love, and esthetic enjoyment are but very slightly developed. Everything, in short, suggests that this period may represent in the individual what was once for a very protracted and relatively stationary period an age of maturity in the remote ancestors of our race, when the young of our species, who were perhaps pygmoid, shifted for themselves independently of further parental aid. Rousseau would leave prepubescent years to nature and to these primal hereditary impulsions and allow the fundamental traits of savagery their fling till twelve. Biological psychology finds many and cogent reasons to confirm this view if only a proper environment could be provided. The child revels in savagery, and if its tribal, predatory, hunting, fishing, fighting, roving, idle, playing proclivities could be indulged in the country and under conditions that now, alas! seem hopelessly ideal, they could conceivably be so organized and directed as to be far more truly humanistic and liberal than all that the best modern school can provide. We should transplant the human sapling, I concede reluctantly, as early as eight, but not before, to the schoolhouse. Even if it be prematurely, he must be subjected to special disciplines and be apprenticed to the higher qualities of adulthood; for he is not only a product of nature, but a candidate for a highly developed humanity. N2 - Reviews the article "Der Studienplan" by H. Schiller (1897). The reviewer discusses the topic of fatigue and how it relates to conditions in the school room. The concept of designing opening and closing hours of school as well as the distribution of pauses for recreation based on fatigue is all discussed. In the article by Schiller, it is proposed that the first hour be devoted to the most difficult subject, followed by subjects of more general interest. The second hour should be followed by a somewhat longer recess, after which the child is prepared for another difficult subject. It is suggested that the last hour be devoted to subjects such as writing, singing, and gymnastic drill. Lastly, it is suggested that when only two hours a week are devoted to a subject, it gives much better results if the exercises come on consecutive days, or even on consecutive hours. N2 - Vitamin D is an essential component of bone and mineral metabolism; its deficiency causes growth retardation and skeletal deformities in children and osteomalacia and osteoporosis in adults. Hypovitaminosis D (vitamin D insufficiency or deficiency) is observed not only in adults but also in infants, children, and adolescents. Previous studies suggest that sufficient serum vitamin D levels should be maintained in order to enhance normal calcification of the growth plate and bone mineralization. Moreover, emerging evidence supports an association between 25-hydroxyvitamin D (25(OH)D) levels and immune function, respiratory disease, obesity, metabolic syndrome, insulin resistance, infection, allergy, cancers, and cardiovascular diseases in pediatric and adolescent populations. The risk factors for vitamin D deficiency in the pediatric population are season (winter), insufficient time spent outdoors, ethnicity, older age, more advanced stage of puberty, obesity, low milk consumption, low socioeconomic status, and female gender. It is recommended that all infants, children, and adolescents have a minimum daily intake of 400 IU (10 mug) of vitamin D. Since the vitamin D status of the newborn is highly related to maternal vitamin D levels, optimal vitamin D levels in the mother during pregnancy should be maintained. In conclusion, given the important role of vitamin D in childhood health, more time spent in outdoor activity (for sunlight exposure) and vitamin D supplementation may be necessary for optimal health in infants, children, and adolescents. 2013 by The Korean Pediatric Society

N2 - Background: The epidemiology of Alkhurma hemorrhagic fever disease is yet to be fully understood since the virus was isolated in 1994 in the Kingdom of Saudi Arabia. Setting: Preventive Medicine department, Ministry of Health, Kingdom of Saudi Arabia. Design: Retrospective analysis of all laboratory confirmed cases of Alkhurma hemorrhagic fever disease collected through active and passive surveillance from 1st January 2009 to December, 31, 2011. Results: Alkhurma hemorrhagic fever (AHFV) disease increased from 59 cases in 2009 to 93 cases in 2011. Cases are being discovered outside of the region where it was initially diagnosed in Saudi Arabia. About a third of cases had no direct contact with animals or its products. Almost all cases had gastro-intestinal symptoms. Case fatality rate was less than 1%. Conclusions: Findings in this study showed the mode of transmission of AHFV virus may not be limited to direct contact with animals or its products. Gastro-intestinal symptoms were not previously documented. Observed low case fatality rate contradicted earlier reports. Close monitoring of the epidemiology of AHFV is recommended to aid appropriate diagnosis. Housewives are advised to wear gloves when handling animals and animal products as a preventive measure. 2014 Memish et al

N2 - Narcolepsy-cataplexy syndrome is characterized by excessive, severe sleepiness during the day, sudden loss of muscle tone with emotional lability (cataplexy), sleep paralysis, hypnagogic or hypnopompic hallucinations and weight gain. Although none of the major symptoms is exclusive to narcolepsy, cataplexy is the most specific symptom and is rarely present outside of narcolepsy. For the first time as a clinical picture shaped by a sudden loss of muscle tone in 1877 was reported by Westphal. The onset of narcolepsy with cataplexy is usually during teenage and young adulthood (10-15 ages) and persists throughout the lifetime. We purposed to report a case with narcolepsy diagnosed. A-11-year-old male was brought to our hospital due to drop attacks, which had occurred two-three times in a week since three months, when he was playing. It was learned that the patient had sudden loss of muscle tone with emotional changes such as smiling, while he was playing, and after these attacks he had continued to play again. He was sleeping all day long. His teachers recognised the decreased academic performance. Routine blood biochemistry and hematological investigations were normal. Brain Magnetic Resonance Imaging (MRI) and Electroencephalography (EEG), and electromyogram (EMG) were normal. He was subjected to Multiple Sleep Latency Test (MSLT) resulting in the mean sleep latency of 1 minute with presence of excessive daytime sleepiness and demonstrated the presence of sleep-onset REM periods (SOREMP). Neuropsychological tests were normal. After the reevaluation of the history and physical examination, he was diagnosed as narcolepsy. Methylphenidate 10 mg/day treatment was started and the dose was increased to 20 mg/day after two weeks. After two months of methylphenidate treatment, the symptoms were resolved. Narcolepsy is a syndrome characterized by excessive sleeping. Pathophysiological studies have shown that the disease is caused by the early loss of neurons in the hypothalamus that produce hypocretin, a wakefulness-associated neurotransmitter present in cerebrospinal fluid. The cause of neural loss could be autoimmune since most patients have the HLA DQB1 allele that predisposes individuals to the disorder. Treatment is with stimulant drugs (modafinil or the other stimulants; methylphenidate etc..) to suppress daytime sleepiness, antidepressants for cataplexy, and hydroxybutyrate for both symptoms. A clinical examination and exhaustive medical history are essential for diagnosis and treatment. Narcolepsy is not rare, but it is an underrecognized and underdiagnosed condition at younger age. If left undiagnosed and untreated, early onset narcolepsy can interfere with psychological, social, and cognitive functioning and development and undermine academic and social activities

N2 - Introduction: Recent evidence, about the various effects of vitamin D (vit D) on innate and adaptive immunity has led to search for its role in asthma and allergic diseases. The defects in the innate immune system, such as the capacity to increase the production of broad spectrum antimicrobial peptides like cathelicidin may predispose to infectious complications. The aim of this study was to determine the role of vit D and cathelicidin in the development of acute asthma attacks among 7-17 years old allergic asthmatic-children. Material and Methods: The study included 35 patients with acute asthma exacerbation triggered by an infection, 32 children with controlled asthma and 21 healthy children, all matched by sampling season and for asthma subgroups, matched by mono-mite sensitisation and previous severity and medication score of asthma. In all groups, a comprehensive questionnaire, serum 25-OH vit D, vitamin D-binding protein (VDBP) and cathelicidin levels, markers of allergy, viral serology and spirometric indices were employed. Factors that influence serum vit D levels and the development of asthma attacks were evaluated with multivariate linear and logistic analysis. Results: The mean serum vit D level was 14.09 + 5.75 in the attack group, 28.47 + 13.88 in the stable asthma group and 12.95 + 7.15 in healthy controls. The differences between attack and stable asthma groups were highly significant ($P < 0.001$). On the contrary, mean cathelicidin level was significantly higher in acute asthma group than controlled asthmatics ($P = 0.002$). Cathelicidin levels showed a negative correlation with vit D levels ($P = 0.002$, -0.380 spearman c.c). Furthermore, there was a positive correlation between the spirometric indices and the level of vit D among asthmatics ($P < 0.05$). Multivariate analysis of risk factors that

may influence vit D levels revealed that younger age ($P = 0.046$), high BMI ($P = 0.025$), longer duration of sun exposure ($P < 0.001$), and high amount of dietary vit D ($P < 0.001$) independently increased serum vit D levels. Furthermore, multivariate analysis of risk factors that may result in acute asthma vs controlled asthmatics showed that the increase in serum levels of vitamin D significantly reduced the risk of asthma attacks ($P = 0.030$, adjusted odds ratio 0.862) independent of age, sex, allergic markers, use of inhaled steroids, BMI, time spent outside (as a marker of activity level), serum levels of cathelicidin and VDBP

N2 - Background: At present, there is no European report on clinically relevant systemic reactions due to the regular use of subcutaneous or sublingual allergen immunotherapy (SCIT and SLIT, respectively) outside clinical trials. Using an electronic survey and a 'harmonised terminology' according to MedDRA we aimed to prospectively collect systemic adverse reactions due to (allergen immunotherapy) AIT from real life clinical settings. Methods: Under the framework of the EAACI, a team of European specialists in AIT, pharmacovigilance, epidemiology and drugs regulation, set up a survey to be conducted, first as a pilot, in four countries (France, Italy, Germany and Spain). A designated 'country coordinator' is responsible for following specific country ethics requirements and to select at least 30 doctors per country. Patients have been recruited the same day they received their first dose of either SCIT or SLIT. The survey started on 01/09/12 and is planned to be finished on 31/01/14. Patient inclusion criteria are: adults and children, with IgE mediated pollen and/or house dust mite, Alternaria, and/or animal dander respiratory allergies who will initiate AIT. The Survey Monkey online survey instrument is used by participant doctors to submit information directly into a central base via a blinded coded programme which allows to follow any adverse reaction due to AIT without compromising patients' and doctors' anonymity. A list of symptoms and their definition was selected from the Med- DRA dictionary in order to report all adverse reactions in this survey. Results: Three questionnaires have been generated: the Doctor Questionnaire, the Patient Questionnaire and the Reaction questionnaire; as well as a handbook and a mistake report form. A list of 30 terms for single symptoms has been selected to report adverse reactions. As of Jan 15th 2013, a total of 144 doctors have been recruited, 1233 patients included and 15 adverse reactions due to AIT have been reported. Conclusion: This is the first report in Europe collecting systemic adverse reactions due to AIT in a prospective real life setting. This survey will bring interesting data to the scientific community and could provide the platform for a future pan-European registry on AIT safety

N2 - RATIONALE: Air pollutants may cause respiratory problems in children during adolescence. The study was aimed at assessing the respiratory health of children exposed to pollution in different areas of Delhi. METHODS: Schools were selected from commercial-Chandni Chowk (CC), industrial- Mayapuri (MP) and residential -Sarojini Nagar (SN) areas. Indoor and outdoor levels of SO₂, NO_x and Particulate matter (PM) were estimated using samplers in classrooms and at monitoring stations. Questionnaire was designed based on internationally valid questionnaires for respiratory illness. Students completed the questionnaire and performed spirometry test. RESULTS: Indoor and outdoor PM₁₀ concentration was highest in CC (815+354.45 & 337+85 mug/m²) and lower in MP (694.6+322.9 & 274+78mg/m²) and SN (534.3+94.22 & 197+48 mg/m²). These were too high & above the permissible limits of 100mg/m². However, levels of SO₂ and NO_x were below the limit. Students (1814) aged between 12-16 years participated in the survey. Questionnaire data showed that "wheeze, cough and cold" were most prevalent in CC (29.6%) panel of students followed by MP (15.9%). Spirometry tests demonstrated that 19% of CC & 14% of MP subjects suffered mild obstruction whereas 16% of CC & 32% of MP subjects had severe obstruction. Conditional logistic regression analysis of the association between chronic exposure to PM and respiratory symptoms showed a significant positive relationship in these areas. CONCLUSIONS: Commercial and industrial zones with high traffic movement and human activities contribute more PM which affects the pulmonary health. The study indicates that high pollution levels may lead to respiratory illness in children

N2 - In diets that require the calculation of protein/amino acids from natural food it is a constant demanding task to turn the dietary prescription into a "meal". Difficulties in dietary compliance are frequent and can be solved with educational strategies involving the child and family, to anticipate everyday situations and problems. Participatory multithematic workshops were designed based on the real needs. The aim of the study was to achieve nutritional treatment compliance through the implementation of educational workshops for IMD patients and their families. Seventeen patients (6m-14y) and 26 relatives attended 3 workshops planned according their needs, including educational and culinary activities. The topics discussed were qualitative (understanding IMD and diet, allowed/prohibited foods, use of medical/low-protein foods, handling special situations, self-care, eating outside the home) and quantitative (weigh-measure food, calculations, food records, exchanges). Recipes were designed to encourage participation and consumption of foods allowed, expanding to a variety of menus. Educational workshops encourage dietary compliance in a practical way, improve conventional instruction, and provide the opportunity to share ideas and experiences in the diet management. The continuation of these activities is important to measure and evaluate the impact of changes on adherence and hopefully improve the longterm metabolic control

N2 - Miglustat is the only therapy options in NPC patients. Here discussed the effect of miglustat therapy in four children with NPC disease and initial symptoms of visceromegaly. Case 1 A 10 days old female infant was diagnosed NPC. Due to her vertical gaze palsy, motor retardation, the miglustat therapy was started at the age of 3 years. She can walk with support outside, start to speak at the first year of the therapy. Case 2 A 10 months old female was diagnosed NPC. Neurological development was completely normal until the age of five years. The abnormal saccadic eye movement was noted and she was started on miglustat therapy. Case 3 A 3 years old male patient was diagnosed NPC. Because of his walking, speech disabilities, abnormal eye movements, miglustat therapy was started at 4 years old. His walking condition was stable, his speech was improved. Case 4 A 2 months old girl patient was diagnosed NPC. The miglustat therapy was started at the age of one year because of her neurodevelopmental delay. But we had to stop the treatment at the three months of the therapy, because of the intractable diarrhea. The level of chitotriosidase activity was decreased in all patients

N2 - Social Emotional NeuroScience Endocrinology Theatre is a novel intervention program aimed at improving reciprocal social interaction in youth with autism spectrum disorder (ASD) using behavioral strategies and theatrical techniques in a peer-mediated model. Previous research using a 3-month model showed improvement in face perception, social interaction, and reductions in stress. The current study assessed a 2-week summer camp model. Typically developing peers were trained and paired with ASD youth (8-17 years). Social perception and interaction skills were measured before and after treatment using neuropsychological and parental measures. Behavioral coding by reliable, independent raters was conducted within the treatment context (theatre) and outside the setting (playground). Salivary cortisol levels to assess physiological arousal were measured across contexts (home, theatre, and playground). A pretest-posttest design for within-group

comparisons was used, and prespecified pairwise comparisons were achieved using a nonparametric Wilcoxon signed-rank test. Significant differences were observed in face processing, social awareness, and social cognition ($P < 0.05$). Duration of interaction with familiar peers increased significantly over the course of treatment ($P < 0.05$), while engagement with novel peers outside the treatment setting remained stable. Cortisol levels rose on the first day of camp compared with home values yet declined by the end of treatment and further reduced during posttreatment play with peers. Results corroborate previous findings that the peer-mediated theatre program contributes to improvement in core social deficits in ASD using a short-term, summer camp treatment model. Future studies will explore treatment length and peer familiarity to optimize and generalize gains. *Autism Res* 2014,7: 4-16. 2013 International Society for Autism Research, Wiley Periodicals, Inc

N2 - Objective: Little research has investigated children's physical activity levels during school recess and the contribution of recess to school day physical activity levels by weight status. The aims of this study were to examine non-overweight and overweight children's physical activity levels during school recess, and examine the contribution of recess to school day physical activity. Design: Cross-sectional. Setting: Four elementary schools located in Nebraska, United States of America (USA). Methods: Two hundred and seventeen children (99 boys, 118 girls; 47.9% overweight) wore a uni-axial accelerometer for five consecutive school days during

autumn 2009. The proportion of time spent engaged in sedentary (SED), light (LPA), moderate (MPA) and vigorous (VPA) intensity physical activity during recess was determined using age-specific accelerometer thresholds. Results: Overweight children engaged in more %MPA and less %VPA than non-overweight children, respectively. No differences were found between overweight and healthy weight children's moderate-to-vigorous physical activity (MVPA). Recess contributed 16.9% and 16.3% towards non-overweight and overweight children's school day %MVPA, respectively. Conclusion: Examining %MVPA as an outcome variable may mask differences in recess physical activity levels between non-overweight and overweight children. Future research is needed to establish why healthy weight and overweight children engage in differing levels of %MPA and %VPA during recess. 2013 The Author(s)

N2 - Background For children the prevalence of generalized joint hypermobility (GJH) varies from 7-36%, primarily depending on the tests and criteria used for diagnosing GJH. Children experience a great variety of impairments as a result of increased laxity of connective tissues. This not only affects physical fitness, motor development, and proprioception, but also include problems with organsystems (skin, vessel and internal organs) and psychological distress. As a result, children experience functional disability, which often presents difficulties in normal daily life. Objectives To provide a state of the art on diagnostics, clinical characteristics and treatment of GJH and JHS in children and young adults. Methods A narrative review was performed regarding diagnostics and clinical characteristics. A systematic review with a critical appraisal and best evidence synthesis was performed regarding interventions. Searches of databases Medline and Central were performed. The search terms used were joint hypermobility in GJH, JHS, as well as collagen diseases with joint hypermobility, child, treatment and rehabilitation. Results Transition literature was explored by ICF domains body function and structure, activity, participation and environmental factors. Knowledge on function and activity in GJH and JHS showed joint hypermobility (based on the Beighton scale with different cut-off points) associated with joint pain, reduced muscle strength and proprioception while children with GJH did not experience functional limitations in daily activities. Children with GJH did not spend fewer weekly hours of physical activity than healthy reference groups. In children with JHS and exercise-induced pain reduced aerobic fitness was found. Knowledge on participation showed a significantly decreased participation in housework, riding a bicycle, taking part in sport or outdoor games, and a higher frequency for non-sporting games. The initial search on interventions identified 1318 studies, eventually leading to three studies (JHS: n=2, Osteogenesis Imperfecta: n=1) available for critical appraisal. These studies showed significant benefits of enhancing physical fitness in terms of relieving musculoskeletal complaints and reducing disability. Conclusions Based on the narrative and a systematic reviews, function and activity in GJH and JHS were negatively influenced, especially in JHS. Regarding participation, personal and environmental factors was significantly decreased for participation in housework, taking part in sport or outdoor games, as well as a higher frequency for non-sporting games. Based on the sparsely available knowledge of intervention studies, future longitudinal studies should focus on the effect of physical activity and fitness interventions, as well as muscle strength and stabilization training in general, in particular in relation to the hypermobile joints in particular. In JHS and chronic pain, the effectiveness of a multidisciplinary approach should be investigated

N2 - Introduction: Recently, there has been an increased interest in integrating mobile computing devices, such as the iPad, into medical education. Five months ago, the Stanford Anesthesia residency program provided mobile computing devices (iPad 3, Apple, Cupertino, CA) to 63 of our residents for the duration of their residency. A cross-sectional survey study was conducted in order to understand how these residents are using mobile computing devices for anesthesia education. Specifically, we sought to understand how often the residents were using the mobile computing devices, in what ways they were using the devices, and how this has impacted their anesthesia residency training. **Methods:** iPad Information: We provided our residents with 64 GB wifi iPad 3 units, which were preloaded with Anesthesiology Journals (Anesthesia & Analgesia, Anesthesiology, NEJM Journal), Crisis Code (an application to teach crisis management principles in the context of ACLS, iLarynx (a fiberoptic intubation simulator), ePocrates (a drug reference guide), ComunicatOR (an operating room translation application), StanMed (a critical care medicine application) and Ether Mobile (a paging application). Textbooks installed on the iPads included: Miller's Anesthesia, Seventh Edition, Obstetric Anesthesia Handbook, Fifth Edition, Datta, Smith's Anesthesia for Infants and Children, Eighth Edition, Handbook of Neuroanesthesia, Fourth Edition, Handbook of Ambulatory Anesthesia, Second Edition, Essentials of Pain Medicine, 3rd Edition, Complications of Regional Anesthesia, Second Edition, Clinical Anesthesia Procedures of the Massachusetts General Hospital, Eighth Edition, Case Studies of Near Misses in Clinical Anesthesia, Brock-Utne, Anesthesia Student Survival Guide, and Anesthesia Intensive Care and Pain in Neonates and Children. **Survey Design:** After testing for reproducibility and clarity, we deployed our survey to our 63 anesthesia residents. The survey asked the residents questions about how they used the iPad for studying and residency tasks. The survey included 9 open-ended questions, and 17 multiple-choice questions. We organized the questionnaire into three general domains: * **General Information:** We collected demographic information from the students such as gender, age, and previous experience with mobile technology. * **iPad Usage:** We collected information about when the residents were using the iPads, and the impact on their desktop computer use. * **iPad Applications:** We collected information about individual applications that we preloaded onto the iPad. **Data Analysis:** After we received our results, we analyzed them using a mixed-method. The open-ended collected data was entered into NVivo 10 and the questions were analyzed using qualitative methods. **Results:** 90.2% of Stanford Anesthesia Residents agree or strongly agree that an iPad would enhance their ability to learn anesthesia. 85.7% of residents surveyed also agreed or strongly agreed that iPads were underutilized in anesthesia education. After receiving the iPad, 64.3% of our residents said that they were using their personal desktop computer less. When asked what frequency the residents used their iPad, 46.4% used them daily, 39.3% used them every other day, and the remaining 14.3% used them once a week. The two main activities that the residents used the iPads for most frequently are e-mail and reading medical books or papers. The places that the residents are using the iPad most often are at home, followed by inside the OR, and then inside coffee places. The main reason stated for using it at home was because the iPad was too bulky to carry with them at all times. We also asked the residents how useful the iPad provided by Stanford was for specific activities. 85.7% of residents said that the iPads were useful or very useful for accessing medical papers and 95% said that the iPads were useful or very useful for studying. 71.4% thought the iPads were useful or very useful for clinical issues. Out of the individual applications that we provided to the residents, the applications rated most useful were the books and journals. One of our residents stated: "[the iPad] has revolutionized access to texts and primary literature for studying and preparing every day." **Conclusions:** We found that a majority of our residents reported that the iPad is underutilized in medical education. Our survey has shown us that when given iPads, the majority of our residents use their iPads almost daily, and that the iPads have been reported to be useful for studying and accessing medical books and journals. The residents have also reported that they are reading more, chiefly because the iPad is an excellent resource for studying at home and outside of the operating room clinical environment. However, the residents did voice concerns that they would lose the iPad because of its small size and inability to securely store the device in the clinical environment. Some residents also reported that the iPads were too bulky to carry around in the operating room. Future work in exploring the use of mobile computing devices may focus on implementation of the iPad Mini as a more portable option for in anesthesia medical education

N2 - Background People with rheumatoid arthritis (RA) are provided comprehensive health care most commonly in institutionalized settings. Critique has been raised that such settings are organized primarily to treat illness and disease-related symptoms of people rather than maintaining and promoting people's health and full participation in their daily lives. Inadequacy in addressing particularly women's health issues has also been described. Objectives The aim of this study was to understand how Austrian mothers with RA manage their everyday lives and how their needs are attended in arthritis-related health care in Austria. Methods An institutional ethnographic study was conducted. Seven Austrian mothers with RA, aged between 28 and 41, and varying working and living conditions (being on maternity leave, part-time employment, social assistance and invalidity pension recipient) were recruited. Data collection included interviews and participation observations. Women's health care records were included into analysis as they are exemplary for the interaction between the patient and health care over time. Institutional ethnographic analysis comprised first inductive reading of the data to understand what the women are actually doing in their daily lives; an analysis of the hospital records to understand the organization of and relations within arthritis-related health care in an outpatient rheumatology department; and consequently an analysis of how women's daily lives are met within these relations was explored. Results The ethnographic account of this study reveals how participants try to satisfy and meet the needs of their families, put effort into maintaining paid employment and continuing (outdoor-) activities with

family and friends, engage in informal caregiving for their children and significant others, while also integrate their disease-related symptoms. Given the multiple demands due to family and work, the women highlighted that challenges in daily life are not necessarily due to disease-related symptoms or limitations in performing a particular task, but in the coordination of multiple tasks simultaneously as they unfold throughout the entire day. The analysis of the documents revealed that arthritis-related health care is ruled by relations based on biomedical concepts that focus predominantly on disease parameters and measurable, objectifiable dimensions of people's functioning. The complexity of participants' daily life remains likely unattended in specialized arthritis-related health care as its multidimensionality cannot be easily reduced into distinct measurable concepts and outcomes. Conclusions This study underscores the importance of interdisciplinary treatment in specialized arthritis-related health care based on a comprehensive understanding of and attendance to how the disease might affect people's health and participation in daily life

N2 - Background The Evaluation of Daily Activity Questionnaire (EDAQ) is a patient reported measure of activity limitations in Rheumatoid Arthritis (RA) (1,2) which we have revised and updated for use in the UK. This version includes 138 items in 14 "domains" (Eating/Drinking; Personal Care; Dressing; Bathing; Cooking; Moving Indoors; House Cleaning; Laundry; Moving and Transfers; Moving Outdoors; Gardening/Household Maintenance; Caring; and Leisure/Social Activities). Each domain is split into two sections: one (A) scores whether activities can be performed without aids, alternate methods or help; and another (B) which scores whether the activities can be performed with aids or alternate methods. All items are scored on a 0-3 scale (no difficulty to unable to do). Objectives To test the validity, reliability and minimal detectable difference of the EDAQ in people with RA in the UK. Methods Participants from 14 Rheumatology clinics completed postal questionnaires of demographic questions, the EDAQ (UK version), HAQ, SF36v2, RAQOL, pain, hand pain and fatigue numeric rating scales (NRS) and a current condition severity scale. Three weeks later, the EDAQ was mailed again to evaluate test-retest reliability: using kappa co-efficients for individual items; and non-parametric correlations for domain scores. Non-parametric correlations assessed the validity of the 14 domains of the EDAQ against the other measures. Cronbach's alpha evaluated internal consistency. Results 383 people participated: 286 women; age =60.38 (SD 11.18) years; RA duration =13.2 years (SD 10.72). 118 (31%) were employed; 65 had children <18y at home. Average pain score =4.99 (SD 2.59) and fatigue =5.61 (SD 2.53). All domains of the EDAQ correlated significantly ($p < 0.0005$) with; An exception was the "Caring" domain; most (59%) felt this domain inapplicable to them and validity was lower although still significant ($r_s = 0.22$ to 0.35). Internal consistency was high in all domains (Cronbach's alpha=0.89-0.97 for Section A and 0.88-0.98 for Section B). 309 (81%) completed Test 2 and test-retest reliability was moderate for most ($n=108$) items (0.41-0.60); substantial for 28 (0.61-0.80) and fair (0.21-0.40) for two. Reliability of total scores was excellent for 11 domains ($r_s = 0.81$ -0.88) and moderate-substantial for three ($r_s = 0.54$ -0.73. Minimal detectable differences was 1.60 to 4.61. Conclusions The UK version of the EDAQ is a unidimensional, valid, reliable, sensitive measure of daily activity in people with RA. It can therefore be used in both clinical practice and research. IS - var.pagings

N2 - Background: Cystic fibrosis (CF) is the most common profoundly lifeshortening genetic disease among Caucasians. Poor exercise capacity, as represented by low maximal oxygen consumption ($VO_{2\max}$), has been shown to be a powerful independent predictor of mortality in pediatric and adult CF patients. However, the testing required to measure $VO_{2\max}$ is uncomfortable and resource-intensive. Submaximal exercise tests that can be performed outside an exercise physiology lab have been developed to address these concerns. A 3-minute step test at a cadence of 30 steps per minute has been verified as a feasible submaximal field exercise test for use in children and adults with CF. Also, heart rate recovery after sub-maximal exercise correlates closely to all-cause mortality in adult non-CF populations. Hypothesis: In children 8 and older with CF, a shorter time to return to resting heart rate (HR) and a greater percent change from maximum HR one minute following a submaximal exercise test will positively correlate with greater percent predicted $VO_{2\max}$ as measured by a maximal exercise test. Methods: Twenty-two children 8 years of age and older (range 8-19, 59% male) with CF were recruited from the CF center at Children's Hospital of Pittsburgh. Each subject performed a 3-minute stepping exercise on a 15 cm step at a cadence of 30 complete steps per minute (STEP). HR and SpO_2 were measured at rest, during, and after STEP. Subjects then performed a maximal oxygen consumption test. Data from routine pulmonary function tests were also collected. Percent of maximal HR at one minute post-STEP and time in minutes to reach resting HR were compared with $VO_{2\max}$ by calculating Pearson's Correlation Coefficients. Results: All subjects were able to complete STEP, with no adverse events. Average percent predicted FEV₁ was 86% (range 36%-111%) and average percent predicted $VO_{2\max}$ was 110% (range 83%-137%). Maximum HR on STEP was on average significantly lower than maximum HR from the maximal test (139 vs. 190, $p < 0.01$). Fifty percent of subjects returned to their resting HR less than one minute after completing STEP. Altogether, neither shorter time to resting HR after STEP nor change in percent of maximal HR at one minute post-STEP correlated significantly with percent predicted $VO_{2\max}$. However, lower peak HR during STEP correlated significantly with percent predicted $VO_{2\max}$ ($R = 0.5$, $p < 0.02$). Also, in children with mild CF (FEV₁ > 80%), shorter time to resting HR correlated significantly with percent predicted $VO_{2\max}$ ($R = 0.5$, $p < 0.05$). Conclusions: All subjects completed STEP without any adverse events. STEP is a submaximal test in this patient population. As fifty percent of subjects returned to resting heart rate within one minute of completing STEP, change in percent of maximal heart rate at one minute post-STEP is not a useful measure of heart rate recovery after STEP in children with CF. Lower peak heart rate during STEP correlated with percent predicted $VO_{2\max}$, as did shorter time to resting heart rate in children with mild lung disease. HR during and after STEP may reflect maximal exercise tolerance in children with CF

IS - var.pagings

N2 - Continuous development of interventional radiology (IR) techniques has led to an increased demand of high-quality anaesthetic services to support patients undergoing diagnostic or therapeutic procedures. In most cases, IR techniques are accompanied by minor stimulation and pain, requiring light or deep sedation. However, in some instances, general anaesthesia with endotracheal intubation or laryngeal musk is required. Such cases include procedures necessitating complete immobility to obtain improved images, special operations (neuroradiological, interventions near vital organs or vessels, lengthy or painful procedures, procedures in children), or involve uncooperative patients. In addition, general anaesthesia is preferred in patients who require adequate airway control or have a risk of aspiration of gastric contents (i.e. severe ascites, risk of oesophageal varices rupture, increased intra-abdominal pressure of any cause). The choice of the anaesthetic technique and the drugs used are selected on the basis of the type, duration and demands of the procedure to be performed, age and the medical history of the patient, medications administered and the facilities of each IR suite. One of the biggest problems for anaesthesiologists during IR procedures is the administration of anaesthesia in places outside the operating theatre, with a large distance with the operating rooms and the post-anaesthesia care unit, without the ability to obtain immediate help when required. This makes decision-making in IR anaesthesia rather difficult, especially in highly demanding procedures or in critically ill patients or patients with airway difficulties. Early communication and planning of the procedure with the radiologists is essential to obtain safe and high-quality anaesthesia. The American Society of Anesthesiologists (ASA) has provided guidelines on administration of anaesthesia outside the operating theatre, which should be strictly followed. Radiology rooms where patients are under sedation or anaesthesia should have all the necessary equipment and drugs for patient's resuscitation. The same applies to adequate monitoring, which should include pulse oximetry, capnography and non-invasive blood pressure, in addition to continuous electrocardiogram and a neurostimulator in cases where neuromuscular blocking agents are administered. All monitoring equipment and intravenous lines should be adequately distanced to be easily reached and observed by the anaesthesiologist. It is of great importance that all patients that are going to receive general anaesthesia are adequately assessed pre-operatively and an informed consent is obtained. A full medical history (including possible contrast media allergies, pregnancy, implants, comorbidities) is essential, in addition to physical examination and airway evaluation. Patients with difficult airways, whether anticipated or not, can be problematic in a setting outside the operating theatre; if a difficulty is suspected, endotracheal intubation should be performed in the operating suite because of the greater availability of help and equipment. However, equipment for difficult airway control should be available also in the radiology department to manage the unanticipated difficult airway. Fasting should follow the guidelines for all general anaesthesia procedures. The anaesthetic technique varies according to the procedure and patients' requirements and co-morbidities. Inhalational (sevoflurane, desflurane) and intravenous agents (propofol, midazolam, etomidate) may be used, selected according to their pharmacokinetic properties on an individualised basis. Drugs of short duration, with no active metabolites and no residual post-operative action, are the best option for the IR patient. Opioids with this profile include small doses of fentanyl, sufentanil or alfentanil, but mainly remifentanyl, a strong opioid with rapid initiation and termination of action. In cases where a neuromuscular blocking agent is required to facilitate immobility, intermediate acting drugs may be used (rocuronium, cisatracurium, mivacurium). Succinylcholine is the gold standard for rapid sequence induction, but its side effects and contraindications may not allow its use. Rocuronium is a great alternative in this setting; it can be rapidly reversed because of the presence of a specific reversal agent sugammadex. Post-operative care

should be performed in a post-anaesthesia care unit, as in all cases of general anaesthesia. Patients should be observed for signs of haemodynamic or respiratory instability, with control of blood pressure, heart rate and post-operative pain. Paediatric patients require special consideration, with early preoperative evaluation and involvement of specialised anaesthesia personnel familiar with paediatric anaesthesia and peri-operative management. Special considerations CT-guided procedures: CT-guided procedures under general anaesthesia require attention with intravenous lines and breathing circuit to prevent their dislodged by movement of the patient during the scan. Tumour ablation may require advanced analgesia because most of these procedures are painful, especially when they involve bony metastases. Magnetic Resonance Imaging: The most important issues in MRI diagnostic studies are the necessity of monitoring and ventilation equipment appropriate for use in an MRI suite; the need for keeping the patient immobile in to obtain the best quality of MRI scan; the problem of patient distance and inaccessibility, especially during prolonged scanning; the extended length of most MRI procedures; the heating of monitoring wires that can cause thermal injury underneath the ECG electrodes and pulse oximetry probe; the effect of the magnet on ferrous materials (stents, cardioverters-defibrillators, pacemakers, implanted pumps and neurostimulators, all of which should be identified from patient history). The anaesthesia provider should be present in the MRI suite or watch the patient from the control room, if mirroring of the monitors and direct observation of the anaesthesia machine is adequate. Transjugular intrahepatic portosystemic shunt (TIPS): The procedure is usually performed under general anaesthesia to achieve immobility and safety because patients have severe liver failure, requiring total control of airway (with rapid sequence induction in cases of ascites) and advanced monitoring (cardiovascular and respiratory). Anaesthetic drugs used should be carefully selected in the course of pharmacokinetic changes that accompany severe liver disease. Interventional radiology/neuroradiology procedures: Angiography/embolisation, ureteral stents, trauma interventional procedures, thermography or radiofrequency ablation of tumours are more painful than simple imaging, requiring deeper levels of analgesia to achieve patient comfort. Interventional neuroradiologic procedures (such as endovascular embolisation of AVMs, coil embolisation of cerebral aneurysms, angioplasty, thrombolysis) are being performed under various CNS pathological states and most of the times general anaesthesia is required to achieve the optimal imaging. These procedures are highly-demanding and may require deliberate hypotension, hypocapnia, control of endocranial pressure or rapid transition between deep sedation and awake states. Monitoring in this case may be advanced, with intra-arterial and/or central venous pressure measurement, or may include neurophysiological parameters. These procedures follow the principles of neurosurgery as for brain protection and optimisation. In conclusion, the minimally-invasive nature of interventional radiology procedures puts the necessity of development of anaesthetic techniques, towards optimisation of anaesthesia, analgesia and immobility, in addition to minimal or no residual action of anaesthetic drugs after surgery and provision of safety throughout the procedure

N2 - Recess plays an integral role in the social and emotional development of children given the time provided to engage in interactions with others and practice important social skills. Students with ASD, however, typically fail to achieve even minimal benefit from recess due to social and communication impairments as well as a tendency to withdraw. Implementation of evidence-based interventions such as peer-mediated social skills groups, are necessary to ensure recess is an advantageous learning environment for students with ASD. A multiple-baseline design across participants was used to determine if a functional relationship exists between a social skills instructional program combined with peer networks with school staff as implementers and increases in level of communicative acts for participants with ASD at recess. Results indicate all participants demonstrated an immediate increase in the number of communicative acts with the introduction of the intervention. Implications for practice are discussed. 2013 Elsevier B.V. All rights reserved

N2 - Background: Nowadays, adolescent population begins sexual activity earlier, a behavior with negative psychological and social consequences. Aim: To determine the association between family factors and early sexual activity in adolescents of low and middle socioeconomic level. Material and Methods: A sample of 3,210 adolescents, who confidentially requested care in a sexual and reproductive health university center, between 2000 and 2007, was analyzed. Adolescents who started sexual activity before 15 years of age, and those who started sexual activity after 15 years of age, were compared. Data was collected from structured interviews conducted at the adolescent's first visit. Logistic regression was used to identify family factors associated with early sexual initiating in both, men and women. Results: Family factors associated with early sexual activity start were not being raised by both parents, a poor parent-child relationship, a poor family communication, mothers with a history of adolescent motherhood, mothers employed outside the home and family dysfunction. Among women, the variables associated with a higher risk of early sexual debut were not married parents and history of adolescent fatherhood record among parents. Among men, these variables were permissions without restriction during the week and punishment when family rules were broken. Conclusions: Family factors must be considered in the design of strategies to prevent early sexual activity

N2 - Objective: To assess the physical activity of children attending grades 1-3 of the primary schools in the region of southern-central Poland (the Malopolska Region). Methods: The study was conducted in selected primary schools in the years 2009-2012. These included 1,140 students aged 7-9 years, coming from rural areas (658), small towns (284), and one large city (198) - the regional capital: Krakow. The parents of the children completed questionnaires, which included questions pertaining to their children's performance of physical activities at school and outside of school. Results: Among the 1,140 children studied were 560 (49.1%) boys and 580 (50.9%) girls. Both boys and girls living in Krakow spent the least time (less than one hour aday) in front of aTV or computer screen as compared with the other children. Children living in rural areas would spend 2-3 hours aday on those activities. The largest percentage of children who attended PE classes regularly was from Krakow (100% of the boys and 97.6% of the girls). The case was similar with extracurricular activities that required alot of exercise - 84.7% of the boys and 85.7% of the girls attended those. Children living in smaller towns were significantly less likely to undertake additional physical activity ($P < 0.05$). Parents of boys were less likely to decide to excuse their children from participation in PE classes than parents of girls ($P < 0.05$). Conclusions: The place of residence and the gender of the child both have an effect on his or her participation in exercises and recreational activities. Copyright 2013 Medicina Sportiva

N2 - AIM: To investigate the visual acuity, refraction and influence factors of preschool children in some nurseries in Nanjing. METHODS: Children from 4 to 6 years old in Nanjing attended the visual acuity examination, and filled in factors questionnaire. The results were analyzed. RESULTS: Visual acuity at $P < 0.05$ was 0.4 of 4 years, 0.5 of 5 years, and 0.6 of 6 years. Refraction, gestational age, birth weight, closely using eyes, daily watching television time, daily outdoor activity time, picky eaters situation, chewing situation, parents diopter, home lighting status were associated with vision disorders. Factors score at $P < 0.05$ is 5. CONCLUSION: The visual acuity less than $P < 0.05$ at each ages was abnormal vision. Child whose factors score of less than 5 had high risk of abnormal vision, and need to pay close attention to visual conditions

 N2 - Purpose or Case Report: Shoulder dislocations are relatively common in adolescents, with 40% of all cases occurring in patients less than 22 years of age. Structural damage ensued can lead to significant pain and morbidity and predispose children to re-injury. When the static stabilizers of the shoulder are disrupted, patients will often experience recurrent dislocation. With surgical correction, young athletes are afforded the best opportunity to achieve long-term stability and return to play. MR arthrography (MRA) of the shoulder offers detailed joint anatomy; enabling depiction of ligament, tendon, bone and cartilage injury and is used to assist the orthopedic surgeons in surgical planning. This exhibit will serve to provide the general pediatric radiologist with a practical approach to shoulder MR arthrography from intraarticular injection to image interpretation. Methods & Materials: Proper intraarticular injection technique will be demonstrated including the authors' experience using a posterior shoulder injection approach used because most abnormalities are found in the anterior labrum. Optimal MR patient positioning, sequence selection and imaging parameters will be described. The normal glenohumeral joint anatomy will be depicted as well as tips to depict normal variants (coracoid physis, sublabral recess, Buford complex and the bare spot) and image artifacts that should not be mistaken for pathology. Common pathologies involving the glenohumeral ligaments and anteroinferior glenoid will be explored including hints to differentiate between cartilaginous Bankart injuries, Bony Bankart injuries, Perthes lesions and Anterior Labroligamentous Periosteal Sleeve Avulsions (ALPSA). In addition, strategies for accurate diagnosis of superior labral anteropeosterior (SLAP) tears will be highlighted. Results: A good knowledge of the MR appearance of normal shoulder anatomy and anatomic variants is crucial in order to accurately evaluate for pathology. With proper intraarticular injection, MR acquisition and diagnostic experience; MRA is effective method for the detection of labroligamentous abnormalities, bone injuries and musculotendinous pathology. Conclusions: When performed correctly, shoulder MRA is an important diagnostic modality that can aid with preoperative planning in the pediatric population

IS - var.pagings

N2 - Introduction: Education of transplant recipients and their care-givers is an important aspect of post-transplant care. As biliary atresia is the main indication for liver transplant in children, education is given to their parents. Often, physicians may neglect to "educate" these children as they grow older. This may have implications for adolescents and transition to adult service, where the shift in medical care is from parent-led to self-managed care. Aim: To assess the knowledge of the transplant recipients or their care-givers regarding various aspects of care, in order to identify knowledge gaps. Method: A questionnaire was administered over a period of 24 months (2009-2011). The questionnaire was completed by a caregiver proxy for children <12 years, and self-administered by adolescents > 12 years. These questions focused mainly on understanding of liver graft, post-transplant medications and lifestyle modifications. Results: These patients were aged 1-25 (mean

9.69) years and between 0.03-13 (mean 4.67) years post-transplant. All adolescent questionnaires (n = 9) were self-administered while parent proxy for children <12 years (n = 20) were mostly mothers (60%, n = 12). Results showed that parents were significantly more knowledgeable than the adolescents in terms of liver function, $p = .001$; graft dysfunction, $p = .037$; and dietary/environmental safety practices, $p = .000$. There was no statistically significant difference between parent-proxy and adolescent knowledge of; and attitude towards taking medications, adherence, sports and outdoor safety, pet-keeping and illness exposure post-transplant. Conclusion: Although adolescent patients did not receive active education regarding medications, they were aware of their medications, indications and dose timings. They may have learnt it from their parents or picked it up after being on the medications for some time. However, they had poor knowledge of liver function and implications of liver disease. This may imply that adolescents who are non-compliant may have a lack of insight to the implications of graft dysfunction

N2 - Background Achieving daily recommendations of 60 min of moderate- to-vigorous physical activity (PA) during childhood has well documented benefits. Despite this knowledge many children do not engage in sufficient PA and children from disadvantage families are known to have even lower levels of PA. Time spent outdoor is highly correlated to higher levels of PA, however safety concerns within disadvantage communities may be limiting children's outdoor play. Therefore the aim of this study is to examine the association between parents' safety perceptions of the neighbourhood environment and children's physical activity according to socio economic status (SES). Methods Participants were 298 adolescents (164 girls) with mean age of 11.59 (+0.80) years old from Porto, Portugal. PA was obtained with Actigraph accelerometer model GT1M. Parent's safety perceptions of the neighbourhood environment were obtained by a selfreport questionnaire with 11 items on road safety, crime and stranger danger; SES was obtained based on parent's educational level and was collapsed into two categories: B9 years of education (low) and >10 years of education (high). Results Adjusted (gender, age) binary logistics regression analysis showed that parental overall safety perception is associated with achieving PA recommendations only in children from low SES. In low SES families children from parents perceiving more "Safety for outdoor playing during the day" have higher odds (OR = 3.50 CI: 1.55-7.91) of achieving PA recommendations than children whose parents recognize less safety. Conclusions Parent's perceptions of safety in the neighbourhood appear to be an important correlate of PA in low SES families. Therefore interventions to promote neighbourhood safety within these families may be of particular relevance from a health perspective, since they may rely more on the neighbourhood to get their daily PA, than children from high SES

N2 - Background Despite trends indicating a recent stabilization in the upward obesity trend in children in some countries such as Portugal, the present values remains a huge public health problem. Although the causes of this epidemic are multifactorial, environmental factors such as unsafe neighborhoods are one factor that has been thought to increase obesity risk in younger children by limiting their outdoor play and increasing sedentary indoor activities such as television, computer use and play electronic games. Recent studies have pointed to associations between parental perceptions of neighborhood and their children's health. Objectives The main purpose of this study is to analyze the association between sedentary behaviors, children's outdoor play and parents' perceptions of some characteristics of the built environment. Method A cross-sectional study was done in a sample of 1,466 children, aged 6.0-10.0 years living in Oporto. Private and public schools were randomly selected. Parents filled out a questionnaire about family and child behaviours such as TV viewing, PC use, electronic games and outdoor play during weekdays and at the weekend. They also filled out the "Environmental Module" standard questionnaire of the International Physical Activity Prevalence Study (IPS, 2002). Environmental characteristics were combined into two neighborhood dimensions- factor 1-neighborhood built environment, factor 2-neighborhood social environment and safety. A Multivariate Logistic Regression analysis adjusted for age, parental education and the cluster of schools was used. Results A negative parental perception of the residential environment was positively associated with the following behaviors: more time watching Television, among boys (> 2 h/day, OR = 1.66, CI 1.18-2.33, p<0.05); more time spent using the computer, in boys and girls respectively: (> 1 h/day, OR = 2.17, CI 1.31-3.6, p<0.05; OR = 1.13, CI 0.84-1.9, p<0.05); more time spent playing electronic games, in boys and girls: (> 1 h/day, OR = 2.97, CI 1.56-5.6, p<0.01; OR = 1.66, CI 1.12-2.45, p<0.01); less time playing outdoors, in boys and girls: (activity outside<1 h/day, OR = 1.69, CI 1.22-2.33, p<0.01; OR = 1.31, CI = 1.01-1.7, p<0.05). Conclusion When parents have a negative perception of their residential environment the children tend to spend more time inside house watching television, using the computer and playing electron games and less time playing outside. Our results point out for a need to improve the urban design and promoting mixed land uses-as well as the social environment, especially, safety

N2 - Background Sedentary behaviors such as television viewing is one of the major factors contributing to childhood obesity. Objectives This study aims to analyze the association between sedentary behaviors such television viewing, passive play inside house, outdoor play and children obesity. Methods A cross-sectional study was done in a sample of 11,554 children, aged 6.0-10.0 y. Private and public kindergartens and schools were randomly selected. Sampling was based on a sex and age-specific proportionate stratified random design with the district are the primary sampling unit. Weight and height were measured, and parents filled out a questionnaire about family and child characteristics: TV viewing, passive play inside house and outdoor play. Overweight and obesity, using cut-off points as defined by the IOTF, were used. Data was analyzed using the Chi-square test and multivariate logistic regression analysis adjusted for age, sex and the cluster of schools. Results We found 21.1 % of overweight and 9.0 % of obese children. The prevalence of obesity increased by time of TV viewing:<2 h, 26.9 %, 2-4 h, 30.2 %, and +4 h 34.2 %, $p<0.001$; decreased by time spent with

passive play inside house: <2 h, 32.6 %, 2-4 h, 30.3 %, and +4 h 27.7 %, $p < 0.001$ and decreased by active play outdoor: <1 h/day 37.4 %, 2-4 h/day 30.1 %, >3 h/day 26.4, $p < 0.001$. The odds ratio (OR) for childhood obesity increased by television viewing (reference <2 h; 2-4 h: 1.18; [4 h: 1.39), decreased by time spent in passive play inside house (reference <2 h; 2-4 h: 0.72; [4 h: 0.58). Conclusions We conclude that TV viewing is positive associated with childhood obesity and either passive play inside house or active play outdoor are both effective ways to decrease childhood obesity

N2 - Background Compelling evidence suggests that a sedentary lifestyle is being encouraged, at least in part, by environmental factors that affect individuals' physical activity choices. Encouraging physical activity early in life is crucial to positively influence current and future health. Active travel to school is one possible routine to assist children increasing daily physical activity. However, previous studies demonstrated that children may be spending less time unsupervised outside the home. Thus, children's independent mobility has been declining, which may in part explain the reported declines in active commuting to school Objectives This cross-sectional study investigated whether independent mobility was related to active travel to school. Methods six hundred and twenty-five 10-14 years old boys (n = 292) and girls (n = 333) from 10 schools in a large Portuguese city were included. The independent variable in logistic regression analysis was mode of travel home to school measured by a self-reported questionnaire, asking "How do you usually travel to school". Options were walk, bicycle, car, bus or train; those travelling by car/ motorcycle and bus/train were merged into a single "passive transport" group and those travelling by bicycle or walking were merged into an "active transport" group. Dependent variable was independent mobility assessed using the stem "How often are you allowed to go to the following places on your own or with friends (without an adult)"; from the eleven questions, which were part of the self-completed questionnaire, one dimension (scale) was derived using categorical principal components analysis (Cronbach alpha = 0.901). Minutes of moderate to vigorous physical activity (MVPA) were objectively measured using accelerometers. The analysis was adjusted for gender, age, and MVPA. Results Independent mobility was significantly associated with active transport to school: i.e., children with high independent mobility were 1.44 times more likely to walk or cycle (95 % CI 1.12-1.86). Conclusions Independent mobility appears to be an important independent correlate of active transport to school. Conversely, low level of independent mobility can negatively influence physical activity, which may lead to decreased levels of social, emotional, and cognitive development

N2 - Background Physical activity, both as formal sports and free play, has an important role in the cognitive, physical and relational development of the child and also contributes to the maintenance of good health and ideal bodyweight. For these reasons, it is suggested that children should participate in physical activity (including that at school, sports training and active recreation) for at least one hour per day. The Italian child surveillance system, OKkio alla SALUTE, has collected data relating to the physical activity of children aged 8-9 years, and the contribution made by the school. Objectives To investigate the association between the physical activity of children and their family background, and to assess the contribution of the schools. Methods The survey has been conducted on a representative sample of children from the 3rd year of primary school using a standardized procedure. The children were classified as "active" if in the day before the survey they had participated in physical activity at school, or sports or played outside. The study uses multiple logistic regression to investigate the effects of environmental, familial and scholastic variables on the risk of being classified "active". The analysis uses appropriate methods to take account of complex sampling scheme used to collect the data (stratified cluster sample design and representativeness at local or regional level). Results In the 2010 survey, 42,549 children participated with only 3 % who refused. The percentage of children not classified as active was 18.4 % (95 % CI: 17.5-19.3 %). The regression analysis revealed a statistically significant association with the educational level and the citizenship of the parents. The odds ratio (OR) associated with high school education was 0.88 (95 % CI: 0.80-0.97), while for a university degree the OR was 0.84 (95 % CI: 0.73-0.96). For children of foreign parents the OR was 1.22 (95 % CI: 1.05-1.41). The presence of initiatives to improve physical activity in the schools was protective, OR = 0.74 (95 % CI: 0.61-0.90), as was the inclusion of two hours per week of physical education in the children's timetable, OR = 0.83 (95 % CI: 0.72-0.95).

Conclusion The data collected in 2010 has revealed that about 1 out of 5 of Italian children aged 8-9 is not physically active, especially in the South of the country. The schools can make an important contribution to promote a healthy lifestyle, including adequate physical activity, in Italian schoolchildren

N2 - PURPOSE -To reduce movements of children improving image quality -To reduce scan times allowing a greater number of explorations -To avoid or minimize number of sedations reducing costs -To allow performing MR in non-candidates patients for sedation -To improve patient comfort by reducing the claustrophobic feeling -Availability for visual and auditory functional MRI METHODS We have been studying the benefits of our developed audio-visual rearprojection (AVRP) system that works in 1.5 and 3 T Magnetic Resonance for two years in our institution at The Vall d'Hebron University Hospital. The system consists of: -DVD-DVD player, Movies, Projector (outside the room) -Display and Cranial coil-mirrors (inside the room) -Audio-system (both outside and inside the room) RESULTS In our clinical practice, the group of patients considered 'uncooperative' represents about 50 %. These patients require sedation depending on the anesthesiologist's availability, patient's respiratory status, and parental consent, among other factors. AVRP system has been demonstrated as a very useful tool in the 1.5 and 3 T MRI to improve image quality, as patients remain still over the duration of the scan, with less need to repeat sequences, reducing scanning times. It also minimizes claustrophobic feelings of anxiety and discomfort, avoiding to practice sedation for MRI in these cases. Furthermore, it has been observed a significant reduction in the number of sedation in children age limit. Similarly, patients with medical contraindications for sedation such as patients with lung problems who had to be studied with CT, now take

advantage of MRI thus, preventing the undesirable intrinsic effect of ionizing radiation. Additionally AVR system opens the door to functional MR evaluation of primary auditory and visual areas. Finally, AVR system has a very low cost of implementation, an ease of use and involves a not inconsiderable cost reductions enabling the potential realization of a larger number of studies in a lesser time, requiring less personnel and equipment for sedation. CONCLUSIONS The AVR system has proven very useful for the practice of MRI in pediatric population. It has demonstrated significant benefit to children as young as 3 years of age in completing an interpretable brain MR exam without sedation/anesthesia

N2 - Introduction: Physical activity (PA) is important for weight management but PA may be restricted by environmental influences (obesogenic environments). The study aims to assess the importance of outdoors environments in deprived areas on PA engagement. Methods: 46 children (8.6 + 0.55years;BMI:17.7 + 4.4kg/m², BF% 21 + 9) from the two most deprived wards of Coventry, UK wore a combined HR and GPS monitor (Garmin 406) for 4 days from which time spent in moderate to vigorous physical activity (MVPA) was determined. Children took part in focus group interviews exploring environmental facilitators and barriers to PA which were analysed using thematic analysis. Results: Children spent more time in MVPA in outdoor (greenspace, street) than indoor environments (outside = 49 + 35% vs. inside 27 + 25%, P = 0.00) for both weekdays and weekends (P=0.01). Children reported that they were more active and preferred PA in outdoors environments. Children spent more significantly more time in MVPA outdoors on weekdays during

increased hours of sunlight (spring/summer) compared to reduced hours of sunlight (autumn/winter) (69 + 30mins vs 44 + 60mins , P=0.01). Children reported that weather, parental constraints and safety were barriers to PA. There was no difference in time in MVPA outside or inside between weight status groups (P<0.05). Conclusion: Outdoor environments are important for health enhancing PA but interactions with outdoor environments is limited by seasonality, parental constraints and safety in deprived environments. Interaction with outdoor environments was not influenced by weight status

N2 - Introduction: Lack of physical activity in primary school children is considered to be a major driver of the obesity epidemic. In an English county with slightly above average obesity levels, an intervention to increase physical activity in and outside school in 7 to 10 year olds placed facilitators in schools to help five schools to achieve this aim. Methods: A pre and after design (baseline and post intervention) collects questionnaire data from children. Schools were selected to represent a range of areas in the county with a range of deprivation levels as measured by the index of multiple deprivation. Questionnaires ask about the type and intensity of activities children engage in and their attitudes towards physical activity. Children completed the internet survey in class at school. In addition qualitative data will be collected from children, teachers and facilitators. An opt-out consent procedure was used with parents and children. Results: At baseline 419 children have taken part in

the study. Mean age was 8 years (SD 0.95); 51% of the children were boys. The most popular physical activities were football, cycling, swimming and walking. Attitudes towards physical activity were generally positive.

Conclusion: The baseline data indicate that the pupils are active and have a positive attitude to physical activity. It will be interesting to see whether the facilitators' tailored interventions will improve on these baseline data

N2 - Background: The prevalence of overweight among children is rising rapidly and childhood overweight increasingly occurs at a younger age. The 'BBOFT+' intervention aims at implementing healthy lifestyle habits through focusing on effective child rearing from birth: sleeping, breastfeeding, (outdoor) activity, breakfast, soft drinks and TV time. This study aims to evaluate the effects on the prevention of overweight of the BBOFT+ intervention, compared to care-as-usual (CAU), as applied to children of 0-3 years and their parents. Method: In a cluster-randomized control trial, 68 Youth Health Care teams participated. Parents of more than 2500 children

filled out questionnaires at the age of 2 weeks, 6, 15 and 36 months. Parent-reported child's weight and length are used. Results: The first univariate analyses show no difference in nightly sleep duration between the BOFT+ and the CAU group at the age of 6 months. However, at the age of 15 months, children of the CAU group slept at night on average 6.6 minutes shorter than children in the BBOFT+ group ($p < 0.05$). At age 15 months, no difference in BMISDS, parental control, reinforcement or warmth was found between the BBOFT+ and the CAU group. Conclusion: The BBOFT+ intervention seem to have an effect on sleep at the age of 15 months. Further analyses will be conducted for the topics outdoor exercise, activity and play, breakfast, soft drinks and TV time. Furthermore the differences in BMI between BBOFT+ and CAU will be evaluated. These will be presented during the congress

N2 - Brown adipose tissue (BAT) is important for regulating body weight. Environmental temperature influences BAT activation. Activated BAT is identifiable using F 18 -fluorodeoxyglucose positron emission tomography/computed tomography (F 18 -FDG PET/CT). F 18 -FDG PET/CT scans done between June 2005 and May 2009 in our institution in tropical southern Taiwan and BAT studies from PubMed (2002-2011) were reviewed, and the average outdoor temperatures during the study periods were obtained. A simple linear regression was used to analyze the association between the prevalence of activated BAT (P) and the average outdoor temperature (T). The review analysis for 9 BAT studies (n = 16, 765) showed a significant negative correlation ($r = -0.741$, $P = 0.022$) between the prevalence of activated BAT and the average outdoor temperature. The equation of the regression line is $P = 6.99 - 0.20 T$ (Cdegree). The prevalence of activated BAT decreased by 1 for each 5 Cdegree increase in average outdoor temperature. In a neutral ambient temperature, the prevalence of activated BAT is low and especially rare in the tropics. There is a significant linear negative correlation between the prevalence of activated BAT and the average outdoor temperature.

N2 - Playgrounds are spaces in urban environments where children spend most of their free time. Continuous and various games in the open, with numerous physical and emotional reactions, have great significance for their health. The importance of playgrounds is based on possibilities for children to realize different needs for their proper psychophysical development. The aim of this research was to explore what kinds of playgrounds are adequate for children according to their development levels. Focusing on playgrounds in the urban area of

Novi Sad (Serbia), the paper analyzes different playgrounds and sport fields. The analyzed examples are differently positioned, shaped and various in used elements, as well as in the overall quality of surroundings. Play opportunities and problems within playgrounds were identified and documented in order to determine possible strategies and recommendations to improve their quality and provide children with healthy and secure environments. Upon analyzing playgrounds in Novi Sad, conclusions were made that the unified need of children for play does exist in diversified places and that all spaces have certain influence on children's development and health. There is an obvious lack of adequate playgrounds, which would fully satisfy modern children's needs

N2 - Objectives: Vitamin D status was investigated in 200 children (100 males and 100 females) visiting the Pediatrics Clinic at Jordan University Hospital. Methods: Subjects were categorized into two age groups: 1-3 years (toddlers) and 3-6 years (preschool children). Data were collected on children's lifestyle factors, dietary intake, height, weight and BMI. Serum 25-hydroxyvitamin D ₃ (25 (OH) D₃) concentration was determined. Results: 16.5% of the children had vitamin D deficiency (serum 25 (OH) D₃ < 15 ng/mL), while 15.5% had vitamin D insufficiency (serum 25 (OH) D₃ from 15 to 20 ng/mL). Serum 25 (OH) D₃ levels for the toddlers (26.25 + 1.16) were significantly higher (P<0.05) than those of the preschool children (21.49 + 1.16). Serum 25 (OH) D₃ was significantly higher (P<0.05) for exclusively formula-fed children (27.42 + 0.86) or children with mixed feeding (26.69 + 0.92) than for those who were exclusively breast-fed (17.02 + 0.90). Also, serum 25 (OH) D₃ levels were positively correlated with the duration of formula feeding (r = 0.4849, P<0.0001), duration of outdoor physical activity (r = 0.3940, P<0.0001), monthly frequency of outdoor physical activity (r = 0.61087, P<0.0001), and vitamin D (r = 0.4678, p<0.0001) and calcium (r = 0.4951, p<0.0001) intakes. However, serum 25 (OH) D₃ levels were negatively correlated with duration of breast feeding (r = -0.3554, P<0.0001) and BMI (r = -0.4235; P<0.0001). Conclusions: It is concluded that hypovitaminosis D is common in preschool children and that lifestyle conditions influence vitamin D status. 2011 DAR

N2 - LEARNING OBJECTIVE 1: Recognize clinical features of hemophagocytic lymphohistiocytosis (HLH)
 LEARNING OBJECTIVE 2: Treat HLH CASE: A 53 year-old woman presented to an outside hospital with complaints of 1 week of fevers, myalgias, URI symptoms, and 1 episode of "fainting." She was hypotensive, but responded to fluid resuscitation. Marked hematologic derangements were seen, including leukopenia of 1.3 with 15% bands, transaminitis AST 397/ALT 239, ferritinemia 65,000 and LDH 2,000. A chest radiograph showed a possible infiltrate, leading to the diagnosis of presumed severe sepsis secondary to community-acquired pneumonia, but pancytopenia and transaminitis worsened despite broadspectrum antibiotics, prompting the transfer to our hospital. Additional labs at our hospital showed neutropenia of 0.5, hypertriglyceridemia 379, and a positive DIC panel. Flow cytometry and a peripheral smear did not indicate malignancy. All infectious and rheumatologic studies were negative except for a positive EBV DNA PCR. A bone marrow biopsy showed hemophagocytosis with numerous nucleated erythroid precursors engulfed by histiocytes, indicative of HLH.
 DISCUSSION: There are two types of HLH which present similarly. Primary HLH is due to an autosomal recessive trait and is predominantly seen in children. Secondary HLH is seen more often in adults, and is caused by the body's reaction to another condition such as infections (EBV is the most commonly associated infection), autoimmune disease, malignancies, immune deficiencies or suppression, and post-transplantation. The central pathophysiology of HLH is an excessive immune response. A cytokine storm leads multi-organ dysfunction via infiltration of activated T-lymphocytes, natural killer (NK) cells and histiocytes. Autoantibodies may also contribute to the cytopenia. The key diagnostic finding is hemophagocytosis of blood cells in the bone marrow, spleen and lymph nodes. HLH can typically be diagnosed if at least five of the following criteria are fulfilled: fever, splenomegaly, cytopenia, hypertriglyceridemia or hypofibrinogemia, hemophagocytosis, hepatitis, low or absent NK cell activity, marked ferritinemia and elevated IL-2 receptor. Though HLH is a rare condition, incidence may be higher given the need for complex diagnostic workup and is commonly misdiagnosed as severe sepsis (as in this patient's case), FUO, hepatitis, renal failure, ARDS, and various CNS diseases to name a few. Prompt diagnosis is crucial, since without treatment, median survival is 1 to 2 months. To address this, the first international treatment protocol, HLH-94, was developed and studies have shown a significant improvement in survival rates. The HLH-2004 protocol (Grade 1B) is the current standard of care: immediate immunochemotherapy with dexamethasone and etoposide, aggressive supportive therapy and for selected patients, hematopoietic cell transplantation (HCT). Whether cyclosporine should be administered upfront as proposed by HLH-94 or later is controversial. This patient was treated with dexamethasone and intravenous immunoglobulin since the latter is an appropriate adjunct for most viral infections. The patient improved following 2 days of therapy and supportive care, and etoposide was never started. EBV-associated HLH can range from spontaneously resolving inflammation to persisting illness requiring HCT, and the patient's presentation is closer to the former. During her outpatient follow-up visit, her laboratory values normalized except for a slight down-trending ferritinemia

N2 - Introduction: Obesity among school going children is one of the major global health challenge. Childhood obesity is the result of a long lasting imbalance between energy intake and energy expenditure. A major contributing factor is physical inactivity which is also closely linked to bone health, cardiovascular disease, overall body fitness and psychological well being .The objectives of this study were to identify the pattern of physical activity and its difference among adolescent girls and boys. Aim: Level of physical activity is poor amongst adolescents in Pakistan. Method: A cross-sectional, questionnaire based survey was conducted in five inner city secondary schools serving predominantly middle and lower socioeconomic class in Karachi and Quetta. In all, 314 adolescents (13 to 17 years) completely responded to the questionnaire. All the data was collected and managed by trained medical graduates. Chi-square test was used to calculate the differences of physical activity pattern among girls and boys. Results: Questionnaire was administered to 159 boys (50.6%) and 155 girls (49.4%). Large majority (83.7%) of adolescents were using vehicle to and from school and over half (55.1%) of respondents spent three hours or more on watching television, playing computer games or doing other sitting activities. Only 35.7% of adolescents were involved in vigorous activities; more boys compared to girls (52.2% vs. 18.7%; $p < 0.001$). Similarly, boys were found to be more physically active for at least thirty minutes per day as compared to girls (45.3% vs. 27.7%; $p = 0.001$). More than half of the study participants (55.7%) were taught about physical education and 61.2% of them had accessibility of play ground other than school. Conclusion: Substantially large proportion of adolescents particularly girls were physically inactive in this study. There is a need for those with responsibility for adolescent's health, including parents, schools, and

community health providers, to consider and address the need for effective interventions to encourage increased physical activity level among adolescents

IS - var.pagings

N2 - Objective: Intensive therapy, such as constraint-induced movement therapy and BIG and LOUD, have been shown to improve outcomes better than standard care rehabilitation for a wide range of client groups, including adults and children with stroke (Wolf, et al., 2006; Duncan, 2011; Szaflarski, 2008; Lo, 2010), Parkinsons Disease (Fox, 2006), and individuals with spinal cord injury (Dobkin, 2006). In September of 2012 Courage Center started an intensive therapy intervention for all therapy and fitness programs to help therapists change their practice and incorporate higher intensity interventions to improve outcomes. The evaluation plan includes two patient and staff surveys of patient effort (1 month prior, and 2 months into the project). At baseline, clients reported 40% of sessions outside targeted effort range, and staff reported 29% of sessions outside the targeted range of effort. Two months into the project, clients reported 36% of sessions outside targeted effort range, and staff reported 20% of sessions outside the targeted range of effort. A survey of staff about implementation of intensive intervention revealed that 95% of staff said the implementation had gone well. The most common strategies implemented included "use it or lose it" and increased repetition. The most common strategies they were planning to implement next were "use it and improve it" and transference. Staff report that patients are making faster improvements than expected, and early results from outcome measures are promising. Design: This was a quasi-experimental prospective cohort design, examining comparisons of staff and patient reports of effort during sessions collected prior to and after implementation of the intensive intervention project. Setting: Courage Center is a community-based rehabilitation and resource center for persons with disabilities located in Minneapolis, Minnesota. The Center has both inpatient and outpatient physical, occupational, and speech therapy, as well as an extensive fitness programs, and serves a population with a wide spectrum of rehabilitation needs. Participants: All staff in therapy and fitness began implementing intensive strategies beginning in November 2012. This included 28 occupational, 49 physical therapists, 15 speech language pathologists, as well as 25 fitness staff. Clients prior to this date received standard care treatment and are the historical comparisons for this project. Interventions: Intensive therapy and behavioral techniques that encourage greater patient engagement and effort in rehabilitation were used. These techniques were modeled after and Kleim-s (2008) review, and involve specific 10 strategies to increase intensity, regardless of the intervention. Representatives from all departments, all professions and all sites made up an Intensive Intervention Implementation Team. They developed training materials, a self-assessment, and reminder materials that could be used during sessions to remind staff to incorporate more intensity into the session. Reminders to implement the new strategies were incorporated into all staff and department meetings, as well as into diagnostic specific clinical practice groups that met monthly. The members of the Intensive Intervention Implementation Team and the clinical practice groups were asked to practice intensive interventions, and became local leaders in the process. All staff were asked to complete the self-assessment, and to select 2 strategies to implement across all clients for the following month. All other activities in the facility, including Journal Club and the quality committee focused on this project. Main Outcome Measure(s): Outcomes for this project were patient and staff ratings of session intensity, measured at two points (1 month prior and 2 months into the project) as well as a staff survey about the implementation process and practice change. Results: As of February 2012, all staff had been charged with implementing intensive interventions for 2 months. At baseline, clients reported 40% of sessions outside targeted effort range, and staff reported 29% of sessions outside the targeted range of effort. Two months into the project, clients reported 36% of sessions outside targeted effort range, and staff reported 20% of sessions outside the targeted range of effort. A survey about implementation of intensive intervention revealed that 95% of staff said the implementation had gone well. The most common strategies implemented included "use it or lose it" and increased repetition. The most common strategies they were planning to implement next were "use it and improve it" and transference. This survey was responded to by 49% of the staff. Conclusions: The findings from this study provide additional support for the importance of increased patient effort early in the rehabilitation, and speak to the value of incorporating intensive intervention techniques in post-acute rehabilitation settings

N2 - Objective: This study is to develop the Chinese-version of the Children's Assessment of Participation and Enjoyment (CAPE-C) and examine its psychometric properties for Chinese speaking children with and without neuromuscular disorders. Design: The CAPE was translated and culturally adapted into a Chinese version (CAPE-C). All the parents assisted their children to complete the CAPE-C. The content and response process validity were established by an expert panel and the cognitive interviews for six participants. The internal consistency, item discrimination, omega coefficient reliability, and known group validity were evaluated through a crosssectional design. The test-retest reliability was examined by a repeatedmeasures design. Setting: All the questionnaires were completed by mail. Participants: A total of 201 parents of 157 unaffected children, and 44 children with cerebral palsy and Duchenne muscular dystrophy aged 6-15 years were included. Interventions: No intervention in this project. Main Outcome Measure(s): The content validity, response process

validity, internal consistency, item discrimination, omega coefficient reliability, test-retest reliability, and known group validity were evaluated. Results: For the CAPE-C overall and five domain items, the internal consistency was 0.55 to 0.87, and the test-retest reliability was 0.82-0.97. Six items with insufficient discrimination were found in both overall and domain scores. The omega coefficient was 0.831, excluding skill-based domain items. The unaffected children significantly participated more in overall and domain activities than affected children (except for skill-based activities). Apart from self-improvement activities, the participation intensity of CAPE-C activities was significantly higher in younger (6-10 years) children than older (11-15 years) ones. Girls significantly took more skill-based activities than boys. Conclusions: Consequently, to enhance children's participation outcome generalization across cultures, this newly developed and standardized CAPE-C provides an evidence-based tool to measure outside-class activity participation for children with and without neuromuscular disorders of Chinese speaking background. Future studies with larger sample size and different diagnosis samples are recommended to further support different types of construct validity of the CAPE-C

N2 - BACKGROUND: Obesity has been shown to spread through social networks. However, further data are needed on social network structure and function in weight loss behaviors, particularly in race/ethnic minority populations. The aim of this analysis was to examine social network structure, its influence on eating habits and relationship to weight loss among adults enrolled in a behavior change weight loss study. **METHODS:** The Small Changes and Lasting Effects (SCALE) trial is an ongoing 1 year weight loss intervention among non-Hispanic black and Hispanic adults, BMI > 25 kg/m², living primarily in Harlem and the South Bronx, New York. Participants made small changes in their eating behaviors and set individual physical activity goals. Social network members were defined as people important in the participant's life; for example family, friends, coworkers. Data on participants' social network structure were collected at study close-out using the convoy model of social support. The convoy model consists of 3 concentric circles (Fig. 1); the closest network members were listed in the inner circle (circle 1), members not as close in the middle circle, and least close in the outer circle. Participants identified the network members who influenced their eating habits and if they helped or hindered their eating goals in SCALE. Weight loss was calculated as the difference between weight measured at study enrollment and close-out. Data were analyzed using chi-square and ANOVA tests as appropriate. **RESULTS:** There were 45 index participants included in the analysis (mean age 51 years, 38 % female, 40 % non-Hispanic black, 60 % Hispanic) and 469 social network members. The average network size was 10.4 members, with the largest percent of network members in circle 1 (60 %) followed by circle 2 (25 %) and circle 3 (15 %). The majority of network members were women (62 % circle 1, 77 % circle 2 and 74 % circle 3). 77 % of participants indicated that at least one social network member influenced their eating habits, these members were primarily in circle 1 (74 %). Among the social network members who influenced eating habits, 80 % helped participants with their SCALE eating goals, 8 % made it more difficult, and 11 % had no impact ($p < 0.0001$). Network members who helped participants with their eating goals were primarily in circle 1 (74 %). Children and friends were identified as being more helpful than partners/spouses (25 %, 25 % and 8 % respectively). Network members identified as helpful lived primarily outside the home (70 %). There was a trend towards greater weight loss among participants who reported having social network members that helped them with their eating goals compared to those without help (-3.4 lbs vs. + 3.8 lbs, $p = 0.06$). **CONCLUSIONS:** In SCALE, the majority of participants indicated that social network members influenced their eating habits. There was a trend towards greater weight loss among participants who had social network help in their eating behavior goals compared to those without help. These data provide information on the structure of social networks among overweight/obese adults residing in an urban setting and provide evidence that social networks can be helpful in weight loss efforts

N2 - Although Mycobacterium tuberculosis is the causative agent of pulmonary tuberculosis (PTB), environmental factors may influence disease progression. Ecologic studies conducted in countries outside the USA with high levels of air pollution and PTB have suggested a link between active disease and ambient air pollution. The present investigation is the first to examine the ambient air pollution-PTB association in a country, where air pollution levels are comparatively lower. We used Poisson regression models to examine the association of outdoor air pollutants, PM10 and PM2.5 with rates of PTB in North Carolina residents during 1993-2007. Results suggest a potential association between long-term exposure to particulate matter (PM) and PTB disease. In view of the high levels of air pollution and high rates of PTB worldwide, a potential association between ambient air pollution and tuberculosis warrants further study. 2013 2013 Taylor & Francis

N2 - The accident at the Fukushima Daiichi Nuclear Power Plant (NPP) in Japan resulted in the release of a large number of fission products that were transported worldwide. We study the effects of two of the most dangerous radionuclides emitted, ¹³⁷Cs (half-life: 30.2years) and ¹³⁴Cs (half-life: 2.06years), which were transported across the world constituting the global fallout (together with iodine isotopes and noble gasses) after nuclear releases. The main purpose is to provide preliminary cancer risk estimates after the Fukushima NPP accident, in terms of excess lifetime incident and death risks, prior to epidemiology, and compare them with those occurred after the Chernobyl accident. Moreover, cancer risks are presented for the local population in the form of high-resolution risk maps for 3 population classes and for both sexes. The atmospheric transport model LMDZORINCA was used to simulate the global dispersion of radiocaesium after the accident. Air and ground activity concentrations have been incorporated with monitoring data as input to the LNT-model (Linear Non-Threshold) frequently used in risk assessments of all solid cancers. Cancer risks were estimated to be small for the global population in regions outside Japan. Women are more sensitive to radiation than men, although the largest risks were recorded for infants; the risk is not depended on the sex at the age-at-exposure. Radiation risks from Fukushima were more enhanced near the plant, while the evacuation measures were crucial for its reduction. According to our estimations, 730-1700 excess cancer incidents are expected of which around 65% may be fatal, which are very close to what has been already published (see references therein). Finally, we applied the same calculations using the DDREF (Dose and Dose Rate Effectiveness Factor), which is recommended by the ICRP, UNSCEAR and EPA as an alternative reduction factor instead of using a threshold value (which is still unknown). Excess lifetime cancer incidents were estimated to be between 360 and 850, whereas 220-520 of them will be fatal. Nevertheless, these numbers are expected to be even smaller, as the response of the Japanese official authorities to the accident was rapid. The projected cancer incidents are much lower than the casualties occurred from the earthquake itself (>20,000) and also smaller than the accident of Chernobyl. 2013 Elsevier Ltd

N2 - Two-story apartment complexes in Florida commonly have a large exterior staircase made from CCAtreated wood. Children living in these residences have frequent contact with steps and handrails while walking, sitting and playing on the staircases outside their homes Soil arsenic concentrations under twostory staircases at 6 large apartment complexes, where over 1,500 people reside, ranged from 6 to over 160 ppm, representing a source of arsenic exposure to children playing under and around these structures. Currently, we are measuring arsenic concentrations in the surface residue of these staircases and on objects stored under them, including grills, toys and children's bikes. These results will be used to identify variables that may lead to increased exposure to arsenic by children living in these types of apartment complexes and provide evidence in support of mitigation strategies

N2 - Background and Aims: Braddock and Clairton, Pennsylvania, in the eastern suburbs of Pittsburgh, are home to the Edgar Thomson Steel Works and Clairton Coke Works, which are two active steel mills. These towns exceed average annual (>15 mug/m³) and daily (>35 mug/m³) National Ambient Air Quality Standards (NAAQS) for particulate matter (PM_{2.5}). Within the past few decades, asthma rates have been increasing in the Pittsburgh region. Methods: A subset of 14 homes from an asthmatic cohort was selected for a 1 week sampling session of indoor air during the summer 2011, which was repeated for an additional week in the winter of 2012. Personal Exposure Monitors (PEMs) were used to sample particulate matter (PM_{2.5}) and passive Ogawa badges were used to sample NO₂. Teflon filters were pre- and post-weighed to calculate PM_{2.5} concentration, NO₂ badges were analysed by UV-VIS spectrophotometry, and EC and trace metal analysis were performed. Results: Within the 21 homes for summer sampling, a mean PM_{2.5} concentration of 25.8 mug/m³ (SD = 22.7 mug/m³) and a mean NO₂ concentration of 13.9ppb (SD = 7.2ppb) were detected. Homes with an asthmatic child had a mean concentration of 30.4 mug/m³ for PM_{2.5} and 13.9ppb for NO₂, whereas the other 7 homes with no asthmatic child had a mean concentration of 16.6 mug/m³ for PM_{2.5} and 9.7ppb for NO₂. For elemental carbon, a mean of 2.8 absorbance units (SD = 1.2 abs) was found. A seasonal comparison will be made.

Temperature, number of cigarettes smoked, and time spent cooking appear to have strong correlations to PM. Conclusions: This pilot data was used to detect PM, EC, and NO₂ concentrations in homes that have an asthmatic child and are located in communities near an active steel mill. Indoor results will be compared to an outdoor stationary monitoring campaign throughout Pittsburgh

N2 - Background The Global Burden of Diseases Study 2010 updates the first international Comparative Risk Assessment as part of the Global Burden of Disease Project, which estimated that the annual burden attributable to household air pollution (HAP) from use of solid fuels in 2000 was 1.6 million premature deaths and 54 million lost years of healthy life (DALYs), largely due to child pneumonia and COPD in women in sub-Saharan Africa and Asia. Objectives We quantify for 1990, 2005, and 2010 the revised burden attributable to HAP based on additional epidemiologic studies and new approaches for estimating exposure and exposure-response functions. Methods We estimated world-wide household exposure to fine particulate air pollution, PM_{2.5}, by combining 500+ nationally representative household energy surveys with a model of household PM_{2.5} levels based on data from Indian monitoring studies. We derived risk functions for ischemic heart disease, stroke, COPD, lung cancer, cataracts, and child pneumonia using recent systematic reviews and meta-analyses and for some endpoints drawing on Generalized Exposure Response relationships derived along with evidence from the literature on active and passive smoking and outdoor air pollution. Since household sources contribute substantially to outdoor pollution, we also include a portion of the outdoor air pollution burden in the HAP estimates for Asia. Conclusions Preliminary estimates suggest the burden attributable to HAP is considerably higher than the previous estimate because evidence supports 1) impacts on men as well as women, 2) inclusion of additional diseases (heart disease, cataract, and stroke); 3) a portion of outdoor air pollution impacts are now included under HAP; and 4) a lower counterfactual level is applied, equivalent to cooking with gas fuels

N2 - The Koppers Superfund site, in Gainesville, Florida, operated as a wood treatment facility for nearly 100 years before closing in 2009. At that time, soil testing in residential yards around the site found elevated levels of dioxin, directly impacting hundreds of residents. Sampling of indoor dust from 200 homes using the CALUX assay detected high levels of dioxin-like chemicals in homes up to .5 mile from the site. To address the concern and confusion generated by these findings, Suwannee River Area Health Education Center developed the Gainesville Area Health Education Project and received a \$25,000 USEPA Environmental Justice small grant to implement the project. Community outreach activities over the year will culminate in the Eco-Health Festival, to be held in the center of the impacted neighborhood on Earth Day, 2012. Local experts from the University of Florida and other organizations will speak on over 30 topics identified by residents as areas where they desire more information related to the soil contamination, such as impacts on water quality, gardening, raising chickens, keeping children safe and reducing overall chemical exposures in the home. A Superfund Art Show will highlight related work from adults and children in the neighborhood. Local musicians will perform social justice and environment-related music. A mini-film festival will highlight environmental justice struggles experienced by other communities around the world. The overall goal of the festival is to strengthen the resiliency of this low income neighborhood through building community ties and empowering residents with accessible scientific information related to the contamination of their homes and yards. The results from this project will be used to develop future family-friendly environmental education forums in similarly impacted communities around the country, with an emphasis on providing parents with easy-to-understand information on ways to protect infants and children from exposure to hazardous chemicals in and around the home

N2 - Background/Aims: Children's facilities are an important indoor environment for children and exposure area with potential harmful health effects for children who spend most of their daily life. This study was performed to investigate concentration of aldehydes in indoor air at children's facilities. Methods: The samples of indoor air were collected at various children's facilities (40 day-care houses, 42 child-care centers, 44 kindergartens, and 42 indoor playgrounds) in summer (July-September, 2007), winter (January-February, 2008), and spring (March-April, 2008) periods, and analyzed by HPLC. Indoor air measurement after that assessed the lifetime cancer and non-cancer risk of aldehydes exposure of young children. We estimated the lifetime excess cancer risks of formaldehyde, acetaldehyde, and the hazard quotients of non-carcinogens (benzaldehyde and formaldehyde). Formaldehyde evaluated both cancer and non-cancer risk. Results: The indoor and outdoor (I/O) ratio of aldehydes exceeds 1.0. It appeared the interior materials have indoor source. Also, the relationship between childcare facilities and formaldehyde level was statistically significant. Aldehydes of health assessment result, formaldehyde average excess cancer risks of young children were 1×10^{-4} - 1×10^{-5} level in all facilities. And hazard quotients of 4 non-carcinogens did not exceed 1.0 for all subjects in all facilities. Conclusion: To better understand results, investigators need to account for the variability of contaminants both within and between children's facilities

N2 - Background/Aims: Lead exposure is associated with impairment of nerve system. In particular, children are at the greatest risk due to their proximity to the floor and nature for placing hands in their mouths. Further

research is necessary for better understanding of lead exposure in children. However, little is known about blood lead levels of younger children in Korea. The objective of this study was to characterize lead levels in blood of children; and to investigate the environmental factors associated with blood lead levels. Methods: We took blood samples from 68 children (5-9 years) who resided in an industrial complex (n = 19) and residential areas (n = 49) in Seoul, and did not have any disease and clinical symptoms related to lead poisoning. Frozen samples were moved to the laboratory and kept in freezer before analysis. Graphite furnace atomic absorption spectrometry was used for analysis followed by pretreatment with 0.1% Triton X-100 and standard solution. Statistical analyses (SPSS, version 12.0) were performed to compare lead concentrations between an industrial complex and residential areas. The multiple logistic regression was performed to investigate the influence of environmental factors (house types, distance between house and vehicle road, types of drinking water, smoking of housemate, time spent outdoor, and ground types in the playground) on blood lead levels. Results: Mean age of subjects was 74.6 months. Blood lead levels ranged from 0.3 to 2.2 mug/dL, and mean was 1.1 + 0.4 mug/dL. Environmental variables and sex were not significantly associated with blood lead levels in this study. However, lead levels for residential areas (mean: 1.2 mug/dL [range: 0.5-2.2]) were significantly higher than those for an industrial complex (mean: 0.8 mug/dL [0.3-1.4]) (P < 0.01). Conclusion: This result may suggest that exposure to lead may often occur through lead-contained materials (eg, toys, food, and house dust originated from lead-based paint), as well as polluted soil and air

N2 - Background/Aims: Children's exposures to environmental contaminants are expected to be different and, in many cases, much higher than adults. Differences in the behavior of children, particularly the way in which children interact with their environment, may also have a profound effect on the magnitude of exposures to contaminants. Especially, children's facilities are an important indoor environment for children and exposure area with potential harmful health effects for children who spend most of their daily life. Therefore, the present study was performed to assess the levels and characteristics of several pollutants in indoor environments, and to predict the child-specific health risk of indoor pollutants at children's facilities. Methods: The levels of 25 indoor pollutants (8 volatile organic compound [VOC], 3 aldehydes, 5 metal, 2 pesticides, 4 retardants, 3 phthalates) were assessed in indoor samples (dust, respiratory particulates, vapor, surface) at various children's facilities (40 day-care houses, 42 child-care centers, 44 kindergartens, and 42 indoor playgrounds) in summer (July-September, 2007), winter (January and February, 2008), and spring (March-April, 2008) periods. We analyzed using gas chromatography-mass spectrometry for VOCs, pesticides, inductively coupled plasma for metals, and phthalates, and high-resolution gas chromatography/high-resolution mass spectrometry for polybrominated diphenyl ethers. Results: The levels of VOCs, aldehydes, polybrominated diphenyl ethers, and pesticides showed the seasonal variations, but the levels of phthalates and metals in summer period were similar to those in winter periods. The excess cancer risks of 9 carcinogens for children were 10⁻³-10⁻⁵ level in all facilities and excess cancer risks of dichlorvos and formaldehyde were more than 10⁻⁴ level, respectively. The 14% in the subject facilities were exceeded to 1.0 of hazard index for 16 noncarcinogens. The exposure of dichlorvos could be done through various routes such as inhalation, handto- mouth, and skin contact, and major route of formaldehyde was inhalation for child in indoor environment. Conclusion: The dichlorvos and formaldehyde were selected as the major concern pollutants and need the risk reduction management plan at children's facilities

IS - var.pagings

N2 - Background/Aims: Although it is increasingly recognized that environmental concentrations do not necessarily equate to individual exposure, concentrations at place of residence are often used to approximate exposure. However, individual exposure can vary, depending on circumstances such as the amount of time spent indoors and outdoors (Jarup 2004). Furthermore, environmental pollutants and exposures vary spatially and temporally with, for example, different levels during day and night (Briggs 2005). A better approximation of exposure can be obtained through time-activity modeling, using a mixture of individual level data and statistical (aggregated) data from time-activity surveys. Methods: A model has been programmed in a geographical information system (ESRI ArcGIS) using network analysis tools. The model can use geocoded data for start and end locations of each trip (X/Y), start and end times of each trip, trip mode, travel speed, route, and destination type. Using these data, the model is able to reproduce the time-activity sequence. However, in many cases much, if not all, of these data will not be known and so the model can probabilistically impute, on the basis of available statistical information, any of these data. These statistical data comprise generalized distributions for the study population (eg, national surveys). Results: Using data collected as part of a study to analyze the effect of traffic-related air pollution on the journey to school (Walker et al, 2009), model results have been validated. Results using 31 time-activity diaries, including actual routes taken by school children (captured using global positioning system technology), showed the model to be a reasonable predictor of routes. Conclusion: This

research demonstrates the difference obtained in exposure values from fixed home location in comparison with modeled spatio-temporal data. These results allow some quantification of exposure misclassification that may be introduced into small-scale spatial epidemiological analysis

N2 - Background/Aims: On the basis of results of a questionnaire distributed to the parents of students in an elementary school located in Seongbuk-gu, Seoul, an asthma case group and a control group were selected.

Methods: Through written messages sent to the parents of students, informed consent was obtained; 33 and 40

students were enrolled in the case and control groups, respectively. To determine the volatile organic compounds (VOCs) and formaldehyde levels of exposure, we performed personal, indoor, and outdoor measurements using a passive sampler for 3 days. In addition, the behavior patterns for the 3 days in the case and control groups were determined through daily time-activity pattern-diaries. The VOCs were analyzed by gas chromatography with flame ionization detection, and formaldehyde was analyzed by a UV spectrophotometer. Results: In comparing the results of the levels of VOCs and formaldehyde exposure between the case and control groups, it was shown that toluene and o-xylene were higher in personal sampling, and the benzene concentration was higher in the case group in indoor measurements. In outdoor measurements, benzene and methylcyclohexane were higher in the patient group ($P < 0.05$), the asthma ORs were 1.1 and 32.9, respectively. Based on the activity content analysis by time, it was shown that the students spent 88.0%, 7.2%, and 4.9% of their time indoors, outdoors, and in traffic, respectively. Conclusion: In conclusion, it was shown that the childhood asthma case group was exposed to higher VOCs than the control group, and it was found by measurement methods that VOCs in personal sampling were higher than the values obtained in indoor and outdoor measurements, and the formaldehyde value was the highest in indoor measurements. Therefore, management of VOCs and formaldehyde is required for the prevention of childhood asthma, and personal measurement should be considered for proper evaluation

N2 - Background/Aims: Accurate measurement of air pollutants in outdoor, indoor, and or personal air is critical for assessing exposure to air pollution and potential health effects. Passive sampler is becoming more and more an effective alternative for conventional active sampler in exposure and health effects studies, given its simplicity and low cost. Also, many passive samplers are capable of providing comparable performance to active samplers in terms of sensitivity and reproducibility. Methods: A variety types of passive samplers with different adsorption media, trapping principles, geometric designs, and the techniques used for the release of the trapped analytes and their final determination techniques have been developed to measure different air pollutants, including single pollutant, such as O₃ and SO₂, and a group of chemicals, such as Volatile organic compounds, carbonyls, semi-volatile organic compounds (such as polycyclic aromatic hydrocarbons and polybrominated diphenyl ethers). Those samplers have been widely used in exposure and epidemiological studies and found very desirable in many situations, such as monitoring of small children, senior people, and pregnant women, as well as synchronic monitoring air pollutants at multiple locations and microenvironments in community exposure studies. However, limitations still exist for passive samplers. Results: Many samplers are subject to effects of temperature, sampling duration, wind speed, and air concentrations. Also, a long sampling time is often required in order to get enough mass for detection. Further, it is a challenge to measure non-volatile species by passive sampler due to the low diffusion of particle to the adsorption medium. Thus, there is a need to develop a sensitive, reliable, inexpensive, and friendly use passive sampler for the species primarily distributed in particle phase. Conclusion: Last, a suitable and simple validation system needs to be developed for the evaluation of passive samplers performances for semivolatile organic compounds and particles

 N2 - Background/Aims: Multimedia and multipathway aggregate exposure assessment for polycyclic aromatic hydrocarbons (PAHs) was conducted for 180 individuals in different age groups. Methods: PAHs were analyzed in several types of samples for inhalation exposure (personal air, indoor air [at house, school, office, and kitchen], outdoor air) and oral exposure (indoor floor dust, dust adhering to hand, soil, and food/beverage) routes. The 180 persons were divided into 5 groups: toddler (0-6 years), children and teenagers (7-18), and 3 adult groups including housekeeper (19-60), office worker (19-60) and the elder (>60). The concentrations of PAHs were expressed as sum of toxicity equivalent quotients (TEQs) for the 15 individual PAH concentrations in the samples. Results: The median concentrations (~15 PAHs) ranged from 0.073 to 11 ng-TEQ/m³ for personal air samples, 0.073 to 2.2 ng-TEQ/m³ for indoor air samples, 0.073 to 4.1 ng-TEQ/m³ for outdoor air samples, 0.0029 to 41 ng-TEQ/g for dust and soil samples, and 0.32 to 2.6 ng-TEQ/g for food/beverage samples. Average daily dose in toddler group was 27.5 ng-TEQ/kg/d (median), which was 2.8-4.1 times higher than those in the other age groups (6.7-9.7 ng-TEQ/kg/d). Lifetime average daily dose for all the subjects was 16.9 ng-TEQ/kg/d. Conclusion: Food intake for all age groups was found as a major exposure route in all age groups (96.0%-99.5%). Except for food ingestion, dust ingestion by mouthing activities, such as hand-to-mouth activity, was the most important exposure route in toddler group (76.8%). In other age groups, inhalation of gaseous and particulate PAHs is the most important exposure route (92.9%-97.1%)

 N2 - Background/Aims: Manganese (Mn) is a naturally occurring element, and presence of Mn in water, food, and air low level are ubiquitous. Excessive exposure to Mn, in spite of its essentiality, in earlier life can affect neurodevelopment and could possibly be associated with development of neurodegenerative disorders in later life. The goal of this study was to examine the association between low levels of Mn in blood and symptoms of attention-deficit hyperactivity disorder (ADHD) among Korean school age children. Methods: Subjects were recruited from a nationwide school age children's cohort, Children's Health and Environmental Research (CHEER) on the first graders of 22 elementary schools from 10 Korean cities in the year from 2005 to 2007. We have selected 1045 children (543 males and 497 females) between 6 and 8 years old (mean 6.9 + 0.6 years) from 6 elementary schools in 3 metropolitan areas of Korea. We measured the blood Mn level and conducted DuPaul scale questionnaire for screening ADHD. Questionnaire on the general characteristics, developmental history, disease history, current behavioral features, computer using skill, environmental exposures including environmental tobacco smoking, and food frequency was done on the parents of the children. Results: The mean blood Mn level was 14.9 µg/L (SD: 4.0 µg/L). The mean scores of sum of DuPaul scales were 8.87 + 7.4. Mean DuPaul score of group categorized by children's blood Mn levels of <12.0, 12.0 -18.0, 18.0 -24.0, and 24.0 µg/L was 9.17, 8.84, 7.70, and 10.56, respectively (P < 0.05). After adjusting for potential confounders: age, area of residence, gender, birth order, maternal age at delivery, education level, familiarity with computer, environmental tobacco smoke, calories of total intake, and frequency of outdoor activities; DuPaul scale level was significantly related with the blood Mn level group. Conclusion: This study suggests that blood Mn level was significantly associated with ADHD scale improvement. Relatively narrow range of blood Mn levels in

children without prominent environmental sources of Mn might have been a factor for this less strong relationship. Further study in a population with higher level of exposure may provide a different relationship

N2 - Background/Aims: The capital city of Mongolia, Ulaanbaatar, has experienced a recent period of urbanization and population growth, which has resulted in increased pressure on the environment and public health, and on the city to provide necessary infrastructure. Survey data indicated that air pollution in Ulaanbaatar is higher in the winter months. High levels of emissions from the increased burning of fossil fuels over the winter, contribute to the outdoor and indoor air pollution. Objective: The aim of the study was to determine the prevalence of asthma, bronchitis, and other respiratory symptoms in children, and to identify factors that may affect the indoor air quality in different types of dwellings. Methods: A cross-sectional study was designed to determine the prevalence of respiratory diseases in children, and describe some of the environmental factors to which those children are exposed (for example, type of residence, type of heating used, levels of indoor smoking). A modified questionnaire of the American Thoracic Society 3 was used with questions including age, gender of the child, education of parents, family income, health status of parents and siblings, parental and maternal smoking, ventilation, and type of heating and cooking. Results: The study recorded high levels of diagnosed bronchitis (19%) and reported respiratory symptoms (77.8%). Results indicated that more than 50% of households' burnt fossil fuels on a daily basis and almost 60% reported regular smoking indoors. There were 59.2% of households with at least one smoker; of these, 86% smoked every day. Almost onethird of households had smoking visitors at home. Despite major differences in the use of fossil fuels, respiratory symptoms were similar across all dwelling types. The high prevalence of respiratory symptoms and bronchitis in this study suggests that indoor air pollutants are probably having a detrimental effect on the respiratory health of children in Ulaanbaatar. Wood and coal were the main source of cooking and heating fuels in Mongolian dwellings, electricity was used for cooking in 38% of ghers and houses. Conclusion: The rates of diagnosed bronchitis and reported respiratory symptoms reported in this study indicate that these are major health problems in Ulaanbaatar. Questionnaire results indicated that more than 50% of households burnt fossil fuels on a daily basis, almost 60% of dwellings had regular cigarette smoking and almost all dwellings had no active ventilation in winter time. All of these factors can contribute to the production of air pollutants such as SO₂, CO, PM₁₀, and nitrous oxides. The major health effects of these common indoor air pollutants, expected from the burning of fossil fuels and cigarette smoke, are respiratory effects. The high prevalence of bronchitis and respiratory symptoms in this study suggests that indoor air pollutants may be having a detrimental effect on the respiratory health of children in Ulaanbaatar. The level of bronchitis and respiratory symptoms in apartments indicates that factors other than the burning of fossil fuels within the dwelling, such as smoking and outdoor air pollution, need to be considered

N2 - Objective: The aim of this study was to identify promoting and inhibiting correlates associated with the physical activity (PA) of children and adolescents (aged 3-18). The intention was to demonstrate the complexity of correlates of PA and to determine possible influencing factors. Design: A systematic review of reviews.

Methods: Systematic database research was carried out in Medline, Cochrane Library, EMBASE, PsycInfo, Springer Link and Thieme Connect. Inclusion criteria were that the study: (a) was classified as a systematic review with or without meta-analysis; (b) was published between 2000 and 2009; (c) dealt with children and adolescents aged 3-18; (d) had as its dependent variable any measure of overall PA; and (e) reviewed associations between quantitatively measured variables and PA. The internal validity of the systematic reviews thus identified was evaluated using a validated quality instrument. Results: Nine systematic reviews without meta-analysis and one systematic review with meta-analysis were selected. Altogether 16 correlates were identified which were consistently associated with PA of children and/or adolescents: sex, age, ethnicity, parental education, family income, socioeconomic status, perceived competence, self-efficacy, goal orientation/motivation, perceived barriers, participation in community sports, parental support, support from significant others, access to sport/recreational facilities und time outdoors. Conclusions: Although the findings of the reviews covered are to some extent heterogeneous, it is possible to identify consistent correlates of PA in children and adolescents. The results show that PA is a complex and multi-dimensional behaviour determined by numerous biological, psychological, sociocultural and environmental factors. The Author(s) 2013

N2 - Abstract Purpose: Currently, there are few effective adjuvant therapies for pediatric ependymoma outside confocal radiation, and prognosis remains poor. The phosphoinositide 3-kinase (PI3K) pathway is one of the most commonly activated pathways in cancer. PI3Ks transduce signals from growth factors and cytokines, resulting in the phosphorylation and activation of AKT, which in turn induces changes in cell growth, proliferation, and apoptosis. **Experimental Design:** PI3K pathway status was analyzed in ependymoma using gene expression data and immunohistochemical analysis of phosphorylated AKT (P-AKT). The effect of the PI3K pathway on cell proliferation was investigated by immunohistochemical analysis of cyclin D1 and Ki67, plus in vitro functional analysis. To identify a potential mechanism of PI3K pathway activation, PTEN protein expression and the mutation status of PI3K catalytic subunit α -isoform gene (PIK3CA) was investigated. **Results:** Genes in the pathway displayed significantly higher expression in supratentorial than in posterior fossa and spinal ependymomas. P-AKT protein expression, indicating pathway activation, was seen in 72% of tumors (n =169) and P-AKT expression was found to be an independent marker of a poorer progression-free survival. A significant association between PI3K pathway activation and cell proliferation was identified, suggesting that pathway activation was influencing this process. PTEN protein loss was not associated with P-AKT staining and no mutations were identified in PIK3CA. **Conclusions:** Our results suggest that the PI3K pathway could act as a biomarker, not only identifying patients with a worse prognosis but also those that could be treated with therapies targeted against the pathway, a strategy potentially effective in a high percentage of ependymoma patients. 2013 American Association for Cancer Research

N2 - Introduction: The global war on terrorism has resulted in many warfighters sustaining lower extremity injuries including amputations. The key factors that limit the ability of patients with amputations to achieve maximum functional capabilities are falls and fear of falling. This research program was designed to rehabilitate lower extremity amputees to increase trust in their prosthesis and reduce falls by using a novel training method. Patients/materials and methods: Four service members with unilateral traumatic transtibial amputations were recruited at the Naval Medical Center San Diego (NMCS D). A perturbation testing protocol was developed utilizing a Computer Assisted Rehabilitation Environment (CAREN). This immersive virtual environment contains a motion platform and instrumented dual belt treadmill. The testing protocol delivered a perturbation simulating a trip in the natural environment and was used as a pre-test and post-test assessment of the rehabilitative program. Select biomechanical data using motion analysis methods were collected and calculated to determine effectiveness of the subjects' ability to recover from these disturbances. The fall prevention training program utilized a microprocessor-controlled Active-Step treadmill (Simbex, Lebanon, NH) designed to deliver task specific training perturbations. Three types of perturbations were used during six, 30 min training sessions: static and static walk, during which the belt moved while the patient was standing still and to which the patient responded with one or multiple forward steps, respectively; and eTRIP perturbations, during which the perturbation was delivered at a random time while the subject was walking and required the subject to recover with multiple forward steps. Results: These preliminary data report on four male subjects, 24.3+2.1 years of age, who had been walking without an assistive device for 7.1+1.7 months. After participating in the fall prevention program, all subjects successfully avoided falling during the post-training perturbation test. The mean maximum trunk flexion angle from pre to post-test improved (38+7degree vs. 25+7degree on prosthetic limb perturbation; 32+13degree vs. 20+3 degree on non-prosthetic limb perturbation) and trunk velocities at time of recovery step also improved. Questionnaire responses indicated improved reaction times, increased confidence and heightened awareness of their ability to recover from a stumble or trip in the community. Discussion and conclusions: This novel rehabilitation method uses an innovative treadmill training method aimed at increasing the ability of the subjects with amputations to rely on their prostheses during challenging perturbations and thus improving their functional capabilities. This type of training has been shown to reduce falls in older adults [1]. The preliminary results indicate that this rehabilitation method will also be effective for those with amputations by increasing their ability to recover from a major perturbation as well as their functional performance. Funding: DoD Grant No. DM090896; The Navy Bureau of Medicine and Surgery, Wounded Ill and Injured. Views in the article are those of the authors and not of the DoN, DoD, or the US Government

N2 - Purpose: Participation in youth athletics provides an opportunity for developing self-esteem and leadership qualities and socializing with peers and promotes general health and fitness. Despite these important benefits, there is little data describing why youngsters withdraw from sports. The purpose of this study was to assess the reasons youth discontinue sport participation. Methods and Study Design: A questionnaire was administered to National Collegiate Athletic Association Division 1 student-athletes at a single institution. The survey included information on overall sport participation during childhood and asked subjects to cite specific reasons as to why they ended participation in a given sport. Subjects were also asked to rate their feelings of burnout during different stages of participation. Results: Two hundred ninety-six subjects (162 women, 134 men, average age 19 years) representing 22 sports completed the survey. The 3 most common reasons for discontinuing a sport were: subjects felt they were better at another sport (35%), loss of interest/burnout (26%), and too busy with

other activities (19%). Between 14 to 17 years, discontinuation due to an injury or a poor relationship with a coach markedly increased. Only 1% cited too much pressure from a parent or coach for ending sport participation. Subjects rating their level of burnout from moderate to high more than doubled between 12 to 18 years (26.8%) versus 6 to 11 years (10.4%). Reported levels of burnout were higher among adolescent girls (37%) versus boys (24.5%). Conclusions: This study demonstrates that for successful athletes who participated in multiple sports as children, choosing to focus on another sport or preserving time for interests outside of sports accounted for the vast majority (54%) of reasons for sport discontinuation. Feelings of burnout affected more than one-fourth of athletes beyond 12 years of age

N2 - Introduction: The purpose of this study was to identify some risk factors related to the occurrence of dental trauma to the deciduous teeth and to identify particular type of dental injuries in children referred to Department

of Paediatric Dentistry, School of Dental Medicine, University of Zagreb. Methods: The study was carried out in the sample of 97 children, aged 1 to 5 years, with injured 166 primary teeth. The sample of 97 patients included 63 boys and 34 girls. The epidemiological model "agent-host-environment" has been applied in the study. Data have been entered into a data base program (Microsoft Access) designed for this project. Results: The analysis has shown that the highest frequency of injuries occurred in children between 2 and 4 years of age. The frequency ratio between boys and girls was 1.8:1. The most frequently affected teeth were maxillary central incisors (in 79 %). Lateral luxation as the most common type of injury was observed in 34.9 % of cases. Most of the injuries occurred at home (62.8%) or on the playground (15.1%). Crashes against hard objects (49.5%) and falls (36.1%) were the main causes of trauma. Conclusion: Predominant types of traumatic injuries to the primary teeth are luxations and subluxations (66.2%). The most of injuries to the primary teeth occurred during children's play and were consequences of falls. Since the most common place of incident occurrence is the home (62.8%). The parents and caregivers should be informed about possibilities for prevention of traumatic injuries in young children

N2 - Background Sickle cell disease (SCD) is characterized by marked heterogeneity in clinical manifestations, severity and utilization of health care services. This heterogeneity is particularly evident with regards to utilization of inpatient services, which account for a large percentage of total health care costs and significant absence from school and work. Previous studies of utilization, based on analysis of administrative datasets, have been limited by inaccuracies in ICD-coding, inability to differentiate among SCD genotypes, and/or inability to capture individuals never hospitalized. Single center studies have been limited by potential disease severity referral bias, inability to capture service utilization at outside facilities, and relatively small numbers. Objectives We sought to identify children and adolescents with SCD with high hospital utilization (HHU) and to determine the relationship of HHU with age, SCD genotype, and insurance coverage. We also sought to examine trends over a three year period (2010-2012) and explore the relationship of any trends in hospital utilization over time. Methods The clinical database of the SCD Program at Children's Healthcare of Atlanta (CHOA) was used to identify all patients with SCD, ages > 5 years, who received comprehensive outpatient, acute care, and inpatient services at three CHOA facilities in metro Atlanta during 2010-2012. SCD genotype was confirmed for each patient by review of hematologic and clinical data, including results of diagnostic hemoglobin electrophoresis. All outpatient clinic, emergency department, and inpatient utilization was captured as well as insurance (payer) status at each encounter. HHU was defined as >3 admissions during a calendar year. Data were analyzed for significance by Chi-square. The extent to which the data were population-based was determined from the Georgia Hospital Association database which includes DRG-level data for all inpatient hospitalizations in Georgia. Results Hospitalizations at CHOA accounted for 96.1% of all SCD admissions for children within the 28-county greater metro Atlanta area. During 2010-2012, 1348 individual children and adolescents > 5yr of age with SCD received comprehensive care at CHOA (1076 in 2010, 1112 in 2011, 1159 in 2012): 928 (68.8%) had SS/S betadegreethal, 334 (24.8%) SC, 86 (6.4%) S beta+thal. Of 1159 active patients in 2012, 441 (38.1%) were 5-9 yr of age, 419 (36.2%) 10-14 yr, 299 (25.8%) > 15 yr; 474 (40.9%) had traditional medicaid (MC), 205 (17.7%) managed-care medicaid (MMC), 374 (32.3%) private payer (PP), and 105 (9.1%) multiple payers (MP). HHU (> 3 admissions/yr) decreased from 119 of 1076 (11.1%) in 2010 to 96 of 1112 (8.6%) in 2011 and 95 of 1159 (8.2%) in 2012 (p <.01). The Table shows percentage HHU for each year by age, genotype, and payer. Conclusions For children and adolescents with SCD, HHU decreased during the three year period. HHU was significantly associated with older age and with MC and MP insurance coverage during all three years. HHU was significantly associated with the SS/S betadegreethal genotype in 2010, but not in 2011-12. The extent to which the decline of HHU among patients with SS/S betadegreethal genotype was related to increasing use of hydroxyurea is being investigated. (Table Presented)

N2 - Purpose: Many epidemiological studies have revealed a consistent inverse association between High-Density Lipoprotein Cholesterol (HDL-C) level and the risk of coronary heart disease in adults. Frequent Japanese style diet, which is characterized by adequate total calories, increased intake of fish and plant foods, and decreased intake of animal fat, has been shown to cause an elevation of HDL-C level. The present study was designed to examine the relationship between serum HDL-C level and dietary patterns and habits and physical activity in a sample of healthy Japanese junior high school students. Methods: Between April 2006 and March 2009, we conducted a cross-sectional study of 1064 Japanese junior high school students (570 boys and 494 girls, aged 12.1 to 15.0 years) who had annual school health examinations and received care programs for prevention of lifestyle-related diseases. The students underwent measurements of resting blood pressure, waist circumference, and weight and provided overnight fasting venous blood samples. Each participant was then asked to complete a simple self-administered questionnaire addressing lifestyle factors, such as dietary patterns and habits and physical activity, as well as the co-existence of cardiometabolic risk factors. Results: Students in the lowest quartile of HDL-C (< 55 mg/dL for boys and < 56 mg/dL for girls) showed increased prevalence of abdominal obesity, hypertriglyceridemia, and increased fasting plasma glucose compared with the highest quartile (> 74 mg/dL for boys and > 75 mg/dL for girls). In both genders, the ratios of students who were often commuting to and from school by car were significantly higher and who were liking exercise and doing sports outside of school were lower in the lowest quartile of the students compared with those who showed HDL-C level more than these values. The ratio of students who were watching television during meals was significantly higher in boys with lower HDL-C level than those without. There was no significant difference in other dietary patterns or habits between students with and without low HDL-C level in both genders. Conclusions: Serum lower HDL-C level was strongly associated with reduced daily physical activity among junior high school students. This study may provide insights into the role of HDL-C in the school screening system for the development of more effective educational programs on prevention of lifestyle-related diseases in the Japanese population of school children

N2 - In a matter of decades, the prevalence of myopia has reached exceptionally high levels in urban East Asia, with some locations reporting levels as high as 70% or more in school leavers, with the prevalence of high myopia escalating to around 20%. While there is an assumption that myopic refraction is associated with a genetic propensity among East Asian populations, rises in myopia prevalence have also been reported in Western countries including the USA. This widespread rapid increase in myopia between generations indicates that there is a strong environmental component in the development of refractive error. While it is intuitive to link this rise in prevalence with excessive levels of near work inducing high and sustained accommodative effort and/or the rise in the use of electronic media including computers, after years of scientific investigation there is little evidence to support these contentions. More recently studies, including longitudinal population-based studies, have shown that time spent outdoors in childhood is a factor that may prevent the development of myopia and a plausible biological mechanism for this effect has been suggested. However, this factor alone does not explain all the variance in refractive error in a population. Despite the lack of strong association with near work, there has been a long established association between number of years of education and/or high levels of educational attainment and the development of myopia. Systematic investigation of global education measures provided by the Organisation for Economic Cooperation and Development (OECD) Program in Secondary Assessment (PISA) and the Trends in International Mathematics and Science Study (TIMSS) predominantly demonstrate on a country-to-country basis, the known link between education performance and myopia, yet there are notable exceptions and variations. Closer examination of the available data, however, implicates the combination of high educational outcomes and high education load, the latter largely associated with attendance at out-of-school educational tutorials or cram schools. The mechanism of this effect is only speculative but may involve limitations on the time available for school aged children to spend outdoors during sunlight hours. These investigations suggest that policy initiatives in relation to education and childhood activities may be needed to reverse the trend to towards high rates of myopia and associated health costs, as well as limiting the potential for greater levels of visual impairment through ocular pathology associated with high myopia

N2 - Purpose: To conduct a systematic review of the clinico-epidemiological patterns of paediatric ocular trauma reported worldwide. Method: The literature search included nine databases (PubMed, Medline, Embase, Google Scholar, Cochrane Library, Scopus, Science Direct, Web of Science, Web of Knowledge) including articles with key words related with eye injuries in children and synonyms. No limitations of language were made. Results: Paediatric ocular trauma has incidence rates of 0.746 to 9.9 per 10,000 worldwide. Global similarities are found in the higher involvement of boys and poor or absent adult supervision in the domestic environment. Eye injuries occur in developing countries in road accidents and working places due to inexistence or poor compliance to safety legislation and exposure to activities incommensurate with their abilities. Seasonal trends for eye injuries exist, as they are associated with outdoors recreational activities and exposure to hazards such as game weapons or unprotected contact sports. Likewise, festive events include serious eye hazards such as fireworks. Sports account for 10% of severe eye injuries in children. Children are particularly vulnerable to

severe ocular trauma in warfare scenarios and terrorist attacks, representing up to near 40% of all casualties. Conclusion: Adoption of specific measures for eye protection has dramatically reduced the incidence of ocular trauma. Globally, a great need for education concerning eye injury prevention continues to exist. Parental level of education and access to specialized medical assistance are associated with better outcomes. Ocular trauma prevention and optimum management also relies on investment in research/data collection and surveillance resources

N2 - The authors hypothesized that prospective, systematic Internet searches could identify occurrences of sudden cardiac death (SCD) in athletes and would be useful for establishing a system of active surveillance. Weekly advanced Google searches of the Internet were conducted for cases of SCD in young athletes during a 12-month period (2007-2008). Athletes ages 11-30 years who collapsed during a game, practice, or within an hour of exercise were included in the study. Individuals with known histories of cardiac issues and events occurring outside the United States were excluded. Verification of SCD was by autopsy reports and death certificates from county coroner offices and vital record agencies. Initially, 71 events were identified. Verification for the cause of death by coroner reports was possible in 45 cases, 43 (96 %) of which were confirmed to be SCDs. A total of 69 individuals 11-30 years of age (mean 17 + 5 years) died suddenly of cardiovascular causes while participating in 15 different organized sports and a variety of nonorganized physical activities. The most common cause of death was hypertrophic cardiomyopathy (30 %), followed by coronary artery anomalies (9 %), and myocarditis (9 %). The incidence of athlete SCD, the types of sports involved, and the cardiac causes of death in our study were comparable with those of previous reports. Readily available Internet searches have the potential to be a powerful tool for identifying occurrences of athlete SCD. An active surveillance system using Google searches followed by coroner report verification can provide important epidemiologic and clinical information. 2013 Springer Science+Business Media New York

N2 - Background Identification of hospitalized carbapenem-resistant Enterobacteriaceae (CRE)-positive patient is important in preventing nosocomial transmission. The objective of this study was to illustrate the implementation of proactive infection control measures in preventing nosocomial transmission of CRE in a healthcare region of over 3200 beds in Hong Kong between October 1, 2010 and December 31, 2011. Methods The program included active surveillance culture in patients with history of medical tourism with hospitalization and surgical operation outside Hong Kong within 12 months before admission, and "added test" as an opportunistic CRE screening in all fecal specimens submitted to the laboratory. Outbreak investigation and contact tracing were conducted for CRE-positive patients. Serial quantitative culture was performed on CRE-positive patients and the duration of fecal carriage of CRE was analyzed. Results During the study period, a total of 6533 patients were screened for CRE, of which 76 patients were positive (10 from active surveillance culture, 65 from "added test", and 1 secondary case from contact tracing of 223 patients with no nosocomial outbreak), resulting in an overall rate of CRE fecal carriage of 1.2%. The median time of fecal carriage of CRE was 43 days (range, 13-119 days). Beta-lactam-beta-lactamase-inhibitors, cephalosporins, and fluoroquinolones were associated significantly with high fecal bacterial load when used 90 days before CRE detection, while use of cephalosporins, carbapenems, and fluoroquinolones after CRE detection are significantly associated with longer duration of carriage. The duration of fecal carriage of CRE also correlates significantly with the initial fecal bacterial load (Pearson correlation: 0.53; P=0.02). Conclusion Proactive infection control measures by enhanced surveillance program identify CRE-positive patients and data obtained are useful for the planning of and resource allocation for CRE control

N2 - Current national and international publications describe a suboptimal vitamin D intake or an inadequate vitamin D status in all age groups. The aim of this statement issued by the Nutrition Committee of the German Society of Paediatrics and Adolescent Medicine (DGKJ) in cooperation with the working group of paediatric endocrinology (APE) is to summarize the available literature and evidence for reference values of vitamin D intake and vitamin D supply as well as for the current consumption. On this basis, recommendations for infants, children, and adolescents living in Germany were developed. Reasonable measures for achieving an improved vitamin D status are: protected sunlight exposure, intensive physical activity (at least 1 h daily) outside, and increase of vitamin D intake via supplements. Special attention is given to risk groups (children nourished on a vegetarian diet, migrants, persons with limited sunlight exposure, and chronically ill persons) for which regular control of serum 25-hydroxyvitamin D levels has to be considered. A systematic supervision of vitamin D supply in childhood and adolescence and a cost-benefit analysis of recommended or conducted measures should be performed

IS - var.pagings

N2 - OBJECTIVES: 1.Compare and discuss the nature of and risk factors for the various forms of adolescent sexual violence in culturally diverse/multinational urban settings 2.Explore known preventative strategies and discuss novel approaches to identification and intervention. METHODS: Sexual violence affects individuals of all ages, cultures, gender, orientation and abilities. Some groups may be disproportionately affected. 30% of under 18s in London, England, are non-white but in the years 2008-2011, 50% of 13- 17 year olds attending the London Havens Sexual Assault Referral Centres came from census groups other than White British, White Irish or White Other. Ten percent had learning difficulties compared with a population average of 2.5%. Based on

evidence submitted to the current CSEGG (Child Sexual Exploitation In Gangs* and Groups*) Inquiry in England, at least 16,500 children under 18 years were identified as being at risk of child sexual exploitation during one year and 2,409 children were confirmed as victims of sexual exploitation in gangs and groups during the 14-month period from August 2010 to October 2011. There was a higher rate of victimisation amongst black and minority ethnic (BME) children and young people than has been previously identified. (* where gangs mainly comprise men and boys aged 13 - 25 years old, who take part in many forms of criminal activity, such as knife crime or robbery, who can engage in violence against other gangs, and who have identifiable markers such as territory, a name, sometimes clothing etc. While children can be sexually exploited by a gang, this is not the reason why a gang is formed. Groups involves people who come together in person or online for the purpose of setting up, co-ordinating and/or taking part in the sexual exploitation of children in either an organised or opportunistic way.) In terms of intimate partner violence in adolescent relationships, a recent National Society for the Prevention of Cruelty to Children (NSPCC) study in the UK echoed findings in the USA in that high numbers of adolescents experience physical, emotional and sexual violence in their intimate partner relationships (a quarter of girls and 18 per cent of boys reported some form of physical partner violence, three-quarters of girls and half of boys reported some form of emotional partner violence. One in three girls and 16 per cent of boys reported some form of sexual partner violence). The incidence, frequency and level of negative impacts rates for all forms of violence were greater for girls. The majority of young people either told a friend about the violence or told no one. Most respondents in this study were white. We propose an interactive session to: *compare and contrast risk factors for adolescent sexual assault among urban youth in major cities of different countries with attention given to particular characteristics and vulnerabilities associated with adolescents who are trafficked, homeless, unaccompanied minors run-aways and/or in the care of the state *share experiences of preventative strategies among workshop attenders- including government/public health preventative policies and measures, school-based educational measures or those targeted at preventing revictimisation *identify and discuss obstacles to interventions: particularly those related to culture, social marginalisation and legal frameworks *examine and discuss efficacy of interventions CONCLUSIONS: Large numbers of adolescents are victims of sexual violence and exploitation in settings outside the family: in intimate partnerships and by gangs and groups. There are high rates of under-identification. Better understanding of the settings, susceptible groups, risk factors and behavioural identifiers that might increase the likelihood that an adolescent is a victim of sexual violence is needed. In many countries existing health, judicial and social care structures have started but struggle to address these emerging problems. Effective strategies are needed for education and early identification of at-risk adolescents and treatment of those already affected by sexual violence

N2 - Background: Urban air pollution (indoor and outdoor) poses a major health hazard for city dwellers. Exposure to ambient air pollution may result in respiratory health disorders. The aim of this study was to correlate air pollutant levels to the respiratory health of school children in Delhi. Methods: The questionnaire was designed based on the internationally valid questionnaires for respiratory illness. The respiratory health survey was approved by the Directorate of Education-Delhi and schools were selected based on land usage pattern i.e. commercial (Chandni Chowk), industrial (Mayapuri) and residential (Sarojini Nagar) areas. Approximately 1800 students (600 / zone) of age 10-14 years participated in the survey which included spirometry tests also. Indoor and outdoor levels of SO₂, NO₂ and PM were also measured in the school premises. Results: The questionnaire data showed that the students having respiratory disorder symptoms was maximum in Chandni Chowk (66%) followed by Mayapuri (59%) and Sarojini Nagar (46%). Spirometry test results demonstrated that a significant population of subjects in Chandni Chowk (19%) had mild to severe pulmonary obstruction. However the percentage of subjects with such conditions was comparatively less in Mayapuri (17%) and Sarojini Nagar (14%) area. Indoor and outdoor PM₁₀ concentration at schools located in Chandni Chowk, a commercial zone, was observed to be 815+354.45 mug/m³ & 337+85 mug/m³ respectively, which is ten times above the permissible limits. The PM₁₀ concentration was lower in Mayapuri (694.6+322.9 mug/m³ & 274+78 mug/m³), an industrial zone, and was least in Sarojini Nagar (534.3+94.22 mug/m³ & 197+48 mug/m³) which is a residential zone. However, levels of SO₂ and NO₂ were under the permissible limits in all three areas. Conclusions: There is a correlation between pollutant levels and symptoms of respiratory illness in children. Commercial zones like Chandni Chowk with high traffic movement and human activities contribute more PM which affects the pulmonary health of children

N2 - Introduction: We experienced a living liver transplantation of an unusual indication of uncorrectable intra- and extrahepatic biloma after transcatheter arterial chemoembolization (TACE) which could be a relative

contraindication so that we are reporting it. Case report: A 45 year old patient was a carrier of HBsAg for more than 25 years. He was diagnosed to be hepatocellular carcinoma (HCC) in 2004. He then underwent TACE 6 times and had a complication of biliary stricture in Nov. 2007. At that time the problem was solved with an interventional procedure. In Apr. 2008, he underwent another TACE for HCC, and after that a long segment of biliary stricture was developed. With recurrent cholangitis, there developed two huge biloma, one in the liver and one outside the liver. Percutaneous transhepatic biliary drainage (PTBD) for the intrahepatic biloma and percutaneous drainage (PCD) for the extrahepatic biloma with long standing antibiotics administration were done, but with all effort there was no improvement. The Child- Turcote-Pugh score was 6 and Klebsiella pneumoniae (sensitive with only imipenem and meropenem) was detected in culture for the drain discharge. The CT shows two large biloma, one in the liver and one outside the liver. The only well looking portion was the posterior section of the liver. There was massive adhesion due to recurrent infection and inflammation and about 300cc of ascites was in the abdominal cavity. Despite the effort not to spill the pus from cavity, it was inevitable. The extrahepatic biloma was found to be abdominal wall abscess which was covered with thick peritoneum. The total recipient operative time was 12 hours and 25 minutes and required transfusion was 8 units of packed RBC and 4 units of FFP. The biopsy showed HCC of 3.0 x 1.5 x 1.2 cm in the caudate lobe. Hepatolithiasis with chronic and active cholangitis and multiple abscess formation was also seen. He is now visiting outpatient clinic without a problem. Usually active and uncontrolled infection outside of the hepatobiliary system is thought to be an absolute contraindication to liver transplantation and chronic and refractory infection is thought to be a relative contraindication. But in this case, we concluded the infection is localized and controlled under drain and antibiotic administration. So with this conclusion and the situation with no other options we can think of, we decided to do a living donor liver transplantation with the risk of infection and turned out with a good result

N2 - This study evaluated the effect of a 10-week fundamental motor skill programme in pre-schoolers with motor problems. Alongside the general effect of the intervention, we also explored possible gender differences and the role of the environmental context (living community, socio-economic status, and recreational space inside/outside the house). The intervention group (n=47; 20 and 27) received twenty 60-min motor skill sessions (2 per week) in addition to the regular physical education curriculum for pre-schoolers; the control group (n=46; 21 and 25) did not receive additional practice. General motor competence, and locomotor and object control subscales, were assessed before and after the intervention using the Test of Gross Motor Development 2nd edition (TGMD-2). Data regarding environmental factors were gathered through a questionnaire. A Group. x. Gender. x. Time ANOVA revealed that the intervention group benefited significantly from the intervention and scored better than the control group at the post-test for general motor competence and both sub-categories (locomotor and object control skill). Moreover, the intervention programme was found to be effective in helping 49% of the intervention group to achieve an average motor skill level, according to the TGMD-2 norms, while a further decline in motor competence was observed in the control group. Interestingly, the effect appeared to be gender-specific, since object control skill improved only in girls of the intervention group. Considering the environmental context, none of the above-mentioned factors was found to have an influence on the effectiveness of the intervention. The present study highlights the need for an early motor skill programme with a gender-specific approach in order to help low skilled boys and girls master a diverse set of motor skills. 2013 Elsevier Ltd

N2 - Objectives: This study was performed to evaluate the epidemiological status of cutaneous leishmaniasis (CL) in the most important endemic foci of Qom Province, central Iran. The city of Qom is the largest center for Shi'a scholarship in the world and is a significant pilgrimage destination. Methods: During 2006-2011, all suspected CL patients with skin lesion(s) referred to regional health centers of Ghomrood and Ghanavat regions, and all actively detected cases, were examined clinically and parasitologically for CL. Patient information was recorded and patients were categorized based on the number and size of the lesions. Odds ratios (OR) of different risk factors were calculated. Results: A total of 849 (59.2% male, 40.8% female) confirmed cases of CL were enrolled; the average incidence rate of the disease was 14.9 per 100,000 people. During the study period 2006-2011, the trend in CL incidence showed no sudden variations in the areas studied, except for an outbreak of CL in 2009. *Leishmania major* was identified as the causative agent based on internal transcribed

spacer 1 (ITS1) ribosomal DNA PCR analysis. During the study period, the age distribution of CL cases was relatively stable, with the majority (50%) of patients aged 1-25 years. Most cases (n = 468; 55.1%) had a single lesion and 82 (9.6%) patients had four or more lesions (range 1-29). The risk of developing multiple lesions was significantly increased in patients with seasonal jobs (summer workers) (p = 0.023; OR 1.516) and significantly decreased in patients who were affected in winter (p = 0.010; OR 0.398). The risk of developing large-sized lesions (>1. cm) was significantly increased in patients in the age groups >25 years (p = 0.001-0.015; OR 2.5-3.5) and decreased in patients with seasonal jobs (summer workers) (p = 0.005; OR 0.570). Conclusions: The present data show the importance of CL as a health problem in suburban areas of Qom Province. In order to identify other epidemiological aspects of leishmaniasis in this area, studies on vectors and reservoirs are recommended. Since leishmaniasis caused by *L. major* is typically zoonotic, control measures should focus on rodents as the main reservoirs and *Phlebotomus papatasi* as the main vector. Awareness should be raised in the high-risk populations comprising people with diabetes, young adults (<25 years old), and those who work outdoors during the summer. 2013 International Society for Infectious Diseases

IS - var.pagings

N2 - During the past two decades, low vitamin D status has re-emerged as a major paediatric health issue both in developed and in developing countries. First of all, the concern is related to increased prevalence in paediatric age, due mainly to modification in lifestyle, cultural attitudes (less time spent outdoors, use of veils or covering clothes, sunscreen), air pollution and incorrect diet. In addition, recent studies suggest vitamin D, besides the well-known role in bone mineralization, is linked to several extra-skeletal effects. Most of the vitamin D requirements are provided by sun exposure. However, sunlight is not risk-free, and vitamin D absorption varies a lot according to different seasons, degree of latitude, time of day, area of skin exposure and skin pigmentation. Natural content of vitamin D in paediatric diet is mostly found in non staple food such as fatty fish, nuts and egg yolk; alternative sources are fortified foods, which however are not very common in Europe. A major risk for infants is maternal vitamin D deficiency, in particular in dark skinned or veiled pregnant women and in infants breastfed for a long period. In older children risks of deficiency include long term hospitalizations due to chronic illnesses or patients with skin pathologies. A debated topic is if lower levels of 25(OH)D found in obese children have negative consequences for bone health. Children suffering from various severe intestinal diseases may present vitamin D deficiency due to malabsorption. Interference with the activation of vitamin D may be caused by severe chronic hepatic or renal diseases, or by the chronic use of several drugs. The supplementation of vitamin D is a subject of active debate among authors. While supplementation is univocally accepted for all children with chronic diseases or other vitamin D-deficiency risk factors, supplementation is still under discussion for healthy children

N2 - Background: As Anti Retroviral Treatment (ART) programmes improve survival in early life the number of adolescents in need of ART will continue to increase. Programmes will need to scale up services which address the particular needs of adolescents. Here we assess the experience of such scale up in a large urban adolescent cohort. Methods: Between 2004 and 2010 9,360 adults and 1,776 adolescents commenced antiretroviral therapy (ART) at Mpilo OI ART clinic, Bulawayo. A package of specific activities for adolescents was implemented, to provide comprehensive care including active defaulter tracing, a comprehensive, dedicated counselling programme and psycho-social activities operating both inside and outside the clinic, such as a youth club. Adolescents were engaged in decisions regarding their care. In this retrospective cohort analysis adolescents were defined as those > 10 and <19 years old at ART initiation date. Cox's proportional hazards model was used to calculate hazards and the log rank test to assess significance. Results: Between 2004 and 2010 a six-fold increase in adolescent ART initiations occurred (Figure 1). 12 month adolescent loss to follow increased in the first 3 years of the programme, peaking at 7%, subsequently falling to below 5% by the end of the study period. There was no significant difference between adult and adolescent (Figer presented) hazard of death. (HR=0.92, p=0.3793) Loss to follow up was significantly higher in adults than adolescents. (HR=1.92, p<0.0005) (Figure 2). Conclusion: These results contrast other research, which generally show adolescent outcomes to be worse than those in adults. Outcomes in expanding programmes have also been shown to suffer elsewhere. As more HIV positive children survive into adolescence, ART programmes must scale up comprehensive services for this group; we show that good results are feasible with dedicated clinical and psychosocial resources in resource poor settings

N2 - Background: Knowledge and practice about air pollution are essential subjects in special groups such as cardio-pulmonary patients. For children with air pollution-related diseases, knowledge and attitude of parents play a determining role in this respect. Since providing a coherent curriculum needs evidence-based information, this survey was conducted to assess the knowledge and practice of asthmatic children's parents about daily air quality since asthmatic children are among the most vulnerable at-risk groups when it comes to air pollution. Materials and Methods: All parents of asthmatic children referred to the Pediatric Clinic of Masih Daneshvari Hospital during one year period (250 people) completed knowledge and practice questionnaire on air pollution. Knowledge questions consisted of familiarity with pollution standard index (PSI), ways to find out about it, respiratory effects of air pollution and etc. Practice questions consisted of reducing outdoor presence and activity of children and actions taken to reduce air pollution in polluted days. Results: In general, 3.2% of parents were familiar with PSI, 12.5% were aware of ways to find out about daily air quality, 65.2% were aware of air pollution respiratory effects, 65.6% were aware of air pollution effects on asthmatic children and 4.4% were aware of ineffectiveness of surgical masks in prevention of air pollution health effects. The obtained practice score ranged from 4 to 16, and the participants' mean score was equal to 11.79. Conclusion: This study revealed that parents of asthmatic children were aware of air pollution hazards for their children and wanted to

prevent them but they did not know how. Therefore, asthmatic children in Tehran are still exposed to risks of air pollution. 2013 NRITLD, National Research Institute of Tuberculosis and Lung Disease, Iran

N2 - Background and objectives: Food-food and food-drug interactions are emerging topics in literature and risk factors for ADE in practice. Substrates may modify absorption or interact with the 57 metabolizing CYP450 isoenzymes. The aim of this work is to describe relevant interactions outside the current interaction tables on absorption (PPI) and on CYP19A1 (aromatase inhibitors). Settings and method: 188 references from a systematic online literature research were evaluated. Nutritional and/or medication reconciliation options rely on a multidisciplinary focus group approach. Main outcome measures: Around 130 ingredients have been retrieved and listed. Results: PPIs change gastric pH permanently to >4.0, thus suppress gastric acid secretion and impair pepsin activation for cleavage of peptide bonds. This loss of acidity brings with it bacterial overgrowth, community or hospital acquired pneumonia (increased risk ratio of 1.89 in PPI patients), increase of asthma among children from mothers treated with PPI in pregnancy, mucosal degeneration/transmucosal leak/hyperpermeability, thus increase of drug availability (e.g. nifedipine, digoxin, penicillin's, erythromycin, or

alendronate), and malabsorption, thus reduction of drug bioavailability (e.g. carboxylic or vinylogous carboxylic acids as a result of altered dissociation). Prevention options comprise allergenic food avoidance, buffering, pepsin replacement, peristalsis stimulation, and melatonin. Intervention may focus on nutrition and medication reconciliation. Inhibition of aromatase has been described for tea and soy, whole grains from buckwheat, millet, or brown and purple rice, cruciferous vegetables (cabbage, broccoli, cauliflower), grapefruit, grape seed oil, and mushrooms. Induction of aromatase can be associated with ethanol. Liquorice (glycyrrhizin) reduces serum testosterone in men and women and supports regular ovulation by induction of aromatase. Conclusions: Concise interaction tables do not explain extra-hepatic interactions. Inappropriate long-term PPI treatment is a documented risk factor for bacterial overgrowth, mucosal degeneration, hyperpermeability, and altered bioavailability. Care should be given to ingredients having $pK_a < 4.5$. Breast cancer develops mainly post-menopausally, when estradiol levels have decreased by 90 % due to ovarian exhaustion. Therefore, endogenous production in the mammary gland catalyzed by aromatase is determinant for tumor genesis rather than estrogen uptake. However, a practical benefit arising from adjuvant nutritional treatment of breast cancer patients remains to be elucidated

N2 - Background and objectives: Paediatricians are often forced to extrapolate drug doses from older children and adults, to manipulate with drug's formulations or to change indicated route of administration resulting in off-label drug use. In general, off-label drug use may result in benefit, no therapeutic effect, or adverse reaction. The aim of this survey was to determine the extent and pattern of off-label used medicinal products in newborns and to highlight the therapeutic areas with the highest need. Settings and method: The research was performed over 3 month period in April-June 2012, and involved all newborns admitted to Neonatal Pathology Unit of Children's University Hospital in Bratislava who received a pharmacotherapy. From the medical records at the ward, data about patients' gender, gestational age, weight and diagnose were collected. Dose, frequency, intended route of administration and dosage form were recorded for each prescribed drug. In line with other studies, intravenous replacement solutions, blood products and dietary supplements were excluded. Each recorded medicine was reviewed for off-label use status, based on the information in the approved Summary of Product Characteristics (SPC). A medicinal product was regarded as off-label if it was used outside the age range specified in SPC. Main outcome measures: Proportion of off-label administered medicinal products, identification of the most frequently off-label used drugs in newborns. Results and conclusion: In total, 389 medicinal products containing 67 different active substances were administered to 88 hospitalised neonates (48 male, 40 female). The median gestational age was 34.9 + 4.8 weeks and 46 % were preterm newborns. Retinopathy of prematurity (n = 17) and low birth weight (n = 11) were the most common reasons for hospitalisation. According to the ATC classification the most prescribed medicinal products were drugs for the alimentary tract and metabolism (30 %), drugs for blood disorders (22.3 %), ophthalmologicals (10.5 %) and anti-infectives for systemic use (7.9 %). Of all drug prescriptions, 20.5 % were used in off-label manner. Fifty percent of the newborns received at least one off-label drug. The most frequently off-label prescribed drugs were clotrimazole, ofloxacin, diclofenac and tramadol. Our results indicate that off-label prescribing is common in neonatological field in Slovak Republic, and we believe that our data will stimulate national regulatory authorities to monitor safety concerns associated with off-label drug use in newborns as well as identify research priorities in this field

N2 - Aims: Muscle satellite cells (SCs) are responsible for the regenerative events following muscle fibre injury. This study aimed to improve our understanding of SC behaviour in two models of muscle disorder with different pathological mechanisms and onset of disease. Methods and results: Pax7⁺SC content was assessed in types I and II fibres of patients with Duchenne muscular dystrophy (DMD; n = 9; age 13 + 2 years), polymyositis/dermatomyositis (PM/DM; n = 9; age 52 + 12 years) and in controls (n = 5; age 26 + 5 years). Pax7⁺SCs number in type I and II fibres was higher (P < 0.05) in DMD and in PM/DM compared to controls. Type I fibres were associated with a higher number of Pax7⁺SCs compared to type II fibres only in DMD; Pax7⁺SCs number in type I fibres was about threefold higher in DMD compared to PM/DM (P < 0.05). In DMD, Pax7⁺SC content in small regenerating fibres (0.09 + 0.09 SCs/fibre) was similar to that in fibres from healthy skeletal muscle. The proportion of activated SCs (Ki-67⁺SCs) was fivefold lower in DMD (0.4 + 0.4%) compared to PM/DM (2.8 + 2%). Pax7⁺ cells located outside the basal lamina were observed in DMD muscles only. Conclusion: The capacity to generate new SCs is increased even in severely impaired muscles and a fibre type-specific enhancement of SC occurs in type I muscle fibres in DMD. 2013 John Wiley & Sons Ltd

N2 - Introduction:Buruli Ulcer (BU) is caused by the environmental microbe *Mycobacterium ulcerans*. Despite unclear transmission, contact with a BU endemic region is the key known risk factor. In Victoria, Australia, where endemic areas have been carefully mapped, we aimed to estimate the Incubation Period (IP) of BU by interviewing patients who reported defined periods of contact with an endemic area prior to BU diagnosis.Method:A retrospective review was undertaken of 408 notifications of BU in Victoria from 2002 to 2012. Telephone interviews using a structured questionnaire and review of notification records were performed. Patients with a single visit exposure to a defined endemic area were included and the period from exposure to disease onset determined (IP).Results:We identified 111 of 408 notified patients (27%) who had a residential

address outside a known endemic area, of whom 23 (6%) reported a single visit exposure within the previous 24 months. The median age of included patients was 30 years (range: 6 to 73) and 65% were male. 61% had visited the Bellarine Peninsula, currently the most active endemic area. The median time from symptom onset to diagnosis was 71 days (range: 34-204 days). The midpoint of the reported IP range was utilized to calculate a point estimate of the IP for each case. Subsequently, the mean IP for the cohort was calculated at 135 days (IQR: 109-160; CI 95%: 113.9-156), corresponding to 4.5 months or 19.2 weeks. The shortest IP recorded was 32 days and longest 264 days (Figure 1 & 2). IP did not vary for variables investigated. Conclusions: The estimated mean IP of BU in Victoria is 135 days (IQR: 109-160 days), 4.5 months. The shortest recorded was IP 34 days and longest 264 days. A greater understanding of BU IP will aid clinical risk assessment and future research. 2013 Trubiano et al

N2 - Background: Human herpes virus 8 (HHV-8), a gamma herpes virus, is the etiological agent for Kaposi sarcoma (KS). HIV-infected adults with advanced immunodeficiency are at risk. Prevalence data of HHV-8 infection in HIV-infected children living in non-endemic areas are limited. Serologic studies indicate low seroprevalence rates of 3-4% for healthy children living in United States and Germany [1]. Purpose of the study: The aim of the study was to determine the seroprevalence of HHV-8 antibodies among vertically HIV-infected pediatric patients in Germany and to evaluate their association with age, gender, ethnicity, and other demographic factors. Methods: In 2012, a multi-center cross-sectional study was conducted in four University Hospitals in Germany. Stored frozen serum specimens obtained from vertically HIV-infected children and adolescents were tested for antibodies against lytic and latent HHV-8 antigens. Data on patients' demographic characteristics and medical history were recorded. Results: A total of 214 HIV-infected children and adolescents (105 males, 109 females) were included. The median age was 10.2 years (range 1 months-22.6 years). A high proportion of these children (62%) was born in Western Europe, whereas 65% (139/214) of their mothers were born in countries outside Western Europe. The majority (91%) of the children had been treated with highly active antiretroviral therapy and 55.2% (116/210) had a HIV-viral load <50 copies/mL. The median CD4 cell count was 1000/L (range 3-4400). The overall seroprevalence of HHV-8 antibodies was 23.8% (51/214). Seroprevalence rates did not show significant differences between age or gender. In the group of young children aged 1 month to 35 months, 19.4% (46/31) had HHV-8 antibodies, compared to 25% (25/100) in children aged 36 months to 11 years, and 24.1% (20/83) children 12 years and older. In the study group, seroprevalence rates were significantly lower in children who were born in Western Europe ($p < 0.01$) compared to those born in Africa, Asia, or Eastern Europe. Clinical symptoms of HHV-8 infection were reported to be uncommon; only one child had a history of KS at 2 years of age. Conclusions: Vertically HIV-infected pediatric patients living in Germany showed a high HHV-8 seroprevalence of 23.8%. These rates were higher as expected in the normal pediatric population. The findings suggest that HHV-8 infection occurred already in the first years of life

N2 - Video self-modeling (VSM) has been used to teach social skills to children with autism older than 4 years of age. Attempts to use VSM with younger children with disabilities have produced less than favorable results; however, it is unclear whether VSM could be used to promote social initiations by typically developing children. Thirty minutes of staged filming, in which the four typically developing participants were prompted to interact with a peer with autism on the playground and inside during center time, was edited into 2.5- to 3-min clips. Each clip took less than 2 hr to edit. Data were collected on frequency of solitary play, initiations, parallel play, and engaged play and were then analyzed in a multiple-baseline-across-participants single-case design. Visual analysis led to the conclusion that VSM did not affect the typically developing children's behavior. Limitations of the study and cautions for using VSM with very young children are discussed. N2 - Introduction: Parents of children < 6 years frequently report that their child has sleep problems. Poor sleep is often related to bedtime associations and routines, behavioural issues surrounding sleep, or night time fears. Sleep hygiene factors, including the sleep environment, screen time, and meals prior to bed, may also impact on sleep and socio-cultural factors and parent knowledge about child sleep may also affect family sleep practices. This study investigated relationships between family demographics and environmental factors in relation to reported sleep difficulties in children aged 2-5 years. Method: Questionnaire packages were given to 204 families attending a childcare centre and 38 families (56%) of children aged 2-5 years on a university participant registry responded to an email. The primary caregivers (n = 96) of 101 children, mean age 47.5 months (SD = 12.9 months) returned completed packages which consisted of a demographic questionnaire, an environment

and sleep questionnaire and the Children's Sleep Habits Questionnaire (CSHQ). There were 63 boys and 34 girls; 28 of the children had ASD and 2 children had a global developmental delay. Results: On parent report 55.4% of the children had a sleep problem (79% of the children with ASD); the average CSHQ total score was significantly higher in these children than in children without a reported sleep problem ($p < .001$). CSHQ scores did not differ for children with and without ASD. Results showed that higher CSHQ scores were related to family income, and primary caregiver employment and education. CSHQ score was not related to timing of meals prior to bed, or to meal type or drinks consumed, or outside play. CSHQ score was related to the child feeling too hot or cold during sleep, use of electric or gas heaters, time spent watching television and time spent on computers or tablets. Discussion: These results indicate the importance of considering the impact of family and environmental factors on sleep problems in toddlers and pre-school children, regardless of whether the child has a developmental disability. In particular the temperature associated with the child's sleep environment and screen time appear to be important factors. It was surprising that even at this young age screen time is impacting on children's sleep

N2 - Purpose/Objective: The Waldpiratencamp is a camp for kids, teenagers and young adults with and after cancer and their siblings. The camp of the Deutsche Kinderkrebsstiftung (German Childhood Cancer Foundation) was established in August 2003 in Heidelberg, Germany. Main goal is to support the young survivors in their return to everyday life. They should relax after the strenuous cancer therapy and gain strength and new courage in a cautious way. Materials and Methods: The Waldpiratencamp offers 8-day camps for survivors and siblings as well as weekends for different kind of groups, e.g. bereaved parents. The program is always best suited for the needs of the participants. The staff of professional educators and pediatric nurses offers various activities in nature like hiking, rock climbing and canoeing. Collective experiences in outdoor activities should facilitate the exchange of experiences within the survivors / siblings community. Results: Patients suffer from helplessness and passiveness during their therapy. The camp wants to retrieve the patients from this distressed situation. Every child gets individual support to rediscover his still existing abilities and his power for life. Fears are recognized as 'normal' and self-doubt experienced as surmountable. Group activities consolidate self-esteem and self-confidence. The participants take individual responsibility and consideration for handicapped survivors at the climbing wall and on the high rope course (latter is also suitable for wheelchair users). Conclusions: There are camps for kids with and after cancer in France, Ireland, Hungary, Italy, Canada and in the United States. The Waldpiratencamp is the only camp of this kind in Germany. In 2008 the Waldpiratencamp was awarded with a prize for aftercare for young cancer patients. In 2009 it was elected from the Federal Government of Germany as one of 365 outstanding places in Germany

N2 - Background. At any age, physical activity (PA) is critical to maintaining health. Different PA guidelines have been formulated to improve the health of children and adolescents. We undertook this study to analyze the difference in physical activity levels in school children during the day and week and to determine whether two recommendations of physical activity (frequency and duration vs. accumulated duration) in school children identify difference in physical fitness and fatness. Methods. Seventy-one school children participated. A tri-axis accelerometer (ActiGraph) was used for 7 consecutive days. Minutes spent on moderate or vigorous physical activity (MVPA) were estimated. Two criteria were used to define whether a child is active: >60 min of MVPA/day and 300 min of MVPA/week. Nutritional status was assessed using the body mass index (BMI) and physical fitness with the FITNESSGRAM protocol. Results. It was shown that 12.5% of school children were active according to 60 min MVPA/day criterion and 55.5% with 300 min MVPA/week criteria. School children were more active during school recess and afternoons on weekdays and afternoons and nights on weekends. Boys were more active than girls. The time spent on vigorous and moderate activities was positively correlated with aerobic fitness ($r = 0.23$, $p = 0.057$ and $r = 0.32$, $p = 0.007$, respectively). There was a positive correlation between the time spent on sedentary activities and body fat ($r = 0.343$, $p = 0.003$) and negative with light and moderate activities ($r = -0.249$, $p = 0.003$; $r = -0.249$, $p = 0.013$, respectively). School children classified as active according to 300 min of MVPA/week criteria showed better aerobic capacity. Conclusion: The proportion of active school children differs according to the physical activity criterion. It was shown that physical activity varied according to gender and time of day. The time spent on high intensity activities appears to have an influence on aerobic fitness of school children

N2 - OBJECTIVES: 1.Compare and discuss the nature of and risk factors for the various forms of adolescent sexual violence in culturally diverse/multinational urban settings 2.Explore known preventative strategies and discuss novel approaches to identification and intervention. METHODS: Sexual violence affects individuals of all ages, cultures, gender, orientation and abilities. Some groups may be disproportionately affected. 30% of under 18s in London, England, are non-white but in the years 2008-2011, 50% of 13- 17 year olds attending the London Havens Sexual Assault Referral Centres came from census groups other than White British, White Irish or White Other. Ten percent had learning difficulties compared with a population average of 2.5%. Based on evidence submitted to the current CSEGG (Child Sexual Exploitation In Gangs* and Groups*) Inquiry in England, at least 16,500 children under 18 years were identified as being at risk of child sexual exploitation during one year and 2,409 children were confirmed as victims of sexual exploitation in gangs and groups during the 14-month period from August 2010 to October 2011. There was a higher rate of victimisation amongst black and minority ethnic (BME) children and young people than has been previously identified. (* where gangs mainly comprise men and boys aged 13 - 25 years old, who take part in many forms of criminal activity, such as knife crime or robbery, who can engage in violence against other gangs, and who have identifiable markers such as territory, a name, sometimes clothing etc. While children can be sexually exploited by a gang, this is not the reason why a gang is formed. Groups involves people who come together in person or online for the purpose of setting up, co-ordinating and/or taking part in the sexual exploitation of children in either an organised or opportunistic way.) In terms of intimate partner violence in adolescent relationships, a recent National Society for the Prevention of Cruelty to Children (NSPCC) study in the UK echoed findings in the USA in that high numbers of adolescents experience physical, emotional and sexual violence in their intimate partner relationships (a quarter of girls and 18 per cent of boys reported some form of physical partner violence, three-quarters of girls and half of boys reported some form of emotional partner violence. One in three girls and 16 per cent of boys reported some form of sexual partner violence). The incidence, frequency and level of negative impacts rates for all forms of violence were greater for girls. The majority of young people either told a friend about the violence or told no one. Most respondents in this study were white. We propose an interactive session to: *compare and contrast risk factors for adolescent sexual assault among urban youth in major cities of different countries with attention given to particular characteristics and vulnerabilities associated with adolescents who are trafficked, homeless, unaccompanied minors run-aways and/or in the care of the state

*share experiences of preventative strategies among workshop attenders- including government/public health preventative policies and measures, school-based educational measures or those targeted at preventing revictimisation *identify and discuss obstacles to interventions: particularly those related to culture, social marginalisation and legal frameworks *examine and discuss efficacy of interventions CONCLUSIONS:Large numbers of adolescents are victims of sexual violence and exploitation in settings outside the family: in intimate partnerships and by gangs and groups. There are high rates of under-identification. Better understanding of the settings, susceptible groups, risk factors and behavioural identifiers that might increase the likelihood that an adolescent is a victim of sexual violence is needed. In many countries existing health, judicial and social care structures have started but struggle to address these emerging problems. Effective strategies are needed for education and early identification of at-risk adolescents and treatment of those already affected by sexual violence

N2 - The larval forms of nematodes belonging to the genus *Toxocara* causing infection in humans are: *Toxocara canis* (specific to dogs), *Toxocara cati* (specific to cats). They lead to syndromes called Larva migrans visceralis (LMV) or Larva migrans ocularis (LMO), due to ingestion of viable, embryonated eggs transmitted by soil. The LMV syndrome appears in children under 5 years and the most affected organs are the liver, lungs and Central Nervous System (CNS). The LMO is present in children aged between 5- 10 years, and is characterised by unilateral ocular impairment. We review the cases of children suspected of *Toxocara* infection. Each case came from rural area and they all were less than 8 years old. Two cases were associated with decreasing of the sight and three with cough and expectoration. One child was detected accidentally, without having any symptoms. No CNS implication was evidenced. The clinical findings were not specific, laboratory results showed increased white blood cell counts with hypereosinophilia and lower red blood cell counts. In one case severe anaemia was detected. The increased IgE titers were guiding us to the diagnosis of toxocariasis, which was confirmed by specific IgG anti- *Toxocara* ELISA and by Western Blot. Using the ELISA test, titers over 1,1 UI/ml were considered as positive results. Appropriate treatment was based on Albendazol, with good compliance. The normalised eosinophil counts and disappearing of symptoms showed improving of their status. In conclusion, toxocariasis has to be considered in children from rural area with coughing and expectoration or visual acuity problems. This disease can be prevented by strictly respecting personal hygiene measures, by avoiding contamination of soil and playgrounds designated for children, by washing fruits and vegetables before use, by thorough hand wash before meals, by avoiding children's geophagy, applying regulate anthelmintic treatment of pets, especially for dogs under 6 month

N2 - Background and objectives: Chest pain is a complaint for which children are frequently evaluated. Cardiac causes are rarely found despite expenditure of considerable time and resources. We describe validation throughout New England of a clinical guideline for cost-effective evaluation of pediatric patients first seen by a cardiologist for chest pain using a unique methodology termed the Standardized Clinical Assessment and Management Plans (SCAMPs). Methods: A total of 1016 ambulatory patients, ages 7 to 21 years initially seen for chest pain at Boston Children's Hospital (BCH) or the New England Congenital Cardiology Association (NECCA) practices, were evaluated by using a SCAMPs chest pain guideline. Findings were analyzed for diagnostic elements, patterns of care, and compliance with the guideline. Results from the NECCA practices were compared with those of Boston Children's Hospital, a regional core academic center. Results: Two patients had chest pain due to a cardiac etiology, 1 with pericarditis and 1 with an anomalous coronary artery origin. Testing performed outside of guideline recommendations demonstrated only incidental findings. Patients returning for persistent symptoms did not have cardiac disease. The pattern of care for the NECCA practices and BCH differed minimally. Conclusions: By using SCAMPs methodology, we have demonstrated that chest pain in children is rarely caused by heart disease and can be evaluated in the ambulatory setting efficiently and effectively using minimal resources. The methodology can be implemented regionally across a wide range of clinical practice settings and its approach can overcome a number of barriers that often limit clinical practice guideline implementation. 2013 by the American Academy of Pediatrics

N2 - of caregivers of children with developmental disabilities. Design: 200 caregivers were surveyed using the SF36 health survey and demographic questions from the National Survey of Children with Special Healthcare Needs. The SF36 Health Survey employs 36 questions to assess a subject's functional health and wellbeing in 8 health domains. The SF-36 bodily pain scale was used to assess the magnitude and interference of bodily pain. How much bodily pain have you had during the past 4 weeks? (1-none, 2-very mild, 3-mild, 4-moderate, 5-severe, 6-very severe) During the past 4 weeks how much did pain interfere with your normal work (Including both work outside the home and housework)? (1- not at all, 2-a little bit, 3-moderately, 4-quite a bit, 5-extremely) Setting: Two specialty care centers - one in a community hospital and a second in an outpatient university hospital setting Participants: 200 caregivers of children with predominantly autism or cerebral palsy participated. Interventions: n/a. Main Outcome Measures: SF-36 bodily pain scale. Results or Clinical Course: How much bodily pain have you had during the past 4 weeks? (1-none, 2-very mild, 3-mild, 4- moderate, 5-severe, 6-very severe) Average score caregivers of children with CP affecting arms and legs = 3.0; legs only 2.3. During the past 4 weeks how much did pain interfere with your normal work (Including both work outside the home and housework)? (1-not at all, 2-a little bit, 3-moderately, 4-quite a bit, 5- extremely) Average score caregivers of children with CP affecting arms and legs = 2.3; legs only 1.7. Conclusions: Our results indicate that caregivers of patients with CP affecting both arms and legs have more bodily pain when compared to CP affecting legs-only. We propose that this is likely due to the necessity of active repetitive lifting of these children, over many years versus having the option of providing support through less strenuous means, as is the case with CP affecting only the legs. We propose that anticipatory guidance through physical therapy and education in proper lifting technique from an early age for caregivers would improve their pain. Further studies should validate our findings

N2 - Case Description: An 18-year-old female with a history of Rett Syndrome and secondary spasticity with baclofen pump placement in January 2007. She presented to her pediatrician with 1.5 months of abdominal swelling without fever, change in tone, or recent illness. An abdominal x-ray was ordered and showed a moderate stool burden. The patient received multiple clean-outs and manual disimpaction without any improvement. She was seen by numerous subspecialists in the subsequent weeks without any additional symptoms. At her scheduled baclofen pump refill, the patient had an unchanged exam aside from a small egg sized mass under her right ribs. During the refill, the physician was unable to access the pump even with the longest needle. An abdominal CT scan was obtained, which showed a 6.5 x 8.0 x 10.0 cm abscess surrounding the baclofen pump. Setting: Tertiary care pediatric hospital Results or Clinical Course: Upon admission to the hospital, surgical exploration of the site revealed a large purulent fluid collection, requiring removal of the baclofen pump. Post-operatively, baclofen and diazepam were administered via her gastrostomy tube to prevent acute withdrawal. Labs eventually revealed group B streptococcus in her aspirate, urine, and vaginal swab cultures. She was treated with ampicillin and gradually improved to her baseline. The patient was discharged home on oral baclofen and has been scheduled for pump reimplantation this month. Discussion: Intrathecal baclofen (ITB) therapy has been a common treatment for spasticity and dystonia for many years. We are continuing to understand the complications of ITB including cerebrospinal fluid leakage, catheter malfunction, and infection. The incidence of infection has decreased significantly over the last 10 years as implantation techniques have improved. Despite the relatively low incidence of infection, particularly outside of the initial implantation time window, it must be considered as part of any differential when patients present with abdominal distention or pain. This case is especially unusual because the child did not demonstrate any additional infectious symptoms such as change in activity, fever, or increased tone. Conclusions: Caution must be taken when evaluating patients with ITB therapy and abdominal distention, as infection must always be on the differential

N2 - Energy drinks (EDs) are beverages marketed to improve energy, weight loss, attention, athletic performance, and concentration. Caffeine is the main active ingredient in EDs; many of them contain 70-80mg of caffeine for a 33 cl serving. Heavy caffeine consumption, such as drinking EDs, has been associated with serious consequences such as seizures, mania, stroke, and sudden death. Adolescent's and child's caffeine consumption should not exceed 100 mg/day and 2.5 mg/kg/day, respectively. The daily caffeine's intake should take account of all sources of this substance (coffee, tea, soft and energy drinks). Objective: (1) To investigate the extent of energy drink consumption in adolescents; (2) to understand the reasons why teens' consumption is widespread; (3) to estimate the amount of daily caffeine taken from coffee and beverages containing caffeine (including EDs). Methods: A self-report questionnaire related to EDs' consumption has been developed and then proposed to 1232 students aged 12-19 years old (mean age 14.8+3.8). The data have been collected and then analyzed. Results: According to our surveys, EDs are consumed by 378/1232 (30.7%) of subjects; among them 27/378 (7.1%) drink these beverages 1 time/day at least, 122/378 (32.3%) 1-2 times/week and 179/378 (47.3%) 1-2 times/month. Most of them, 341/378 (90.2%) admit to consume EDs for the flavour, 147/378 (38.9%) find them refreshing, 68/378 (18%) and 39/378 (10.3%) declare to achieve an improvement in sports performance and intellectual activity, respectively. 270/378 (71.4%) of participants declare to consume these beverages when outside, 106/378 (28%) at meals, 74/378 (19.6%) in front of TV/PC, only 39/378 (10.3%) at school and 38/378 (10%) during or after physical exercise. We have also evaluated the amount (in mg) of caffeine (from coffee and caffeinated beverages) taken daily. Among consumers of caffeine (891/1232 - 72.3%), 495/891 (55.5%) consume less than the daily maximum level allowed, 265/891 (29.7%) consume between 100 and 200 mg/day of caffeine and 131/891 (14.7%) exceed the maximum dose, consuming daily more than 200mg and up to 300 mg/day. Conclusions: Our data show that, among a pediatric population consuming caffeine, 396/891 of subjects (44.4%) exceeded the maximum recommended dose. Pediatricians should be aware of the possible effects of EDs and screen for their consumption to educate children and their families to decrease or eliminate the inappropriate use of these beverages

N2 - Information about heavy metal intake of children in Nigeria related to playground soils and classroom dusts compared to economically advanced countries is lacking. Playground soil and classroom dust samples were therefore collected from 8 public primary schools - 6 urban and 2 semi-rural - located within Ibadan North-West Local Government Area of Oyo State in Nigeria. Blood and spot urine samples were also collected from the pupils of the selected schools (n = 253). The samples were analysed for Pb, Cu, Zn, Fe and Mn by flame atomic absorption spectrophotometry. Higher Pb levels were detected in blood of the children (mean blood Pb level of 57.40+28.56µg/dl) as well as in dust and soil samples from the 6 schools located in urban areas while

lower levels were obtained in the other 2 schools located in semi-rural area (mean blood Pb of 17.43+8.54µg/dl). Mean metal concentrations in the samples were as follows: classroom dusts - Pb 54.71+36.91, Cu 26.71+29.67, Zn 413.07+324.33, Fe 7828.30+2852.83, Mn 96.46+10.88 mg/kg; playground soils - Pb 45.76+36.23, Cu 18.29+16.69, Zn 368.97+425.73, Fe 7633.40+4191.23, Mn 92.70+7.87 mg/kg; blood - Pb 36.23+29.43µg/dl, Cu 0.67+0.21, Zn 3.50+1.42, Fe 272.09+115.87, Mn 0.07+0.05µg/ml and urine - Pb 0.42+0.36, Cu 0.07+0.05, Zn 0.37+0.38, Fe 0.32+0.33, Mn 0.01+0.02µg/ml. No correlation was observed between blood and dust metals of these children. A positive correlation ($r = 0.168$, $p = 0.008$) was however observed between blood Pb and playground soil. These suggest that heavy metal accumulation in these children might be from their schools' playgrounds and other sources

N2 - Objective: The foundation stage/phase was introduced into the primary schools of England and Wales in September 2008. Government guidelines recommend a whole school approach (ages 3 - 11) to an ethos of learning which includes using the outdoors as a learning environment alongside traditional classroom-based education. Students are encouraged to learn by direct, hands-on experience through play and pupil-led investigations and consequently they have access to a much larger variety of potentially toxic agents and plants. Methods: Enquiries to NPIS between 1st September 2009 and 31st August 2011 relating to exposures of children (ages 3 - 11) to potentially toxic materials in schools were analysed with regard to type of material involved and severity of symptoms. Results: A total of 574 enquiries were received during the study period, 37.5% involving girls and 61.5% involving boys. Children aged five were the subject of the highest number (17.6%) of enquiries. The most common agents involved in exposures to pupils were plants (leaves, flowers, seeds and nuts), low toxicity miscellaneous products, chemicals, ice packs (food), cleaning products and pharmaceuticals. Although the majority of exposures resulted in minimal symptoms only, 12.7% of enquiries from schools required referral to hospital for treatment and a further 24% of enquiries were from hospital where the child had already been admitted. Some of the more serious cases involved exposure to agents such as isopropyl methyl sodium hydroxide, unused EpiPens (epinephrine auto-injector) and rat bait. Conclusion: Schools are encouraged to provide a new learning experience for pupils but should ensure that a comprehensive risk assessment is carried out on all materials, including plants, to which children might become exposed. Do NPIS centre staff have a role to play in providing expert poisoning-prevention education to schools

N2 - Objective: Lead is an established environmental toxin and the most common metal responsible for poisoning. Through the combination of environmental regulation and whole population screening, the incidence of lead poisoning has been greatly reduced in many countries world-wide. Similar approaches are now being adopted in West African countries like Ghana, which banned the sale of leaded gasoline in 2003. However such regulations are far from institutionalized and many adults and children remain at risk. Methods: This research was undertaken as a first step to identify common environmental sources of lead in Accra, Ghana, with the goal of developing testing and risk reduction strategies. Samples of soil, pottery, paint, and other objects from thoroughfares, playgrounds, markets, and gas stations were collected. Samples were taken from areas easily accessed by passersby, including children, in a convenience sample of neighborhoods suspected of being at greatest risk of lead exposure. Coordinates for each sample were determined using a handheld Global Position Satellite device and were marked on a standard map. Each sample was tested in an identical manner using Lab Inspector Lead Test Kits from Abotex, which uses a sulfur-based solution to produce a semiquantitative color change in the presence of lead. Results: Out of a total of 332 samples, there were 75 positive Results: 33 soil, 10 eating utensils, 14 building tiles that had fallen onto the road, 5 cans that had previously contained foodstuffs, 2 bowls with chipped paint, 5 pieces of metal jewelry, 2 paint chips scraped from walls, 2 pieces of solder/wire, one discarded battery, and one sample of liquid herbal medicine. Thirteen of the positive soil samples were taken from the sites of gasoline retailers. The majority of the positive samples were collected in less-developed residential neighborhoods and lower socioeconomic areas. Conclusion: The data presented above indicates that lead is likely present in the environment in Accra, Ghana, and exposure to the population is a concern. We advocate consideration of lead exposure in both individual and population-based environmental health risk assessments, and hope to begin widespread testing in areas where risks of exposure seem highest

N2 - Background: Clustered symptoms, such as headache, vomiting, and vague neurologic symptoms in carbon monoxide (CO) exposure, suggest a common toxin. Carboxyhemoglobin levels are often unavailable, and clinical suspicion often guides management. In this series, we report three sisters transferred from a rural hospital for CO toxicity. Their history betrayed the true exposure. Case report: 3 sisters ages 3, 5 and 5, were transferred from a rural hospital for CO toxicity. The mother reported 1 week of headaches in her children. The children described acute nausea and intractable vomiting on arrival to an aunt's home that afternoon, unchanged

by prochlorperazine. Relatives sharing space with the children denied similar symptoms. Outside workup revealed moderate leukocytosis and normal metabolic panels in all three patients. The elder children suffered brief seizures prior to transfer; additional medication exposures were denied. Accompanying blood samples were sent for carboxyhemoglobin content. On arrival, the patients were tachycardic but otherwise vitally normal. Both elder children were incontinent of urine. All were markedly mydriatic and variably agitated. All had gait instability; one child actively hallucinated. All remained altered until admission, nearly 10 hours past presumed exposure. Parents were pressed separately regarding additional history. The mother's fiancée confided that she was "on the highest dose" of bupropion XL; she admitted to finding this out of place. One of the 5-year olds endorsed finding the pills and feeding them to herself and her sisters. The children were admitted to the pediatric intensive care unit with child protective services and poison center input. Carboxyhemoglobin levels were normal, and the three were discharged the next day. 9 days later, bupropion and hydroxybupropion levels returned markedly elevated (Table). Case discussion: This cluster of pediatric bupropion overdoses was complicated by seizure activity and missed diagnosis. The initial diagnosis of CO toxicity led to transfer to a hyperbaric center, but serial inquiries by staff in light of an incongruous clinical setting led to the diagnosis. Early discordance between symptomatic patients and asymptomatic relatives was highly suggestive of an exposure other than CO, and subsequent history gathering made the diagnosis. Conclusion: History matters in the workup of potential exposures. This case demonstrates both the importance of accurate history taking and the effect of premature closure in clinically significant bupropion toxicity. (Table Presented)

IS - var.pagings

N2 - Background: Crotalid bite fatalities are rare in the US: about 10 deaths per 7000 bites annually. No pediatric deaths have been reported since the advent of crotaline Fab. We report the death of a 23 month old girl due to crotalid envenomation. Case Report: A 23 month old girl screamed at a playground. Her parents found her near a small rattlesnake with blood on her left ankle. Within one minute she vomited, became unresponsive, and had generalized convulsions. EMS transported her to a pediatric hospital within two hours, receiving O₂ and IV NS en route. Initial VS were: BP, 106/85 mmHg; HR, 184/min; RR, 46/min; SpO₂, 100% on NRB; and GCS, 11 (E4 V3 M4). The patient had blood in her nares and mouth. Respirations were labored with coarse breath sounds and stridor. Capillary refill was sluggish. Skin was cool and pale with petechiae. Her medial left ankle had four puncture wounds. She was intubated within 20 minutes. Fresh blood was noted in the ETT. Laboratory studies revealed: WBC 33 k/mcL; Hct 22%; Plt 10 k/mcL; hemolysis on peripheral smear; INR 19; PTT > 300 s; fibrinogen < 70mcg/ml; D-dimer > 22 mcg/ml; FDP 320 mcg/ml; ABG: 7.09/31/116/-19. IV crotaline Fab was begun 3 hours post bite. The patient received 6 vials as well as 4 units PRBC, 5 units plasma, 2 units platelets, and 10 units cryoprecipitate. In PICU at 3.5 hours post bite she received factor VII per hematology consultation. She became hypotensive and acidotic (pH 6.9), requiring resuscitation with multiple vasopressors. Poison control was consulted 4.5 hours post bite and advocated repeat doses of crotaline Fab. Prior to a second dose the patient became pulseless. She was pronounced dead less than five hours post bite. Postmortem findings included: four fang marks anterior to the medial left malleolus; cutaneous and serous petechiae; and acute hemorrhagic pancreatitis and gastritis. The cause of death was listed as hemorrhagic

diathesis due to snake bites. Discussion: Pediatric death from snake envenomation is extremely rare in the US. We found no case reported in the literature since the advent of crotaline Fab. In this case the snake was not formally identified, but the history, examination and laboratory findings were most consistent with crotalid envenomation. The rapidity of systemic symptoms and clinical deterioration suggested envenomation directly into a blood vessel. The possibility of an anaphylactoid reaction could not be ruled out. Extended transportation time may have contributed to mortality, but it is unclear whether earlier treatment would have prevented death given the extreme presentation. Conclusion: Children who quickly develop systemic effects may succumb to crotalid envenomation despite comprehensive management including crotaline Fab

N2 - Purpose: To present a patient view of a treatment journey, highlighting the strengths and the weaknesses from that experience and recognising a potential for Advanced Practice on behalf of Radiation Therapists. The patient was aged 7 when diagnosed in December 2007 with an anaplastic ependymoma tumour in the occipital lobe and had surgery to effect maximal tumour resection. The pathology of the tumour upon removal indicated that it was a Grade III anaplastic ependymoma some 3cm across. In early 2008 the patient embarked on radiation therapy receiving 59.4Gy over 33 treatments. This case was an inaugural patient for a novel intervention which aimed at reducing anxiety and helping the patient to cope with paediatric radiotherapy. The intervention was outstandingly successful and the diversionary activities within the treatment regime undoubtedly added to the effectiveness of the treatment. The patient maintained near normal daily activities missing only the first couple of hours of school each day during the treatment period. The paper will cover this from that patient's perspective and then report on the post treatment impact of that treatment. It will present the patient's view and outcomes in the evolution of the patient management process and improved healthcare.

Results: The paper identifies the important role of communication and understanding amongst all members of the team, including the patient. It comments on the need to recognise the full range of options available and the best practice guidelines which could be adopted. Above it touches on the impact the adoption of all of these has on the patient treatment journey. It opens up the question of the appropriate mechanisms of involvement for the patient in this journey and the associated decision making surrounding this involvement, and this paper specifically comments on this. It identifies other professionals' world-wide who are working on elements of this approach. Conclusion: The paper will highlight some significant areas of patient need following the weeks of treatment as the longer term impact and effects of treatment emerged. It focuses on recognition of the patient's place and how best to use multidisciplinary care as a two-way communication tool. It asks the profession to translate what appears to be a practice based outside of core resources into one which is central to effective support for the patient journey. It is a report on the patient feedback, on what is a successful and highly desirable programme and offers further comment on the longer term issues surrounding post treatment events and experience. 2013 The College of Radiographers

N2 - Background and objectives: The prevalence of metabolic syndrome is increasing worldwide, and has followed the global trend to obesity. It is essential to identify and control all the factors that make up metabolic syndrome both in adolescents and in children for the prevention of cardiovascular disease in adulthood. The aim of the study was to assess the nutritional status of children and adolescents who are overweight and/or obese and their predisposition to metabolic syndrome. Methods: We evaluated 100 patients, age 5 to 18 years, of both genders, in routine clinical care and that were diagnosed with overweight (BMI p 85-95) or obese (BMI p 95) second WHO/2007. We carried out anthropometric measurements, biochemical tests and questionnaires with the mothers. Results: The study showed that 87% had family history of disease related to nutritional status like hypercholesterolemia, diabetes mellitus and overweight/obesity; 42% started the overweight/obesity under the age of 5 years; 72% don't make any treatment for weight control; 32% eat their meals everyday in front of TV/computer, of these, 45% for more than 4 hours daily; 69% do not do any kind of physical activity outside of school; 57% of the population has no control food intake, consuming them anytime even without being hungry, and 38% eats until feeling sick; 11% have a habit of vomiting inducing after meals showing signs of eating disorders; 39% have high daily consumption of sweets; 74% have cholesterol levels increased considering that this is a population of minors and that many factors are present characteristic of the metabolic syndrome. Conclusions: To improve the health and nutritional status of children and adolescents is necessary to develop

strategies and activities that promote nutrition education, good eating habits and encourage regular physical activity. These actions contribute to the reduction of risk factors for metabolic syndrome

N2 - Background and objectives: The beneficial effect of vitamin D in bone health is acknowledged and the vitamin has also been associated with several chronic diseases. It is therefore relevant to determine the prevalence of vitamin D insufficiency in different groups, and vitamin D statuses within families have not been studied previously. The objective of the present study was to evaluate serum 25-hydroxyvitamin D (25(OH)D) concentrations among families in Denmark (56 degreeN) after seasonal UVB peak and to ascertain determining factors. Methods: Cross-sectional study with 755 children and adults (4-60 y) recruited as families in the VitmaD study. Blood samples were collected in September-October 2010, and vitamin D status was measured as serum 25(OH)D concentration by LC-MS/MS. Vitamin D intake and life style factors were assessed in self-administered questionnaires. Determinants of vitamin D status were identified in a linear mixed model with

family as a random variable. Results: Mean (+SD) serum 25(OH)D concentration was 75 + 20 nmol/l (range 9-162 nmol/l) and only 10 % had 25(OH) D <50 nmol/l. Determinants of serum 25(OH)D were age (p=0.036), BMI class (p=0.001), multi vitamin use (p=0.033), sun behaviour (p=0.005), outdoor stay (p=0.033), sun vacation (p<0.001), and physical activity (p=0.040). Gender (p=0.692) and vitamin D intake (p=0.238) were not associated to serum 25(OH)D. Conclusions: The prevalence of vitamin D insufficiency among families in Denmark was low after seasonal UVB peak. Sun vacation was the strongest determinant for vitamin D status at this time of the year

N2 - Background and objectives: The chewing ability is one of important factors for good health and thus for developing and educating dietary good habits. Recently, the decrease in chewing abilities of children is discussed. We examined their chewing consciousness and its relation to daily and dietary habits through questionnaire survey. Methods: Questionnaire survey about daily and dietary habits was done in 592 children (294 males and 298 females, 11- 12 years old) from four primary schools at the Kansai area in Japan. When high score was allotted in their better habits, there were significantly positive correlations between gCC: chewing consciousness and gHIC: having interest in cooking h or gFVFI: frequency of vegetables and fruit intake h. According to each category score, they were divided into high and low score groups. Statistical analysis in contingency tables was done by chi-square test. And then the multiple regression analysis, as CC or gLMLA: learning motivation and learning attitude h with a dependent variable, was done. Results: In the higher score group of HIC, scores of FVFI, CC, and LMLA were significantly higher than those in the lower score group of HIC. In the higher score of FVFI, scores of HIC, g playing sports and studying well h, and also CC were significantly higher than those in its lower score group of FVFI. The multiple regression analysis, as CC with a dependent variable, indicated that CC was affected by HIC and FVFI with 27 % coefficient of determination. Also, LMLA was affected by FVFI, g self-efficacy h, g refrain from between meals and eating outside h, and CC with 23% coefficient of determination. Conclusions: The present analytical results indicated that the chewing consciousness was affected by having interest in cooking and frequency of vegetables and fruit intake, and the learning motivation and learning attitude was affected by FVFI and CC

N2 - Background and objectives: The International Network for Food and Obesity/NCD Research, Monitoring and Action Support (INFORMAS) is setting benchmarks for creating healthy food environments. This paper describes the framework for assessing the extent of children's exposure to food marketing and the nature of these promotions. A standardised framework is needed to allow comparisons between countries, between companies and between different time periods. Methods: A review of studies measuring the nature and extent of food marketing was undertaken to identify approaches to monitoring across media platforms. This was supplemented with detailed methods used by the authors in national and international monitoring studies since 2007 to describe food marketing across multiple media, including television, print, internet and outdoor advertising. Results: Food marketing studies indicate children in both high and low/middle income countries are exposed to large volumes of unhealthy food promotions on different media. Active monitoring using a standard assessment tools is currently underway in a range of countries, including China, Mongolia, Malaysia, Philippines and these 2012/3 data will be released. A step-wise approach to monitoring food marketing is proposed, suitable for differing levels of engagement and resources. This framework includes monitoring activities that assess the frequency of food promotions across different media and time points, and measures of persuasive appeal of promotions. Conclusions: Globally, children are exposed to high volumes of unhealthy food promotions. The monitoring framework proposed here will assist in the implementation of the World Health Organization's set of recommendations on the marketing of foods and non-alcoholic beverages to children, which recognise the need for reducing the impact of unhealthy food marketing to children

N2 - Background and objectives: The health properties of the New Nordic Diet (NND) are increasingly being investigated in response to awareness of sustainability and public interest in eating local and traditional foods. The purpose of the present study was to investigate the association of NND adherence with risk of excessive gestational weight gain (EGWG) in the Norwegian Mother and Child Cohort Study (MoBa). Methods: A diet score was constructed from relevant items of the food frequency questionnaire (FFQ) completed by pregnant women in the MoBa study in week 22 of pregnancy. The score comprises ten subscales summarizing meal pattern, intake of fruits, root vegetables, kale, potatoes, oatmeal porridge, whole grain bread versus white bread, foods from the wilderness (fish, game and berries), milk versus juice, and water versus soft drinks. Each subscale was dichotomized by the median and assigned a value of "0" or "1". Adding the subscales yielded a score from 0 to 10 with increasing score indicating higher adherence to the NND. EGWG was defined as gestational weight gain in excess of the range considered optimal and recommended by the Institute of Medicine (2009) according to pre pregnancy BMI. For analysis participants were grouped into "low", "medium" and "high" NND-adherence, and the relative risk of EGWG across groups was analyzed with multi-nominal logistic regression. Results: 56771 pregnant women were included in the study. Moving from low to high NND-adherence was associated with reduced odds of experiencing EGWG in the crude model (OR: 0.837; 95%CI:

0.795, 0.882) and after adjusting for energy intake, pre pregnancy BMI, length of gestation and physical activity level (OR: 0.875; 95%CI: 0.825, 0.928). Conclusions: Higher adherence to this a priori defined New Nordic Diet was associated with reduced risk of experiencing EGWG

N2 - Vitamin D deficiency occurs rather commonly among healthy pregnant women, newborns and young children, especially in certain risk groups. Since vitamin D plays a role in calcium and phosphor metabolism

essential for bone health and in the physiopathology of some autoimmune diseases it seems important to provide recommendations for prevention of vitamin D deficiency. Risk factors include maternal vitamin D deficiency, low intake of fortified food, eg. breastfeeding, low compliance of supplementation, dark skin, inadequate sun exposure, premature birth, overweight, living at high latitude. The aim of this paper is to summarize available data of vitamin D sources, known situations in which deficiency is common and published guidelines on vitamin D supplementation, and translate this information in recommendations for prevention of vitamin D deficiency in healthy paediatric population in Flanders. Infants should receive an oral supplementation of 400 IU/day of vitamin D from birth and this should be continued till the age of 6 years. In cases of dark skin the dose should be 600 IU/day. An healthy life style with outdoor activities and associated sun exposure and intake of fortified nutrition should be advised. The implementation should be promoted by all healthcare professionals working with young children

N2 - Ireland currently has no access to an established psycho oncology service outside of the capital city, Dublin. Patients who attend their gynecologist or oncologist for treatment outside of Dublin depend on

voluntary organizations for their therapeutic support. These services work outside of the National Health Service, and have major limitations on what they can offer. Gynecological cancers have a direct impact on the lives of thousands of Irish women and their families. Annually this number is increasing. It has been well documented internationally that cancer patients who receive the appropriate emotional support are less likely to attend the hospital, feel psychologically stronger, higher compliance rate to treatment and thus increasing survival (Carlson, Bultz, 2002, 2003, 2004). A. Mitchell (2011) highlights the importance of a psychosocial intervention in directly improving anxiety, depression and quality of life in women with gynaecological cancer. We describe the establishment of a comprehensive psycho oncology service in the southern part of the country but unique to Ireland. It specifically meets the needs of gynaecological oncology patients, their families and significant others. We discuss the sourcing of therapists from a broad therapeutic background (systemic psychotherapists, psychologists, psychotherapist, psycho-sexual therapist, child psychologist, art therapists and play therapists). We explain the geographic challenges in meeting the patients' needs group. We outline a specific training module facilitated by clinicians from an interdisciplinary background addressing clinical, practical and emotional needs of this patient group. We examine the need for protocols and the logistics for those embarking on a similar journey

N2 - INTRODUCTION: The overuse of medical imaging has recently started an initiative to diminish radiation exposure particularly in children, given the risk of developing cancer. Our goal was to identify the current amount of radiation used for a pediatric trauma evaluation and correlate the levels of radiation with trauma activation status in order to identify the subset of patients most at risk. METHODS: We retrospectively evaluated pediatric trauma patients (N=1050) at a Level I independent children's hospital for all levels of trauma activation (Stats, Alerts, Consults) from June 2010 to January 2011. 215 patients had full dosimetry data available and were analyzed for demographics, mechanism of injury, injury severity score (ISS), imaging modalities, and radiation dosages in milliSieverts (mSv). RESULTS: The demographics include: gender (143M, 72F); age 5.5 yrs [<1-16]; average ISS of Consults, 7.7 [1,16]; Alerts, 8.8 [1,17]; and Stats, 17 [3,38]. Per Stat, the number of CTs ranged from 0-10 with 2-3 CTs in 35% and 4-10 CTs in 40% for one admission. The studies most often repeated were head CTs (45%), face/sinus CTs (13.8%), and neck CTs (10%). The average non-accidental trauma (NAT) Consult patient had four times as many CTs as the average trauma Consult patient. The majority (66%) of outside CTs delivered more radiation, of which 50.0% of the doses were at least double the pediatric dosage. CONCLUSIONS: The identified factors associated with the most radiation include suspected NATs, Stat activations, and outside imaging. This study is the first to correlate the amount of radiation exposure with trauma activation status. (Table Presented)

N2 - Background:While Australian paediatricians also manage rare conditions, the bulk of their time is spent on common, chronic conditions such as obesity, autism, attention deficit hyperactivity disorder, allergy, asthma, and developmental problems. This comprises a significant proportion of the estimated \$4.5 billion per annum

spent providing health care to 0-14 year old Australian children. Despite the cost, there has been very little research into how best to systematically and consistently manage chronic child health conditions outside tertiary settings. Addressing the need to develop evidence-based interventions in real-life health care settings requires new research platforms that can engage and support paediatricians to participate in large-scale multi-site research. The Australian Paediatric Research Network is one such platform. Aims/Objectives: Formed in 2007, the APRN aims to improve the quality and quantity of research into common child health conditions managed in secondary care settings. Two core problems drive our Network: (1) the substantial cost of secondary care, in the face of a weak evidence base as to its effectiveness; and (2) an under-utilised capacity of Australian paediatricians to participate in research that could improve this evidence base. Methods: With our 400-strong membership, we have conducted a suite of activities that inform practice, training and further research. This includes our annual multi-topic surveys, the first ever national audit of practice outside hospital settings (n = 8,500 children), and establishing our members' research priorities. The coming 18 months will see a repeat of the last two activities, five years on, and a forum of multi-disciplinary experts to shape the APRN's future research. Findings and Conclusions: The bulk of care for children with chronic health conditions takes place outside of hospitals but there is very little research into its effectiveness. The APRN provides an exciting vehicle for such research and is engaging paediatricians in the very research which will change their practice

N2 - **PURPOSE:** At Boston Children's Hospital Pediatric Transplant Center, we aim to provide quality care and support throughout the transplant experience, not only while in the hospital but also out-patient. For the past 6 years, we have offered solid organ transplant (SOT) recipients and their families an opportunity to connect with other SOT recipients, their families, and staff outside of the hospital at our annual Family Celebration Day. Patients, families, and staff are encouraged to share experiences while socializing and participating in activities. **METHOD:** Upon arrival, attendees sign in, obtain a name tag (identifying what organ he/she received), and review the activity and food schedule. Activities such as bumper boats, miniature golf, a driving range, arcade games, a batting cage and more are offered at the facility. Child Life Specialists provide an opportunity for SOT recipients and their siblings perform a "check-up" at Transplant Clinic on stuffed animals given to them upon arrival. Kids of all ages participate in medical play with their stuffed animal and even perform surgeries (similar to what they have been through). Besides medical play and art, organized games occur including transplant bingo and a scavenger hunt to encourage socialization and educate patients about transplant. **RESULTS:** Feedback is collected each year which has always been overwhelmingly positive. Families report they appreciate the opportunity to meet and connect with other SOT recipients. They often share experiences and stories, and stay connected after the event. Families also report they look forward to socializing with staff outside of the hospital, seeing their doctors and nurses in "normal" clothes. Several attendees have started fundraising efforts to help support this free event so it can continue for years to come. **CONCLUSION:** The Pediatric Transplant Center at Boston Children's Hospital's Annual Family Celebration Day is an event that recipients, their families, and staff look forward to year after year. It provides an opportunity for participation in normalizing activities and socialization with peers and families that have similar experiences

N2 - Among all head and neck (H&N) cancers, nasopharyngeal carcinoma (NPC) represents a distinct entity regarding epidemiology, clinical presentation, biological markers, carcinogenic risk factors, and prognostic factors. NPC is endemic in certain regions of the world, especially in Southeast Asia, and has a poor prognosis. In Indonesia, the recorded mean prevalence is 6.2/100 000, with 13 000 yearly new NPC cases, but otherwise little is documented on NPC in Indonesia. Here, we report on a group of 1121 NPC patients diagnosed and treated at Dr. Cipto Mangunkusumo Hospital, Jakarta, Indonesia between 1996 and 2005. We studied NPC incidence among all H&N cancer cases (n =6000) observed in that period, focusing on age and gender distribution, the ethnic background of patients, and the disease etiology. We also analyzed most prevalent signs and symptoms and staging of NPC patients at first presentation. In this study population, NPC was the most frequent H&N cancer (28.4%), with a male-to- female ratio of 2.4, and was endemic in the Javanese population.

Interestingly, NPC appeared to affect patients at a relatively young age (20% juvenile cases) without a bimodal age distribution. Mostly, NPC initiated in the fossa of Rosenmuller and spreaded intracranially or locally as a mass in the head. Occasionally, NPC developed at the submucosal level spreading outside the anatomic limits of the nasopharynx. At presentation, NPC associated with hearing problems, serous otitis media, tinnitus, nasal obstruction, anosmia, bleeding, difficulty in swallowing and dysphonia, and even eye symptoms with diplopia and pain. The initial diagnosis is difficult to make because early signs and symptoms of NPC are not specific to the disease. Early-age Epstein-Barr virus (EBV) infection combined with frequent exposure to environmental carcinogenic co-factors is suggested to cause NPC development. Undifferentiated NPC is the most frequent histological type and is closely associated with EBV. Expression of the EBV-encoded latent membrane protein 1(LMP1) oncogene in biopsy material was compared between NPC patients of < 30 years old and those of >30 years old, matched for sex and tumor stage. Higher LMP1 expression in patients of <30 years old was observed, which was related to more locoregional progressivity. Increased medical awareness of prevailing early stage signs and symptoms coupled to use of EBV-related diagnostic tumor markers may lead to down-staging and timely treatment to improve survival of patients with this aggressive disease

N2 - Although the health benefits of physical activity are well documented, it appears that even children may exhibit levels of physical activity that are insufficient to prevent or reduce excess weight gain. In light of the current child obesity epidemic, our objective was to survey children to identify the main reasons they might give for not engaging in outdoor play in the summer, ostensibly a time when school is out and weather is most favorable. For this study, 300 children (age 6-14) were surveyed at four county/4-H fairs and asked to indicate how important various factors (e.g., heat, traffic, mosquitoes) were in preventing them from playing outside. The reasons ranked highest were bad weather, bullies/gangs, fear of strangers, no street lights, and it being too hot. These results are somewhat consistent with studies that indicate neighborhood safety as a concern (Carver et al., 2008), but add weather conditions as a factor to be considered when seeking to promote outdoor activity. Allowing access to unused school gyms might be a useful strategy for facilitating large motor activity in summer months

N2 - We examined the implementation of Pilas!, a community-based intervention aimed to reduce risk factors for chronic diseases (unhealthy diet, physical inactivity, alcohol and tobacco use) in school-age children. The intervention consisted of three components (school, food kiosk and community) that were implemented by teachers, children, food vendors, religious leaders, and government workers in two poor communities and two public schools in Guatemala City. Intervention activities included a classroom-based program (4th-6th grade), active games during school recess, healthy recipes and marketing strategies to promote healthy foods in kiosks, and community events. Quantitative and qualitative methods (structured observations, surveys, logs) were used to examine process indicators, which included the extent of delivery (reach), proportion received by target audience (dose), fidelity of intervention protocol, and context. The school component was implemented with high reach, dose and fidelity. The kiosk component was implemented with moderate dose and fidelity, and low reach. The community component was implemented with low dose and reach. Lack of communication and organizational difficulties were identified as barriers to implementation in the kiosk and community components. These findings will be used to plan a randomized controlled trial in Guatemala City

N2 - This study evaluated the association between childcare center policies about physical activity (PA) and children's PA and screen-time behaviors at 50 childcare centers. Data were collected in 2008-2009 using the Environment and Policy Assessment and Observation (EPAO) tool. Directors reported center PA policies (written, unwritten but general practice, no policy). Preschool children's PA and screen-time behaviors were assessed via 4-day observation at each center. Time spent per day in outdoor play, teacher-led PA, sedentary activities, and screen-time were 67.7+33.6, 16.5+11.3, 52.2+28.8, and 39.7+47.9 minutes, respectively. Children engaged in more minutes of outdoor play at centers with a written policy about amount of active playtime; and a

written/unwritten policy about amount of time spent outdoors. Written policies about amount of active playtime and time spent outdoors were also associated with more minutes of sedentary activity. Children engaged in more minutes of teacher-led PA at centers with written policy about amount of time in teacher-led activities. Children spent fewer minutes watching television and using computers at centers with written policies about such behaviors and written policy about staff supervision of media use. Results suggest that written and unwritten policies may be effective at increasing PA, but may be insufficient to help children achieve recommended levels of PA

N2 - Background: Childhood adversity is associated with significantly increased risk of psychiatric disorder. To date, functional magnetic resonance imaging studies of children have mainly focused on the impact of institutionalization rather maltreatment at home and investigated conscious processing of affect. The aim of the current study was to investigate neural response to pre-attentively presented affect cues in a community sample of children with documented experiences of familial maltreatment. Methods: A masked dot-probe paradigm involving pre-attentive presentation of angry, happy and neutral facial expressions was employed using fMRI.

Eighteen maltreated children aged between 10 and 14 years of age, were compared with 23 non-maltreated peers, matched for age, gender, SES, Tanner stage and IQ. Results: Increased neural response was observed in the right amygdala for preattentively presented angry and happy faces in maltreated versus non-maltreated children. Significant negative associations were found between degree of amygdala response and age of onset / duration of abuse for measures of emotional abuse and neglect. Conclusions: We demonstrate for the first time that maltreatment in children is associated with increased amygdala activation to pre-attentively presented positive and threatening faces. In other words, our findings suggest that maltreated children show a general pattern of atypical affect processing, even outside of conscious awareness. Given the evidence for pre-attentive affect processing is also altered in individuals with anxiety disorders, we suggest that this pattern of heightened amygdala activation may constitute a latent neural risk marker, associated with increased vulnerability to future psychiatric disorder

N2 - Objective: To evaluate the repercussion of sedentary habits in the lifestyle of children and adolescents, 7 to 18 years old, both sexes, from public schools of the city of Campinas, Brasil. Methods: A cross-sectional epidemiological study with sampling from a school population pool was carried out. Eleven schools were randomly selected in central and peripheral city areas. The assessment protocol comprised a structured questionnaire, anthropometry, and a non fasting lipid profile. In 2010, 4699 students (47,14% of the male sex; mean age, 11.07+2.9 years) were evaluated. Results: Reports showed that 67.25% of the children that practiced outside school physical activities did not present weight excess. Overweight (>+1SD) and obesity (>+2SD) prevalence rates were 15.7% and 16.0%, respectively. Sedentary habits (television, videogames and computers) corresponded to 3.29 hours daily. Low and moderate time for interaction with electronic devices (television, computers and video games) was up to 3,5 hours daily and moderate, intense and exaggerated was considered for more than 4 hours daily. Children that spent more time in front of screens also report having significant stress in the home environment ($p<0,0001$). A significant correlation between time spent in front of screens and stress in school was also true. ($p<0,0001$). Conclusion: Physical activity is associated to a healthy life style in a young population, in opposition to sedentary habits generating stress and weight gain. Interventions are required to improve physical activities and reverse the unfavorable tendency of future cardiovascular risk and potential chronic degenerative pathologies in the adult population

N2 - Objective: To assess the effect of a governmentally-led center based child care physical activity program (Youp'la Bouge) on child motor skills. Patients and methods: We conducted a single blinded cluster randomized controlled trial in 58 Swiss child care centers. Centers were randomly selected and 1:1 assigned to a control or intervention group. The intervention lasted from September 2009 to June 2010 and included training of the educators, adaptation of the child care built environment, parental involvement and daily physical activity. Motor skill was the primary outcome and body mass index (BMI), physical activity and quality of life secondary outcomes. The intervention implementation was also assessed. Results: At baseline, 648 children present on the motor test day were included (age 3.3 + 0.6, BMI 16.3 + 1.3 kg/m², 13.2% overweight, 49% girls) and 313 received the intervention. Relative to children in the control group (n = 201), children in the intervention group (n = 187) showed no significant increase in motor skills (delta of mean change (95% confidence interval: -0.2 (-0.8 to 0.3), p = 0.43) or in any of the secondary outcomes. Not all child care centers implemented all the intervention components. Within the intervention group, several predictors were positively associated with trial outcomes: 1) free-access to a movement space and parental information session for motor skills 2) highly motivated and trained educators for BMI 3) free-access to a movement space and purchase of mobile equipment for physical activity (all p < 0.05). Conclusion: This " real-life" physical activity program in child care centers confirms the complexity of implementing an intervention outside a study setting and identified potentially relevant predictors that could improve future programs. 2013 Bonvin et al.; licensee BioMed Central Ltd

N2 - Background: A national survey conducted in 2008-2009 by the French Institute for Public Health Surveillance for detection of lead impact in childhood identified a high blood lead level in a young boy living in the town of "Le Port", Reunion Island. Previously, cases of lead-poisoning on the island had been exceptional; only a dozen cases were reported in the 1980s in adults, related to the use of lead-containing instruments for food preparations. Methods: The family of the index case was invited to participate in screening tests and an environmental investigation was conducted using a standardized questionnaire. Screening was then broadened to the neighborhood of the index case and samples of soil outside the home and in the immediate vicinity were taken. The environmental survey was then extended with soil samples taken from the entire geographical area. Information was then provided to local inhabitants (87 families and 287 people) in order to encourage lead blood testing for all children under six years and all pregnant women living in the area. Results: The index case lived in the neighborhood of "The Oasis", a shantytown of Le Port. The results of soil analysis revealed heterogeneous pollution of superficial soils by lead throughout the area of the shantytown, the highest level recorded (5200. mg/kg) reached more than 300 times the background level of the natural soils of the island. The screening identified 76 cases of childhood lead-poisoning (blood lead level greater or equal to 100. µg/L) among 148 samples (51%). All cases of blood poisoning involved children under the age of 15 years. The median age of children with a positive test was 5.6 years; the median blood lead level was 196. µg/L [102-392. µg/L]. Conclusion: The main hypothesis to explain the contamination of the soil in the area of the shantytown is the presence of waste deposits (car batteries) and diffuse activities of metal recovery. The authorities managed to remove all the families from the environmental exposure to lead by rapidly ensuring rehousing outside the contaminated area. 2013 Elsevier Masson SAS

N2 - Purpose: To present children admitted to the hospital due to loss of consciousness and convulsions related to sports. Sports commonly leading to concussions include contact martial arts sports, football, soccer and others. Main post-concussive symptoms are headache, followed by convulsions, dizziness, vomiting, lack of motor coordination, cognitive and emotional problems. Repeated concussions can lead to persistent neurological problems. Method: Retrospective data analysis of patients with symptoms related to loss of consciousness and suspected epilepsy, playing different contact sports treated at our Neuropediatric Department during 16 months was done. Results: Fifty four children (mean age 12.5 years) playing different contact sports were admitted to our Department. Epilepsy was suspected in 8 urgently admitted children (3 from playground): 3 had epileptic fits, 3 loss of consciousness, 2 confusion with unilateral cramps; after an outpatient visit 2 came with cramps and 1 with tremor. All children had on average training during 2-7 years, 2-3 times a week, and nearly each weekend. Three children had the diagnosis of epilepsy followed by antiepileptic treatment with a good control

of seizures. Conclusion: Concussions cause different neurological symptoms and convulsions if rest is not long enough to allow the brain to fully heal afterwards. Repeated concussions may lead to epilepsy and chronic encephalopathy. A neuropsychiatrist must monitor children involved in contact sports, perform diagnostic procedures according to medical history and clinical presentation, advise a child to avoid the activities that may put them at risk for future head injuries and to discontinue contact sports if necessary

N2 - Background:In France, the 2009 A(H1N1) influenza epidemic occurred between September 2009 and January 2010. Sparking widespread controversy, it was intensely reported in the media. Despite therapeutic inefficacy, antibiotic consumption and viral respiratory infections are positively correlated, particularly in France, where antibiotic overconsumption is well-known. We first determined the period when media coverage was high, and then compared, during this period, observed outpatient antibiotic consumption to estimated outpatient antibiotic consumption "without media attention".Materials and Methods:To evaluate media coverage, two online databases were consulted: Factiva and Europresse. To quantify outpatient antibiotic consumption, we used data on reimbursements of outpatient systemic antibiotics from the computerized

databases of the two main National Health Insurance agencies. Influenza-like syndromes data came from the French GPs Sentinelles Network. Weekly time-series of antibiotic consumption were modeled by autoregressive moving-average models with exogenous inputs and interventions. Analyses were computed for the entire series and by age group (0-5, 6-15, 16-60, and >60 years). Results: Media coverage was intense between April 2009 and January 2010. No effect on total outpatient antibiotic consumption was observed during the whole mediatic period. However, during the epidemic in France (September 2009-January 2010), we found an antibiotic underconsumption for the entire series, 0-5 and >60 years. Additionally, at the beginning of the pandemic, when cases were still outside France (June 2009-August 2009), we found an antibiotic overconsumption for patients >16 years. Conclusion: The early period of A(H1N1) virus circulation compared with seasonal influenza or an overdeclaration of ILS cases might explain the antibiotic underconsumption observed during the period of active A(H1N1) virus transmission in France. At the pandemic onset, when uncertainty was high, the overconsumption observed for individuals >16 years might have been caused by alarmist media reporting. Additional analyses are needed to understand the determinants of antibiotic consumption during this period.

IS - var.pagings

N2 - Introduction Sickle Cell Disease (SCD) is one of the most prevalent genetic diseases with an incidence of ~1 in 200 Afro-Caribbean children in the UK (WHO; 2006). Since SCD can result in significant respiratory morbidity,[1] lung function tests (LFTs) could play an important role in the clinical management of children with SCD. Aim To determine the extent to which LFTs identify differences in children with SCD when compared with healthy Black children. Methods A respiratory health questionnaire was administered, and four commercially available LFTs (Impulse oscillometry (IOS), specific effective airways resistance (sReff), plethysmographic lung volumes, and spirometry) were undertaken in up to 214 healthy Black children and 85 children with SCD aged 4-12y. Results Amongst children with SCD, 50% reported cough on most days, and 25% had been reviewed by a specialist respiratory consultant within 3 months prior to the assessments. When compared with healthy children, 20% had a reduced total lung capacity (TLC), with concurrent reductions in FEV1 and FVC No differences in sReff were observed and IOS outcomes proved to be of limited value, due to poorly defined limits of normality and large between-subject variability. No significant group differences in bronchodilator responsiveness in SCD or healthy children were observed regardless of the outcome measured (Table 1). Conclusion Despite the high proportion of respiratory symptoms reported, the number of children with LFTs falling outside the limits of normal was relatively small. Results suggest a pattern of restrictive lung disease in children with SCD. Of the outcomes assessed, baseline spirometry appears to be the most useful for routine assessment of lung disease in young children with SCD. (Table presented)

N2 - Students generally spend their time in their nearby environment. This environment consists playing areas in school grounds and playgrounds on their way to school. By considering this hypothesis, the aim of the study is to determine whether school grounds and neighbourhood playgrounds on their accessible routes in three different parts of Aydi{dotless}n which are characterized by different patterns of environmental development meet students' needs. Observation and questionnaire forms are used to determine the interaction between environment-student-playing areas and the study is conducted in nine schools and thirty-one playgrounds in their proximity. The results indicated that the interactions of students with the near environment, school grounds and neighbourhood playgrounds can partially meet the needs of children, but address different age groups. School grounds are designed for older children, but playgrounds for younger children. In distorted settlements among the studied areas, playgrounds were limited in their usefulness for group games, while schoolyards were suitable for these games. Because of this situation, 81.1% of the 12-15 age group and all of the 16-18 age group preferred schoolyards. The relationship between school and play was relatively ignored for older age groups, while for younger groups this relationship was taken into account at a rate of 87.2% in all the settlements. It was consequently found that schoolyards and playgrounds do not show differences in their quality and in meeting children's needs for the three settlements studied. Students preferred games related to school. The results show that environmental quality of playing areas should be developed to meet the expectations of different ages of students

N2 - Background: Passive smoke exposure is an important public health problem which has causal relationship between pneumonia, bronchiolitis, broncopneumonia, asthma exacerbation and development, otitis media, tooth decay and growth retardation in children. In this study we aimed evaluate the effects of passive smoke exposure on children's health by urinary cotinine levels with objective parameters. Method: A total number of 80 children whose family reported at least one active smoker in the house and 80 control subjects with no active smoker who admitted to Ankara Training and Research Hospital, Children's Outpatient Clinic were enrolled to study. Parents of children were administered a questionnaire involving sociodemographic characteristics of children and families, smoking habits and diseases within a year. First morning urine was collected to assess passive smoking exposure of children objectively and cotinine level which is the main metabolite of nicotine in the urine was measured by the method of solid-phase competitive immunoassay kemoluminesans with Nicotine Metabolite Immulite 2000 Analyzer (PIL2KNM-10) (DPC, USA) device. The 'cut-off' value of cotinine was recognized as 10 ng/ml for the diagnosis of passive smoking. Subjects with cotinine levels above this value were considered as 'are exposed to passive cigarette smoke'. Result: The number of the disease and frequency of wheezing within the last year was found to be increased in the passive smoking exposure group. Children whose mothers smoked during pregnancy, had a significantly increased incidence of prematurity and wheezing ($P < 0.05$). The median cotinine level was 10 ng/ml in the nonpassive smoking exposure group while, in the exposure group was 20.8 ng/ml, respectively ($P < 0.01$). The cotinine level was over threshold value, 10 ng/ml, in 68.7% of patients in the passive smoking exposure group and 25% of the control group. Conclusion: Twenty-five percent of children who have not active cigarette smokers in their home was shown to be passive exposed smokers. This finding shows families with sick children are biased for reporting the frequency of active smoking and children are exposed to cigarette in places outside the home

N2 - Background: Vitamin D has also been inconsistently associated with atopic diseases, although large-scale prospective and randomised studies are lacking. Among the existing studies were giving the supplements of vitamin D. And, there is no research on these outdoor activities (forest). The role of vitamin D in atopic dermatitis is uncertain. We have analysed the association between serum 25(OH)-D3 levels in atopic dermatitis children. Method: A total of 35 children were enrolled for this study, being referred from local health centers in Republic of Korea, from April to October 2009. They were conveniently assigned to either 'forest group' participating in the forest therapy program or control group. Measurements of salivary cortisol level and QoL were done at initial visits and at 8-week final visits. And also the serum samples were collected and check for 25(OH)-D3 levels. From the blood samples we measured eosinophil counts, total IgE, specific IgE of D. pteronyssinus, D. farinae, Milk, Egg, Cat, Dog, and Cockroach. (Pharmacia & Upjohn Uni-CAP FEIA system) Result: Both groups did not differ significantly in baseline clinical characteristics. The salivary cortisol level change at week 4 and week 8 did not differ between the two groups. But SCORAD index reduction was

significantly and QoL measures slightly improved in the forest group at week 8 compared with the control group. The mean 25(OH)2-D3 levels significantly increased after the outdoor activities, the level were 25.82i3/44.81 and 49.90i3/419.77 pg/ml (P = 0.000). Conclusion: The forest therapy program did not induce salivary cortisol level reduction. However, considering the significant decrease in SCORAD index and improvement in vitamin D level, this may be a useful model of atopic dermatitis management program

N2 - In Chile, in 1985 rabies was detected in insectivorous bats. Since then the epidemiological surveillance activities was extended to these species and the epidemiological pattern was characterized as endemic in bats. In this study we analyzed positive rabies cases in the Metropolitan Region between 2000 and 2009. We identified 325 cases of rabies in 11.472 analyzed samples. We determined an increase of positivity cases in bats between the years of the study. Places with the highest number of positives cases were Las Condes, Santiago, Providencia, Puente Alto and Nunoa. In 147 cases we identify the circumstances in which the bat was found: 89 inside, 45 outside the building and 13 in public spaces. In 39 cases there was contact with humans or animals. These results reinforce the relevance of educating the population against the contact with bats and allow health authorities to take early surveillance and control measures

N2 - This paper examines the potential for community conversations to strengthen positive responses to HIV in resource-poor environments. Community conversations are an intervention method through which local people work with a facilitator to collectively identify local strengths and challenges and brainstorm potential strategies for solving local problems. We conducted 18 community conversations (with six groups at three points in time) with a total of 77 participants in rural Zimbabwe (20% HIV positive). Participants were invited to reflect on how they were responding to the challenges of HIV, both as individuals and in community groups, and to think of ways to better support openness about HIV, kindness towards people living with HIV and greater community uptake of HIV prevention and treatment. Community conversations contributed to local HIV competence through (1) enabling participants to brainstorm concrete action plans for responding to HIV, (2) providing a forum to develop a sense of common purpose in relation to implementing these, (3) encouraging and challenging participants to overcome fear, denial and passivity, (4) providing an opportunity for participants to move from seeing themselves as passive recipients of information to active problem solvers, and (5) reducing silence and stigma surrounding HIV. Our discussion cautions that community conversations, while holding great potential to help communities recognize their potential strengths and capacities for responding more effectively to HIV, are not a magic bullet. Poverty, poor harvests and political instability frustrated and limited many participants' efforts to put their plans into action. On the other hand, support from outside the community, in this case the increasing availability of antiretroviral treatment, played a vital role in enabling communities to challenge stigma and envision new, more positive, ways of responding to the epidemic

N2 - The nature of young children's communicative environment has been central to theoretical debates about the importance of innate and environmental factors in the development of communication and language. In this paper, we explore aspects of the communicative development and environment of young children growing up in two very different cultures, one in a village of eastern Nepal and the other in a rural area of Western Germany. We analysed longitudinal video recordings of 6 children from each culture in naturalistic settings, at age-matched time points over a period of 8 months. Four children were 8 months old at the outset of the study, 4 were 2 years and 2 months old, and 4 were 3 years old. There were major differences between cultures in the number of adults and children present during the recordings, with other children playing an increasingly important role for the older children in the Nepal recordings. We found no difference between cultures in the onset of pointing and imitation or of reaching, requesting and offering, indicating that these behaviours may be part of a human-specific timetable for socio-cognitive development. We also found that imitation by both the target children and those around them was strictly limited to the youngest group in both cultures. This suggests that imitation may be very important for early development in the prelinguistic phase, while around the age of 2, with the child's developing competence, other ways of interacting take over. The theoretical implications of our results are discussed with reference to the roles of child-intrinsic and environmental factors in the developmental process. Copyright 2013 S. Karger AG, Basel

N2 - Objective: The purpose of this study was to determine whether carbidopa (Lodosyn), an inhibitor of dopa-decarboxylase that blocks the synthesis of dopamine outside the brain, is an effective antiemetic in patients with familial dysautonomia (FD) and hyperdopaminergic nausea/retching/vomiting attacks. Methods: We enrolled 12 patients with FD in an open-label titration and treatment study to assess the safety of carbidopa. We then conducted a randomized, double-blind, placebo-controlled, crossover study to evaluate its antiemetic efficacy. Results: Previous fundoplication surgery in each patient studied prevented vomiting, but all of the subjects experienced severe cyclical nausea and uncontrollable retching that was refractory to standard treatments. Carbidopa at an average daily dose of 480 mg (range 325-600 mg/day) was well tolerated. In the double-blind phase, patients experienced significantly less nausea and retching while on carbidopa than on placebo ($p < 0.03$ and $p < 0.02$, respectively). Twenty-four-hour urinary dopamine excretion was significantly lower while on carbidopa (147 ± 32 mg/gCr) than while on placebo (222 ± 41 mg/gCr, $p < 0.05$). Conclusions: Carbidopa is a safe and effective antiemetic in patients with FD, likely by reducing the formation of dopamine outside the brain. Classification of evidence: This study provides Class II evidence that carbidopa is effective in reducing nausea/retching/ vomiting in patients with FD. 2013 American Academy of Neurology

N2 - Introduction: This literature review examines the link between outdoor activities and children healthy development and well-being. So far, only a few studies have directly examined the influence of children's outdoor activities, physical exercise and motor development. State of the art: Children are more and more growing up disconnected from nature and the outdoors; this is a worldwide phenomenon, occurring in industrialized nations in every setting and in all urban environments throughout the world. As we face contemporary health challenges, such as a growth in level of obesity and stress there is an emerging research and policy interest in the health and wellbeing outcomes associated with use of outdoor spaces. Theoretical and practical implication: To summarize the body of research there is evidence to suggest that outdoor activities are beneficial for health. Time spent in outdoor settings, for example, is associated with adequate blood pressure and cholesterol levels; prevention of depression; it is also effective in tackling obesity, preventing osteoporosis; better motor development (strength, balance and coordination); development of children's understanding of risk; increase social interaction; better levels of cognitive functioning and developing creative play activities.

Conclusions: This literature review shows that there is general agreement about a positive relationship between outdoor activity and health, in particular there is a link between use of the outdoors and increased physical activity levels bringing also physiological benefits. Encouraging use of the outdoors for positive health benefits requires an understanding of the myriad of influences on children's and of the role of society for policy and interventions

IS - var.pagings

N2 - Introduction: Childhood obesity (OB) has tripled in adolescents in the past 30 years. Obese youth are more likely to have risk factors for cardiovascular disease, diabetes, bone and joint problems, sleep apnoea and psychological problems. Objectives: To determine the prevalence of overweight (OW), OB and hypertension (HT) in an adolescent school population and to correlate with eating habits (EH) and physical activity (PA). Methods: Analytical cross-sectional study with students from the 5th and 7th grades of 5 schools of 2 different cities based on surveys about EH and PA, determination of Body Mass Index (BMI) and blood pressure (BP). Statistics: SPSS 18 ($p < 0.05$). Results: The study included 501 students, aged from 10 to 17 (median 12 years), 51% males and 60% from the 7th grade, 16% were OW and 12% obese. BP was measured in 492 students, 23% had HT, 18% of those being OW and 22% OB. There was a statistical significant relationship between BMI and BP ($p = 0.004$). Regarding EH: 56% had less than 5 meals/day, 47% had multiple snacks between meals, 5% didn't take breakfast every day, 52% didn't eat soup for lunch and dinner, 91% ate fish less than 5 times/week, 7% always ate sauces at meals, 6% never ate vegetables, 48% ate fried food more than 1 time/week and 21% ingested fast food regularly. Regarding PA: 13% spent more than 2 hours/day watched TV and played video games during school time and 48% during holidays; 32% didn't practice sports outside school. Conclusions: This study showed a high percentage of children with OW/OB and HT, similar to literature values for the Portuguese population. Incorrect EH and PA are present in most cases even in those with normal BMI, which reinforces the need for educational intervention in childhood and adolescent school population

N2 - Few studies have examined risk factors for bites by the family dog to persons living in the same home. This veterinary clinic-based retrospective cohort study was aimed at identifying canine environmental risk factors for bites by the family dog to children aged five to fifteen years and living in the same home as the dog. Data were collected by interviewer-administered questionnaire from veterinary clients in the waiting room of clinics in Kingston, Jamaica (236) and San Francisco, USA (61). Exposures of interest were factors relevant to the dog's living environment. Dog bites, in the two-year study period, included those occurring both while the children were (20) and were not playing (9) with the dog and exposure information pertained to the period preceding the dog bite incident. Data were analyzed using binomial regression in SPSS version 20, with confounders selected using directed acyclic graphs and the change-in-estimate procedure. No heterogeneity by city of origin was found and thus data from both cities were pooled for final analyses. Dogs living in homes having no outside yard space (4%) were at higher risk (RR = 3.0; 95% CI: 0.9-9.8) for biting than dogs living in homes that had. Additionally, dogs that were allowed inside (64%) the home (RR = 3.0; 95% CI: 1.0-8.6) and dogs routinely allowed to sleep in the bedroom (23%) of a family member (RR = 3.9; 95% CI: 2.0- 7.9) were also at higher risk for biting than those that were not. Finally, dogs that could leave the premises unaccompanied (16%) were at higher risk (RR = 2.8; 95% CI: 1.4-5.7) for biting than those that could not. While a study with a larger sample size is necessary to detect possible heterogeneity by city, these elevated RRs generally suggest

that family dogs living in closer physical proximity to members of the family may be at elevated risk for biting children living in the same home

N2 - Brain-computer interface devices have recently been developed that record electroencephalogram (EEG) activity using a single dry-sensor electrode, and provide data comparable to that obtained from multi-channel EEG systems at the F3 electrode location. Our lab has previously shown that structured saccadic eye movement tasks probe executive functions and are a sensitive measure of cognitive dysfunction in children with Fetal Alcohol Spectrum Disorder (FASD). Our goals are to: 1) quantify the changes in frontal lobe EEG activity that result from manipulating cognitive load during the performance of eye movement tasks; and 2) determine whether differences in frontal lobe EEG activity correlate to deficits in the performance of eye movement tasks in children with FASD compared with typically developing children. Children aged 8-18 with (clinical group) or without

(control group) an FASD diagnosis performed a memory-guided saccadic eye movement task with one, two or three target stimuli, and EEG was recorded at the FP1 position using the NeuroskyMindwave. In the two or three stimuli conditions, children with an FASD made errors in remembering the sequence of target presentation more frequently than control children (two-way ANOVA, $p < 0.05$). When children made sequence or timing errors during trials in which they were required to remember the location of three stimuli, the FASD group exhibited more relative theta band (3-8 Hz) activity in the frontal lobes compared to the control group. Baseline relative theta activity was also different between the two groups (two-way ANCOVA, $p < 0.05$). Children with FASD exhibit performance deficits in saccadic eye movement tasks that probe executive functions (e.g., spatial working memory, response inhibition) involving frontal lobe circuitry. The results of this study suggest that single-channel EEG recording can be used to help identify underlying neural mechanisms of these deficits. For example, previous studies in the literature have shown that greater relative theta activity is correlated to memory impairment. Additionally, portable single-channel devices offer greater user comfort than typical EEG recording equipment as well as flexibility for use outside the laboratory. This will greatly facilitate the study of children with FASD, who may be less tolerant of typical laboratory environments

N2 - Introduction: Rapid response teams (RRTs) have become standard in American pediatric hospitals, but there is little guidance about their optimal structure and function. Hypothesis: We gathered data characterizing the standard of care across the country to identify factors that correlate with a reduced arrest rate. We hypothesized that an increased RRT dose (# RRTs/# hospital beds) and larger hospital size would correlate with a lower arrest rate. Methods: 62 question telephone survey, including a description of arrest and rapid response team composition and function, and number of events for 2011. Results: We collected data from 30 top American pediatric hospitals, all of which provide ECMO support, have a PICU fellowship, and 24 hour RRTs. A PICU doctor is part of 93% of arrest teams and 73% of RRTs. Of the 17 hospitals with only 1 PICU doctor (fellow or attending) in house overnight, 59% have the single PICU doctor on the RRT. 77% of institutions receive no additional staffing or financial support to run the RRT. 77% of responders have a family activated RRT program, but only 60% report having any family activated calls in 2011. 90% of institutions list "Respiratory" as the reason for most RRT calls. 55% of RRT calls result in a patient transfer to the PICU. The definition for "code event" varies drastically between hospitals, including hospitals belonging to the Children's Health Corporation of America, which has provided a standard definition for codes outside the ICU. Only 60% of responders thought the presence of RRTs had decreased the number of non-ICU chest compressions or emergent intubations. For the 27 hospitals who tracked this data, the median number of RRT calls in 2011 was 130 (range 11 to 664). We found no correlation between RRT dose and arrest rate ($r = 0.04$). We found a weak correlation showing a decreased arrest rate in the hospitals with more total beds ($r = 0.3$). Conclusions: This study demonstrates the wide variability in RRT practice in American pediatric hospitals. Although larger hospitals show a weak correlation with lower arrest rates, RRT variability makes it difficult to identify which RRT characteristics are most important in realizing the ultimate goal of preventing floor arrests

N2 - Background: The ¹⁸F-fluorodeoxyglucose (¹⁸F-FDG)-detected brown adipose tissue (BAT), is enhanced by cold stimulus and modulated by other factors that still have to be disentangled. We investigated the prevalence, mass, and glucose-uptake activity of ¹⁸F-FDG-detected BAT in a population of adults living in the temperate climatic zone of the Rome area. Methods and Findings: We retrospectively analyzed 6454 patients who underwent ¹⁸F-FDG positron emission tomography/computed tomography (PET/CT) examinations. We found ¹⁸F-FDG BAT in 217 of the 6454 patients (3.36%). Some of them underwent more than one scan and the positive scans were 278 among 8004 (3.47%). The prevalence of patients with at least one positive scan was lower in men (1.77%; 56 of 3161) compared with women (4.88%; 161 of 3293). The BAT positive patients were most frequently younger, thinner and with lower plasma glucose levels compared with BAT negative patients. The amount of BAT in the defined region of interest, the activity of BAT and the number of positive sites of active BAT were similar in both sexes. The prevalence of patients with ¹⁸F-FDG positive PET/CT was highest in December-February, lower in March-May and September-November, and lowest in June-August and was positively correlated with night length and negatively correlated with ambient temperature. Changes in day length and variations of temperature, associated with the prevalence of positive BAT patients. Among the patients who had multiple scans, outdoor temperature was significantly lower and day length was shorter on the occasion when BAT was detected. Conclusions: This study identifies day length, outdoor temperature, age, sex, BMI, and plasma glucose levels as major determinants of the prevalence, mass, and activity of ¹⁸F-FDG-detected BAT. 2013 Persichetti et al

N2 - Introduction: Most parents think that taking their children to a playground is a safe activity on a hot summer day. The newer equipment and surfaces are marketed as being made of 'safe' materials to help prevent injuries from falls and hidden objects that might be found in gravel or sand. Parents seldom think of burn injuries when they take their children to the park, especially parks with water features and sprinklers. A child can become injured in a matter of seconds when a surface heats up to 140 degrees. With temperatures reaching record highs this year, and with a lack of rain, these safe materials and structures can hold hidden dangers for children. Methods: During June, July and August a study was conducted to determine the surface temperature of various playground equipment and surfaces. Using an infrared laser thermometer, serial temperatures were taken of playground equipment and surrounding surfaces in a Midwest neighborhood playground. Air temperature, humidity and general weather conditions were also documented. Surfaces scanned included rubber mats under equipment, sand, wood mulch, benches, slides, swings and various climbing equipment both plastic and metal. Results: The most significant readings were taken at 3pm when the temperature was 97 degrees with sunny skies. Of 12 surfaces scanned, only 2 were under 120 degrees. The hottest was a dark rubber safety mat (175), light mat (160), baby swing (126), H₂O fountain (131), metal climbing gym (131), and bark mulch (136).

A bench made of composite material registered 133 degrees. The concrete walkways were 132 degrees and the concrete in the water play area was 104. The other 'safe' play area was the sand play area which had some shade. On another day at 6pm with the temperature at 82 degrees and overcast skies, the rubber mats were each 142 degrees. On all visits to the park there were many families with young children, mostly without shoes. One toddler walked onto the dark rubber mat as I was scanning at 175 degrees and started screaming. I told his mother to place him in the water and warned the families about the high surface temperatures. Conclusions: Parents need to be made aware of the hidden dangers of thermal injuries from playground equipment and surfaces. They also need to check the equipment and surfaces themselves, and make sure their children wear shoes when not in the water play areas. The goal of this project was to have data to show the local park commissions the need for proper warning signs related to park safety issues and potential burn injuries, especially when temperatures make the playground equipment unsafe for children

N2 - Background: Of the 90,000 exposures involving children younger than 6 years of age reported to German poison centers (PCs) every year a fifth are caused by plants. A list of especially poisonous plants, which should not be planted in children's playgrounds, was published in the "Bundesanzeiger" (Federal Gazette) in 2000. The BfR-Committee "Assessment of Intoxications" founded a working group to re-assess the toxicity of plants to protect especially children from severe plant poisoning. Methods: The members of the working group defined criteria for risk assessment of plants in the close proximity of children's playgrounds. Human exposure data, provided by the German PCs in Berlin, Freiburg and Erfurt and by the Swiss PC Zurich were reviewed as well as scientific publications about human exposures and about toxicity of ingredients of plants. Following the assessment of the toxicity of chemicals in analogy to the German Regulations on Dangerous Substances, poisonous plants were re-classified into three categories, namely plants which could lead to minor poisoning, moderate poisoning and severe or deadly poisoning. Results: Out of 43,000 confirmed accidental plant exposures from PCs in Freiburg and Berlin moderate or severe poisoning was experienced in 1.3% restricted to 39 plants. Altogether, 280 plants were re-evaluated. Risk assessment changed for some of the especially poisonous plants of the 2000 list. For example the formerly moderate poisonous plants *Lantana camara*, *Ilex spec.*, and *Euonymus spec.* were re-assessed as minor poisonous, and the formerly minor toxic *Chelidonium majus* was re-assessed as moderately toxic for the eyes. Conclusion: Human data about the risk of health damage after accidental ingestion of small amounts or by accidental dermal or ocular contact are mainly restricted to published case reports. The toxicity of ingredients and of preparations of plants for medical or psychoactive purposes may be completely different. The exposure data of PCs are very useful for risk assessment of plants present in the close proximity of children's playgrounds, kindergartens, etc. The re-assessment and the final table of especially poisonous plants will be published again in the "Bundesanzeiger" SN - 1556-3650

N2 - Objective: The purpose of the present study was to assess children's physical activity, social play behaviour, activity type and social interactions during elementary school recess using a pre-validated systematic observation system. Design: Cross-sectional. Setting: Two elementary schools located in Merseyside, England. Method: Fifty-six elementary school children (27 boys, 29 girls) were systematically observed during recess over a three-month period using a standardized physical activity observation instrument. Results: The results revealed the boys were engaged in significantly higher levels of physical activity during recess than girls. The boys were also involved in more sport-specific activities and participated in larger group sizes. Positive associations between physical activity and availability of equipment during recess were also reported. Conclusion: This study has confirmed recess as a valuable opportunity for elementary school children to increase their levels of physical activity. However, further studies with larger sample sizes need to identify and explore the relationship between physical activity (PA) and availability of equipment. The Author(s) 2012

N2 - Similar to myriad health conditions, sleep disturbances evidence a socioeconomic gradient. Poorer sleep (latency, efficiency, awakenings) is more prevalent among adults with lower household income, less educational attainment, and unemployment. Individuals of lower socioeconomic status (SES) often live in neighborhoods with more crime, violence, and crowding. Yet, neighborhood disorder does not affect all people equally. In adults, perceived neighborhood safety is protective against the effect of neighborhood disorder on sleep. The present aim was to evaluate whether children's perceived neighborhood safety moderated the association between neighborhood disorder and sleep. Children (N=91, M=10.8yrs) and their parents participated in the Healthy Heart Project. The Canadian Census and Montreal Crime Index were used to derive neighborhood data. SES was measured for family (parent education, household income) and neighborhood (unemployment, poverty, median income, high school degree or less; by census tract). Neighborhood Disorder was measured objectively (violent incidents, total offenses, mobility status, population, persons per household). Neighborhood Safety was based on children's perceptions of safety playing outside or walking alone after dark, as well as neighborhood cleanliness and dangerousness (litter, drinking in public, burglary). Children's sleep was based on self-reported sleep quality and Pediatric Daytime Sleepiness Scale, as well as parent-reported sleep duration and Children Sleep Habits Questionnaire. Regression analyses using latent factors indicated greater perceived neighborhood safety moderated the effect of neighborhood disorder on sleep, even after controlling for age, sex, family SES, and neighborhood SES (interaction: Fisher's Z = .33, $p < .05$). Thus, children's perceived neighborhood safety buffered the association between neighbourhood disorder and sleep, suggesting perceived safety is protective and contributes to resiliency. Future research should examine objective sleep measures. These findings have potential public policy implications for housing and the concentration of disorder and poverty, which contribute to perceived safety and adversely impact children's sleep

N2 - Intensive malaria control interventions in Zanzibar, including indoor residual spraying, long-lasting insecticidal nets and artemisinin -based combination therapy have resulted in malaria pre elimination phase (prevalence below 1% in 2011). However, a number of transmission foci have been identified after implementation of a clinic-based passive surveillance system to gather weekly malaria notifications. In 2011 Zanzibar introduced a proactive case detection (pACD) effort to screen the population in transmission foci with the aim to find and treat asymptomatic malaria cases and reduce transmission by decreasing the parasite prevalence in the population. Two small geographic areas were selected, Area-1 with high seasonal transmission (64 km²) and Area-2 with sustained perennial transmission (28 km²). In Area-1 the entire population was tested using a HRP2-based rapid diagnostic test (RDT) and assessed for current fever. In Area-2 all children <15 yrs were tested using the same procedures. Screening posts were positioned within the targeted villages over a 3-day period in mid-May 2011, just prior to the predicted increase in seasonal transmission. Confirmed malaria cases were treated with artesunate-amodiaquine according to national guidelines. A total of 6,276 (83%) of the targeted population was screened (83.4% in Area-1 and 83.3% in Area-2). Screening in Area-1 and -2 yielded 13 and 64 RDT-positive cases, respectively, with a positivity rate of 0.1% among residents <5 years of age in both

areas. Residents older than five years had a positivity rate of 0.4% and 1.9% in Area-1 and -2, respectively. Variation in village-level positivity rates was detected (0.2-0.6% Area-1 and 1.0-2.7% Area-2). Data regarding clinical symptoms are being analyzed. A second screening session is planned in the first week of June 2011. The community participation in Zanzibar's first pACD effort was high and yielded 77 malaria cases outside of a clinic setting. Malaria cases with potential to perpetuate transmission were identified and treated successfully. Effects of the first and second screening activity on reducing malaria incidence in these communities will be carefully monitored through the existing weekly surveillance system

N2 - The effectiveness of household water treatment (HWT) devices against diarrheal disease is often measured with intervention trials. It can be difficult to generalize these results outside the study population, and compliance with HWT is often incomplete. We constructed a quantitative microbial risk assessment (QMRA) model to address these issues. The QMRA model simulates a placebo-controlled trial (Boisson et al. 2010, PLoS One 5(9):e12613) of an HWT filter, and accounts for bias due to: A) incomplete compliance with filtration, and B) unexpected antimicrobial activity by the placebo filter. The QMRA model simulates a chain of events in children < 5 years over 12 months with a time unit of 1 day: 1) determine concentrations of 3 marker pathogens (diarrheagenic E. coli, Giardia, and rotavirus) in drinking water; 2) calculate daily doses of pathogens, using pathogen concentrations and water consumption; 3) convert doses to probabilities of infection, using a different dose response function for each pathogen; 4) assign infection to individuals, using probabilities of infection; 5) assign disease, using morbidity ratios. After calibrating the QMRA model to the results of the published trial, the model was used to estimate device effectiveness under different compliance scenarios. Four levels of compliance were considered: low, 65% of children treating 33% of their water; medium, 65% of children treating 67% of their water; high, 65% of children treating 100% of their water; and perfect, 100% of children treating 100% of their water. Compliance was a major driver of effectiveness. Assuming a perfect placebo and low, medium, high, or perfect compliance, the median preventable fraction of reported disease was 14%, 30%, 50%, and 87%, respectively. Adjustment for the imperfect placebo increased the median preventable fraction of disease by 8 percentage points assuming low compliance, but by 22 percentage points assuming medium compliance. The precise level of compliance can greatly affect measurements of HWT effectiveness; such trials should carefully measure compliance

N2 - Indigenous peoples internationally have poorer health status than non-indigenous populations. In the Peruvian Amazon, remote indigenous populations face dual challenges of isolation from health services and increasing exposure to rapid social and environmental change caused by recent expansion of resource extraction activities in their territories. This research uses interdisciplinary methods to explore social and environmental determinants of health for children aged <5yrs in a case study of indigenous Achuar communities in the Corrientes river basin. Malaria and diarrhoeal diseases are endemic in the region. The communities' living, fishing and hunting territories straddle two internationally run oil concessions and oil extraction activities contribute to community members' daily environments. Indigenous Amazonian populations have distinct health belief systems based on their relationship with their physical and social environment. Aiming to respect and learn from local conceptualisation of health and illness, this research addresses determinants of young children's health from multiple perspectives. Firstly, qualitative methods were used to explore community members' (n=30) and local stakeholders' (n=30) perspectives of factors influencing young children's health. Secondly, quantitative social epidemiological methods were used to characterise structural (e.g. ethnicity) and proximal (e.g. material circumstances) determinants of health based on the framework proposed by the WHO Commission on Social Determinants of Health (n=138 children aged <5 yrs in 97 households). Qualitative results found that respondents across groups identified food - access to sufficient and appropriate kinds of food - as a key child health determinant. 96% of households receive donated food. Also highlighted were; the biological and spiritual importance of the river, protection from mosquitoes, and access to economic resources. Quantitative analysis compared socio-economic and biomedical child health indicators in the case study setting with other indigenous and non-indigenous poor rural Peruvian communities outside oil extraction zones. Research findings have implications for policy development to protect children's health in indigenous communities increasingly exposed to large scale extraction activities across the Peruvian Amazon

N2 - Mycobacterium ulcerans is the etiological agent causing the neglected tropical disease, Buruli ulcer. This disease is endemic to sub-Saharan Africa and Australia, with case reports primarily occurring in children. Clinically, the disease initially presents as a painless nodule, which deteriorates radially to a necrotic ulcer with characteristic undermined edges. There is a pronounced lack of inflammatory response at the site of ulcers, with only anecdotal mention of secondary infection in the literature. The macrolide toxin produced by *M. ulcerans*, mycolactone, is accepted as the sole virulence factor and has been shown to cause apoptosis and necrosis in vivo, as well as possess immunomodulatory properties. We hypothesized that the notable lack of secondary infection may also be a phenomenon mediated by mycolactone. Results in our laboratory have shown that exposure to mycolactone arrests the growth of specific bacterial strains, including *S. aureus* and *S. epidermidis*. Interestingly, there are no reports of clinically isolated mycolactone-deficient bacteria, and the common consensus is that selection pressure must be present to maintain the otherwise genetically unstable megaplasmid that encodes enzymes for mycolactone synthesis. Our results demonstrate an example of this selection. We have found that recovery of pMUM001 plasmid could be achieved simply by inclusion of lysates from arrested cell types. Given this data, we speculate that mycolactone is an "accidental toxin" whose intended function is to provide *M. ulcerans* a competitive advantage in its natural environment

N2 - Eastern equine encephalitis virus (EEEV;Togaviridae:Alphavirus) is a highly pathogenic mosquito-borne virus that produces severe or fatal encephalitis in 30-50% of infected humans and horses. Recently, EEEV has undergone a regime shift in dynamics in the northeastern US and Canada. For three decades (1970-2000) periodic activity was detected in central NY, specifically in counties surrounding Oneida Lake, with 1-2 years of activity in mosquitoes and other hosts, followed by 1-6 years with no detectable activity. However, since 2003, there have been 9 consecutive years with active EEEV transmission, and a significantly higher prevalence of

infection than in previous outbreaks ($p = 0.009$). This string of 9 consecutive years is a highly unlikely event to occur by chance ($p = 0.007$ with 15 of 28 years with EEEV presence). The current epizootic coincides with the arrival of a novel genotype of EEEV, the invasion of WNV to the region, and occurs within the backdrop of long term trends in temperature and declines in key songbird populations. The first human case in 26 years occurred in Oswego County in 2009 in a 70yo male, then again in 2010 in a 77yo male, and in 2011 in a 4yo child. EEEV-infected neurologic deer were found in 2008 and 2009. Serosurveys of hunter killed deer < 2yo also have proven useful in determining the range of EEEV activity with 9 EEEV positive deer out of 179 tested from central NY 2007-2009. In 2011, 46 *Culiseta melanura* pools were found positive (MIR 4.2); the previous 3 year average was 43 (MIR 4.1). Similarly, in 2011, 11 horses died from EEEV, while the previous 3 year average was 7 equines. In addition, two neurologic dogs died in 2011. Phylogenetic analysis of isolates indicates the virus is periodically introduced, most likely by migratory birds, but also overwinters in the central NY focus. However, we identified a genetic change in the virus in 2007, the year preceding the first human cases seen since 1983. In summary, although the level of EEEV activity does not appear to be increasing significantly in the enzootic focus in central NY, it appears to be extending its range and intensity outside this historic focus

N2 - Background: Camp Courage is a non-profit overnight camp for patients with Sickle Cell Disease and their siblings. This camp was started in 1991 and has been held yearly since then. The camp was initially developed by a sickle cell advanced practice nurse (APN). The initial camp involved a small staff of a sickle cell physician, the organizing APN and sickle cell social worker. The camp was initially "sponsored" by Children's Mercy Hospital with involvement of volunteer counselors and group-sponsored activities. The camp has been conducted on six different camp sites and serves children ages 6-14 years with all types of Sickle Cell Disease. Siblings are then offered a spot at camp on a first come, first serve basis depending on space availability. The camp has evolved to include multiple health care disciplines and is currently sponsored by an outside non-profit agency, Turning Point: The Center for Hope and Healing. The most recent camp in July 2011 included 56 campers, 5 physicians, 4 nurses, 2 social workers, 2 child life specialists, 1 psychologist, 1 data coordinator, 16 counselors and 38 volunteers. Physicians and APNs were present 24 hours a day to provide medical care, supervision and disease education. Other disciplines and volunteers provided activity and psychosocial support on a daily basis. Volunteer counselors were present during the entire camp experience including nighttime supervision and support in the campers' cabins. Objective: Camp has long been thought by staff to be a positive experience for patients and families, however formal feedback has never been collected. Our goal is to use the information collected to identify positive aspects of camp and also identify areas for improvement, both recreational and educational. Method: Surveys were distributed via mail to 36 families (this included 36 patients, 20 siblings [32 girls and 24 boys], 36 caregivers) to assess possible benefits and negative experiences of the camp. Results: Preliminary results suggest Camp Courage is a positive experience for patients, siblings and caregivers. We will report a complete analysis and evaluation of the survey data returned at the meeting. Conclusion: The information will help us to identify campers and caregivers' overall perspective of the camp experience

JF - Iranian Journal of Allergy, Asthma and Immunology

VL - Conference: 2nd International Congress of Immunology, Asthma and Allergy Tehran Iran, Islamic Republic of. Conference Start: 20130219 Conference End: 20130221. Conference Publication:

IS - var.pagings

N2 - Asthma is the most common and sometime fatal chronic disease of children and a serious public and global health problem. The prevalence of asthma has increased continuously following changes to a modern urban lifestyle during the past three decades especially among children and adolescents. It has a higher

prevalence in developed nations more among poor populations, and in affluent populations compared to poor populations in developing nations. Increasing asthma prevalence in some developed countries has reached a Plato in past few years and its mortality declined recently due to better medications, guidelines for asthma management and measuring outcomes through electronic medical records systems. The recent meta-analysis of the epidemiological studies done in Iran also showed that the prevalence of pediatric asthma symptoms continues increasing at the national level (Average prevalence of 13.14%) and increasing seriously in Tehran megacity (35.4%) and thus increasing the burden of asthma to individuals and society. Asthma intervention programmes also have led to a remarkable decrease in death rates and hospitalizations in developed, developing and deprived countries. A complex gene-gene and gene by environment interactions including epigenetic mechanisms supposed to be related to the worldwide increasing trend of prevalence and burden of asthma. Atopy, male sex, younger age, obesity, allergen exposure, viral infections, occupational sensitizers, tobacco smoke, indoor/outdoor air pollution, diet, stress, and western lifestyle are the main genetic, environmental, socioeconomic, and susceptibility risk factors for development and expression of asthma. About 25 percent of asthmatic adults in low and middle income countries are active smokers and have more severe asthma symptoms, decline in lung function and reduced response to corticosteroid therapy. Large and crowded cities of most developing countries with a heavy traffic are severely polluted which is another environmental risk factor especially for children and elderly. This asthma epidemic has caused a great burden, not only in terms of health care costs but also of reduced participation in family life, of lost school days and days lost from work. The burden of asthma assessed by disability adjusted life years (DALYs) ranks 22 worldwide, which is similar to diabetes, liver cirrhosis and schizophrenia. The surveillance of asthma as part of a global WHO programme is essential for controlling asthma prevalence and burden. Different international and national guidelines are designed and implemented in past 1-2 decades but current level of asthma control still falls short of published guidelines. The experience of the 10 years Asthma Control Programme of Finland showed considerable reduction in the burden of asthma. In Iran the National Asthma Guideline was published under the supervision of the National Committee on Asthma and Allergy in 2009 to be implemented especially at the primary health care physicians level. the First National Asthma Control Programme of our country is expected to be launched in near future too. The First Asthma Registry Programme too is established in Immunology, Asthma and Allergy Research Institute (IAARI) since 2008. In this article an overview of the challenges and strategies of asthma prevention and control in Iran, developing and developed countries are presented

IS - var.pagings

N2 - Introduction: A majority of preschool-age children spend a significant portion of every weekday in a preschool or child care setting. Studies have shown that children in these settings spend a majority of their time in sedentary behavior and very little time in physical activity. Hypothesis: A multi-component preschool physical activity intervention will increase the amount of time young children spend in moderate-to-vigorous physical activity (MVPA) and decrease the time they spend in sedentary activities, compared to children in control preschools. Methods: The study included 16 preschools with 4-year-old classrooms, paired and randomly assigned to intervention and control groups. The intervention focused on increasing children's physical activity by changing instructional practices and the classroom environment. Research staff trained preschool teachers to engage children in physical activity throughout the school day and provided physical activity materials, ongoing support and technical assistance. Intervention components included physical activity opportunities in the classroom, physical activity outdoors, and active lessons. The intervention was designed to be flexible, and research staff encouraged teachers to adapt it to their classroom environment. Four-year-old children and their parents were recruited in two waves at each school. Measures included child height and weight, child physical activity by accelerometry, and parent questionnaires, measured during the fall and spring of each wave. Mixed model analysis of covariance with preschool as a random variable tested the effects of the intervention on physical activity in the total group and by sex. Results: A total of 379 children (188 intervention and 191 control) were measured at baseline. Children were 4.5+0.4 years of age, and 50% were boys. The intervention schools included a higher percentage of white children compared to the control schools (44.2% versus 39.3%). After adjusting for wave, parent education and length of the school day (half day vs. full day), children in the intervention schools engaged in significantly more MVPA than children in the control schools (7.4+0.2 and 6.7+0.2 minutes/hour, respectively). In the sex-specific analyses, differences between intervention and control were significant for girls (6.9+0.2 vs. 6.1+0.2 minutes/hour of MVPA, respectively) but not for boys (7.8+0.3 vs. 7.3+0.3 minutes/hour, respectively). No differences in time spent in sedentary behavior were observed between intervention and control preschools. Conclusions: In conclusion, a flexible, multi-component physical activity intervention that trains teachers to provide children with opportunities to be active throughout the school day increased MVPA in preschool children

N2 - Outdoor sport is part of leisure time behaviour in the western world which contributes significantly to the annual ultraviolet (UV) exposure. One of the most popular outdoor activities, both in adults and children is tennis. In our field study we measured UV exposure during a training match between two adults and - for the first time - the UV exposure of children playing tennis. The players/parents of the players gave their consent to wear/that their children wear two electronic UV dosimeters (X 2000-10, Gigahertz Optics, Germany; UVA and UVB/C sensor, temperature, 1 min measuring interval), one on the forehead fixed to a shielded headband, the other fixed to the calf by an elastic band with Velcro fastening. We calibrated the dosimeters prior to the field test. The training match between the adult test persons A (43 years) and B (51 years) took place on June 30th from 1:00 to 2:36 PM, the two adolescents C and D, both 17 years of age, played on August 23rd between 1:45 and 14:52 PM on an almost north-south directed tennis court in Vienna. The players were observed by two members of the study team. One of the observers took photos of the players and at 15 min interval standardized photos of the sky. We measured ambient radiation with the help of two dosimeters fixed to a tripod in horizontal position: one dosimeter with the UV sensors directed upward, the second dosimeter with the sensors directed to

the tennis ground in order to measure the reflectance. Sky was absolutely clear on June 30th with an ambient temperature of 35degreeC, whereas on August 26th there was variable cloudiness. The temperature on that day was around 30degreeC. The test persons were asked to behave as usual especially with respect to physical activity and photo protective measures. All our test persons wore similar tennis kits: T-shirt, shorts or short skirt, and tennis socks. All of them applied sunscreens with SPF 30. Three of them used sunglasses. The UV exposures (standard erythema dose = SED) on June 30th were: test person A (head 2.82/calf 2.58), B (head 5.09/calf 1.41) which represent 20.05% to 72.3% of ambient radiation (7.05 SED). The respective values for the training match on August 26th were: test person C (1.54/0.63), test person D (1.98/0.62) which is equivalent to 32% to 100.15% of ambient (1.98 SED). 2.6% of the ambient radiation was reflected from the ground (red sand). The adult tennis players played two sets, our adolescent test persons, however, played only one set. Children are at high risk especially when playing in spring and early in summer when ambient radiation is highest. This should be considered by organizers of tennis tournaments and tennis trainers when scheduling their training lessons

N2 - Background: Pediatric hemodialysis (HD) patients face many psychosocial factors that affect adherence and morbidity. Social interventions could benefit these patients, but very few structured programs currently exist within the hospital system. The PALS program at Stanford University School of Medicine (SUSOM) pairs medical students with chronically ill children to provide social support. We present our PALS experience in the pediatric HD unit. Methods: Five pairs of SUSOM students (Mentors) and Lucile Packard Children's Hospital's outpatient pediatric HD patients (Pals) met weekly or biweekly in the dialysis unit. Activities included: arts and crafts, board games, and homework help. Group field trips facilitated interactions outside of the hospital. Pals and families, Mentors, and HD unit nurses completed surveys regarding their PALS experience. Results: (1) Pals greatly enjoyed doing projects and going on field trips with Mentors. Parents noted a less isolating experience for the child and the family. (2) Medical students valued the opportunity to share the HD experience alongside patients and their families. (3) Nurses felt Mentors supported Pals emotionally and medically, helping patients complete three-hour HD runs with fewer complications. More consistent visits were suggested as a possible improvement to the program. Discussion/ Conclusion: The PALS program achieved its goal of providing support to chronic HD children and families. Important factors in a successful mentoring system include an established program with institutional support, one-to-one matches, longitudinal engagement, and consistent, frequent, and planned interactions

 N2 - The presence of mineral contents, mostly those of calcium (Ca⁺⁺) and magnesium (Mg⁺⁺) decides hardness in water. In Chiba, where our university hospital is located, the hardness in home tap water is 92 mg/L and it is the second highest area in Japan. The mineral ions react with some components of soap to form an insoluble precipitate known as "soap scum". Since soap scum remains tightly on the skin and can not be easily rinsed away, it may become one of causes that exacerbate dermatitis. In this study, we used cation-exchange resin to prepare ultra-pure soft water (UPSW) almost completely removing both Ca⁺⁺ and Mg⁺⁺, and investigated clinical and objective improvement of skin barrier functions in children with atopic dermatitis (AD). Our clinical trial targets 30 child patients of AD from 3 to 6 years old. After installing a UPSW machine (Bihadakko; Miura CO., LTD, Japan) in the bathroom of each home, child patients were randomly assigned to two groups depending on whether they received shower treatment with UPSW or ordinal tap water for 6 weeks. After a washout period of 2 weeks, the treatment protocol was switched each other. The pre- and posttreatment values of the following were compared: the eczema area and severity index dermatitis score (EASI), TEWL and the outside to inside skin transparency of yellow dye (tartrazine) measured by a colorimeter. In addition, serum TARC was measured and itch was evaluated using a VAS. After shower treatment with UPSW for 6 weeks, most child AD patients improved their dry skin and itch in addition to their EASI. TEWL and the outside to inside skin transparency were slightly reduced. Based on our study, the use of UPSW is considered to be beneficial for skin care of children with AD, especially in the area where the hardness in water is high

N2 - Children in the cardiac intensive care unit (CICU) with congenital or acquired heart disease are at risk for hematologic complications, both hemorrhage and thrombosis. The overall incidence of hematologic complications in the CICU is unknown, but risk factors and target groups have been identified where the essential physiologic balance between bleeding and clotting has been disrupted. Although the best management of life-threatening bleeding and clotting is prevention, the cardiac intensivist is often faced with managing life-threatening hematologic events involving patients from within the unit or those who present from outside. Part I of this review deals with the propensity of children with congenital and acquired heart disease to complications of both bleeding and clotting, and includes discussions of perioperative bleeding, thromboses in single-ventricle patients, clotting of Blalock-Taussig shunts and thrombotic complications of mechanical valves. Part II deals with the subject of stroke in children with heart disease. Part III reviews monitoring the effectiveness of

anticoagulation and thrombolysis in the CICU. Currently available diagnostics modalities, medications and management strategies are reviewed and future directions discussed. The Author(s) 2012

N2 - Background: During the summer of 2005, multiple cities in the United States began to report outbreaks of fentanyl-associated fatalities among illicit drug users. The objectives of this study were to (1) determine if an outbreak of fentanyl-associated fatalities occurred in mid-2005 to mid-2006 and (2) to examine trends and compare features of fentanyl-contaminated heroin-associated fatalities (FHF) with non-fentanyl, heroin-associated fatalities (NFHF) among illicit drug users. Methods: Baseline prevalence of fentanyl- and heroin-associated deaths was estimated from January to May 2005 based on recorded cause of death (determined by the medical examiner (ME)) using the Wayne County, MI, USA toxicology database. The database was then queried for both FHF and NFHF between July 1, 2005 and May 12, 2006. A FHF was defined as having fentanyl or norfentanyl (metabolite) detected in any postmortem biological sample and either (1) detection of heroin or its metabolite (6-acetylmorphine) and/or cocaine or its metabolite (benzoylecgonine) in a postmortem biological specimen or (2) confirmation of fentanyl abuse as the cause of death by the ME or a medical history available sufficient enough to exclude prescription fentanyl or other therapeutic opioid use. A NFHF was defined as detection of heroin, 6-acetylmorphine (heroin metabolite) or morphine in any postmortem biological specimen, heroin overdose listed as the cause of death by the ME, and absence of fentanyl detection on postmortem laboratory testing. Information was systematically collected, trended for each group and then compared between the two groups with regard to demographic, exposure, autopsy, and toxicology data. Logistic regression was performed using SAS v 9.1 examining the effects of age, gender, and marital status with fentanyl group status. Results: Monthly prevalence of fentanyl-associated fatalities among illicit drug users increased from an average of two in early 2005 to a peak of 24 in May, 2006. In total, 101 FHF and 90 NFHF were analyzed. The median age of decedents was 46 and 45 years for the fentanyl and non-fentanyl groups, respectively. Fentanyl-contaminated heroin-associated fatalities (FHF) were more likely to be female ($p = 0.003$). Women aged over 44 years ($OR = 4.67; 95\% CI = 1.29-16.96$) and divorced/widowed women ($OR = 14.18; 95\% CI = 1.59-127.01$) were more likely to be FHF when compared to women aged less than 44 years and single, respectively. A significant interaction occurred between gender and age, and gender and marital status. Most FHF had central (heart) blood samples available for fentanyl testing ($n = 96; 95\%$): fentanyl was detected in most ($n = 91; 95\%$). Of these, close to half had no detectable heroin (or 6-acetylmorphine) concentrations ($n = 37; 40.7\%$). About half of these samples had detectable cocaine concentrations ($n = 20; 54\%$). Median fentanyl concentration in central blood samples was $0.02 \mu\text{g/ml}$ ($n = 91$, range $<0.002-0.051 \mu\text{g/ml}$) and $0.02 \mu\text{g/ml}$ ($n = 32$, range $<0.004-0.069 \mu\text{g/ml}$) in peripheral blood samples. The geometric mean of the ratio of central to peripheral values was 2.10 (median C/P = 1.75). At autopsy, pulmonary edema was the most frequently encountered finding for both groups (77%). Conclusion: Illicit drugs may contain undeclared ingredients that may increase the likelihood of fatality in users. Gender differences in fentanyl-related mortality may be modified by age and/or marital status. These findings may help inform public health and prevention activities if fatalities associated with fentanyl-contaminated illicit drugs reoccur. 2013 American College of Medical Toxicology (outside the USA)

N2 - Background/Purpose: Inflammatory arthritis (IA) may limit participation in life roles such as parenting. Surprisingly little research has investigated the impact of IA on parenting tasks and experiences of fathers. This descriptive pilot study adapted a mail survey used in a cross-sectional study of mothers to an online format to (a) examine feasibility of the tool and items for use with men, and (b) assess self-reported performance of parenting tasks, parenting satisfaction, and parenting efficacy in fathers with rheumatoid arthritis (RA), psoriatic arthritis (PsA), or ankylosing spondylitis (AS). Methods: Men with IA were recruited through rheumatologists' offices, arthritis consumer newsletters and web sites, and public education forums on arthritis. Eligibility criteria included a diagnosis of IA confirmed by a rheumatologist and at least one child >18 yrs living with them. Volunteers were sent a web link and password to access the survey. The Parenting Disability Index (PDI) and Parenting Sense of Competency Scale (PSOC) were used to measure parenting outcomes. Surveys also inquired about employment, household work, social support, family quality of life, health status, demographics, and survey feasibility questions. Descriptive statistics were used to assess numeric responses and thematic content analysis used to examine text responses. Results: Twelve men volunteered and 10 submitted complete surveys, and reported taking 15 to 60 minutes to do so. They ranged in age from 38 to 59 years, and had 1 to 5 children ranging in age from 4 months to late 20s. Eight were married, 2 were separated/divorced. Four had RA, 4 had AS, and 2 had PsA, from 1 to 32 years in duration (mean = 17.5). Seven were employed. Health Assessment Questionnaire II scores ranged from 0 to 1.5 (mean = .53, median = .40); the common functional limitation was lifting and moving heavy objects. They reported few limitations in parenting tasks, with PDI scores ranging from .20 to 1.26 (0 to 3 scale), mostly related to having energy to be patient with their child, getting up during the night or early morning, and playing (on the floor or outdoors). PSOC total scores ranged from 2.0 to 2.82 (0 to 6 scale; mean = 2.28, SD = .29), while parenting sense of efficacy subscale ranged from 1.67 to 3.56 (mean = 2.32, SD = .60) and parenting satisfaction subscale ranged from 1.50 to 2.75 (mean = 2.22, SD = .38). Men reported many joys in parenting ("to love and to hold" their children), and several challenges ("communicating the fact I'm in pain in a way that doesn't make my 7 year old worried or overly protective; I also don't want to downplay it"). A key motivator for participating in the survey was "most seminars and clinics are directed at or attended by women, so a men's questionnaire is a must!" Conclusion: The online parenting survey was relevant to the participating men. Although this sample is too small to generalize, findings suggest men with IA experience specific limitations in parenting, but experience great satisfaction with this role. Assessment of parenting task performance may be important to assess in both practice and research settings when selecting outcomes that are meaningful to people living with arthritis

N2 - Purpose of Study: Obesity is endemic in the United States and an increasing problem worldwide. Childhood obesity leads to increased risk for T2DM, hypertension, and cardiovascular disease. It is linked to depression and low self-esteem in children. These issues are a major concern in Ferndale, Washington. The goal of the project was to create an interactive and reproducible nutritional curriculum for after school/summer programs like the Boys & Girls Club. Methods Used: Key social service leaders provided input on the health concerns of Ferndale's diverse community. All interviewees identified obesity, T2DM and hypertension as the major health concerns. The Ferndale Boys & Girls Club director indicated their programs covered physical activity, but lacked healthy nutrition. Through collaboration, an hour and a half nutritional education program focused on 8-10 year olds was developed. The professional literature was reviewed for the best teaching methods indicated for the target population. MyPlate.gov and other websites were activity sources. The curriculum produced included: an interactive educational component, outdoor physical activity reinforcing discussion points, "snack art" with healthy foods, and nutrition computer games. Summary of Results: 15 children attended the activity. All were female. Most recognized the nutrition plate and its components, but had trouble identifying to which category food belonged. The range of activities maintained interest and covered concepts repetitively. "Food art" was a favorite and included a healthy snack, creativity, and category identification. Many children saved both their snack and designed plates. Most were eager to know when this session would recur. Conclusions: Childhood obesity is a widespread problem that leads to devastating long-term health consequences. It will not disappear quickly, and it is important that children are educated in a multitude of ways how to make good choices about what they put in their body. Although children are not meal preparers, evidence shows they play a key role in directing family consumption. Positive feedback was received from participants, Boys & Girls Club administration, and the community. The program is inexpensive and reproducible if the club chooses to continue nutritional education

N2 - Purpose of Study: The Miles City community is largely agriculturally based and has many opportunities for outdoor recreation. Both of these factors result in prolonged sun exposure for community participants. Evidence suggests that ultra-violet radiation from sun exposure during early life is associated with increased risk for various adulthood skin cancers. The project's purpose was to implement a sun safety curriculum that teaches youth how to limit sun exposure and prevent skin damage. Methods Used: Studies suggest optimum health behavior modification occurs where a learning infrastructure already subsists. I partnered with a youth summer enrichment program (ROCKS) to implement an evidencebased curriculum. It encompassed sun safety knowledge and behaviors from current literature including: the sun's benefits and harmful effects, healthy skin functions, components of sun protection, and proper sunscreen use. The program was conducted in a multistep fashion that included interactive learning. The first activity was a sun safe relay that reinforced the effectiveness of wearing sun protective articles. In the second activity, children constructed UV sensitive bead bracelets that enhance exposure awareness to damaging UV rays and promote sunscreen use. Summary of Results: The project conveyed sun safety behaviors to 48 children (grades 1-6). Education material was interactive, succinct, and age appropriate. The attendance level, enthusiastic participation, and positive feedback from the program's staff suggest that the project was well received. Children were able to acknowledge appropriate sun safety methods in a Q&A session post-activity. Access to materials and the curriculum used were given to staff for future use. Conclusions: Agricultural and outdoor recreation based communities like Miles City increase children's risk to sun exposure. Fortunately, community programs like ROCKS take interest in youth health and education. They provided great support and guidance throughout the development of this project. By

introducing an evidence-based curriculum for youth members, it seems reasonable to expect promising results related to sun protective methods and awareness. Further studies should be conducted to see if the project leads to increased sun safety behavior among Miles City youth participants

N2 - Each child is a future of nation, so it is our duty to protect and safeguard that but unfortunately they are not safe in their home, education center, playground and social places. We are living in a scientific era and proud about our progress, new achievements, post and position but we are fail and unable to provide a safe atmosphere to the children. Nineteen percent of the world's children live in India, which constitutes 42% of India's total population. It is shakeable for us 69% of Indian children are victims of physical, emotional and

sexual abuse. Higher rate of abuse is also in Srilanka, Malaysia, China, Germany and Europe. The National Commission for Protection of Child Rights has received 75 cases of child abuse up to October 2011 in Delhi. Any type of abuse gives an unforgettable grief and pain. So we are discussing in the reference of these topics: Child Abuse an Overview: A picture presentation. Biological changes in brain of abused child Impacts of child abuse in late life. Child abuse relation with substance abuse. Child abuse: Psychiatry Aspect Preventive measure of mental health abused children. Child Abuse: Role of mental health professional Legal rights of child abuse

N2 - An 87-year-old female came to the ED for a laceration on her thumb. While waiting, she experienced near syncope and confusion. She was admitted for evaluation. She described anorexia without weight loss, six months of lethargy, fatigue, and pruritis. She was not aware of yellow eyes or dark urine. She had well controlled hypothyroidism, dyslipidemia, hypertension and coronary artery disease. She was a widow who lived alone. She managed her own affairs and mowed her own yard with a riding mower. She was afebrile. Vital signs were normal. Her sclera were icteric and her skin had a yellow hue. She had no enlargement of liver or spleen. There was a flat, 2X3 cm black lesion with irregular borders involving the nail bed and surrounding tissue of the right great toe. Laboratory: Albumin 2.2g/dL (3.4-4.8), total protein 6.9g/dL (6.4-8.3g/dL), total bilirubin 4.4 mg/dL, direct=3.5mg/dL, Alkaline Phosphatase 293 uL (53-148), AST 556 uL (5-34), ALT 319uL (0-55), hemoglobin 9.6gm/dL, white blood count 4.6x10³ and platelets 163x10³. Hepatitis panel was negative. Anti-mitochondrial antibody titer was 1:320 (NL <1:20) Her jaundice proved to be due to Primary Biliary Cirrhosis (PBC). Biopsy of the toe revealed acral lentiginous melanoma. The anemia with abnormal total protein/albumen ratio prompted evaluation with serum immunofixation, which identified a monoclonal spike, which proved to be an IgA multiple myeloma. After collaboration with her doctors and her children, she accepted ursodeoxycholic acid for the PBC, which provided relief of her pruritis. She reluctantly allowed amputation of her toe. She declined therapy for the myeloma though she did agree to follow up, realizing at some point she will need symptom care. This case is intriguing because it addresses a confluence of three simultaneous "interesting" diagnoses that a proud and independent elderly lady had dealt with for many months without complaints or requests for intervention. After diagnosis, she still exercised her independence, accepting therapy based on her assessment of its potential affect on her functional status and her quality of life. At each of her clinic visits, she continues to profess regret at her decision to visit the ED for the laceration, noting with a smile that her health has taken a decidedly downward trend ever since

N2 - Objective: To assess the exposure and popularity of cricket among Trinidadian school boys. Method: A cross-sectional study with stratified random sampling of public secondary schools was done in Trinidad, utilizing a questionnaire to assess exposure and participation in cricket. Data were analysed using SPSS version 16.0. Results: The mean age of 509 school boys from 17 schools was 15.3 years (range 12-19 years, SD 0.8), with ethnicity: East Indian (52%), African (24%), Chinese (2%) and other (22%). Football was the favourite sport of 39% and cricket 29%, compared to 34% and 50% respectively when they were in primary school. Football was favoured 2.3 times more than cricket among Afro-Trinidadians, but equally among Indo-Trinidadians. Since primary school, 130 students discontinued cricket, 45% played football instead and 36% played no sport. Half participated in physical education, down from 88% in primary school. Only 38% participated in cricket at school. This was unrelated to ethnicity ($p = 0.124$). However, 73% played cricket outside of school. Students with access to a cricket pitch ($p = 0.011$) or to protective gear ($p = 0.004$) were more likely to participate in cricket at school. Those who did not participate cited lack of interest (50%) or no time (32%) as the main reasons. Students with cable television (70%) were less likely to watch cricket on television. Twenty-twenty cricket was preferred by 73%. Conclusions: In spite of the high level of exposure to cricket

among school boys in Trinidad, its popularity decreases in secondary school. Lack of facilities and access to cable television decreases participation

IS - var.pagings

N2 - Background: Neuroblastoma is the most common extracranial malignancy of childhood. Myc family proteins regulate cell growth and proliferation in response to mitogenic stimulation, and N-Myc plays a role in the pathogenesis of a subset of highrisk neuroblastoma. In particular, MYCN amplified neuroblastoma is associated with a poor prognosis. Mxi1, a member of the MAD family of transcriptional regulatory proteins, counteracts Myc by repressing transcription of Myc target genes. We hypothesize that Mxi1 antagonizes N-Myc activity in neuroblastoma by inhibiting cell proliferation and viability. Objectives: To determine the impact of modulating Mxi1 expression on N-Mycmediated neuroblastoma cell proliferation and apoptosis.

Design/Method: We constitutively expressed Mxi1 in non-MYCN-amplified SHEP neuroblastoma cells, and also SHEP cells stably transfected to express high levels of MYCN (SHEP/MYCN). We also created neuroblastoma cell lines (Non-MYCN-amplified SH-SY5Y and MYCN-amplified IMR32) that inducibly express Mxi1 upon exposure to doxycycline. Cell proliferation and survival were quantified using BrdU and MTT assays, respectively. Apoptosis was measured by propidium iodide staining and caspase-3, caspase-8 and caspase-9 immunohistochemistry. **Results:** In non-MYCN-amplified SHEP cells, Mxi1 overexpression independently inhibits cell proliferation and induces cell apoptosis. In the context of MYCN overexpression in SHEP/MYCN or IMR32 cells, Mxi1 inhibits N-Myc-dependent cell proliferation and blocks N-Myc-dependent apoptosis. Outside of MYCN expression, Mxi1 induces cell apoptosis via the caspase 8 pathway. In contrast, in SHEP/MYCN or IMR32 cells that undergo N-Myc-dependent apoptosis upon exposure to low serum, the caspase 9 pathway is active. **Conclusion:** Overexpression of Mxi1 in MYCN-expressing neuroblastoma cell lines leads to inhibition of N-Myc-dependent cell proliferation and low serum-induced apoptosis. Furthermore, Mxi1 expression decreases cell proliferation and induction of apoptosis independent of N-Myc. The use of distinct caspase pathways by N-Myc and Mxi1 highlights the complexity of cell death regulation in neuroblastoma. The interaction between Mxi1 and N-Myc in neuroblastoma must be considered in the development of novel targeted therapies to improve outcomes in children with neuroblastoma

N2 - Background: A significant number of children with ALL relapse due to the persistence of chemotherapy-resistant leukemia cells. CXCR4, a cell surface receptor expressed by various leukemias, is activated by the chemokine stromal-derived factor- 1 (SDF-1 or CXCL12), causing migration of leukemia cells to bone marrow niches that may contribute to chemoresistance and relapse. Objectives: We hypothesized that the CXCR4 inhibitor plerixafor would sensitize leukemias to chemotherapy through the interruption of leukemia-stromal cell signaling. Because B-precursor ALL are known to highly express CXCR4, we tested this hypothesis in vitro using ALL cell lines and in vivo using a xenograft model of MLL-rearranged (MLL-r) infant ALL. Design/Method: In vitro, we treated ALL cells with dose ranges of chemotherapy using various culture conditions with or without bone marrow stromal cells to highlight the importance of CXCR4/SDF-1 signaling in chemoresistance. In vivo, we transplanted primary samples of MLL-r ALL into immunodeficient mice and treated cohorts with chemotherapy alone, plerixafor and chemotherapy, or vehicle control. After treatment, we measured leukemic burden and surface CXCR4 (s-CXCR4) expression by organ to determine the effects of our treatment regimen. Results: ALL cells that upregulated s-CXCR4 in response to chemotherapy treatment were protected from chemotherapy-induced apoptosis when co-cultured with bone marrow stroma. Plerixafor diminished stromal protection and conferred chemosensitivity. Mice treated with plerixafor and chemotherapy had decreased leukemic burden, compared to those receiving chemotherapy alone or vehicle control. S-CXCR4 expression was higher in blasts located outside the bone marrow, suggesting that blasts migrating out of the marrow upregulate s-CXCR4 as they home to new niches. Plerixafor also induced increased expression of the SDF-1 receptor CXCR7 and the integrin VLA-4, suggesting that CXCR4 inhibition may lead to recruitment of other molecules critical to leukemia cell trafficking and adhesion. Finally, the efficacy of plerixafor as a chemosensitizer both in vitro and in vivo was predicted by the degree of chemotherapy-induced s-CXCR4 upregulation, identifying a biomarker with the potential to select optimal patients for CXCR4 inhibition. Conclusion: The bone marrow microenvironment is an important mediator of chemotherapy resistance. Inhibition of the CXCR4/SDF-1 axis may result in improved outcomes in children with ALL

N2 - Purpose: Pediatric palliative care (PPC) is being recognized as an important aspect of holistic care for children with cancer. PPC can offer a wide range of services including symptom management of dying child, support for the parents, spiritual services, home care, bereavement services etc. Method: Kuwait Association of Care of Children in Hospital (KACCH) is a NGO, which provides support to hospitalized children through Child Life Specialists (CLSs). In November 2005, this NGO started PPC in Kuwait and made a PPC team, which consist of pediatric oncologist, pain management specialist, CLSs, nurses, and physiotherapist. One CLS is assigned for each child. CLSs are key contact person with child and family. The first contact between CLS

and family is made in the hospital. Subsequently home visits are made by CLS to establish better rapport with child and family. The home care services include pain medications, blood sampling, blood transfusion, dressing, care of Hickman's line, physiotherapy, oxygen inhalation etc. The children are also taken out for outdoor activities. The emphasis is on keeping the child at home as long as possible. The family members are encouraged to contact CLS at any hour of the day. Results: Till date 58 children have been registered for palliative care. They suffered from various malignancies including brain tumors, bone tumors, neuroblastomas, adrenocortical carcinoma etc. Out of these 58 children, 50 have died of their disease. They were under care of palliative care team ranging from few weeks to more than 18 months. Majority of the children died in the hospital, but few died at home also. In our assessment and feedback, the patients and their families got tremendous benefit from palliative care services in terms of pain control, social support, and bereavement services. Conclusion: Hospital and home based PPC services make a tremendous impact at "end of life care" SN - 1545-5009

N2 - Background: The anti- IL-6 Receptor monoclonal antibody Tocilizumab (TCZ) has demonstrated its efficacy in Japanese children with systemic onset juvenile idiopathic arthritis (SJIA). Aim: To evaluate the efficacy and safety of TCZ in European patients with active SJIA outside a clinical trial (off-label use). Patients and methods: Retrospective review of the files of the patients treated by TCZ in two French, one Swiss and one Italian center. Response to treatment was defined as control of the fever and systemic features for at least 7 days, Improvement of the pediatric ACR score and normalization of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were also considered. Results: 18 patients aged 4-15 years were included. The median disease duration at treatment onset was 4.7 years (0.4-8.8). The median dose of prednisone at TCZ onset was 0.63mg/kg/d. Four patients were also on MTX. Fourteen patients had previously failed to respond one or several biologics, including anti-TNF alpha in 10 cases, anakinra in 14 and canakinumab, in 4. All patients but 4 had active systemic and polyarticular features at TCZ onset. The doses of TCZ ranged between 6 and 12 mg/kg every other week at treatment onset. The mean follow-up on TCZ was 18.2 months (range0.5-48). 90% improvement of the pediatric ACR score was achieved by 9 patients after 3 months. The dose of steroids was tapered in most cases (11/14) within 3 months, and five patients could discontinue steroid treatment after 12 months. TCZ treatment was withdrawn in 5 children for adverse events: anaphylactic reaction in 3 cases, skin vasculitis in 2 other cases. Conclusion: In this study TCZ treatment was effective in most patients with SJIA who previously failed one or several biologics. Adverse events require particular attention since almost one third of patients had to discontinue treatment

N2 - **RATIONALE:** This study aimed to investigate various lifestyle factors and their association with symptoms of allergic rhinitis in schoolchildren. **METHODS:** A questionnaire regarding lifestyle factors and allergic rhinitis was distributed to the parents of 7-year-old schoolchildren at every primary school in Ohmi-Hachiman City, Shiga Prefecture, Japan. The International Collaborative Study of Asthma and Allergies in Childhood questionnaire provided information about the prevalence of allergic rhinitis. Following the descriptive statistics, we developed univariate and multivariate logistic regression models to evaluate the association between lifestyle factors and allergic rhinitis. P values <0.05 were considered to indicate statistical significance and P values <0.1 were considered to indicate a tendency. **RESULTS:** Among the parents of 759 7-year-old children who attended primary school, 640 (84.3%) answered the questionnaire. Of these children, 223 (34.8%) had allergic rhinitis symptoms. Among the lifestyle factors investigated, children who did not participate in any sports activities after school had significantly fewer allergic rhinitis symptoms than those who did (OR 50.69, P=0.03). Similarly, children whose commuting time to school was less than 30 minutes tended to have fewer allergic rhinitis symptoms than those whose commuting time was 30 minutes or more (OR 50.72, P=0.07). No significant association between other lifestyle factors (passive smoking, obesity, bedtime, wake-up time, and eating habits) and allergic rhinitis symptoms was found. **CONCLUSIONS:** Participating in sports activities and commuting were associated with a higher prevalence of allergic rhinitis. Increased exposure to pollen or other outdoor allergens may contribute to these associations

N2 - Purpose of Study: National studies estimate that over 60 percent of Americans are overweight. The CDC reports that obesity rates in adolescents aged 12-19 and children aged 6-11 are 18% and 20% respectively. In 2008, the medical care costs related to obesity were \$147 billion. Many rural Alaskan communities endure 9-month winters that feature limited daylight and temperatures of sixty below zero, making it difficult to maintain an active lifestyle. 67% of rural Alaskans are overweight, which is significantly higher than the national average as well as urban areas of the state. The purpose of the project was to promote physical activity in the rural community of Delta Junction, Alaska by increasing public interest in the town's new Frisbee Golf course.

Methods Used: In order to increase community interest in Frisbee Golf, an event was held at the town's new Frisbee Golf course. The event was free and featured an overview of the game rules, a tour of the course, and group lessons from members of the Professional Disc Golf Association. People who attended also received a free Frisbee Golf disc and a brief lecture on the health benefits of physical activity. Promotion for the event was accomplished with the use of flyers and the recruited help of city hall and the course creator. The local outdoor survival store was also convinced to begin selling Frisbee Golf discs to the community. Summary of Results: People of all ages spend the afternoon in the park learning about Frisbee golf. Over 25 Frisbees were given away. Many members of the community who had never heard of Frisbee Golf learned the rules as well as valuable health information. The local outdoor store sold-out of Frisbee Golf discs within the week and the traffic on the local course increased. Conclusions: Obesity has become one of the most significant health concerns for Americans, especially those living in rural Alaska. Studies have indicated the importance of regular physical activity in preventing the multitude of health issues associated with obesity. Promoting an interest in

Frisbee Golf, a sport that is affordable, easy to participate in, and accessible to all ages, will hopefully encourage people in Delta Junction to engage in a more active lifestyle, thus improving the health of the community

N2 - Blind people can learn to understand speech at ultra-high syllable rates (ca. 20. syllables/s), a capability associated with hemodynamic activation of the central-visual system. To further elucidate the neural mechanisms underlying this skill, magnetoencephalographic (MEG) measurements during listening to sentence utterances were cross-correlated with time courses derived from the speech signal (envelope, syllable onsets and pitch periodicity) to capture phase-locked MEG components (14 blind, 12 sighted subjects; speech rate. =. 8 or 16. syllables/s, pre-defined source regions: auditory and visual cortex, inferior frontal gyrus). Blind individuals showed stronger phase locking in auditory cortex than sighted controls, and right-hemisphere visual cortex activity correlated with syllable onsets in case of ultra-fast speech. Furthermore, inferior-frontal MEG components time-locked to pitch periodicity displayed opposite lateralization effects in sighted (towards right

hemisphere) and blind subjects (left). Thus, ultra-fast speech comprehension in blind individuals appears associated with changes in early signal-related processing mechanisms both within and outside the central-auditory terrain. 2012 Elsevier Inc

N2 - Purpose: African American and Latino adolescents have higher reported rates of HIV/STD compared to other racial/ethnic groups. Although prior research has identified parental-adolescent communication as important in reducing youth HIV/STD risk, specific strategies used by African American and Latina parents to talk to their children about sex, including when and where to have these conversations, have been understudied. We examined approaches used by African American and Latina mothers for sex-related discussions with their children to inform HIV/STI intervention development efforts. Methods: We recruited mother-child (children ages 12-16 years) pairs from an after-school, community-based organization in Southern California. Fourteen maternal-only focus groups were conducted; 8 African American (n = 31) and 6 Latina (n = 24). Data were transcribed, coded for most common themes by 4 independent scientists and reviewed for differences by race/ethnicity and gender of child. Results: Four key themes emerged when focusing on parent-child discussions about sex: 1) sexual activity discussions varied for sons and daughters, 2) protection from HIV/STI and pregnancy were key topics, 3) using a direct, honest approach, and 2) seizing the moment. For sexual activity discussions, Latina mothers were more likely to talk directly to their daughters ("don't have sex early, like me") but preferred to have father figures speak to their sons ("if he doesn't ask me . . . I would never mention it"). African American mothers were more likely to talk directly to both daughters ("I got pregnant the first time, because my mom did not have that talk . . . I try to talk to my children") and sons ("you can get AIDS the first time you lay down with someone") or ask another male figure to speak to their sons. For the direct approach theme, African American mothers were three times as likely to engage in direct communication about sex, sexual development and the consequences of sex (e.g. STDs, pregnancy and loss of opportunities) with their children, than were Latina mothers. Latina mothers used direct approaches more frequently with female than male children. For the seizing the moment theme, Latina motherdaughter pairs and African American mother-son pairs engaged in "seizing the moment of opportunity" to talk about sex more frequently than other parent-child pairs. Mothers intentionally used natural setting opportunities to initiate discussions about sex with their child, such as when driving to school, when participating in an activity together, or when sexual content was shown in a television program. Conclusions: These data help broaden our understanding about the strategies used by African American and Latina mothers for sex discussions with their sons and daughters; evaluations for impact on youth sexual health outcomes are warranted. These data can also contribute to the development of future culturally-tailored and gender-specific parent-child communication efforts and HIV prevention interventions focusing on youth of color

N2 - Introduction: To advance the design and implementation of outdoor smokefree area policies, we aimed to develop simple, low-cost methods for measuring smoking in a variety of public places. Methods: Two methods were developed and were used by solo observers during March 2011-February 2012 to measure the proportion of people smoking at a variety of sites. Results: Both methods performed well (n=5553 people observed); the first at 58 sites in the UK and New Zealand (n=3191 observed); the second at 33 sites in New Zealand (n=2362 observed), with significant differences found between the smoking at types of sites and between countries. For the two countries combined, the proportions of people smoking (amongst those over 12 years) in children's play areas was significantly lower compared to all the other sites combined (risk ratio=0.39; 95%CI: 0.20 to 0.76; p=0.002). Conclusions: Solo observers can establish the proportion of people smoking in a range of outdoor sites. Such methods can inform outdoor smokefree area policymaking by providing baseline and post-policy data to enable location targeting and policy evaluation. 2012 Elsevier Ltd

N2 - Background: The effect of low dose radiation on immune system is shown. Ionizing radiation can affect cytokine production and polarization of T helper cells. Objective: The current study focused on ionizing radiation in Ukrainian children residing in a contaminated area with clinical irritable bowel syndrome. Method: Our study included 75 rural children population aged 4-18 yrs, who lived in a contaminated area exposed to natural environmental radiation with clinical irritable bowel syndrome (categorized in three groups) and 20 rural children participants aged 5-15 yrs who were living in areas with similar levels of radioactive contamination without clinical irritable bowel syndrome as control group. Internal radiation activity was measured by gamma-ray spectrometry. Serum levels of IL-4 and IFN- were measured by enzyme linked immunosorbent assay. Results: A trend towards increased levels of IL-4 was observed in children with clinical irritable bowel syndrome. In these children, IFN- levels were lower than that of the control group. Conclusion: The IBS symptoms in Ukrainian children residing in a contaminated area may have stemmed from Th1 to Th2 immune deviation and differential expression of IL-4 and IFN-

N2 - Objective: To compare counseling concerning sun protection and outdoor exercise with the parent's report of the behavior of a child aged 9-16 years old. Study design: Structured interviews of medical personnel in 3 Chicago area practices elicited information about counseling methods and recommendations. In each practice, a convenience sample of parents completed a self-reported survey of their and their child's behavior. Results: Sun protection counseling occurred more frequently than exercise counseling in all practices ($P = .014$). Sun protection counseling was associated with parental prompting ($P = .004$), performing a summer camp physical ($P = .002$), and the child having a sunburn ($P = .003$). After controlling for the child's age, sex, and skin tone, sun protection counseling was not associated with the child's use of sun protection. In multivariate analysis of the child's sun protection behavior, parental sunburns, indoor tanning in the last 12 months, perception of skin cancer risk, and sun protection self-efficacy were significant ($P = .02$). Children who pursued outdoor sports were twice as likely to use inadequate sun protection and sustain sunburns (CI 1.3-1.7). Conclusions: The child's sun protection behavior was influenced by parental sun protection, parental perception of skin cancer risk, and parental sun protection self-efficacy; therefore, sun protection for children needs to be aimed at parents as well as children. Communication with parents in a way that incorporates the principles of motivational interviewing may be more effective in promoting behavioral change than admonitions to use sunscreen. N2 - Introduction: Emerging evidence suggests that sedentary behaviour is negatively associated with health. Workplaces are convenient settings for delivering health promotion interventions and reduce occupational sitting time. However, most studies have focused on quantitative analyses to understand the impact of workplace physical activity interventions on reducing occupational sedentary time rather than employees, experiences. We assessed employees, perspectives who undertook a 20-week pedometer-based programme (Walk&WorkSpain)-based on Web technology-that aimed at reducing daily sitting time and increasing daily step counts at work. Method: Two-hundred and sixty-four inactive employees from 4 Spanish universities engaged in Walk&WorkSpain. The intervention group (n = 129) accessed gradually to different strategies through a Webpage: "incidental walking" (active work tasks, i.e. walk talk meetings), "short and long Campus walking routes" (10 minutes, i.e. parking the car a bit far; 20 minutes, i.e. walking at lunch time respectively). Semi-structured interviews were conducted with 8 employees from the intervention to gather qualitative data on personal experiences. The most inactive employees who volunteered were recruited. Participants were evenly divided between men/women and job roles; academic-male (n = 2), academic-female (n = 2), administrative-male (n = 2) and administrative-female (n = 2). Each participant was interviewed three times at the beginning (baseline), middle (8 weeks) and two months after completing the intervention. Interviews were transcribed

verbatim and subjected to inductive coding within the major themes of opinions on sitting reduction strategies and experiences of success when implementing them. Results: At baseline, participants had little awareness about the need of reducing sitting time. Most employees were on the contemplation stage for changing this behavior. Eight weeks later, most participants perceived to implement the different strategies successfully, being incidental walking the mostly widely used followed but short walking routes. However, they could not implement them as regularly as they wanted. At this stage, participants were on preparation for reducing sedentary behavior. The long walks around the Campus could not be implemented successfully at work but most employees put these into practice outside work by the end of the program (i.e. walking to school to pick up their children). At this point, all participants reached the "action stage". Discussion: Walk@WorkSpain was perceived to be a feasible program to promote sustained reductions on sitting time and increases on physical activity both inside and outside work. The program was perceived to be successful not only in improving participants, awareness but also in gradually introducing changes to reduce sitting time in employees, lives SN - 1440-2440

N2 - Introduction: Several studies show that as children grow older and enter their teenage years their physical activity level decreases. The study 'SPACE-Space for physical activity, seek to prevent this decrease in everyday physical activity through a combination of physical and organizational interventions. The Danish public school is the basis for the SPACE-study, almost 90% of children in Denmark attend public school. My PhD. is part of the SPACE-study and explores the connections between the students, social identities, their physical and organizational surroundings and their patterns of movement i.e. during recess. The anthropological fieldwork has been conducted over a three year period making it possible to follow the children from the 5th to the 7th grade; during this period of time the student go from the age of 11 to 14 years old, a transformation from being a child to becoming an adolescent. Methods: The analysis is based upon an anthropological fieldwork

conducted at two Danish public schools. At each school the fieldwork focused primarily upon one class of approximately 25 students. The fieldwork consists of participant observation during the school day both during periods and breaks, participant observation during after school activities, and in depth interviews with the students. All in all I spend 4 months at each school. Results: The norms for movement and physical activity among the students in the 5th to the 7th grade are created and influenced crosswise by the different places and spaces that the students stay and move between. The school yard can be compartmentalized in areas on the basis of the activities that are going on, the school yard elements, the group of students engaged in the activity, the proximity to the school building and the visibility to others. In this presentation the starting point will be the proximity to the school building and the visibility of the area to other students and the teachers on playground duty. The students engaged in physical activities close to the school building where others can see them generally speaking are students with high social status whereas the students engaged in activities on the outskirts of the school grounds have a lower social status. Discussion: The anthropological approach to this area of research contributes with a different type of knowledge and thus a new angle to understanding the processes regarding growing up related to students level of physical activity

N2 - Background: Physical activity is a key modifiable behavior impacting a number of important health outcomes. The path to developing chronic diseases commonly commences with lifestyle patterns developed during childhood and adolescence. This study examined whether parent physical activity and other factors correlated with physical activity amongst children are associated with self-reported physical activity in adolescents. Methods: A total of 115 adolescents (aged 12-14) and their parents completed questionnaire assessments. Self-reported physical activity was measured amongst adolescents and their parents using the International Physical Activity Questionnaire for Adolescents (IPAQ-A), and the International Physical Activity Questionnaire (IPAQ) respectively. Adolescents also completed the Children's Physical Activity Correlates (CPAC), which measured factors that have previously demonstrated association with physical activity amongst children. To examine whether parent physical activity or items from the CPAC were associated with self-reported adolescent physical activity, backward step-wise regression was undertaken. One item was removed at each step in descending order of significance (until two tailed item alpha = 0.05 was achieved). Results: A total of 93 (80.9%) adolescents and their parents had complete data sets and were included in the analysis.

Independent variables were removed in the order: perceptions of parental role modeling; importance of exercise; perceptions of parental encouragement; peer acceptance; fun of physical exertion; perceived competence; parent physical activity; self-esteem; liking of exercise; and parental influence. The only variable remaining in the model was 'liking of games and sport, ($p = 0.003$, adjusted rsquared = 0.085). Discussion: These findings indicate that factors associated with self-reported physical activity in adolescents are not necessarily the same as younger children (aged 8-11). While 'liking of games and sport, was included in the final model, the r-squared value did not indicate a strong association. Interestingly, parent self-reported physical activity was not included in the final model. It is likely that adolescent physical activity may be influenced by a variety of direct and indirect forms of socialization. These findings do support the view that intrinsically motivated themes such as the liking of games and sport take precedence over outside influences, like those presented by parents, in determining youth physical activity behaviors. These findings do not suggest that parents have no influence on adolescent physical activity patterns, but rather, the influence is likely to be more complex than physical activity behavior modeling perceived by the adolescent. Further research in this field is warranted in order to better understand potential contributors to successful physical activity promotion interventions amongst young adolescents

N2 - Introduction: While evidence of the relationship between dog ownership and physical activity in adults is emerging, the nature of this relationship in children requires further investigation. Given 60-80% of Australian and US households with children have a dog, dog-facilitated physical activity may be an effective way to increase physical activity and decrease child obesity. The study aims were to: 1) examine the individual and environment factors associated with dog ownership and 2) after adjusting for significant individual and environment factors, examine the association between dog ownership and physical activity, walking and sedentary behaviour. Methods: Cross-sectional data from the Western Australian TRavel, Environment, and Kids project (TREK) were analyzed for 1218 children aged 10-12 years. Individual socio-demographic, intrapersonal, social and physical environment factors, child physical activity (walking; physical activity outside of school) and sedentary behavior (screen use) and dog ownership status was collected from child and parent questionnaires. Children's weekly pedometer steps, height and weight were measured. Regression models progressively adjusted for significant socio-demographic, intrapersonal and environment factors. Results: Approximately 60% of children had a family dog. Dog ownership was associated with, on average, 29 more minutes of walking and 142 more minutes of physical activity/week ($p < .01$). After adjustment, children who had a dog were 49% more likely to be sufficiently active (420mins) and 32% more likely to have walked in their neighborhood in the last week, compared with non-dog owners ($p < .05$). Boy, but not girl, dog owners walked more minutes/ week and were more likely to walk in their neighbourhood than non-dog owners ($p < .05$). Girl, but not boy, dog owners were more likely to be sufficiently active and did more minutes of physical activity than non-dog owners ($p < .05$). Dog ownership was not associated with screen use, pedometer steps or weight status. Discussion: These results highlight the potential for dog ownership to significantly impact children's physical activity levels. It is likely that the nature of the relationship and interaction that boys and girls have with their dog may influence physical activity measures differently. Further research is needed to examine how the relationship between (self-report and objective) measures of physical activity and dog ownership and dog walking varies by child age and gender. To optimize the benefits of dog ownership in terms of increased physical activity, there is a need to encourage children (and their parents) to walk with and actively play with their dogs

N2 - Introduction: The national recommendation for physical activity for children in Australia is a minimum of one hour and up to several hours of moderate to vigorous activity per day. This project focused on play space for children aged 8-12 years and asked whether providing enticing, attractive play spaces would result in more children getting active outdoors. The Space for active play project featured children,s voices briefing the designers of four play spaces in metropolitan Melbourne. Three of the play spaces developed were then evaluated to see if they did in fact attract the target audience identified. Methods: A four method children,s consultation exercise involving experiential learning, reflective notebooks, photography and discussion was developed. The results of this consultation were then validated by classroom based children of the same age, community members and a range of professionals. Once design was completed a pre-construction site evaluation was developed and undertaken in three of the sites, involving the Most Significant Change (MSC) methodology with a small group of children, a classroom based survey, a parents survey and park observation. Following completion of the construction phase follow up evaluation was done in all three sites. Results: The children provided an abundance of ideas and activities that they would like to see and do in their local park. Their ideas went well beyond the traditional play equipment and sports opportunities offered in many municipal parks. These ideas influenced the play space designers in their approach to designing the new play spaces. The evaluation of the actual sites will be completed in June 2012, with early analysis of results suggesting that increased physical activity and outdoor play has been achieved. Discussion: This project has recorded what older children want of their play spaces, and it reveals a strong appetite for a much broader range of play experience than is currently on offer. This information has been documented in order to influence planners and designers of park space and others about older children,s needs. This paper will provide insights into what the children desire in a play space and to what extent the resulting play spaces were successful in attracting older children to engage in active outdoor play. The Space for active play project is an initiative of the Heart Foundation in partnership with Brimbank, Frankston and Moonee Valley city councils and Parks Victoria, with funding from Parks Victoria and VicHealth

N2 - Introduction: In Australia, life expectancy of people of Indigenous descent is 16-17 years lower than their non-Indigenous counterparts. Physical inactivity is the third leading cause of the burden disease for Indigenous adults. However, in children the situation is more positive with almost three quarters (74%) of Indigenous children aged 4-14 years meeting national physical activity recommendations. Adolescence is typically a period where physical activity declines and is an important target point for interventions. This study describes frequency and duration of out-of-school physical activity in a sample of Indigenous and non-Indigenous Australian adolescents and explores relationships between physical activity participation and demographic, health and lifestyle factors. Methods: The Health and Lifestyle of NSW School Students Survey was developed using established measures from surveys conducted in adolescents from similar populations. The survey was

completed by 348 Indigenous and 633 non-Indigenous students aged 13-17 years residing in rural New South Wales (NSW). The survey included questions on frequency and duration of physical activity out of school. These items were combined to establish whether national physical activity recommendations were being achieved. Bivariate analyses stratified by Indigenous status identified demographic, health and lifestyle behaviours statistically related to meeting physical activity recommendations. These variables were included in multiple binary logistic regression models conducting including the total sample and stratified by Indigenous status. Results: Indigenous adolescents were less likely to meet physical activity recommendations through out of school activity than non-Indigenous adolescents (21% versus 28%; $p = 0.010$). In the stratified regression analyses, Indigenous females had a higher odds of meeting physical activity recommendations than males (OR = 0.39, 95% CI 0.20-0.77) after adjusting for age, membership of a sports team, parental employment status, feeling confident and community involvement. In the non-Indigenous model, adolescents involved in a sports team had higher odds of meeting physical activity recommendations than those not involved in a team (OR = 2.41, 95% CI 1.58-3.67), after adjusting for age, gender, time spent watching television, maternal employment status, alcohol behavior, feeling lonely, feeling confident and community involvement. Discussion: These results provide an indication of physical activity levels in rural Indigenous and non-Indigenous adolescents outside of the school setting where less than a quarter of this sample were meeting physical activity recommendations. Indigenous adolescents, particularly girls, are a specific target group for intervention. Increased policy and practical efforts to reverse the decline in physical activity during adolescence is essential to reduce population disparities in chronic disease risk in adulthood among Indigenous Australians

N2 - Introduction: Parks are important settings for physical activity. Park features have been shown to be associated with park visitation and physical activity within parks. There is some evidence that children living in rural locations are at an increased risk of overweight and obesity compared with children living in urban areas and this may be a result of decreased opportunities to be physically active such as having fewer facilities in parks. The aim of this study was to examine potential differences in the features and amenities within parks located in urban compared with rural areas. Methods: An audit tool was designed to identify and evaluate features of parks that may be important for children's physical activity including: aesthetics (e.g. landscaping, water features, litter and graffiti), amenities (e.g. toilets, drinking fountains, shade, benches, bike racks), activity areas (e.g. open spaces and basketball courts), playgrounds (e.g. equipment and suitability for different age groups), and the presence of courts/ovals, paths and dog signage. Field observers visited 628 parks across Victoria, Australia during 2009-2010 and completed this paper and pencil audit. Results: Park audits were completed at 434 urban and 194 rural parks. The parks located in rural areas scored significantly higher on aesthetic features (3.5 vs 3.2) and the number of activity areas (0.9 vs 0.7), while urban parks scored higher on playground equipment (8.5 vs 6.8), and the number of courts/ovals (7.1 vs 2.7). A higher percentage of urban parks had walking paths (59% vs 42%) and signage regarding dogs (26% vs 14%). Conclusions: The findings demonstrate differences in park features in urban compared with rural areas. Further research is required to examine whether these differences in park features are associated with park-based physical activity, overall physical activity, or time spent in sedentary behaviours among children in urban and rural areas

N2 - Introduction: A number of recent studies have found associations between the characteristics of schoolyards and the level of PA of schoolchildren using the schoolyards. Based on these findings, it seems likely that making schoolyards more attractive will help to increase the total amount of PA among schoolchildren. Before starting our 'Activating Schoolyards, intervention study, we carried out an exploratory study with the objective to describe activity patterns and localize places for physical activity on 6 schoolyards varying in size and content, located in different types of neighborhoods. Methods: 745 children, 6-16 years old, enrolled at six schools were asked to wear an accelerometer (ActiGraph GT3X) and a GPS (Qstarz BT-Q1000X) for 5 schooldays to determine their level of activity and movement patterns. GPS positions were recorded every 15 seconds and activity levels were recorded every 2 seconds. GPS and accelerometer data were compiled using the Physical Activity Location Measurement System (PALMS), developed by the Center for Wireless and Population Health Systems at the University of California, San Diego. All elements of each of the 6 schoolyards were mapped in detail using a high-precision GPS (Trimble GeoExplorer XT). ArcGIS software was used to combine PALMSoutput with the schoolyard maps. For each participant, average activity counts per schoolyard element were calculated, and associations between schoolyard elements and average levels of physical activity were calculated. Results: Multi-courts with an artificial grass or rubber surface, lawn areas, grass slopes and other more natural elements were associated with higher than average levels of physical activity in schoolyards during recess. Playground equipment such as climbing frames, slides or swings, was not associated with higher levels of physical activity. Our results also show age, gender and time differences with different schoolyard elements being popular for different age groups, at different times of the day. Discussion: In future schoolyard renovations, or when designing new schoolyards, policy-makers and designers should keep our findings in mind. However, the causal relations between these schoolyard elements and higher levels of physical activity will need to be tested in our 'Activating Schoolyards, intervention study, that will commence in 2013. This study will focus on schoolyard characteristics that are likely to influence the least active children

N2 - Introduction: This research was part of a larger study known as the Sydney Playground Project (SPP), which aims to increase physical activity and social skills in primary school children by means of a low-cost innovative playground intervention. For many children pure sports interventions are not the answer, hence this study engaged children's playful nature to promote physical activity and social interactions through play. The purpose of this part of the study was to study the effect of the intervention on physical activity. Methods: 214 (115 boys, 99 girls) 5-7 year old (mean: 6.0 years at baseline) children from 12 Sydney primary schools participated in this CRCT. Baseline data were collected prior to a 14-week playground intervention or recess as normal, followed by post-testing during the last week of intervention. The playground intervention: unstructured items, consisting of or made from recycled material (tyres, balance beams, crash mats) introduced to the school playgrounds for the children to play with freely. Physical activity was measured by accelerometers during school days (0900-1500 for 5 consecutive days at baseline and post-test. Height, weight and BMI were measured. Mixed-effect ML regression (STATA/IC 12), taking clustering and repeated measures into account were used to examine net change from baseline values between groups. Results: Over time, MVPA increased (1.82 min, $p = 0.006$), and sedentary time decreased (-2.13 min, $p = 0.01$) significantly during recess in the intervention group, however effect sizes were small. Activity increased independent of BMI. Anecdotally, schools and children were enthusiastic about the playground intervention, quoting less playground demeanour and more fun. Discussion: This play intervention has the potential to be a cost effective way to engage children in increased physical activity and social interactions and can potentially be implemented in a large range of settings

N2 - Introduction: The benefits of physical activity to maintain optimal health and wellbeing in children and adolescents are undisputed. The school environment offers opportunities for children to be physically active. The aim of this review was to systematically examine the effects of recess-based interventions on the physical activity levels of school-aged children and adolescents. Methods: Two authors independently searched the literature using the same search strategies to identify papers reporting interventions which promote playground physical activity during school recess and lunchtime periods. Methodological quality was assessed using an adapted eight item assessment scale. The effects of the interventions were assessed with a rating system used in a recent review of interventions in youth. Results: The search originally retrieved 2265 articles. Nine published peer reviewed journal articles met the inclusion criteria for this review. Eight studies used randomised controlled trials and one was a controlled trial, though none of the studies adequately described the randomisation process. Three studies demonstrated high methodological quality (33%). None of the studies adequately reported the randomisation procedure or used power calculations. Few studies reported potential confounders and three studies had less than a six week follow-up. Seven studies demonstrated a positive intervention effect on children's physical activity levels, with three reporting statistical significant increases and two significant decreases in recess physical activity. The summary of the levels of evidence for intervention effects found inconclusive results for all intervention types, though promising strategies that require further investigation were identified. Discussion: A strength of all of the studies was the use of objective measures to assess physical activity outcomes, though several criteria were consistently absent from the studies. The summary of the levels of evidence for intervention effects found inconclusive results for all intervention types. This could be largely due to the small number of large high quality studies. The use of methodological checklists as a guide when designing intervention research could assist to improve intervention methodological quality in school recess physical activity research. There is an urgent need for higher quality intervention research to strengthen published findings to inform recess physical activity playground interventions. Intervention research is needed in adolescents due to the absence of school recess intervention research in this population

N2 - Introduction: Physical fitness is a strong predictor of health status in youth. However, a large proportion of children do not participate in sufficient physical activity of moderate-to-vigorous intensity to achieve the associated health benefits. The aim of this study was to evaluate the impact of a multi-component schoolbased physical fitness education intervention (Fit-4-Fun) on the physical fitness and activity levels of primary school children. Methods: The study involved a group randomized controlled trial with a wait-list control group. Four primary schools in the Hunter Region, NSW, Australia, were randomised by school into the Fit-4-Fun intervention or the control conditions. The study sample included 226 primary school children aged 10-13 years (mean age 10.72 years+0.6, 47.8% male). Fit-4-Fun was a multicomponent school-based physical fitness education intervention delivered as part of the Health and Physical Education (HPE) curriculum and targeted fitness improvements. The program utilised a range of evidence-based behavior change strategies to promote and support physical activity of adequate intensity, duration and type, needed to improve health-related fitness. The 8-week program includes three specific components based on the Health Promoting School Framework, a HPE curriculum program (1x60 min/week), a daily break-time activity program (recess/lunch) and a home fitness program (3x20 min/week). The control group participated in their usual weekly 60 min HPE lessons. Cardio-respiratory fitness (CRF) was the primary outcome and secondary outcomes included body composition, muscular fitness, flexibility and physical activity. Assessments were taken at baseline, 3- and 6-month follow-

up, to determine changes in health-related fitness and physical activity levels. Results: After 6-months, significant intervention effects were evident in cardio-respiratory fitness (beep test adjusted mean difference [95% CI] = 1.14 levels [0.74, 1.55]), body composition (BMI adjusted mean difference [95% CI] = -0.96 kg/m² [-1.42, -0.5] and BMI z-score adjusted mean difference [95% CI] = -0.47 z-scores [-0.70, -0.25]), flexibility (sit & reach adjusted mean difference [95% CI] = 1.52cm [-0.65, 3.68]), muscular fitness (sit ups mean difference [95% CI] = 0.62 stages [-0.97, -0.26]) and physical activity (steps adjusted mean difference [95% CI] = 3253 steps/day [1776,4730]). There were no group by time effects for three measures of muscular fitness (basketball throw, push-ups and standing jump). Discussion: The Fit-4-Fun program was successful in improving several measures of fitness in primary school-aged children. These findings suggest that well designed HPE programs that promote vigorous activity within and beyond the school day have the potential to improve health-related fitness in children

N2 - Many children engage in suboptimal levels of PA despite the associated health risks. Schools (n = 20) in the Transform-Us! program were randomized to one of four intervention arms that target increases in children's PA (PA), reductions in sedentary behavior (SB), both behaviors (SB + PA) or control current practice (C). This examination focuses on the PA promotion strategies employed in the PA, SB + PA arms compared with the C arm. To promote children's PA each PA, SB + PA class was provided with sporting, circus equipment; asphalt line markings were installed at the school, teachers were asked to encourage PA. Grade 3 children at participating schools were invited to take part in evaluation assessments including the completion of a self-report survey. Findings from the PA promotion strategy questions at baseline (Feb-June 2010), T2 (Nov/Dec) are reported here. Children (n = 425, 55% female) were asked to respond (yes/no) to five items asking about social support for PA from their class teacher, which were then summed to create a 'teacher social support' scale. Children were also asked to indicate if 'there are markings on the walls or on the school playground to help us play games' (perceived availability of line markings); if they are 'allowed to use school sports equipment during recess, lunch breaks' (perceived accessibility of sports equipment), how much they like 'the areas to play in at school' using a 5-point Likert scale (perceived school environment). Between baseline, T2, teacher social support increased in both PA (1.7[1.4] vs 2.1[1.4]), SB arms (1.9[1.4] vs 2.4[1.4]) but declined in C (2.0[1.4] vs 1.7[1.5]). For all three arms, increases were seen in perceived availability of line markings (PA: 53.2% vs 69.4%; SB + PA: 59.3% vs 71.4%; C: 60.0% vs 69.8%); perceived accessibility of sport equipment (PA: 87.7% vs 97.2%; SB + PA: 80.7 vs 94%; C: 85.4% vs 97.6%), perceived school environment (PA: 1.44[0.9] vs 1.42[0.8]; SB + PA: 1.5[0.8] vs 1.6[0.7]; C: 1.4[0.9] vs 1.5[0.7]) between baseline, T2. All findings were significant at a 1% probability level. At the mid-intervention time point, findings suggest that PA strategies have increased perceived availability of line markings, accessibility of sport equipment, perceived school environment in children allocated to the PA, SB + PA arms. However, there were also unexpected increases in the C arm for three out of four items. Post-intervention findings will add to these preliminary findings

N2 - Introduction: Dog ownership is a catalyst for physical activity in adults. Given 60-80% of Australian and US households with children have a dog, dog-facilitated physical activity may be an effective way to increase children's physical activity. Few studies have examined the relationship between dog ownership and children's physical activity. Importantly, the relationship between dog walking and children's independent mobility has not been investigated. This study aimed to: 1) examine the association between dog walking, physical activity and walking in children and 2) examine if children who report walking their dog are more independently mobile than those who do not walk their dog. Methods: Cross-sectional data from the Western Australian Travel, Environment, and Kids project (TREK) were analyzed for 729 children aged 10-12 years who had a family dog. Sociodemographic information, walking, walking with a dog and physical activity outside of school was collected from child and parent questionnaires. Weekly pedometer steps were also measured. Children reported their independent mobility to 15 neighbourhood destinations. Socio-demographic factors were adjusted for in models. Results: Approximately 60% of children had a family dog. Of the children who owned a dog 55% reported walking their dog in the last week and 45% of these did so without an adult. Children who walked their dog were more independently mobile than those who did not walk their dog (all children, boys & girls $p < 0.01$). Boys who walked their dog without an adult had greater independent mobility than boys who walked their dog with an adult ($p < 0.05$). Dog walkers who were independently mobile did more walking/week (184mins) than those dog walkers who were not independently mobile (128mins; all children $p < 0.01$). For boys, dog walkers who were independently mobile were also more likely to be sufficiently active (72% vs 59%; $p < 0.01$). Dogwalking and independent mobility was not associated with pedometer steps. Discussion: Children who walk their dog are more independently mobile than children who own a dog but do not walk it. Dog walking and independent mobility are associated with children's walking and, for boys, are associated with achieving the recommended level of physical activity. These results highlight that dog walking provides opportunities for children to be independently mobile. Strategies aimed at encouraging older children to walk their dog may assist in increasing children's physical activity. Future research should examine if the promotion of dog walking in families is a viable intervention strategy for increasing children's physical activity

N2 - Introduction: Understanding predictors of physical activity in centre based care is important for developing interventions to help ensure young children achieve recommended levels of physical activity and minimise their risk of overweight and obesity. The aim of this study was to describe children's levels of physical activity and modifiable centre-based associated with physical activity in long day care. Methods: Pedometers were used to assess physical activity levels of 328 children aged between 3-5 years in 20 randomly selected long day care services in the Hunter Region of New South Wales, Australia. Staff questionnaires and observational audits were used to assess staff and centre-based characteristics including: staff qualification level, staff training in physical activity; staff participating with children in free active play or prompting children to increase physical activity, time spent playing computer/video games, time spent in seated activity, time spent in outdoor play, staff led physical activity, outdoor play area, portable and fixed playground equipment to encourage physical activity, and opportunities for children to learn and practice fundamental movement skills. Results: Over the 6-hour observation period of 0900-1500, the average step count was 5,466 (+2,383) or 15.8 (+6.8) steps/minute. Step counts were significantly higher in centres that had a written physical activity policy (+3.8 steps/minute, $p = 0.03$), included staff led structured physical activity (+3.7 steps/minute, $p < 0.001$) and staff participation in active play (+2.9 steps/minute, $p = 0.057$). Discussion: It is recommended that Australian preschool children obtain 3-hours a day of active play. For children spending a large part of the day in care, much of this activity will need to be obtained during this time. Interventions to increase children's physical activity while in care should support long day care centres to develop and implement physical activity policies and build the capacity of staff to encourage physical activity through delivery of structured activities and participation in physically active play

N2 - Introduction: Physical activity is important for young children's health yet compliance with recommendations is low. Identifying factors associated with young children's physical activity is necessary to inform development of future interventions and public health programs. This study sought to identify multidimensional correlates of preschool children's physical activity. Methods: The social ecological model (SEM) was used to identify constructs potentially associated with preschool children's physical activity across each of the three domains-individual, social, physical environment. Cross-sectional data were collected from 1004 preschool children, aged between three and five years, and their parents in 2008-2009. Physical activity was measured over eight days using ActiGraph accelerometers. Parents completed a comprehensive survey. Generalized linear modeling was used to assess bivariable and multivariable associations between potential correlates and percent of time in each of three physical activity outcome variables (weekly [which included both week and weekend days], week day, weekend day) for boys and girls separately. Results: Correlates of physical activity were found across all the domains of the SEM and varied between boys and girls and between week and weekend days for each of the sexes. Age was the only consistent correlate, with children spending approximately 10% less time in physical activity for each advancing year of age. Some modifiable correlates which were related to more than one physical activity outcome were rules restricting rough games inside and usual daily sleep time for boys (both inversely associated). Spending time outside on weekends and visiting active play spaces supported boys to be more active. For girls, a preference to play inside/draw/do craft rather than be active and child constraints such as lack of time or someone to play with were inversely associated with more than one of the physical activity outcomes. Paternal provision of logistic support was associated with girls spending a greater percent of their time being active on weekends. Discussion: As correlates of preschool children's physical activity are multidimensional, future interventions and programs should ensure they address factors across all levels of the SEM. Potential strategies for promoting preschool children's physical activity should seek to influence identified correlates. Programs may need to consider whether they address week or weekend day physical activity as different correlates would need to be targeted. Sex-specific strategies may also be warranted

IS - var.pagings

N2 - Introduction: Moderate to vigorous physical activity (MVPA) has a range of social and health benefits among children. Ethnic minority children and children with low Socio Economic Status (SES) often engage in less organized sports than Danish children with high SES. However little is known about objectively measured MVPA among ethnic minority groups in Denmark. Based on baseline data from the When Cities Move Children study, this study investigates the association of the built environment, socio-demographic and social support variables on children's daily physical activity. Methods: Participants were 291 children from four schools in a diverse ethnic minority community in Copenhagen, Denmark (10-16yrs). Physical activity data were obtained using accelerometers (Actigraph GT3X, 30 sec epoch) and Evenson cutpoints were used to determine mean daily time in MVPA. Exposure variables were based on questionnaire data, registry data, GPS/GIS derived variables and accelerometer data. Data were analyzed in STATAmp 12 using a 3-level mixed multilevel model to examine both unadjusted and adjusted models. Results: Among the participants 45% were boys, 42.5% had at least one parent who did not work and 64.3% had at least one parent with an ethnic minority background. The

adjusted analyses showed that boys engage in significantly more minutes of daily MVPA than girls (boys: 57.8, girls: 36.9, $p < 0.001$) and that boys from a Danish ethnic family accumulated significantly less minutes of daily MVPA compared to boys from an ethnic minority family ($p < 0.001$). Girls in grade 7 (13-14yrs) accumulated the least minutes of MVPA ($p < 0.05$). Being in a class with a high average mean MVPA was significantly associated with higher individual MVPA among both boys ($p < 0.001$) and girls ($p < 0.05$). None of the included built environment variables were significantly associated with MVPA in the adjusted model.

Discussion: This study contradicts the notion that ethnic minority boys are less physically active than Danish boys. Anecdotal work so far confirms the hypothesis that these boys are bound to spend the majority of their leisure time outdoors in their local community due to crowding in their home while girls are confined to the home to stay out of trouble and help in the home. Further analyses based on available GPS data on these participants will provide more insight, leading to new documentation on the association on outdoor time and physical activity level as well as new knowledge on which built environment variables may be relevant for this group of children

N2 - Introduction: This research was part of a larger study known as the Sydney Playground Project (SPP), which aims to increase physical activity and social skills in primary school children by means of a low-cost innovative playground intervention. The aim of this part of the project was to investigate what children aged 5-7

years in Sydney do after school hours. Our focus was on whether children spent time indoors or outdoors, who they were with, and the parents' perceptions of the children's levels of physical movement, intensity and involvement. Methods: Experience sampling method (ESM) was used to obtain the data. We asked parents/carers of 221 children, (119 boys, 102 girls; mean age 6.0 years) to keep a palm pilot close by for four week days. On those days, the palm pilot delivered three brief surveys at random times between 1530-1900. The intention of the survey was to find out 'What your child is doing now' and the details of these activities (full details of the protocol can be found at <http://www.biomedcentral.com/1471-2458/11/680>). Results: Baseline survey data relating to after school activities indicated 55% of the time was spent indoors in pastimes involving low levels of physical activity. Children were engaged in higher levels of physical activity when outdoors and/or with peers, but these respectively accounted for < 20% and < 10% of survey occasions. The major contributor to children's pastimes was screen time (television or computer, 22%). Discussion: Our findings are considered in the context of opportunities for children to play outdoors with peers after school hours. We examine some of the pressures on parents and others to keep children safe, which may, paradoxically, lead to children engaging in sedentary pastimes with limited peer interaction, hence increasing the risk of later physical and mental health problems

N2 - Introduction: There are concerning trends for a decline in time spent in physical activity and physical education and increased sedentary time in South African schoolchildren. 'HealthKick' is a primary school-based intervention for low-income settings that aims to promote healthy eating and physical activity through Action Planning. We were particularly interested in school breaktime, as a possible target for intervention. Factors that have previously been shown to positively influence physical activity during break-time include: playground markings and renovations, teacher supervision and the availability of loose equipment. Aims: This study was a quasi-experimental, post-test only, control-group design and aimed to test whether or not physical activity during break-time was greater in intervention schools that had participated in Action Planning. A secondary aim was to determine the extent to which the school environment influenced physical activity during break-time in South African schools. Methods: The System for Observing Play and Leisure Activity in Youth (SOPLAY) was carried out in eight of the HealthKick schools (4 intervention and 4 control). Visual scans were conducted by multiple observers in pre-selected target areas, noting the activity of each individual within a target area, (sitting, standing, eating, walking, or playing). Observers also noted information about the school environment, including whether the area was usable, accessible, and supervised, if organised activity was taking place, and the availability of equipment. Results: There were no differences between intervention and control schools. Approximately 31% of learners were sedentary, 14% were eating, with 29% and 26% involved in moderate or vigorous play, respectively. Supervision during break was associated with a significantly lower proportion of learners engaged in vigorous play ($P < 0.04$, 24% vs 28%) and a greater number of learners eating their lunch (17% vs 11%). Finally, learner density (number of learners per area scanned) was significantly and inversely associated with physical activity. Only 17.6% of learners in low density areas were sedentary compared to 49.6% of those in high density areas; conversely 28.2% of learners engaged in vigorous play in low density areas, compared to only 13.5% in high density areas ($P < 0.001$). Conclusions: Physical activity during break-time in these South African primary schools was adversely affected by over-crowding and teacher supervision. The results suggest that educators were more involved in 'crowd control' than the promotion of physical activity during break-time, and that interventions may be targeted at the school policy environment to reduce these barriers to physical activity

N2 - Introduction: The study of sedentary behavior in rural Africa children and adolescents is scarce, and the goal of this research was to compare the sedentary behavior and light physical activities (LPA) between a rural sample from Mozambican school aged youth (6 to 16 years old) with their European peers, namely from Portugal. Methods: The sample comprises 146 Mozambican (MZ) and 195 Portuguese (PT) youth of both gender, and was split in 3 age groups (6-8yrs; 9-11yrs; 12-16yrs). The Actigraph model 7164 was used to obtain information marking daily PA and sedentary behaviours during 7 consecutive days in PT, and 1 only day in MZ (due to operational and logistic problems). Data files from all participants were screened by detecting blocks of consecutive zeros. Periods with 60 minutes of consecutive zeros were detected and flagged as times in which the monitor was not worn. Participants had to have at least 10 hours of data to count as a valid day. After complete screening, the raw activity "counts" were processed for time spent in the different PA intensities computations. Sedentary behavior was defined as PA with energy expenditure at the level of 1.0-1.5 metabolic equivalent units (METs). LPA was defined as PA with energy expenditure at the level of 1.6-2.9 METs. Puyau regression equation was used to determine the cut-points for PA intensities. Sedentary behavior was identified using a cut-point of <670 counts.min⁻¹, and LPA using a cut-point of >670 and <3003 counts.min⁻¹ Results: Mozambican rural school aged sample showed, at all age-groups and gender, an accentuated lower time spent in daily sedentary activities with a magnitude of difference around 1.5 higher for PT (Boys: MZ=370.9+78.2 vs PT=590.8+81.9; Girls: MZ=389.4+90.5 vs PT=596.2+86.2; F=493.7; p=0.0000). Using country, age and sex as factors, no statistically significant interactions were found. By turn, time spent in light activities were higher in MZ (Boys: MZ=197.5+47.9 vs PT=157.9+42.7; Girls: MZ=211.8+56.0 vs PT=158.9+47.7; F=66.7; p<0.001) in a magnitude of 1.3 higher for MZ. No significant interactions (p>0.05) were observed. Conclusions: Based on simultaneous observational studies, a significant higher time spent in light activities and less in sedentary behavior from the MZ rural school aged population may to be related to survival households activities, long distance walks and outdoor games still present in African rural areas

N2 - Introduction: The home setting is an important sphere of influence on the sedentary behaviour and activity of children and younger adolescents. Whilst there has been much investigation of the neighbourhood level physical environment, the home physical environment has received less attention. The purpose of this study was to systematically review recent literature on the influence of the home physical environment on sedentary behaviour and physical activity of children and adolescents aged 8-14 years. Methods: Medline, Web of Science, PsycINFO and SPORTDiscus databases were searched for English language peer reviewed journal articles published between 2005 and 2011. Thirty-six observational and 11 experimental studies met the inclusion criteria and were reviewed. Results: Most studies were conducted in high income countries including USA (n=14), Australia (n=8), New Zealand (n=4), UK (n=4) and The Netherlands (n=4). Twenty-one observational studies measured physical activity outcomes, with over half including objective measures; while 20 measured sedentary behaviour outcomes, with three using objective measures. The most common measures of the home physical environment were electronic media devices (n=27), physical activity equipment (n=14)

and yard/gardens (n=5). In more than half of studies, positive associations were found between household electronic media devices and sedentary behaviours. Amongst the experimental studies reviewed, the two main strategies to change the home physical environment were, introducing a TV limiting device or an active video game. Introducing a TV limiting device resulted in a decrease in TV viewing in intervention groups compared to control groups. Introducing an active video game showed an increase in active video game play and a decrease in sedentary video game play in intervention groups compared to no intervention control groups in RCT studies. Discussion: In an era of changing home and technology environments, this review provides an up to date summary of the evidence related to the influence of the home physical environment on children's sedentary and activity behaviours. Health promotion interventions should promote strategies to limit electronic media equipment in the home including in children's bedrooms. TV limiting devices and active video games show some promise for decreasing sedentary screen time and increasing children's activity at home, although maintenance remains an issue. Exploration of potential influences in this domain outside of physical activity and media equipment, and further intervention studies, are recommended. The relationship of sedentary time with the physical, social and virtual elements of the home environment is of particular interest

N2 - Introduction: Sedentary behaviours are highly prevalent amongst children and may be adversely associated with cardiometabolic health, independently of participation in physical activity. To inform intervention development, this study examined parental and home-environmental determinants of 1-year change in children's objectively measured sedentary time after-school (Monday-Friday, 1500-2300) and at the weekend (Saturday-Sunday, 0600-2300). Methods: Data are from the Sport, Physical Activity, and Eating Behaviour: Environmental Determinants in Young People (SPEEDY) study. Participants wore accelerometers at baseline and 1 year later. Longitudinal data for the after-school and weekend analyses were available for 854 (41.5% male, mean+SD age 10.2+0.3years) and 718 (41.8% male, age 10.2+0.3years) participants respectively. Information on 26 candidate predictors, including socio-economic status (SES), availability of electronic media and parental rules for active and sedentary behaviours was self-reported by children and/or their parents at baseline. Change in the proportion of registered time spent sedentary (<100cpm) was used as the outcome variable in multi-level linear regression models, adjusted for age, sex, body mass index and baseline sedentary time. Simple and multiple models were run and interactions with sex explored. Results: In absolute terms, sedentary time increased over 1 year (after-school: 4.9+45.1 min/day; weekend 8.0+89.3 min/day). SES was positively associated with change in after-school (beta; 95% CI: 1.02; 0.37, 1.66) and weekend (1.42; 0.65, 2.18) sedentary time. Negative associations with change in after-school sedentary time were observed for having more siblings (-1.00; -1.69, -0.30), greater availability of electronic media (-0.81; -1.29, -0.33), and, for boys, more frequent family visits to the park (-1.89; -3.28, -0.51) and family participation in sport (-1.28; -2.54, -0.02). Maternal weekend screen-time (0.45; 0.08, 0.83) and, in girls, greater parental restriction on playing outside (0.91; 0.08, 1.74) were positively associated with change in weekend sedentary time. For participants with a (step-) father living at home, father's weekend screen-time was positively associated with change in weekend sedentary time (0.40; 0.01, 0.78). Father's physical activity was positively associated with change in boys' after-school sedentary time (1.34; 0.53, 2.15). Discussion: Nine determinants of change in sedentary time were identified, some of which were time- or sex-specific. Higher SES children exhibited greater increases in sedentary time afterschool and at weekends compared to children of low SES, highlighting a potential target population. Intervention strategies that aim to reduce parents' weekend screen-time, increase family participation in sports or recreation (for boys) and promote freedom to play outside (for girls) may contribute towards preventing the age-related increase in sedentary time

N2 - Introduction: Ecological models of health behavior have potential as theoretical framework to comprehend the multiple levels of factors influencing physical activity (PA). The potential is shown by the fact that there has been a dramatic increase in application of ecological models in research and practice. One proposed core principle is that an ecological model is most powerful if the model is behavior-specific. However, based on multi-level interventions in a Danish context, it must be considered that ecological models also should be site-specific to capture local and cultural aspects related to PA. Methods: Three major multi-level intervention studies are carried out in Denmark with the objective to promote PA in 17 local communities. 1) The SPACE-study is a comprehensive intervention in 7 local school districts (N = 1,348). 2) The When Cities Move Children-study is investigating the effects of urban refurbishment on adolescents' movement patterns (N = 653) and 3) The Valuable Detours for PA-project is a intervention study in 9 municipalities measuring the effect of new established outdoor facilities for PA among 12-85 years old citizens (N = 10,434). The SPACE and the WCMC study used objective measurements of PA combined with e-surveys, the VDPA study is based on self-reported e-survey data. Results: Merging the data from the three intervention studies clarifies different local and cultural aspects with specific effect on PA behavior. This finding is closely related to the fact that the new outdoor PA facilities in the 17 local communities have different size, composition and are targeted to different subgroups with different organizational setup to support the use of the facilities. Despite the conceptual and contextual differences PA behavior is also affected by cultural and social values related to the specific site which not alone can be explained by intrapersonal, interpersonal or organizational factors. Discussion: The Ecological Model of Four Domains of Active Living specifies that factors at multiple levels can influence PA behavior, and emphasizes the importance of behavior-specific models. On this theoretical basis the three mentioned multi-level interventions were planned and implemented. Based on the empirical studies we argue that site-specific factors have to be taken into consideration. A theoretical implication of this finding is to develop a site-specific physical activity behavior model adding a layered structure to the ecological model representing the determinants related to the specific site

IS - var.pagings

N2 - Background: In response to the transfusion-transmitted AIDS epidemic the Commission of Inquiry on the Blood System in Canada recommended the development of a monitoring and tracking system of product usage. The Association of Hemophilia Clinic Directors of Canada (AHCDC) implemented the Canadian Hemophilia Assessment and Resource Management System (CHARMS) to track factor concentrates (FC) from the sole suppliers, Canadian Blood Services (CBS) and Hema-Quebec (HQ), to hospitals and to patients' homes. Objective: To identify the indications and locations for infusions of factor VIII (FVIII), factor IX (FIX), recombinant factor VIIa (rFVIIa) and FVIII inhibitor bypass activity (FEIBA) and review utilization during 2000-2009. Methods: All Canadian patients with hemophilia attend the 26 Canadian Hemophilia Treatment Centres (HTCs) and are registered with the Canadian Hemophilia Registry (CHR; ahcdc.ca) from which they

receive a unique number suitable for anonymizing data. HTC's receive product and infusion data from the blood suppliers (CBS, HQ), regional hospitals and patients. HTC's enter these data into their clinic-based CHARMS software program and then export the data to the national database (CentrePoint) where data are validated. Results: From 2000 to 2009, 2,904 patients received, predominantly, FVIII (902 million Units) and FIX (240 million Units). A total of 2,386(82%) had congenital bleeding disorders listed in the Canadian Hemophilia Registry. The remaining 518 were not registered because they either did not have inherited factor deficiency or had registrations pending. Most of FVIII and FIX was infused by patients at home: 90% to 95% for FVIII and 85% to 94% for FIX. The yearly amount of FVIII infused increased over time; this was accounted for by an increase in the number of patients who were treated shown by positive and significant correlation($r=0.89$; $p=0.04$), not so by amount infused per patient which remained constant ($p=0.57$). Furthermore, there was a linear relationship between an increase in patients and increased utilization, each additional patient predicting for an increased utilization of 96,217 units ($P=.04$). The highest proportional utilization of both FVIII and FIX was for prophylaxis, and this proportion increased over time, while the proportion used for bleeding remained steady. In 2009, the proportions used for prophylaxis were 73% and 60% for factor VIII and factor IX respectively; for bleeding the proportions were 16% and 30%, for surgery 1% and 4%, for immune tolerance induction 3% and 1%, and unclassified use was 6% and 5% respectively. Among inhibitor by-passing products, rFVIIa was the product most used by patients without bleeding disorders, 20% of VIIa being used by these patients but only 6% of FIEBA. FIEBA was predominant over rFVIIa for prophylaxis in children. Improvements in data collection included a notable decrease in the proportion of Unclassified usage; for FVIII from 12-36% each year from 2000-2004 to 6-16% from 2005-2009; for FIX from 14-41% each year before 2005 to 4-14% after 2004. Specifically, the decrease in Unclassified infusions of FVIII from 16% in 2005 to 6% in 2009 showed a statistically significant trend ($p=.02$). Conclusions: 1) Data collection became reliable after 2004 when the proportion of Unclassified indications and the annual increase in patient numbers fell to low levels; hence subsequent trends should be compared with the period 2005-2009. 2) The increase in total annual FVIII concentrate use is accounted for by the annual increase in patient numbers, not by the annual use per patient, 3) FC are increasingly being infused for prophylaxis. 4) The major site of infusion is at home, which is outside the scope of the existing tracking system and which comprises only blood suppliers and hospitals; hence, HTC's and a comprehensive tracking data collection system, CHARMS in this case, are both required components of an effective national tracking system and 5) a tracking system involving the entire supply and treatment chain is essential for predicting utilization and planning for future needs

N2 - It is known that physical activity (PA) behavior is influenced by many factors within the social ecological model. Using results from parent surveys distributed after their children's completion of a cardiovascular risk screening program, we explored the relationship between home and community environments on the amount of PA in which children engaged. Our hypothesis was that more immediate factors such as parent activity would have a greater impact on child activity than factors in their community environments. A large sample (n=450) of children (ages 5-10 years) were examined. Children's physical activity was assessed by adding the total minutes of active time weekly. Parent physical activity was measured with two self report items regarding the number of days per week they were active. Two scales were constructed to evaluate to effects of the home (9 items; alpha = .829) and community (16 items; alpha = .868). The home environment scale measured elements related to activity opportunities and home schedules; the community scale assessed presence of playgrounds, or safe sidewalks, for example. To assess associations between factors and children's PA, we conducted a linear stepwise regression with child age, parent PA, Home scale, and Community scale as predictors and the log transformed total weekly activity time as the dependent variable. Sixteen percent of children's PA was explained by the tested model. Figure 1 provides specific information about each variable. The home scale had the greatest weight (beta=0.360, p<.001), and proved to have a larger predictive effect than parent PA. These findings are significant for identifying which aspects of a child's surrounding to intervene for maximum impact on physical activity. Figure 1. R^{2} Change between model levels (Figure presented)

N2 - BACKGROUND It has been proven that males engage in physical activity more than females starting at a young age. The goal of this study was to investigate gender differences based on parenting behaviors such as the frequency with which parents send their children out to play. METHODS Parents of children participating in a free cardiovascular risk-screening program (CARDIAC Project) completed a behavioral survey. Children (n = 472; 43.3% female) who were enrolled in elementary school participated in the study. Parents provided information about children's physical activity and their own ways in which they provided support of activity at home. Children's participation in 12 activities was captured by total number of minutes per week. A combined mean activity score was calculated by summing the children's total time across all of the activities. Parent behavior, specifically the frequency at which parents send their children outside to play was captured using a Likert scale where "1" represented never and "5" represented daily. Child gender and the amount of time allowed outside for play were then entered into a linear regression model to examine their role as potential predictors of child activity. RESULTS A significant gender difference ($p < .001$) was noted in children's total activity time with boys (n = 237; 751 minutes/week) exhibiting higher mean activity each week than girls (n = 229; 521 minutes/week). Child gender and the amount of time allowed outside to play significantly predicted children's activity levels overall. This model explained 28.9% of the variance in children's activity levels ($F = 20.25$ (2); $p < .001$). Specifically, girls had less opportunity (3.75) than boys (4.05) to play outside.

CONCLUSION A factor behind the lesser physical activity in female adolescents is significantly related to the decreased opportunity to play outside. Additional parenting practices will be shared if presented. In conclusion, parent behavior plays a significant role in the proven gender differences with childhood physical activity

N2 - Background: Face memory has been proposed as a candidate endophenotype for bipolar disorder (BD) (Glahn et al 2010). However, researchers have yet to examine the neural correlates mediating face memory and encoding in youth. Both euthymic BD youth and children at familial risk show deficits in face emotion labeling (Brotman et al 2008), and demonstrate amygdala/parahippocampal gyrus hyperactivation during face processing (Olsavsky et al 2012). Pediatric BD patients and youth at-risk also show deficits in cognitive control (Brotman et al 2009), and prefrontal dysfunction during cognitive flexibility tasks (Kim et al 2012). Here, we compare neural activation during emotional face encoding in pediatric BD patients, children at familial risk with a first-degree BD relative, and healthy comparison youth. Behaviorally, we expect that pediatric BD patients and at-risk youth will demonstrate deficits in face memory (Glahn et al 2010) and increased intrasubject variability in response time (ISV-RT) (Brotman et al 2009). During successful and unsuccessful encoding of faces, we hypothesize that both BD and at-risk youth will demonstrate similar dysfunction in parahippocampal (Olsavsky et al 2012) and prefrontal (Kim et al 2012) regions mediating face emotion processing. Methods: Functional magnetic resonance

imaging (fMRI) data were acquired from 77 participants (8-18 years old), including 27 pediatric BD patients, 13 unaffected children at familial risk, and 37 healthy comparison youth. During the encoding phase of the study, fMRI data were acquired while subjects viewed a series of emotional faces in an event-related design. During separate blocks, subjects engaged in an explicit (rating hostility, subjective fear) or implicit (nose width or passive viewing) face viewing task. Using a subsequent-memory paradigm (Dickstein et al 2007), memory for faces was tested in a surprise recognition test outside the scanner. The memory test consisted of viewing neutral faces that included both previously viewed actors who had displayed emotions in-scanner and novel actors. A d' score was calculated to measure performance during the post-scan memory task; higher d' indicates better performance and memory discrimination. The main contrast of interest was activation during the two implicit processing tasks (nose width or passive viewing) while viewing faces remembered accurately (hit) vs. not (miss). We conducted two whole-brain ANOVAs, one for each implicit encoding task, using a $p < 0.005$ threshold with clusters > 45 voxels. Results: Groups did not differ on age, IQ, or sex distribution. There were no between group differences in face memory as measured by d' . However, consistent with our hypothesis, behavioral analyses revealed that BD ($p < .05$) and at risk ($p < .005$) youth demonstrated deficits in attention as measured by higher ISV-RT relative to healthy comparison youth during face encoding ratings (hostility, subjective fear, nose width). Groups did not differ in reaction time or face ratings. Whole brain ANOVAs on the hit vs. miss contrast revealed two patterns of activity, with BD and at risk youth differing from healthy comparison youth. During the nose width encoding task, BD ($p < .05$) and at risk ($p < .005$) youth demonstrated left superior temporal gyrus and left parahippocampal gyrus hyperactivity relative to healthy comparison youth. However, during the passive viewing encoding task, BD ($p < .005$) and at risk ($p < .05$; $p = .10$) demonstrated hypoactivity in the right middle temporal gyrus and inferior frontal gyrus. Conclusions: While memory for faces has been proposed as a potential behavioral BD endophenotype (Glahn et al 2010), this is the first study to examine the neural correlates of this deficit in youth. Unexpectedly, groups did not differ behaviorally in face memory discrimination. However, consistent with prior work, relative to healthy comparison youth, BD and at risk children demonstrated behavioral deficits in attention, manifest as higher ISV-RT. BD and at risk youth also showed similar patterns of neural dysfunction. Together, these findings suggest that when BD and at risk youth are able to successfully remember faces, the attentional and neural mechanisms mediating encoding differ from healthy comparison youth. Specifically, we observed hyperactivation in parahippocampal and superior temporal regions, and hypoactivation in middle temporal and inferior frontal areas. Dysfunction in the parahippocampal gyrus and prefrontal cortex is consistent with prior work in at risk and BD youth (Kim et al 2012; Olsavsky et al 2012). The superior temporal area is involved in face and emotion perception (Saidet al 2010), and is associated with the pathophysiology of pediatric BD (Pavuluri et al 2010). Our results build on work identifying behavioral deficits in face memory (Glahn et al 2010) by suggesting neural deficits associated with emotional face encoding. Future studies should include larger samples and a longitudinal design to determine whether the neural deficits associated with emotional face encoding predict the onset of BD in youth at risk for the illness. With further study, risk stratification and preventive interventions could be used to potentially mitigate the development and prevalence of BD

N2 - Background: Nonhuman primates (NHPs) serve as excellent models for human psychopathology as they share many similarities in behavior, neuroanatomy, and genetics. To determine whether infant monkeys reared in a naturalistic setting could serve as useful models for the development of normally-occurring childhood anxious behaviors, we adapted assessments designed to test anxiety in children. To begin to understand other physiological links to anxious behavior we measured level of physical activity in infancy through pubertal development. Methods: We studied infant rhesus macaques (n=640) raised in a naturalistic outdoor setting. Between 3 and 6 months of age, monkeys were given modified assessments that are routinely used to evaluate behavioral inhibition in children. When monkeys were 3 years of age (just post-pubertal), anxiety tests were again performed and activity was measured by accelerometer. Results: Factor analysis revealed three factors related to anxiety (behavioral inhibition, reticence, impassivity) accounting for 52.8% of variance in observed behaviors. Behavioral inhibition was decreased exploration in the presence of the mother (as defined in children). Reticence was decreased exploration when alone and impassivity was decreased behavioral expression in the face of a threatening or frightening stimulus. Activity measured in infancy was correlated with reticence ($r=0.685$, $p<0.001$) and impassivity ($r=0.728$, $p<0.001$), and remained correlated with these anxious behaviors in late adolescence, such that monkeys that were more reticent to explore and showed greater impassivity when confronted with novel or frightening stimuli were less active. Both anxious behavior and activity measures were significantly heritable. Anxiety traits were strongly associated with physiological correlates of anxiety (i.e., responsiveness to alcohol, CSF monoamine levels, heart rate and sleep). Conclusions: These findings show that monkeys reared in a naturalistic setting exhibit a spectrum of anxious behaviors that parallel what is observed in clinical settings. Level of physical activity is strongly correlated with the display of several anxious behaviors

N2 - Background: Current PENTA guidelines recommend lifelong cART for children. Switching to boosted PI monotherapy in adults with suppressed VL has been shown in randomised open trials to be a viable strategic option with switch/intensification in the occurrence of viral rebound. Outside of studies, boosted PI monotherapy is usually reserved for particular circumstances such as renal dysfunction, simplification, toxicity, or where adherence and drug-selected resistance is a concern. This report describes our experience with children where additional disruptive factors in family, school and home as well as peer pressure and pubertal development are evident. Methods: Patient, pharmacy and laboratory results were reviewed and a database constructed for analysis. Adherence was measured in consultations with patients and their families. Results: Four patients were identified, three patients on PI monotherapy, one on patient on PI double therapy. All patients were male, median age: 14 years (range 11-16 years). Average age at diagnosis of HIV was 6 years (range 2-10 years). All were commenced on combination ARV therapy at diagnosis and had been treated for over 6 years (range 6-10 years). At PI initiation: average CD4 count 677 (range 503-753), 3 patients had undetectable viral loads, one patient whose compliance was poor due to family circumstance had a viral load was 9, 217. Reasons for changing to PI monotherapy included reducing the number of medications (100%),

lipodystrophy(50%),increased protein: creatinine ratio(25%)and drug resistance. The patient prescribed double PI therapy had genotypic resistance to all NRTIs including intermediate resistance to Tenofovir and all NNRTIs. PI prescribed: Loponavir and ritonavir (25%) darunavir with ritonovir (50%) Loponavir, ritonavir and atazanavir (25%) The average CD4 count increase on PI monotherapy was 82 (range 21- 150). All patients had undetectable viral loads after PI monotherapy including the patient with an initial viral load of 9, 217.

Conclusion: Paediatric HIV treatment is a challenge in which boosted PI monotherapy may play a helpful role. Patients showed increased CD4 counts and decreased viral load. PI monotherapy allows adherence issues to be worked through without further resistance, simplifies therapy where there is NNRTI/NRTI resistance. All medication changes have to be made with the child and parents on board until they are able to take control of their own health and medications

IS - var.pagings

N2 - Background: Children with motor disorders such as hemiplegia or acquired brain injury, have particular difficulty performing hand and arm movements, especially those involving bimanual control. The Hand-Arm Bimanual Intensive Therapy (HABIT) programme has been found to be beneficial in improving bimanual function in some children with hemiplegia. However the need for significant repetition and massed practice (hours and intensity of therapy contact) is difficult to achieve in clinical settings and thus may limit outcomes. Incorporating magic 'hand' tricks as a motivator to pursue exercises outside of direct therapy was meant to overcome this limitation. Objective: The aim of this study was to examine the efficacy of a modified HABIT

programme-using Magic Tricks to improve upper limb motor function in children with spastic hemiplegia. Method: Movement exercises designed as 'magic' tricks were incorporated into a HABIT protocol. Children between 7 and 15 years ($n = 23$) participated in a 2-week summer camp involving 60 hours of intervention in a clinical setting. A within ($n = 23$) and between groups (treated vs treatment wait) experimental design was used to contrast performance across manual tasks pre and post intervention. Measurements of bimanual performance in daily tasks were made using the Assisting Hand Assessment and Children's Hand Experience Questionnaire (CHEQ). The results of the CHEQ as a measure of generalisation will be reported here. Results: Results on the CHEQ within participants show a significant increase in the number of activities performed independently ($F(df 2,20) 16,00, p = 0.001$) and number of activities performed successfully with two hands ($F(df 2,20) 17.71, p < 0.001$) following participation in the camp. No significant loss of skills was noted at 3 month review. Conclusions: Preliminary results suggest that a modified HABIT programme using magic as a motivator may enhance therapeutic outcomes in children with spastic hemiplegia

N2 - Purpose: To highlight the importance of high suspicion and early diagnosis of IASA in elderly patients with chronic constipation. Methods: Chart review. Results: We present a case of IASA in an 88 year-old female with past medical history of dementia, insomnia, falls, heart block, non-Hodgkin lymphoma, and CHF. The patient had a history of transverse colectomy for colon cancer 16 years prior. She was admitted to the hospital because of worsening abdominal distention and constipation ongoing intermittently for 10 years. She did not have abdominal pain, nausea, vomiting, hematemesis, hematochezia, or fever and her vitals were normal. Examination revealed a soft but markedly distended abdomen without rebound or guarding. Rectal exam did not show impaction or active bleed, but sphincter tone was significantly increased. Labs revealed a normocytic anemia and normal WBC count. KUB showed markedly distended small and large bowel loops and a dilated rectum measuring 2222 cm. Differential diagnoses considered were Ogilvie's syndrome, ileus due to gastrointestinal dysmotility aggravated by thyroid dysfunction or electrolyte abnormalities. CT abdomen showed resolving right ileopsoas hematoma from a prior fall, mild ascites, absence of pneumatosis, and presence of a markedly dilated sigmoid colon and rectum. The patient had a soft rectal tube placed with which her abdomen very rapidly decompressed. She was also started on intravenous erythromycin, empiric antibiotics, and scheduled soap suds enemas. She had multiple bowel movements and did not require flexible sigmoidoscopy for decompression. Further lab investigations excluded thyroid dysfunction, infectious etiologies

such as C. diff, UTI, and significant electrolyte imbalances. Colonoscopy from a prior admission at an outside hospital was negative for sigmoid volvulus or recurrent cancer. Alternative diagnosis of IASA was made. After improvement, she was started on diet, oral Miralax, and glycerin suppositories and the rectal tube was removed. The patient and her family were informed about treatment options such as anal sphincterectomy and botox injection to the anal sphincter. Given her dementia and the risk of fecal incontinence they decided against these options. The patient was placed on nifedipine cream. Conclusion: Although rarely seen, IASA has been primarily described in children. However, it should be in the differential diagnosis in elderly patients with chronic constipation with increased sphincter tones. High level of suspicion and early treatment with rectal tube decompression leads to rapid resolution of symptoms

N2 - Isolated central congenital hypothyroidism (ICCH) is a rare disease with so far undescribed associations with peripheral features outside the thyroid axis. Here we present three boys, from two separate pedigrees, with ICCH and progressive testicular enlargement under prepubertal levels of FSH, LH and testosterone. We hypothesized that the secretion of an abnormal TSH molecule with low bioactivity towards the TSH receptor (TSHR) but aberrant stimulation of testicular FSH receptor (FSHR), could explain the phenotype. Methods: Thyroid and sex hormone axes were monitored in these children, including TRH- and GnRH-tests, α -subunit, inhibin-B and anti-mullerian hormone (AMH). Bioactivity of patients' sera was studied against TSHR- and FSHR-transfected cells in separate luciferase reporter assays. Cells were stimulated with hrTSH, rhFSH or patients' sera. Luciferase expression under control of a promoter containing 6 CRE (cyclic-AMP-Responsive-Element) sites was measured by luminescence and normalized for transfection efficiency. Likely candidate genes for the phenotype were fully screened for mutations. Results: All patients had a type 2 (pituitary) response to TRH-test, and pre-pubertal responses to GnRH. They started puberty at 12.5 years with testicular volumes of 8-12 ml, reaching 30-37 ml after puberty. α -subunit is normal, but inhibin-B (351-505 ng/L; n: 138-196) and AMH (18.3-48 ug/L, n: 5-9) were strongly elevated. Patient 1 showed decreased TSH bioactivity for TSHR (n=3) and increased stimulation of FSHR-cells (n=1), compatible with initial hypothesis. Patients 2+3 showed normal serum bioactivity. TSHB, CGA and TRHR genes were wildtype. Conclusions: We present an undescribed, genetically "orphan" association of TSH deficiency and macroorchidism. Macroorchidism is due to increased Sertoli cell mass, secreting inhibin-B and AMH. In patient 1, reduced stimulation of TSHR and increased stimulation of FSHR suggest a posttranslational (glycosylation) defect of TSH. Normal serum bioactivity of patients 2+3 towards TSHR/FSHR suggests a mechanistically different entity

N2 - Little is known about the health impact of air pollution on children's cardiovascular health. A cross-sectional study was conducted and data was analysed in 2048 Chinese schoolchildren (aged 8-10 years) in three districts of Hong Kong to examine the association between exposure to outdoor air pollution and cardiorespiratory fitness. Annual means of ambient PM₁₀, SO₂, NO₂ and O₃ from 1996 to 2003 were used to estimate individual exposure of the subjects.

Cardiorespiratory fitness was measured for maximal oxygen uptake (VO_{2max}), predicted by the multistage fitness test (MFT). Height and weight were measured and other potential confounders were collected with questionnaires. Analysis of covariance was performed to estimate the impact of air pollution on complete speed in the MFT and predicted VO_{2max}. The results showed that children in high-pollution district had significantly lower complete speed and predicted VO_{2max} compared to those in low- and moderate-pollution districts. Complete speed and predicted VO_{2max} was estimated to reduce 0.327 km h⁻¹ and 1.53 ml kg⁻¹ min⁻¹ per 10 µg m⁻³ increase in PM₁₀ annual mean respectively, with those in girls being greater than in boys. Being physically active could not significantly result in improved cardiorespiratory fitness in polluted districts. The adverse effect seems to be independent of short-term exposure to air pollution. We concluded that long-term exposure to higher outdoor air pollution levels was negatively associated with cardiorespiratory fitness in Chinese schoolchildren, especially for girls. PM₁₀ is the most relevant pollutant of the adverse

effect. Elevated cardiorespiratory fitness observed in physically activate children could be negated by increased amount of inhaled pollutants during exercise. 2012 Elsevier Ltd

N2 - Background/Objectives: Few investigations have examined cross-cultural or geographical differences in children's outside of school activity participation. The objective of this CAPE International Collaborative

Network study was to conduct secondary analyses of datasets from Canada (Ontario and Quebec), Australia, and the U.S. to examine geographic variation in recreational and leisure participation as a function of region, age group, and gender. Design: Descriptive study (survey). Participants and Setting: Data from 1076 children/youth with cerebral palsy (CP) were included, ages 6 to 20 years (114 from Australia, 217 from Ontario, 245 from Quebec, 500 from the U.S.). There were 611 males and 465 females; 317 were ages 6 to 10, 383 ages 10+ to 13, 233 ages 13+ to 16, and 143 ages 16+ to 21; 358 at GMFCS level I, 405 at level II/III, and 313 at level IV/V. These children and youth had participated in research studies involving the Children's Assessment of Participation and Enjoyment (CAPE) in the four regions. Materials/Methods: Analyses involved CAPE diversity scores for five types of activities (recreational, active physical, social, skill-based, and self-improvement). Three-way analyses of covariance were conducted to examine participation patterns as a function of region, age group, and gender, controlling for family income, education, and GMFCS level. Non-significant interaction effects and covariates were removed from the models, and homogeneity of variance was tested. Effect sizes (partial eta-squared; η^2) were calculated. Results: F-tests indicated the significance of factors or covariates, controlling for all other factors and covariates in the model. Region, age group, gender, income, education, and GMFCS level all significantly affected the number of activities engaged in. The largest effects were for region on active physical, $F(2,2688)=30.6$, $P<0.0001$, $\eta^2=0.08$, and self-improvement diversity, $F(2,2725)=48.4$, $P<0.0001$, $\eta^2=0.12$; age group on recreational diversity, $F(3,3913)=62.4$, $P<0.0001$, $\eta^2=0.17$; and GMFCS level on recreational, $F(2,2913)=53.3$, $P<0.0001$, $\eta^2=0.10$, active physical, $F(2,2688)=45.1$, $P<0.0001$, $\eta^2=0.12$, and self-improvement diversity $F(2,2725)=30.0$, $P<0.0001$, $\eta^2=0.08$. Conclusions/Significance: Children/youth from the U.S. took part in the fewest active physical activities; those from Ontario took part in the most self-improvement activities. The youngest age group took part in the most recreational activities, and those in GMFCS level IV/V had the lowest levels of participation in recreational, active physical, and self-improvement activities, confirming previous research findings. The differences in participation across regions may have important implications for rehabilitation services, health care systems, and community-based services for children with CP

N2 - Background/Objectives: There is increasing interest in measures of the physical and social environment. The 32-item MEQAS is an observer-rated measure providing a global assessment of aesthetic, physical, social, and opportunity-related qualities of leisure activity settings for youth with disabilities (e.g. playing ping pong at a community centre, playing piano in the living room). To describe the measure's development and psychometric properties. Design: Instrument Development and Validation Study. Participants and Setting: Six content experts took part in the consultant review phase, with backgrounds in psychology, AAC, speech-language pathology, occupational therapy, inclusive design, and child/adolescent psychiatry. The pretesting phase involved two adult users of AAC and an architect. The psychometric phase involved four trained raters with backgrounds in occupational therapy. The MEQAS was developed at a children's rehabilitation centre in Toronto, Canada. Materials/Methods: Development involved: (1) item generation based on a literature review and existing environmental assessment tools; (2) consultations with experts, including youth with disabilities, parents, and scholars; (3) pretesting; and (4) psychometric testing. Eighty MEQAS questionnaires were completed by sets of raters who observed and independently rated 22 home and community activity settings (representing active, passive, outdoor, indoor, formal, informal, group, and solitary activity settings). Scales were determined using principal components analyses. Test-retest reliability was determined for eight activity settings, rated twice (an interval of 4-6wks) by a trained rater. Results: The factor structure accounted for 79.5% of the variance. The KMO Measure of Sampling Adequacy was 0.73 and Bartlett's Test of Sphericity was significant ($P < 0.0001$). Cronbach's alphas for the scales (Opportunities for Social Activities, Opportunities for Physical Activities, Pleasant Physical Environment, Opportunities for Choice, Opportunities for Personal Growth, and Opportunities to Interact with Adults) ranged from 0.76 to 0.96. Inter-rater reliability of the scale scores (absolute agreement ICCs) ranged from 0.60 to 0.93. Test-retest reliability ranged from 0.70 to 0.90. Conclusions/Significance: Results suggest that the MEQAS has a sound factor structure and preliminary evidence of internal consistency, inter-rater, and test-retest reliability. The MEQAS is the first observer-completed measure of qualities of environmental activity settings. The measure will be useful for the design of social ecological programs for youth with disabilities, and for research on associations between environmental qualities of activity settings and youths' experiences. The MEQAS can be used to promote youth wellness through the design of settings and environments that provide appropriate developmental opportunities

IS - var.pagings

N2 - Nepal is a developing country in Southeast Asia which has limited health care facilities and low literacy rates. A descriptive observational study assessing social and economic issues impacting diagnosis and subsequent care in 47 children and adolescents enrolled into the Life for a Child (LFC) program at Patan Hospital was undertaken using some questionnaires and reviewing the patient records. The mean age of our children is 15.5 years and the mean age at diagnosis was 11.8 years. The duration of symptoms before diagnosis ranged from a few days to 2 years with a mean duration of 3.3 months. Most children had several visits to the local level health facilities and private clinic visits before a diagnosis of Type I diabetes was made. More than one third of the families went to alternative medicine practices early in the disease course. Eighteen of the children enrolled are from Katmandu valley while 3 families moved to Katmandu after their child's diagnosis. For children from outside Katmandu, the distances to the nearest health facility ranged between 15 minutes to 2

hours. Few of the parents of these children had education beyond grade 10. Many were illiterate and some were literate but with no formal schooling. HbA1c values were lower in children with educated parents and so was the duration of symptoms to diagnosis. Less than a half of the children and/or parents were able to adjust the insulin dosage on their own. Among children and adolescents between 2 to 20 years 36% had a BMI of <5%ile at the time of enrollment. Most children are continuing their studies, though some were at grades not appropriate for their age and a few left schools due to financial constraints. Lack of awareness, unavailability of blood glucose testing at local level health facilities, delay in diagnosis, poor health support system and non-affordability to lifelong treatment are the main challenges. The support from LFC program has played an important role in the lives of these children

N2 - Objective. Athletes may face unique barriers to asthma management and are exposed to many different environmental factors while playing sports. The authors' goal was to study participation in sports and perceptions of environmental exposures (health risks) and barriers to asthma management for adolescent and young adult athletes. The need for asthma education among coaches was also investigated. Methods. This study targeted 3 populations: (a) coaches of middle school through college level athletes, (b) parents/guardians of middle school through college level athletes, and (c) college athletes. Online surveys were conducted anonymously. Questions addressed sport-specific asthma management barriers, perceived environmental exposures (health risks), athlete training intensities, and asthma knowledge and awareness among surveyed coaches. Results. There were 120 participants (26 coaches, 37 college athletes, 57 athlete parents/guardians). Most reported perceived environmental health concerns and potential barriers to asthma management for athletes, with 94% and 84% of participants reporting at least one, respectively. There were observed differences in the numbers of environmental health concerns and potential barriers to asthma management reported per person across surveyed populations depending on sport, training intensity, and athlete asthma status. The percentage of correct responses by coaches to 5 asthma knowledge questions ranged from 12% to 88%. Conclusions. Research should further investigate how to prioritize and develop interventions to address potential barriers to asthma management for adolescent athletes in both school and community parks and recreation facility settings. Additionally, solutions are needed to mitigate outdoor and indoor environmental health concerns of athletes. Coaches may benefit from increased asthma awareness and educational interventions aimed at improving asthma knowledge specific to athletics. 2012 The Author(s)

N2 - Background: Cutaneous leishmaniasis is an important parasitic disease of tropical and semi-tropical areas of the world. The current study is carried out to evaluate the epidemiology of cutaneous leishmaniasis in Qom province during 2007-2009. Methods: The study was performed on patients referred to nine health centers in Qom province. The patients were included in the study by random sampling. This descriptive cross-sectional study was performed during 2007-2009. Diagnosis of the disease was based upon the clinical examination and specimens taken from wound serosity, which then underwent Giemsa staining. The demographic data and results of clinical and laboratory evaluations were recorded in patients' datasheet. Results: From 2007 to 2008, the prevalence of leishmaniasis had a decreasing trend, while it had an increasing trend in 2009. The highest prevalence rates were observed in October and November, and the trend was decreasing in winter. The disease occurred mostly in Iranian males, in the age range of 16-20. In 2007, it was reported mostly in rural population, while in 2008 and 2009, it occurred mostly in urban population. In the years studied, most patients had one lesion in arms, legs, face, and then other regions of the body. Conclusion: The causes of the higher prevalence of the infection in men above 15 can be attributed to their less covering, and spending more time outdoor for daily activity and work, both of which cause higher probability of contact with sandflies. Authorities should pay attention to the importance and priority of leishmaniasis control, as well as allocating adequate funds for control measures

N2 - Unhealthy lifestyle and limited physical activity tend to be main factors adversely affecting the development of the young generation. The aim of this study was to evaluate the prevalence of postural disorders in the sagittal plane as well as to compare posture types taking into consideration physical activity of the examined children. The data was gathered in 2002 and 2008 in Polkowice. The examined group consisted of 2398 children - boys and girls aged 7 to 11. Body posture was measured by means of the photogrammetric method with the use of Moire pattern. A questionnaire was used to gather information concerning the amount of time outside of school spent on physical activity, watching TV or playing computer games. While comparing the prevalence of postural disorders in 2002 and 2008 an overall increase was observed - higher in girls than in boys. The posture types distribution was comparable in both studies. Kyphotic and balanced posture types were predominant in boys, whereas in girls lordotic and balanced types were more frequent. The questionnaire showed that between 2002 and 2008 physical activity after school decreased

N2 - This article presents major epidemiologic features of tick-borne encephalitis (TBE) in the Czech Republic, using data of laboratory-confirmed cases since 1970. A total of 17,053 cases of TBE were reported in the Czech Republic (population 10 million) in 1970-2008. The data show several important features. First, the pattern of TBE incidence changed over time. Until the end of the 1970s, TBE was characterized by periods of alternately higher and lower incidence (between 180 and 595 cases per year); the 1980s were a period of low incidence with minimum variability; since the beginning of the 1990s, there has been a steep rise in incidence, with marked year-to-year variation (e.g., 745 cases were registered in 1995, and a maximum of 1029 cases were registered in 2006). Second, the age distribution of TBE incidence has changed. Until the end of 1990s, incidence peaked among those 15-19 years of age, with a gradual decline with age. In the 2000s, however, TBE incidence has been rising in those aged 60-64 years, with a sharp decline in those older than 65 years. Third, the seasonal pattern of TBE has changed markedly over time. In the earlier period, incidence had a clear peak in July/August; since the 1990s, more cases have occurred in earlier and later months of the year. The proportion of cases occurring in April, May, October, and November increased from 9% in the 1970s to 23% in 2000-2008. Fourth, the geographical distribution of TBE also changed over time, with TBE increasingly occurring in the mountainous districts at higher altitudes. These changes in incidence patterns appear to be linked with changes in climatic and meteorological conditions. The link between climate change and TBE incidence is plausible, since TBE is a recreation-related infection associated with outdoor activities, and since climatic changes affect the life cycle of the vector. N2 - Aim: To investigate the features of a new tularemia outbreak that occurred in the Thrace region. Materials and methods: The research team visited the village after the identification of the index case. Serum and throat samples were taken from 41 villagers who were examined, and environmental samples were taken in order to identify the source of the outbreak. Culture, serology, and molecular methods were used to search for Francisella tularensis in these samples. Results: A total of 8 children were diagnosed with tularemia. The adults and all of the other children were seronegative for tularemia. All of the patients had a history of swimming in a pool filled with water from a local stream, and contact with stream water was calculated to increase the risk of developing the disease 9.3-fold. Polymerase chain reaction analysis was positive in a lymph node aspirate of the index case and in the home tap water of 3 patients as well as in the spring water and stream water in the village. Francisella tularensis could not be isolated from any culture of samples. Interestingly, the waterborne tularemia outbreak affected only children. Conclusion: Although tularemia has been not reported from Tekirdag Province for 74 years, the disease reemerged in the region due to the removal of hygienic measures. These clues may signify that the agent had maintained its presence in the region for many years. TUBITAK

N2 - E. Roy John and Leslie Prichep (2006) proposed an EEG Homeostatic Model for the brain. In this model, neurotransmitters mediate neuroanatomical structures that generate behavior regulated by emotional experience in the moment of the event. They proposed that "psychological and neurological disorders produce and are caused by deviations from homeostasis" (p. 135). If an environment or psychological challenge continues for an extended period, the set point for homeostasis adapts to a new point. This short course provides information about the importance of nutrition, exercise, and sunlight in the process of reestablishing EEG homeostasis. David Siever will review the literature concerning the effects of nutrition, exercise and sunlight on the brain, and Ron Swatzyna will present his EEG/QEEG study on the impact of breakfast patterns in children. Nutrition affects oscillatory rhythms and neuronal functioning. Iodine boosts IQ and helps prevent mental retardation. Omega 3 s, selenium, and magnesium all improve mental function and reduce depression. Exercise has been shown to be highly effective for improving IQ, math ability, and reducing depression. Exercise should be a mandatory part of any academic program. Preliminary findings using QEEG suggest that what is eaten for breakfast has an effect on both mood and mental performance. As for the importance of sunlight, as much as 6% of northern populations are believed to develop winter blues. Depression, anxiety, insomnia, multiple sclerosis, migraine, seizure, fibromyalgia, and dementia are well correlated with a deficiency in vitamin D. Previous research has always assumed that winter blues was the result of seasonal affective disorder, which comes about as a lack of optic stimulation to UV receptors in the eyes and, ultimately, the pineal gland. There are several similarities in the symptoms of SAD and vitamin D deficiency, and therefore it is possible that SAD has been misdiagnosed since its inception. A recent study on vitamin D deficiency has shown that vitamin D supplementation eliminates the symptoms of SAD in SAD sufferers. The human brain was never designed to be healthy; it was designed to survive. Despite the robustness of the brain, we are not sharp and productive, nor social, lively, and joyful unless we address good nutrition and exercise. We have to work at being mentally healthy. As long as we are ignoring our basic needs, the brain will do what it has to along a predictive pathological course to survive, and we will suffer. Active voluntary participation in good nutritional decisions, exercise routine, and outside activities (if possible) are necessary for EEG Homeostasis

N2 - Background. Behavioral modification of malaria vectors in response to vector control methods is of great concern. We investigated whether full coverage of long-lasting insecticide-treated mosquito nets (LLINs) may induce a switch in biting behavior in *Anopheles funestus*, a major malaria vector in Africa. Methods. Human-landing collections were conducted indoor and outdoor in 2 villages (Lokohoue and Tokoli) in Benin before and 1 year and 3 years after implementation of universal LLIN coverage. Proportion of outdoor biting (POB) and median catching times (MCT) were compared. The resistance of *A. funestus* to deltamethrin was monitored using bioassays. Results. MCT of *A. funestus* switched from 2 am in Lokohoue and 3 am in Tokoli to 5 am after 3 years (Mann-Whitney U test, $P < .0001$). In Tokoli, POB increased from 45 to 68.1 (odds ratio = 2.55; 95 confidence interval = 1.72-3.78; $P < .0001$) 1 year after the universal coverage, whereas POB was unchanged in Lokohoue. In Lokohoue, however, the proportion of *A. funestus* that bites after 6 am was 26. Bioassays showed no resistance to deltamethrin. Conclusions. This study provides evidence for a switch in malaria vectors' biting behavior after the implementation of LLIN at universal coverage. These findings might have direct consequences for malaria control in Africa and highlighted the need for alternative strategies for better targeting malaria vectors. 2012 The Author

N2 - Background: To an adolescent or young adult (AYA), a diagnosis of cancer poses unique challenges to personal and social development: interrupting social relationships, halting the move towards independence, and postponing achievement of educational and occupational goals. Isolation, side effects of treatment, dependence upon family members, and changes in body image lead to an interruption of identity development and often results in emotional symptoms including anxiety and depression. The goal of this research was to measure the psychosocial services utilized by AYAs in a pediatric program at a comprehensive cancer center. Methods: The Pediatric Psychosocial Support team at a comprehensive cancer center in the United States collected data on services (emotional coping, family conference, social services, medical education, psychosocial screening, socialization, school, symptom management) rendered by the psychosocial team (psychiatry, psychology, clinical social work, child life, palliative care, chaplain) to all patients over a 2 month period. Quantity and types of services utilized were examined contrasting the Pediatric (0 to 15) and AYA (16+) age groups. Results: A total of 1403 encounters were collected amongst 149 unique patients. Services were provided to 56 AYA patients with an average of 14 encounters per patient. Services were provided to 97 pediatric patients with 6 encounters on average. AYAs had a significantly higher number of encounters per patient than Pediatric patients. ($p < 0.05$). The top interventions provided to AYAs were emotional/coping support (44.7%), school (15.3%), socialization (15.1%), and social services (15%). The top interventions for pediatrics were emotional coping (57.3%), socialization/developmental activities (17.3%) and school (9.9). While AYAs required slightly less emotional/ coping support, they needed more support in the area of social service (financial assistance, accessing resources, and advocacy). Finally, AYAs received emotional/coping resources primary from Clinical Social Work professionals, while Pediatric patients received emotional and coping support primarily from Child Life Specialists. Conclusion: The results suggest that AYA oncology patients continue to need outside support to address the needs that arise from a cancer diagnosis. AYA patients like pediatric patients, need support in the area of coping, socialization, and schooling. Unlike pediatric patients, however, they have many more concerns with regards to navigating financial, resource, and advocacy concerns than pediatric patients and their families

N2 - Background: The age of adiposity rebound (AR), when body mass index (BMI) starts to rise after infancy, is thought to be an origin of obesity in later life. We have already reported that children who exhibited an earlier AR were associated with the higher BMI value and atherogenic metabolic status at 12 years of age. We investigated which factors influenced on an earlier AR, birth weight, initial feeding, family history, meals or exercise. Methods: A total of 533 children in the community were enrolled in the study. Serial measurements of BMI from 4 months to 12 years were carried out prospectively. We calculated the age of AR, defined as the age which the lowest BMI occurred during this period. The subjects were divided into 2 groups according to BMI at 3 years is bigger than at 1.5 years (earlier AR group) or not (later AR group). We asked the answering to the question sheet about weight at birth, initial feeding (breast-feeding, bottle-feeding or mixed feeding), family history, meals, and exercises of their parents when children were at 3 years old. We also analyzed which BMI predicted the obesity at 12 years old, 4, 8, 12, 18 month or 2, 3, 4, 5 or 6 years by using ROC analysis. Results: Weight at birth was associated with earlier AR if birth weight was over 3500g, but was not associated with the timing of AR if it was between 1500g and 3000g. Initial feeding was not related to the timing of AR and the frequency of obesity at 2 years old. None of the breast-feeding subjects showed severe obesity at 12 years old. The factors as follows were associated with later AR; eating breakfast everyday, not eating snacks, non-obese father, the first baby, going to kindergarten. Contrary to expectation the habits of drinking sweet beverages and playing outside were not related to earlier AR. BMI at over 2 years old predicted to the obesity at 12 years old, but BMI in the infantile periods did not. Conclusions: This study showed that obesity at 12 years old was associated with weight gain over 2 years old, but not with the weight gain during infantile period

N2 - Background American tegumentary leishmaniasis (ATL) and sporotrichosis exhibit similar histopathology and low frequencies of microorganism detection. Objectives This study seeks to identify microscopic alterations that can distinguish between these diseases. Methods Haematoxylin and eosin stained slides of 171 ATL and 97 sporotrichosis samples from active cutaneous lesions were examined for histopathological alterations. The lesions were diagnosed by isolating the agent (which was not visible) in culture. An intuitive diagnosis was assigned to each slide. The strength of the association between the histopathological findings and the diagnosis was estimated by an odds ratio, and each finding was graded according to a regression model. A score was assigned to each sample based on the histopathological findings. A study of the interobserver reliability was performed by calculating kappa coefficients of the histopathological findings and intuitive diagnoses. Results The markers 'macrophage concentration', 'tuberculoid granuloma' and 'extracellular matrix degeneration' were associated with ATL. 'Suppurative granuloma', 'stellate granuloma', 'different types of giant cells', 'granulomas in granulation tissue' and 'abscess outside the granuloma' were associated with a diagnosis of sporotrichosis. 'Macrophage concentration' and 'suppurative granuloma' had the highest (substantial and almost perfect, respectively) reliability. The regression model score indicated 920% accuracy. The intuitive diagnosis had 825% diagnostic accuracy and substantial reliability. Conclusions Taking into account the clinical and epidemiological context, some histopathological alterations might be useful for the differential diagnosis between ATL and

sporotrichosis cutaneous lesions in cases in which the aetiological agent is not visible. 2012 British Association of Dermatologists

VL - Conference: 26th Annual North American Cystic Fibrosis Conference Orlando, FL United States.

Conference Start: 20121011 Conference End: 20121013. Conference Publication:

IS - var.pagings

N2 - The Toronto Adult Cystic Fibrosis (CF) Program at St Michael's Hospital was established in 1992 and is North America's largest adult CF program. Two satellite CF clinics were established for patients in northern Ontario communities hundreds of miles away. Frequent follow up in multidisciplinary CF clinics is known to improve patient outcomes. However, satellite clinics do not allow access to the entire multidisciplinary team, as reimbursement is limited for expenses related to physician visits. For appointments at the host hospital scheduling limitations such as accommodating patients' work or school responsibilities, availability of space, the CF physician's schedule, and inclement weather frequently led to last minute clinic cancellations. Objectives: The main goals of this initiative were to improve patient care and education by utilizing videoconferencing. Patients would come to Toronto once a year, attend satellite clinics twice a year and have a telemedicine appointment annually. Methods: In July 2010, monthly telemedicine multidisciplinary CF clinics were established to address the barriers that impede access to care. Patients were interviewed by the local nurse and spirometry and bloodwork were done. Results were sent by FAX to the Toronto clinic and the patients were able to see team members by video link. Results: The telemedicine conference visit was used in two major ways - for routine clinic visits and for episodic illness. To date, there have been 71 patients seen by telemedicine conference with 22 monthly clinics held and 10 patients seen outside of the monthly clinics. As time passed clinicians became more experienced with the format and used the telemedicine link in increasingly diverse ways. Several telemedicine clients in remote locations were cared for on home intravenous therapy. One ventilated client was being considered for transplant while hospitalized 800 miles away and was monitored and coached via telemedicine by both the CF and transplant physicians. For a newly diagnosed client the CF doctor used telehealth to explain how to use enzymes. The nurse practitioner was able to present diagrams of the pathophysiology of cystic fibrosis by video for the patient to see. The physiotherapist used telemedicine to demonstrate correct technique for airway clearance. The mother of a CF child commented that the drive to the telehealth studio took 15 minutes compared with a 10 hour trip to the Toronto clinic. One patient explained that the trip to Toronto meant interrupting her life-sustaining therapies including masks, physio and exercise. Discussion: Telemedicine improved patient care, reduced patient costs and improved inter-professional collaboration. We were able to strengthen relationships with community partners by incorporating visits with local care teams. The telemedicine visits express our client-centred approach to care by maintaining interprofessional collaboration with the CF team while saving the client time and travel costs. Future plans include continuing to promote attendance at telehealth and possibly considering specialized clinics such as CFRD clinics that could be held via telehealth

N2 - Purpose: Mediterranean diet has favorable effects on the cardiovascular system, while albuminuria is associated with atherosclerosis progression. The aim of the study was to investigate the relationship of dietary habits with urinary albumin excretion, expressed as the albumin to creatinine ratio (ACR), in a cohort of adolescents Methods: A total of 365 adolescents 12-17 years of age [212 males, aged 13.9 years, office blood pressure (BP)=115/67 mmHg] that were included in the Lyceum Leontio Albuminuria (3L) study were considered for analysis. In all participants ACR values were determined in a morning spot urine and for each adolescent a questionnaire was completed on lifestyle and socio-economic characteristics. Moreover, the Mediterranean Diet Quality Index for children and adolescents (KIDMED) was estimated and accordingly subjects were divided into those with optimal (>7), average (4-7) and low (<4) score. Results: Only 6.8% of the participants had optimal KIDMED score, whereas 51.2% had an average and 42% had a low score. Participants with at least average KIDMED score (n=187) compared to those with low KIDMED score (n=153) had higher body mass index (22.2 vs 21.4 kg/m², p=0.043) and waist circumference (77.6 vs 75.4 cm, p=0.044), spent more frequently time for sports activities outside school (75.2% vs 58%, p=0.001), reported less consumption of foods outside home (3% vs 14%, p<0.001) and less hours of watching television (1.75 vs 2.05 hours, p=0.013). Moreover, those with at least average compared to those with low KIDMED score exhibited higher systolic BP (117 vs 114 mmHg, p=0.039), whereas had lower heart rate (84 vs 87 bpm, p=0.014) and ACR levels (12.6 vs 20.5 mg/g, p=0.015). In the total population, ACR was associated with age (r=-0.11, p=0.044), body mass index

($r=-0.131$, $p=0.016$), systolic BP ($r=-0.144$, $p=0.008$) and KIDMED score ($r=-0.111$, $p=0.041$). Conclusion: In adolescents there is an inverse relation of KIDMED score with albuminuria and those who adhere to the Mediterranean diet exhibit lower levels of ACR. However, the paradoxical associations of both ACR and KIDMED score with obesity markers and BP levels suggest distinct mechanisms of albuminuria development in adolescents

N2 - Electric stimulation of the peripheral nerves is well established as a diagnostic and research tool to analyze the somatosensory system. However, electric stimulation has some disadvantages. Electric stimulation of the median nerve triggers action potentials in all fiber populations of the nerve. Electric stimulation further creates artifacts and causes discomfort which is usually not well tolerated in the awake child. Therefore, the development of a more specific stimulation has constantly been a goal in recent years. There have been several approaches in the past to deliver somatic stimulation. However, all of them failed short in some aspects. In this study, a new type of somatosensory stimulator device was developed and compared against the gold standard of electric stimulation. The stimulation is achieved by repetitive tactile stimulation of the index finger using a blunt needle. In contrast to all previous approaches, we use a hydraulic system to move the needle up and downward.

Given that water is very well suited to conduct pressure pulses it is possible to place the tactile stimulator device holding the needle close to the subject and the hydraulic driving system outside a critical area. Using a phantom, we showed that our stimulator is capable of delivering a stimulus precise on the submillisecond time scale. In addition, we test our stimulator on a healthy adult and compare the results against the electric stimulation. We can show the feasibility of measuring the electric responses of the peripheral nerve and while using MEG also the response of the primary somatosensory cortex. The tactile stimulation showed a more spatial focuses activation of the primary somatosensory cortex when compared against the electric stimulation. The proposed high-precision tactile stimulator will make it possible to analyze the somatosensory system noninvasively in children in the future. 1964-2012 IEEE

N2 - Objectives To conduct an in-depth investigation of the epidemiology of malaria in the Papua New Guinea (PNG) highlands and provide a basis for evidence-based planning and monitoring of intensified malaria control activities. Methods Between December 2000 and July 2005, 153 household-based, rapid malaria population surveys were conducted in 112 villages throughout the central PNG highlands. The presence of malaria infections was determined by light microscopy and risk factors assessed using a structured questionnaire. The combined dataset from all individually published surveys was reanalysed. Results The prevalence of malaria infections in the different surveys ranged from 0.0% to 41.8% (median 4.3%) in non-epidemic surveys and 6.6% to 63.2% (median 21.2%, $P < 0.001$) during epidemics. Plasmodium falciparum was the predominant infection below 1400m and during epidemics, Plasmodium vivax at altitudes > 1600 m. Outside epidemics, prevalence decreased significantly with altitude, was reduced in people using bed nets [odds ratio (OR)=0.8, $P < 0.001$] but increased in those sleeping in garden houses (OR=1.34, $P < 0.001$) and travelling to highly endemic lowlands (OR=1.80, $P < 0.001$). Below 1400m, malaria was a significant source of febrile illness. At higher altitudes, malaria was only a significant source of febrile illness during epidemic outbreaks, but asymptomatic malaria infections were common in non-epidemic times. Conclusions Malaria is once again endemic throughout the PNG highlands in areas below 1400-1500m of altitude with a significant risk of seasonal malaria outbreaks in most area between 1400-1650m. Ongoing control efforts are likely to result in a substantial reduction in malaria transmission and may even result in local elimination of malaria in higher lying areas. 2012 Blackwell

N2 - Now Childhood obesity is recognized as a public health problem due to prevalence, and rapid development in recent decades. The aim of study was to estimate the prevalence of overweight and obesity among school children 8-9 years living in the region of Constantine and clearly identify their eating habits. An epidemiological study was conducted in 2011 involving 325 school children (165 girls and 160 boys) aged 8-9 years in the town of Constantine. We distributed an anonymous questionnaire, it is reset to be completed by the parents at home, given were treated with EPI info version 6.4. The measurements were performed according to standard procedures (OMS 2007), body mass index (BMI) shows that 3.10% of children are in a state of emaciation, 66.80% are normal, 18.20% are overweight, 12% of children are obese, sex was significantly associated with obesity ($P < 0.001$). Afternoon snack for children recognized as a factor promoting weight gain and found that 50.80% of children who take the afternoon snack are overweight and 48.70% are obese. 93.20% of children are foods high in calories and outside the main meals. 97.40% of obese and overweight children practice saying snacking. Decision-sweetened beverages were significantly correlated with obesity. The results of our survey show that 83.4% of children do not practice physical activity. The relationship between physical inactivity and obesity is significant ($P < 0.001$). The correlation between the type of breastfeeding (breast, bottle, or mixed) and BMI in obese children and not significant ($P > 0.05$). These results suggest that obesity and overweight are a growing epidemic in progress, the unbalanced diet and physical inactivity are key factors that must be controlled by the establishment of a program of early prevention of this silent disease

N2 - Vaccines are biological substances and storage outside of the recommended temperature range may accelerate loss of potency, which cannot be reversed.1 Maintenance of the cold chain for vaccine supply, storage and administration is essential to ensure product quality and patient safety, thereby avoiding serious consequences for both the patient and the NHS, the importance of which was raised in a recent safety report.2 Following the identification of a vaccine incident in Grampian, the Scottish Government Health Department prompted a review of vaccine storage in GP surgeries across NHS Scotland. In this Board a detailed review including a criteria based inspection (audit) of all GP practices was undertaken during May to November 2007. All required improve - ments in their practice, usually in the areas of temperature monitoring or equipment. Subsequently, funding for a one year 'spend to save' project was obtained to establish improved quality assurance processes for vaccine manage - ment in primary care, commencing January 2009. OBJECTIVE To establish a programme of self audit for all GP premises and identify the optimal approach to effective management of vaccines METHODS 1. The previous project had established support for a self audit approach and the previous criteria based tool was adapted for self audit (42 criteria). Engagement with Public Health Facilitators, prescribing leads and lead clinical pharmacists encouraged practices to undertake self audit. In addition practices were asked to place an electronic temperature logger in each fridge to monitor hourly temperatures for 48 hours. Practices could also exceptionally request a practice visit. Following the visits, practices received individualised feedback reports and were asked to return a signed copy to confirm acceptance of the recommendations. A Steering Group was established to monitor the project and review any practices referred for risk management. The project team reviewed individual audit results and provided individualized feedback to practices 2. A retrospective review of all incidents reported during 2008 was undertaken to assess whether these might have been preventable, number of repeat incidences and associated costs. After March 2009 an individualised report for each affected GP practice was generated detailing the incident reported, potential reasons, recommendations to minimise the risk of recurrence and an invitation to undertake self audit where appropriate. This report was copied to the appropriate Clinical Director and lead clinical pharmacist. 3. Guidance and standards relating to vaccine handling and storage is available nationally.1,3 Previous local guidance circulated to practices in May 2007 was reviewed. RESULTS 1. To the end of January 2010, 188 practices (73%) had undertaken audit activity (173 self audits, 15 audit visits, 317 fridges), submitted one month's practice records and undertaken a 48 hour temperature logging exercise of all fridges. The main area for improvement was aspects of temperature monitoring (Figure 1). Where necessary, follow-up actions were arranged e.g. further submission of temperature records. This was required for 76 practices (40%). The Steering Group advised revaccination for three children in one practice. 2. A reduction in the extent and cost associated with incidents was observed (Table 1). 3. The previous local guidance was revised to provide additional background, information on suitable fridges, supplier's details and NHS discount code. (Table Presented) DISCUSSION The project was successful in motivating practices to improve their processes, as indicated by their active participation in self audit, followup actions and return of signed summary reports. Limitations were identified to the self audit process and review of the submitted records and logging exercise revealed some inconsistencies. Prior to March 2009, no attempt was made to identify contributory factors, provide advice on prevention of future incidents or investigate if repeated incidents occur in the same practice. This feedback process is having a positive effect on the number of incidents overall and GPs reporting repeat occurrences, resulting in cost savings of 70k as a result of reducing preventable incidents (from 106.5k in 2008 to 36.5k in 2009). The project methodology and results were successful in raising awareness of the importance of the cold chain, establishing a self audit programme and identifying the priority areas for improvement. Our experience has prompted an application for recurring NHS staffing resource to meet the ongoing service needs. CONCLUSION This project has addressed SGHD concerns and has brought fundamental local change to vaccine management, thereby strengthening health protection, improving risk management and reducing vaccine wastage in GP practices

N2 - It has been suggested that reinforcing problem behavior during functional analyses (FAs) may be unethical (e.g., Carr, 1977), the implication being that doing so may result in an increase in problem behavior outside of FA sessions. The current study assessed whether conducting a FA resulted in increases in problem behavior outside of the FA setting for 4 participants. The rate of problem behavior was measured outside the FA setting prior to and during a FA. Idiosyncratic results suggest that problem behavior outside of the FA setting may increase, decrease, or be unaffected by conducting a FA. 2012 Elsevier Ltd

N2 - Contribution of dietary sources to vitamin D status is not clearly known. Although sunlight exposure is a major source of circulating serum 25(OH)D, diet is an important contributor in absence of or reduced exposure. Objective of this study was to determine relation between dietary patterns and serum 25(OH)D concentrations of US children using assay-adjusted serum 25(OH)D data. Data from 2 cycles of the National Health and Nutrition Examination Survey 2003-2004 and 2005-2006 for individuals aged < 19 y, were used to study the association between dietary patterns and serum 25(OH)D. Dietary patterns were established using factor analysis based on food-frequency questionnaire data. Eigenvalues and Scree plot were used to derive 2 major principle factors. They were labeled as Western and Healthy dietary patterns. Serum 25(OH)D was significantly lower in Healthy dietary pattern group compared to Western dietary pattern group (61.9 vs 66.1 nmol/L; $P < .002$). In multivariate analysis, children with higher Western dietary contribution scores to overall diet showed a significant positive relation with serum 25(OH)D ($\beta = 33.8$, $P = .046$). Serum 25(OH)D is associated with Western dietary pattern but not with Healthy pattern. Children consuming healthy pattern diet may benefit from vitamin D supplementation and sunlight exposure (outdoor activities)

 N2 - Pneumonia complicated by effusion that does not improve with antibiotic treatment warrants further investigation to avoid development of lung restriction due to entrapment. This case demonstrates that thorough history is vital and highlights the importance of selecting the proper array of serologic diagnostic tools to aid in rapid, accurate diagnosis of Blastomycosis pneumonia in children. A 31-month-old previously healthy boy was referred to our center for worsening unilateral pneumonia with a large pleural effusion. 8 weeks prior, he developed low-grade fevers, fatigue, and anorexia. CXR revealed a right middle and lower lobe pneumonia with large right-sided pleural effusion. Shortly before the illness, he was vacationing near Lake Huron, Michigan, during which he choked on some lake water while playing. Despite outpatient treatment with 2 doses of intramuscular ceftriaxone and 10 days of oral cefdinir, his symptoms persisted and the CXR worsened (Image 1). He was admitted to an outside hospital for VATS. 150mL of hypocoellular transudate was drained. Cell

differential was 1% PMN's, 91% lymphs, and 4% eos. Bacterial, fungal, and AFB stains and cultures were negative. Serum ID Blastomyces antibody was negative at that time. No further serologies were obtained. He received azithromycin, vancomycin, and ceftriaxone for 10 days, then discharged home. For three weeks, the symptoms persisted. CXR was unchanged, CRP and ESR remained elevated, so the patient was referred to our center for further evaluation. On exam, he had normal oxygen saturation and was breathing comfortably with diminished breath sounds in the right lung base. There was no notable lymphadenopathy. Chest ultrasound redemonstrated large right-sided pleural effusion. Bronchoscopy was normal and BAL differential: 3% PMNs, 72% lymphs, 22% monos 22%, and 2% eos. Repeat cultures were negative. Serum Blastomyces antibody CF, which has moderate sensitivity and low specificity, was positive to 1:64 dilutions. ID, which is moderately sensitive and highly specific, was positive (Table 2). Histoplasma and Coccidioides antibody ID and Blastomyces serum antigen were negative. Oral itraconazole was initiated. Fever, fatigue improved. Within 3 weeks of therapy, the effusion, CRP, and ESR nearly resolved. Conclusion: Pulmonary blastomycosis evolves insidiously and can be fatal if not treated quickly. Complicated pleural effusions are rare in pediatric pulmonary blastomycosis. Clinical suspicion is necessary for rapid diagnosis, and the history of travel to an endemic area guided our evaluation. Oral -azole antifungals are highly efficacious with few complications and are an alternative to toxic intravenous therapy with amphotericin B. (Figure presented)

N2 - Rationale and objective: Past research has demonstrated a lower prevalence of childhood asthma in rural areas. The mechanism(s) by which this occurs remain unknown. Our objective was to confirm the existence of a geographic gradient in the prevalence of asthma among Canadian youths and to evaluate whether this gradient is mediated by health behaviors. Methods: Cross-sectional data from 4726 youth (grades 6 to 10) representative of the Canadian population were collected during the 2001-02 Health Behavior in School-Aged Children survey. Study variables included: demographics, health behaviors (physical activity, diet, active and passive smoking), and adiposity status. Geographic region was assessed using Beale codes and categorized as metro, non-metro but adjacent to metro, and rural. Asthma was defined via doctors' diagnoses and at least one of: asthma symptoms or a health care visit for asthma in the past year. Analyses involved multiple logistic regression with generalized estimating equations to account for the clustered sampling design. Results: Asthma prevalence was lower outside of metro regions (metro=17.7%, non-metro-adjacent=15.6%, rural=14.8%; $p<0.05$). Compared to the metro region, there was reduced risk of asthma in the non-metro-adjacent (OR=0.81, 95%CI=0.65-1.01) and rural (OR=0.76, 95%CI=0.61-0.95) regions in the fully adjusted model. As potential mediators (adiposity status; each of six health behaviors) were removed from the full model, there was minimal change in the association between geographic region and asthma. Being obese or overweight, high physical activity, and exposure to passive smoking increased the risk of asthma while consumption of whole milk and vegetables were protective. Conclusions: We confirmed a reduced risk of asthma in rural vs. metro areas using a national, representative sample of Canadian youth. This association was not mediated by health behaviors. Speculatively, other factors such as environmental exposures, may be the mechanisms through which rural region is related to a lower prevalence of asthma

N2 - Rationale and objective: Farming environments have been associated with lower childhood asthma prevalence. However, the exposures responsible for this effect are unknown. The objective of this study was to investigate potential risk factors for childhood asthma and to assess whether these associations were consistent between farming and non-farming environments. Methods: Parents of 898 children aged 6-12 years living in an agricultural region of Saskatchewan, Canada, participated in a cross-sectional survey of their children's health. Questionnaires were completed during the winter months between 2004 and 2006, and assessed respiratory health, exposure to farming and household environments health behaviors, and home location. Home location was classified as farm, acreage or town. Asthma was considered present if there was a report of a history of a doctor's diagnosis and at least one of the following in the past year: wheeze, medication use for asthma, or an emergency room or doctor's visit for asthma. Results: Asthma prevalence was the highest in town (16.7%) followed by acreage (15.6%) and farm (14.0%). A parental history of asthma and personal history of allergy were strongly associated with asthma (odds ratios > 3; $p < 0.01$) and were consistent between home locations. Significant interactions ($p < 0.05$) were observed between home location and exposure to cleaning barns as well as sex and father's history of smoking. Children who lived in town but not on farms or acreages and had spent time cleaning or playing in barns in the past 12 months had reduced risk of asthma. Girls, but not boys, whose father smoked at home were at higher risk of having asthma regardless of location. Conclusion: Host characteristics were the strongest predictors of asthma and were consistent between farm, acreage and town locations. However, children's outdoor activities and specific environmental exposures in each home location should be considered in studies investigating risk factors for asthma. Similarly, boys and girls may have different levels of susceptibility to the environment

N2 - Vehicle exhaust is the leading source of toxic air pollution for most communities in the Lower Hudson Valley (LHV) of New York State, and a single vehicle used to commute children to school contributes 3 pounds of air pollution monthly. These findings led to the enactment of vehicle idling restrictions around elementary schools in many states including NY. Particulates and contaminants found in dust from traffic have been found to cause persistent wheezing in preschool children, a response associated with the development of asthma and other pulmonary conditions. In this regard studies demonstrate that initial incidents of asthma develop before age 5, suggesting that preschool years mark the critical period for development of the disease and that prevention should be focused at this age group. However little is known about the impact of no idling ordinances on ambient air quality near schools. We hypothesized that measuring levels of traffic related asthma triggers, and subsequently altering traffic flow to lower asthma trigger levels, will have a significant impact on the quality of outdoor and indoor ambient air at school facilities, In the present studies we have analyzed the baseline levels of asthma triggering contaminants of automobile and bus exhaust (nitrogen dioxide, and particulates) at three preschool facilities in Orange County, NY, to develop a community-based effort to incorporate an idling policy for preschools as part of their environmental program. At the school entrances and in the outdoor play areas on weekdays when students were present, NO₂ levels ranging from 22-24 parts/billion were observed. When children were absent, on the weekends and in the evening, NO₂ levels ranged from 14-19 parts/billion. Similarly traffic related particle numbers exhibited dramatic increases when vehicular traffic increased during the times of student arrival and departure. Plans to change traffic flow during student arrival and departure and to raise awareness of the effects of car idling through advocacy have been developed. A follow-up study measuring changes in exhaust levels and community compliance as a result of the no idling policies at these three sites is planned. Our goal is to incorporate translational research components of the air quality and moving population studies into the community research process in the longer term. This effort will

not only contribute to the existing research, but will be available as a template for other communities to apply towards reducing vehicle exhaust

IS - var.pagings

N2 - Rationale: It is estimated that the majority of people (adults and children) with asthma experience exercise-related respiratory symptoms. However, despite their high prevalence, there has not been a large analysis that has focused on the impact of exercise-related respiratory symptoms on physical activities of children with asthma. Methods: The national EIB Landmark Survey was conducted among parents of 516 children (4-17 years) with asthma or taking medications for asthma in the prior year. Responses assessed whether up to 6 exercise-related respiratory symptoms (shortness of breath, wheezing, coughing, difficulty taking deep breaths, noisy breathing, chest tightness) influenced participation in physical activities. Subgroup

analyses (4-12 and 13-17 years) were also conducted. The survey was sponsored by Teva Respiratory LLC. Results: The majority (80%) of parents with children with asthma reported that their child experienced >1 exercise-related respiratory symptom, and 47% reported >4 symptoms. The most commonly reported symptoms were coughing, shortness of breath, and wheezing. Older children were more likely to avoid activities because of exercise-related respiratory symptoms compared with younger children (31.9% vs 22.9%). Of respondents whose child experienced >1 exercise-related symptom, 37% reported that asthma limited their child's ability to participate "a lot" or "some" in sports/recreation, 26% in normal physical exertion, and 33% in other outdoor activities. A higher percentage of older children were reported to be limited "a lot" in sports participation compared with younger children (13% vs 9%). Only 23% of children with asthma and exercise-related symptoms were reported to take quick-relief medications such as albuterol "always" or "most of the time" prior to exercising; this proportion was higher in older than in younger children (30% vs 19%). Similarly, only 28% of children with asthma with exercise-related symptoms were reported to take quick-relief medications during or after exercise; this proportion was also higher in older vs younger children (37% vs 22%). Conclusions: This large national survey suggests that exercise-related respiratory symptoms among pediatric asthma patients are common. This may reflect uncontrolled asthma, including lack of preventative treatment for these symptoms. The symptoms reported in this study limited the ability of children to participate normally in physical activities, with adolescents compromised to a greater extent than younger children. Importantly, many children do not use short-acting bronchodilators before exercise as per national guidelines. Adherence to controller therapy and prevention of exercise-related symptoms with short-acting bronchodilators should be optimized to support optimal health in children

N2 - RATIONALE: We explored the role of early-life (2-3months) fungal exposures and annually repeated reports of visible mold, water damage, or dampness in children's homes experiencing wheeze by age 13.

METHODS: 498 children of asthmatic/allergic parents in Boston had early-life indoor air and bedroom floor dust samples collected using Burkard culture plates and Eureka Mighty-Mite canister vacuum cleaners, respectively. 383 children also had outdoor air samples when temperatures were sufficiently warm to avoid culture plates freezing. Telephone questionnaires were administered to primary caretakers to assess annual reports of mold, water damage, or dampness in the home, as well as any reports of wheeze (including with cold air or exercise after age 2). Generalized estimating equations with exchangeable working correlation structures included independent predictors of wheeze and potential confounders. Odds ratios (OR) were estimated for an interquartile increase in fungal log-concentrations (colony forming units per cubic meter of air or gram of dust), and for the positive report of visible home dampness. RESULTS: Independent predictors of longitudinally assessed wheeze included early-life dustborne Cladosporium [OR = 1.14 (1.01, 1.29)] and yeasts [OR = 0.91 (0.82, 1.00)], and repeated reports of visible home dampness [OR = 1.32 (1.12, 1.56)]. In subset analyses including outdoor air samples, predictors of wheeze included outdoor airborne Alternaria [OR = 1.33 (0.95, 1.85)] and Cladosporium [OR = 1.27 (0.92, 1.75)], dustborne Cladosporium [OR = 1.18 (1.01, 1.38)], dustborne yeasts [OR = 0.87 (0.78, 0.97)], and annually repeated reports of visible mold, water damage, or home dampness [OR = 1.24 (1.03, 1.50)]. CONCLUSIONS: Accounting for the correlation in repeated measures, early-life Cladosporium and Alternaria, and longitudinally assessed visible reports of mold, water damage, or home dampness increased the odds of wheeze up to the age of 13. The potential protective role of dustborne yeasts may be related to higher levels of cell wall (1-3)-beta-D-glucan, or other correlated unmeasured factors. Whether these long-term effects of early life mold on the risk of wheeze are due, in part, to an increase in sensitization to mold merits further evaluation

N2 - Objectives: Plants delight us in forests and gardens, they produce oxygen, provide comfortable climatic conditions and constitute the most important fraction of human food. Findings made by mankind have resulted in the knowledge that only a defined share of the plants is inedible or poisonous. Deadly poisonous in Middle Europe are only few plants like e.g. *Aconitum napellus*. Most of the fatal cases refer to mistakes or misuse in adults, whereas fatalities among children are extremely rare. To get an objective assessment of plants, the BfR run a Federal research project which led to the first German Classification of Poisonous Plants (GCPP) in 2000. After a review of data, provided by German poison centres, completed by new literature and under the competence of a working group of the German "Poison Committee", we are about to publish the first review. To refresh the knowledge around poisonous plants, we are now under the construction of a public garden for poisonous plants. Method: Following the assessment of the toxicity of chemicals in analogy to the German Regulations on Dangerous Substances, we re-classified more than 80 plants into three categories, namely plants which could lead to (-) minor poisoning, (-) moderate poisoning and (-) severe or deadly poisoning. For all plants, the habitat (garden, park, great outdoors) and a comparable amount of a possible ingestion have been borne in mind. Based on the first GCPP, we listed plants for the garden under educational reasons into two garden beds: 1) plants with moderate poisoning and severe or deadly poisoning 2) plants belonging to the category minor poisoning. Results: The garden is situated in a protected institute's area, but with a public access for an interested audience. The raised garden beds will have small trails and visit points, where informative signboards - close to the plants - show details about the name, family, toxic parts of the plant, the category of toxicity, etc. For the garden bed (ca. 4 times 6 meter) of the moderate, severe or deadly poisoning plants, we

chose 15 plants from *Aconitum napellus* to *Convallaria majalis*. For the counterpart, the garden bed (ca. 4 times 4 meter) of the minor or non-poisoned plants, we chose another 15 plants from *Cyclamen* to *Clematis*.

Conclusions: The German Classification of Poisonous Plants contains useful information more than 150 different plant species. The final table of poisonous plants will find its counterpart in a list of more than 60 non-poisonous plants appropriate to be used in the close proximity of children's playgrounds, kindergartens, schools, public parks etc. The design of the garden is for educational purpose and will be opened in summer 2012

N2 - There is a very large arteriovenous fistula (4.8x2.2x3.2) that appears to originate off the left main pulmonary artery abutting the left major fissure in the superior segment of the left lower lobe. There is a very large draining vein into the left inferior pulmonary vein. There appears to be a smaller AV fistula posteriomedially in the left lung base. Asthma and pneumonia are frequent problems in pediatrics. There may be instances when common findings fail to respond to usual care necessitating a search for alternative explanations. This 9 year old female with a history of asthma presented to her pediatrician's office with a 2 day history of cough, fever, sore throat, chest pain and difficulty breathing. She exercised regularly without limitation. When vacationing at high altitude, she complained of headaches, difficulty breathing, and had perioral cyanosis. Family and social history were unremarkable. When she failed to respond to nebulized albuterol in the office, she was sent to a local emergency room. Chest x-ray revealed a left-sided infiltrate. She was discharged on antibiotics, albuterol and oral steroids. She was admitted to an outside hospital two days later when she was not improved. On admission she was hypoxic with room air oxygen saturations in the mid 80's. CBG showed a PaCO₂ of 35 and a pH of 7.43. CBC revealed WBC of 12,400 with slightly elevated neutrophils and hemoglobin of 16.9. Chemistry panel was normal. Chest x-ray confirmed a left lower lobe infiltrate and minimal left hilar adenopathy. CT of the sinuses showed pansinusitis. Coccidiomycosis serologies were negative. She remained hospitalized for 6 nights and received IV antibiotics for pneumonia. She was discharged home, despite room air oxygen saturations of 85%, on Augmentin and Advair with a referral to a pediatric pulmonologist in 1 week. She presented to the Pulmonary Clinic with central cyanosis, mild tachypnea, and room air oxygen saturations of 78%. Findings on physical exam included coarse breath sounds on the left and mild clubbing. Pulmonary function tests showed a FVC of 78%, FEV₁ of 84%, FEF₂₅₋₇₅ of 105% and TLC of 158% with a significant response after nebulized bronchodilator. With supplemental oxygen at 5 liters per minute, her oxygen saturation was 88%. She was admitted to Phoenix Children's Hospital. Sweat Chloride was normal. Chest CT angiogram showed a large arteriovenous malformation (AVM) in the superior aspect of the left lower lobe and a smaller AVM in the left lung base. Interventional radiology performed coil embolization with significant clinical improvement. A small AVM was also discovered in the left parietal cortex. She was diagnosed with hereditary hemorrhagic telangiectasia. AVMs in children are rare and easily mistaken for other pulmonary problems. This case is a reminder to re-evaluate the diagnosis when the clinical course is not as anticipated. (Figure presented)

N2 - Rationale: Early life predictors of childhood allergic rhinitis (AR) are not well defined. Few studies have addressed host characteristics and environmental exposure determinants of AR in three year old children. The objective of this study is to identify host characteristics, indoor and outdoor environmental exposures during infancy at age one that predict AR at age three in a longitudinal birth cohort. Methods: High risk children from Greater Cincinnati in the Cincinnati Childhood Allergy and Air Pollution Study (CCAAPS) were followed annually in a large birth cohort study from birth to age three. The primary outcome, allergic rhinitis (AR) was defined by parental report of sneezing, runny or blocked nose in the prior 12 months and a positive skin prick test (SPT) to at least one of 15 aeroallergens. AR children were compared to non-atopic, non-symptomatic children. Environmental and standardized medical questionnaires determined exposures and clinical outcomes. Primary activity area dust samples were analyzed for house dust endotoxin (HDE) and (1-3)-beta-D-glucan. Fine particulate matter (PM_{2.5}) sampled at 27 monitoring stations were used to estimate personal elemental carbon attributable to traffic (ECAT) exposure by land use regression model. Results: Of 361 children in this analysis, 116 had AR and 245 were non-atopic, non-symptomatic. Prolonged breastfeeding in African-American children (aOR 0.8; 95% CI 0.6-0.9) and multiple children in the home during infancy were protective of AR (aOR 0.4; 95% CI 0.2- 0.8). Food SPT positivity and tree SPT positivity at age one increased the risk of AR at age three (aOR 4.4; 95% CI 2.1- 9.2) and (aOR 6.8; 95% CI 2.5- 18.7), respectively. HDE exposure was associated with AR, with low and high HDE exposure being protective, (aOR, 0.5; 95% CI, 0.3-0.8) and (aOR, 0.002; 95% CI, <0.001-0.1), respectively. In contrast, medium HDE exposure was associated with an increased risk of AR (aOR, 6.3; 95% CI, 2.3-17.2). ECAT and ETS exposure showed no effect on AR. Conclusions: Prolonged breastfeeding in African-Americans and multiple children in the home during infancy reduced the risk of AR at age three whereas percutaneous reactivity to food and tree allergens enhanced risk. HDE exposure modified the risk of AR bi-directionally depending on the level of HDE exposure

N2 - Myocarditis and Severe Myositis in a 14-year-old Female with 2009 H1N1 Influenza Virus Infection
Michael A. Silverman, MD PhD, Thomas J. Sandora, MD MPH, and Rana I. Sharara-Chami, MD Department of Medicine, Division of Infectious Diseases, Departments of Medicine and Laboratory Medicine, Division of Critical Care Medicine, Department of Anesthesiology, Children's Hospital Boston, Boston Massachusetts.
Introduction 2009 H1N1 influenza virus, a novel influenza A subtype of swine origin, was first detected in humans in Mexico in March 2009. This virus spread rapidly and the WHO declared an influenza pandemic on June 11, 2009. Myocarditis and severe myositis are uncommon but potentially severe manifestations of seasonal influenza. We present the first reported case of myocarditis and severe myositis in association with 2009 H1N1 virus infection. Case Description In June 2009, a previously healthy 14-year-old female presented to an outside

hospital emergency department in shock after two days of fever, muscle aches and diffuse weakness. She reported exposure to "swine flu". Her chest radiograph and bedside echocardiogram were normal. She received intravenous fluids, oseltamivir, vancomycin and cefepime. A nasopharyngeal swab was positive for influenza A by rapid immunoassay and was subsequently subtyped as 2009 H1N1 virus. In our emergency department, she had sepsis physiology and an S3 gallop. EKG demonstrated sinus tachycardia with ST elevation in the lateral leads. Bedside echocardiogram showed mild to moderate left ventricular dysfunction. Troponin T level was initially 0.04 ng/mL and peaked at 0.8 ng/mL. During the course of her hospitalization, she received inotropic support, intravenous immunoglobulin, oseltamivir and broad-spectrum antibiotics. Her illness was complicated by severe myositis (maximum CK 86,900 U/mL) and bilateral transudative pleural effusions requiring intubation and chest tube drainage. She recovered fully from her illness. Discussion A 14-year-old female presented with shock and 2009 H1N1 influenza virus infection. Echocardiogram and laboratory studies indicated myocarditis and severe myositis. 2009 H1N1 influenza infection should be considered in children with shock, myocarditis or severe myositis. Myocarditis and myositis are important complications of both seasonal influenza and 2009 H1N1 virus, and they require a high clinical suspicion for diagnosis. Aggressive management of cardiogenic shock and renal protective strategies are important aspects of care for patients with influenza myocarditis and myositis, and treatment with IVIG and appropriate antiviral medication to inhibit viral activity and suppress inflammation may have added benefit

N2 - RATIONALE: High rates of allergic disease in Westernized countries have led to the hypothesis that lack of microbial exposures early in life may play a key role in subsequent allergy and asthma development. Furred pet ownership has been shown in many studies to be protective against allergic disease development in children which we hypothesize is due to the distinct household microbial communities associated with pet ownership.

METHODS: Dust samples from seventeen households with dog(s), cat(s) or no pets were examined. The 16S rRNA PhyloChip, a high-density bacterial microarray and automated rRNA intergenic spacer analysis and sequencing were used to profile bacterial and fungal communities. Hierarchical cluster analysis (HCA) was used to examine community structure. Wilcoxon or Welch's t-tests were performed to determine differences in community structure, metrics (diversity, richness, and evenness) and taxonomic abundances across groups.

RESULTS: Bacterial communities from dog owning households were significantly richer ($p < 0.036$), more diverse ($p < 0.036$) and possessed 45 taxa in significantly higher abundance compared to those with no pets. The majority of these taxa were Proteobacteria, typically detected in early stages of infant GI colonization. Parallel analysis of fungal communities demonstrated significantly lower fungal richness in dog-owning households compared to cat ($p < 0.010$) or no pet homes ($p < 0.031$). Fungal species detected primarily belonged to the Dothideomycetidae and Eurotiomycetidae, which include plant pathogens and allergenic fungi. HCA demonstrated two clearly distinct groups of samples (G1 and G2). Compared with G2 samples, G1 bacterial communities were significantly richer ($p < 0.008$), more even ($p < 0.002$), more diverse ($p < 0.001$) and were from dog and cat-owning households. In comparison, G2 samples included all of the no pet households and a number of dog- and cat-owning homes which possessed animals that were either exclusively indoor or outdoor pets or were very young and recently introduced to the home. CONCLUSION: These data suggest that homes in which pets are permitted both outdoors and indoors possess significantly higher bacterial diversity that coincide with reduced fungal richness. We speculate that infant exposure to this milieu may shape immune development by a number of potential mechanisms that reduce development of atopic disease

N2 - Rationale: There is little information on the effects of environmental factors, such as meteorological conditions and air pollution, on exercise-induced bronchospasm (EIB) in population studies. While controlled laboratory exposure studies show that cold, dry air has a greater effect on EIB than warm, humidified air, there is little demonstration of this in real-world settings. Also, while epidemiological studies of asthmatic children have shown an association between air pollution and EIB, few studies have assessed air pollution effects on EIB in healthy children. In this cross-sectional analysis based on a large population community sample, we assess the short-term relationship between environmental factors such as temperature, humidity, and air pollution and EIB in healthy children. Methods: The community sample consisted of all 2078 school children from grades one through six in the pulp-mill town of Port Alberni on the west coast of Vancouver Island, Canada. Each child underwent pre-exercise spirometry, then post-exercise spirometry 10 minutes after a 5-minute supervised run outdoors. A central monitoring station measured daily environmental factors including temperature, humidity,

and airborne particulate matter (PM₁₀) and total suspended particles (TSP) concentrations. The final sample consisted of children who completed the supervised run, met ATS acceptability criteria for spirometry at both the pre- and post-exercise test, and had PM₁₀ measured on the day of testing. Based on parental questionnaire, children with doctor's diagnosis of current asthma were excluded. EIB was defined in three ways: (1) the difference between pre- and post-exercise FEV₁ (FEV-absolute), (2) the ratio (%) of FEV-absolute over baseline FEV₁ (FEV-relative), and (3) a decrease in post-exercise FEV₁ relative to pre-exercise exceeding 9% (EIB-positive). Results: The final population sample consisted of 1,544 children aged 6 to 13 (774 males, 770 females). Median FEV-absolute was 0.010L (interquartile range [IQR] -0.003, 0.070), median FEV-relative was 0.63% (IQR -1.81%, 3.47%), and EIB-positive prevalence was 6.4%. Median PM₁₀ concentration was 17mg/m (IQR 17, 33). Multiple linear and logistic regression analyses that included age, sex, race, height, 3 and weight, and same-day temperature, humidity, and PM₁₀ showed consistent relationship between decreasing temperature and increasing EIB (Table 1). Lower humidity also tended to be associated with increased EIB. PM₁₀ had no association with risk of EIB. Results were unchanged with baseline FEV₁ included as an independent variable. Conclusions: In children without asthma, lower temperature increases risk of EIB. Lower humidity contributes marginally to increasing risk of EIB. Increasing PM₁₀ concentrations does not increase risk of EIB. (Table Presented)

N2 - Background: The 2010 Dietary reference intakes for Koreans lowered adequate intake (AI) of vitamin D to 200 IU/day in childhood due to lack of evidence. We evaluated the prevalence of vitamin D deficiency and risk factors for low vitamin D status. We also investigated the relationship between vitamin D status and body composition and bone mineral density (BMD) in pre- or early pubertal nonobese children. We purposed to provide evidence for determining Korean AI of vitamin D. Methods: A total 100 nonobese children (9.3 + 1.9yrs, 45 boys, 71 prepuberty) living in Seoul, Korea were enrolled in wintertime (n = 38, December, 2010 to March, 2011) and summertime (n = 62, June to September, 2011). Z score of the bone mineral content (Z-BMC), fat mass (Z-FM), lean tissue mass (Z-LTM), and total body (Z-TB) and L-spine 1-4 (Z-L1-4) BMD using Dual-energy X-ray absorptiometry were calculated according to the reference for Korean children. Daily calcium (mg/day) and vitamin D intake (U/day) were evaluated by dietitian. The serum level of 25(OH)D below 20ng/mL was defined as vitamin D deficiency. Questionnaires were used to assess regular physical activity and outdoor activities (hrs/week). Results: The prevalence of vitamin D deficiency was 47.4% in winter and 17.7% in summertime. In wintertime, vitamin D status negatively associated with vitamin D intake (P = 0.019) and less outdoor activities (P = 0.015), after adjusting for sex and puberty. About half of children with vitamin D intake below 800 IU/day were vitamin D deficient in winter. The level of 25(OH)D negatively correlated with Z-BMC (P = 0.023), Z-TB (P = 0.018), and Z-L1-4 (P = 0.043), after controlling for sex, puberty, Z-FM, physical activity and the percentage of the adequate calcium intake. However, the Z-FM and Z-LTM had no significant relationship with the level of 25(OH)D. Conclusion s: About half of pre- and early pubertal nonobese children were vitamin D deficient in wintertime. Considering the effect of vitamin D status on bone health in childhood, the importance of adequate vitamin D intake and outdoor activities needs to be emphasized. Current recommendation for AI of vitamin D (200IU/day) in Korean children seems not to be enough to prevent vitamin D deficiency, especially in wintertime

N2 - Rationale: Epilepsy and Mental Retardation Limited to Females (EFMR) is a rare condition in which otherwise normal female infants develop sudden onset of seizures. The clinical spectrum is broad, including a Dravet-like syndrome with multiple seizure types. The disease-causing gene was recently identified as PCDH19, which resides on the X chromosome and encodes protocadherin 19. Ictal apnea (IA) has not been reported in this syndrome, and the genetic mechanism by which alteration of PCDH19 results an atypical X-linked inheritance pattern is uncertain. Methods: Case 1: Whole genome array CGH was performed using the SignatureChip 105K oligonucleotide array (10-35 Kb spatial resolution). Case 2: Standard targeted sequence analysis of exons 1-6 of the PCDH19 gene was performed. Results: Case 1: An otherwise healthy 19 mo old girl presented with new onset seizures at age 11 mos. Initial seizure semiology was bilateral upper extremity clonic movements and unresponsiveness. Seizures were refractory to multiple AED trials but finally stopped with topiramate. At age 18 mos she had another seizure cluster with eye opening, upper extremity flexion, and profound apnea with desaturation to SaO₂ of 10%. Ictal EEG revealed biposterior onset of rhythmic sharp theta activity with rapid secondary generalization. Inter-ictal EEG was normal. Brain MRI was normal. Family history was negative. CGH microarray detected a deletion in Xq21.33-Xq22.1 (estimated size 2.89-3.01 Mb), which contains the PCDH19 gene. Case 2: An otherwise healthy 22 mo girl presented with new onset seizures at age 8 mos. Initial seizure semiology was eye opening, variable extremity movements, unresponsiveness, and apnea with desaturation to a SaO₂ of 50%. Seizures were refractory to multiple AED trials but ultimately controlled on phenobarbital. At age 20 months, she had another seizure cluster with similar semiology and profound ictal apnea with desaturation to SaO₂ of 6%. Ictal EEG showed biposterior onset of rhythmic sharp theta activity with rapid secondary generalization. Interictal EEG was normal. Brain MRI was normal. Family history was negative. PCDH19 sequence analysis revealed heterozygosity for c.434-435insG alteration in exon 1 of the PCDH19 gene, which has not been previously reported. Conclusions: Our findings have two fundamental implications. First, profound IA is unusual and has not been described in the setting of a specific epilepsy syndrome outside of the neonatal period. These two cases suggest IA may be a unique seizure type in children with PCDH19 related epilepsy. Additional cases are necessary to determine the strength of this

association. Second, previous authors have proposed a dominant negative model to explain the atypical X-linked inheritance pattern. Case #1 is the first affected female with a deletion of the PCDH19 gene, which represents the most compelling evidence to date that the dominant negative model is incorrect

N2 - Rationale: DNETs are low-grade, epileptogenic tumors with low glucose metabolism on PET. Our recent studies showed accumulation of a[11C]methyl-L-tryptophan (AMT), a PET tracer for the immunomodulatory kynurenine pathway, in epileptogenic malformations and some DNETs. In this study we used 2-deoxy-2[18F]fluoro-D-glucose (FDG) and dynamic AMT PET scanning to evaluate the relation between glucose metabolism, AMT transport and metabolism as well as clinical seizure variables in children with epileptogenic DNETs. Resected DNET specimens were also studied for the presence of L-type amino acid transporter 1 (LAT1) and indoleamine 2,3-dioxygenase (IDO; a key enzyme of the kynurenine pathway). Methods: Twelve children (age: 2.5-17.5 years) who underwent resective surgery due to epilepsy associated with a DNET were included in the study. Tumors were outlined on MRIs and tumor volumes were calculated. The same tumor regions were superimposed on co-registered FDG and AMT PET images to obtain standardized uptake values (SUVs) and SUV ratios (tumor/contralateral cortex). Furthermore, kinetic parameters of AMT uptake characterizing the tracer transport (by the volume of distribution [VD]) and metabolic rate (by the unidirectional tracer uptake [K-complex]), as well as corresponding tumor/cortex ratios were also calculated in 10 patients and correlated with seizure variables. Resected tumor specimens were immuno-stained for IDO and LAT1. Results: Tumor volumes varied from 0.8 to 51.4 cm³ (median=4.2 cm³). All tumors showed glucose hypometabolism on FDG PET scans (SUV ratio: 0.29-0.64). However, tumor AMT SUV values were above cortical values in 8/12 cases (0.87-1.44) (Figure). Two patients showed increased AMT SUV in additional ipsilateral cortical areas. Kinetic analysis of AMT PET showed increased VD ratios in 8/10 children and high K-complex ratios in 3. Age at seizure onset showed a positive association with FDG SUV of the tumors ($r=0.68$; $p=0.016$, Spearman's correlation). Longer epilepsy duration was associated with higher AMT K-complex values in DNETs ($p=0.036$). Tumor volumes did not correlate with any clinical and PET variables. Nine children had seizure-free outcome, while 3 had recurrent seizures, including the two cases with preoperative cortical AMT increases in areas which were not resected. All tumor specimens showed moderate to intense IDO and LAT1 staining. Conclusions: Despite low glucose metabolic rates and variable sizes, DNETs commonly show high AMT accumulation on PET, which is mostly driven by increased tryptophan transport but also due to tryptophan metabolism. Activation of kynurenine pathway may contribute to immune-resistance of these tumors but can also produce neurotoxic/epileptogenic metabolites. Association of higher tryptophan metabolic rates with longer epilepsy duration suggests a progressive activation of this pathway providing a potential therapeutic target for these lesions. In addition, AMT PET may detect potentially epileptogenic cortex outside DNETs in some cases; this may help optimize surgical resection to facilitate seizure-free outcome

N2 - Rationale: Indications for invasive subdural monitoring in pediatric epilepsy surgery are poorly defined. We sought to critically review our experience with pediatric invasive intracranial monitoring to better delineate when invasive EEG is useful. Methods: Patients who had subdural invasive EEG monitoring for epilepsy surgery were identified from an epilepsy surgery database at Miami Children's Hospital Brain Institute. Exclusion criteria were inadequate subdural data and children with infantile spasms/myoclonic epilepsy. Pre-invasive evaluations were retrospectively reviewed including history, interictal/ictal scalp EEG, MRI and functional imaging in selected cases. Indications for subdural implantation were categorized based on pre-invasive data as :1) Mapping of eloquent cortex 2) Poorly localized epileptogenic zone(EZ)3) Discordant data. Subdural EEG reports, surgical diagrams and functional mapping were reviewed for localization of the EZ and compared with pre-invasive data for congruence. Data on surgical resection, completeness, complications and outcome were analyzed. Results: 102 patients met inclusion criteria. 12 were implanted for mapping eloquent cortex, 76 for non-localized EZ and 14 for divergent data. In the non-localized group 45% had negative MRIs. A focal area for resection was identified in 99% (68% incomplete). Subdural monitoring impacted resection in 84%. Implantation for functional mapping facilitated incomplete resections in 42% due to proximity to eloquent cortex. Of cases implanted solely for language mapping in a presumed dominant hemisphere, 5 were redundant as all underwent anterior left temporal lobectomy. Implantations to determine the extent of involvement beyond the mesial/anterior temporal region were rarely useful particularly if there was a focal MRI lesion. 90% resulted in anterior temporal lobectomies. Most poorly localized cases were multilobar (paracentral n=21, frontotemporal n=15, posterior quadrant n=9, other multilobar n=15). 1 paracentral case resulted in explantation. The EZ was outside motor cortex in 38% and only partially overlapped motor in several cases resulting in 5 complete resections. Frontotemporal implantations resulted in lobar resections in 73%. Posterior quadrant and other multilobar implantations usually resulted in more restricted resections than anticipated by non-invasive data (79%) and no quadrantectomies. 14 cases were implanted for discordant data with 13 resolving the discordance. With divergent scalp EEG and MRI subdural EEG more often was concordant with MRI than scalp EEG (71% vs 28%). Conclusions: There is limited pediatric data guiding the use of intracranial monitoring to localize an epileptogenic focus for resective surgery. This study provides an overview of current indications

at an active pediatric epilepsy surgery centre and examines the utility of those practices. We confirmed the adult experience that subdural monitoring is rarely helpful for MRI-lesional temporal lobe epilepsy. Routine use of functional neuroimaging modalities may obviate the need for many invasive cases previously deemed poorly localized

N2 - Rationale: Sleep-deprived EEGs (SDEEG) are commonly used in clinical practice to detect sleep-induced epileptiform abnormalities, which are diagnostic indicators of specific types of epilepsy. While this is a very useful diagnostic technique, studies have shown that the SDEEG places a notable burden on both parents and children. One study reported that nearly fifty percent of parents found it difficult to keep their child awake at

night and thirty percent of parents found it difficult to wake their child in the morning (1). Objective: To prospectively study the specific strategies used by parents and/or children to ensure sleep deprivation before undergoing a SDEEG. The findings of this study will be used to provide guidance for parents and children on how to adopt a convenient method of sleep deprivation. Methods: Inclusion Criteria: 1) Children between 1-17 years who either had seizures or were suspected to have seizures. 2) Male and female participants were included, with no restrictions based on race or ethnic origin. Children referred from the neurology and general pediatrics outpatient clinics at McMaster Children's Hospital for a SDEEG during May 2008-ongoing, fulfilling the inclusion criteria, were studied. All participants were interviewed by either an EEG technologist or co-investigator and were administered a qualitative questionnaire. The questionnaire collected data about the patient's demographic details, previous EEG history, and sleep-deprivation strategies. The data collected was analyzed for trends and main themes. Results: 93 patients (aged 16mos-17 yrs; mean 8.32 yrs) were interviewed (Table 1), to date. 82.8% of children had a previous EEG, with 24.7% of all patients having had a previous SDEEG. Main themes identified for the patients were: 1) Instruction on amount of sleep deprivation; 52.7% of the patients were instructed on how many hours their child should sleep; 2) Parents' reactions to SDEEG; "Will my child fall asleep during EEG?" was the most common reaction (59.1%) and "I do not want to keep myself awake" was the least common (14.0%); 3) Strategies used to keep child awake at night; most common strategy (77.4%) was to watch TV; 4) Strategies used to keep child awake on trip to the hospital on the day of SDEEG; most common strategy (68.8%) was to constantly talk to child in the vehicle; 5) Success of strategies; 90.3% of children did not fall asleep on the trip to the hospital. Conclusions: Certain sleep-deprivation strategies appear to be used across all seasonal and age-specific subgroups (watching TV, playing computer/video games, constantly talking). Indoor activities are largely preferred over outdoor activities, across all seasons. Outdoor activities for sleep-deprivation are most preferred during the summer months. Similarly, parents, across all patient age groups, are primarily concerned with whether their child will fall asleep during the SDEEG. The data collected can be used to help parents and children better cope with sleep-deprivation before SDEEG and to lessen their anxiety regarding adequate sleep deprivation

IS - var.pagings

N2 - Rationale: Hyperventilation (HV) is a convenient "bedside" method for eliciting absence seizures (AS) and is often used both to establish a new diagnosis of AS and to monitor the effectiveness of ongoing drug therapy of AS. We set out to measure the sensitivity of HV in two types of "gold standard" groups presumed to have active AS by different criteria: 1) a "high confidence group" of children who manifest spontaneous AS on routine EEG testing (outside of HV) 2) a "lower confidence group" of children whose AS was judged active by parental report. Methods: The EEG diagnosis log at Children's Hospital Boston was screened from January 2006 to June 2010 for all patients with 3 Hz generalized spike-wave discharges or absence seizures. The subset of these patients matching ILAE criteria for childhood or juvenile absence epilepsy formed the study group (n=68). Two comparative "gold standard" groups of EEGs (all with adequate HV) in children with presumed active AS were formed: 1) those EEGs which showed spontaneous AS (outside of HV) 2) those EEGs done at a time that the child's parents reported active AS in their child. Hyperventilation was carried out for a minimum of 3 minutes. An AS was defined as an episode of generalized spike-wave discharges associated with clinical change or unresponsiveness. Results: 53 EEGs that captured spontaneous AS were found in which HV was also done (in 44 unique patients). In 41 (77%) of these EEGs HV also elicited an episode of AS (71% of those untreated [n=28] and 84% of those treated [n=25] at the time of the EEG). 95 EEGs were identified (in 55 unique patients) whose parents reported active AS at the time of the EEG. Of these, HV elicited AS in 59 (62%) EEGs (71% of those untreated [n=41] and 56% of those treated [n=54]). Of the 84 EEGs done at a time that parents reported no active AS, AS was seen spontaneously or during HV in 30 (36%) tracings. Conclusions: Even in children with active AS by the strict criterion of the occurrence of spontaneous AS in the EEG, only 77% had an AS during HV, implying that this technique will miss approximately one quarter of children with active AS. When positive parental report was used as the "gold standard" for presumed active AS, only 62% of children manifested AS during HV; the different rates imply that parents may overestimate the activity of AS approximately one quarter of the time in children who are effectively treated. Conversely, in patients in whom AS was definitely still active by EEG criteria, parents underreported AS activity 36% of the time. This percentage represents a minimum estimate since some children with active AS may not have exhibited their seizures during the period of the EEG recording. These findings imply that parental report has an approximate false-positive rate of one quarter and an approximate false-negative rate of more than one third

N2 - **Rationale:** In the puertorrican population, there is scarce information regarding the relative frequency of various types and characteristics of patients with intractable epilepsy. A comprehensive epilepsy program was established in April 2009. We report our data in a group of children and adults who underwent prolonged video-electroencephalographic monitoring in the only Epilepsy Monitoring Unit in Puerto Rico. **Methods:** A retrospective evaluation of all epilepsy monitoring studies performed from April 2009-April 2011 performed. 153 consecutive patients were analyzed. **Results:** The majority of patients were females (61%). Two-thirds (66%) of evaluated subjects were adults; infants and elderly patients comprised only 1% of the patients. The most common diagnoses were psychogenic nonepileptic events (39%), localization-related epilepsies (47%) and generalized idiopathic epilepsies (13%). Of the localization-related epilepsies, roughly half (47%) were reliably traced to the temporal lobe and frontal epilepsies represented 17% of the evaluated cases. Childhood absence epilepsy was established in half (50%) of the cases showing generalized epileptiform activity and juvenile myoclonic epilepsy represented only 10% of the idiopathic generalized epilepsies. **Conclusions:** This study illustrates the wide variety of diagnoses encountered in a population of puertorrican patients evaluated at our epilepsy monitoring unit. More than 40 % of patients had a misdiagnosis. Psychogenic nonepileptic events represent at least one-third of the evaluated cases, a relative frequency that is consistent with results obtained in comprehensive epilepsy centers from other countries. Approximately 1/3 of patients are surgical candidates. Two mesial temporal resection were recently performed. Nine percent of patient had vagus nerve stimulation placed and approximately 10% of patients were referred for epilepsy surgery in level four centers in the United States. Through prolonged video-EEG monitoring, a reliable diagnosis can be established and appropriate therapeutic decisions can be started. The comprehensive epilepsy program in Puerto Rico has reduced need for outside referral to 10-12 %

N2 - Rationale: Data on motor, language, and behavior outcome of children after hemispherectomy is limited to small series with short follow up. We studied the long term functional and longitudinal seizure outcome in a large cohort of hemispherectomy patients from a single center. Methods: 187 children who had hemispherectomy (Jan 1997 - May 2009) at the Cleveland Clinic Foundation were studied. Using a structured questionnaire (17 questions), we contacted families by phone or mail to obtain data on seizure and functional status such as ambulation, visual symptoms, spoken language, reading, schooling and behavior. Questionnaire was drafted to assess function meaningful to the activities of daily life. Medical records were reviewed for pre-operative data. Kaplan- Meier statistics was used to estimate longitudinal seizure outcome. Categorical variables

were analyzed with Chi-square test. Results: Of 187 children (110 males), 104 had right hemispherectomy. Median age for seizure onset was 8 months (1 day-14 yrs) and for surgery was 5 yrs (2 months-18 yrs). At a median follow up of 4.8 yrs (mean 5.3 + 3.3 yrs), 112 of 184 children (61%) were seizure free; additional 13 (7%) had questionable minor spells without habitual pre-operative seizures. 59 (32%) had seizure recurrence, 8 being seizure for 1 year and 16 had >90% reduction in seizures. Overall 149 children (81%) were either seizure free or had major improvement after surgery. On survival analysis, the estimated probability of seizure freedom was 76% at 1 yr, 64% at 3 yrs, 61% at 5 yrs, and stabilized at 56% at 6 years and beyond. Prior hemispheric surgery (n=29, p=0.001), bilateral PET changes (n=23, p= 0.003), presence of generalized seizures (n=67, p<0.05), and bilateral motor deficits (n=8, p<0.05) correlated with poor seizure outcome. Etiology and bilateral MRI abnormalities (n=64, 34%) did not influence the seizure outcome. Functional outcome using questionnaire was obtained in 124 children. 102 (83%) patients ambulated independently, 10 walked with assistance and 11 were unable to walk. 31 (25%) patients reported new visual symptoms. Significant behavior issues often requiring constant supervision was reported in 34 (27%), modest behavior issues not affecting social life outside home environment in 23 (19%) and 67 (54%) reported minor or no behavioral problems. 37 (40%) patients had severe spoken language deficits, 42 (34%) had language skills below age level, while 45 (36%) reported no speech issues. 65 (57%) had poor or no reading skills, 31 (27%) read significantly below their age level, and 18 (16%) had age appropriate reading skills. Of 88 children, 64 (73%) were in mainstream school with special services. Only, 6/26 (23%) adults were gainfully employed. Conclusions: The long-term seizure freedom rate following hemispherectomy was 61% at 5 years. After hemispherectomy, functional deficits in spoken language, reading skills, and behavior were more disabling over long term than ambulation and visual deficits. The findings of our study will assist in counseling families prior to hemispherectomy

N2 - Rationale: Localization of the epileptogenic zone may be challenging in patients with Tuberous Sclerosis Complex (TSC). Previous experience at our institution has identified the single largest calcified tuber as most likely to be epileptogenic. The aim of our study was to analyze whether additional features of the brain MRI could identify the epileptogenic zone in TSC patients independently of other diagnostic and surgical data.

Methods: 31 children with TSC who underwent resective epilepsy surgery at Miami Children's Hospital between 1994 and 2010 were retrospectively studied. Surgical planning had been based on multimodal data with emphasis on electrophysiological investigations. MRI's were independently reevaluated by two experts blinded to all other clinical and diagnostic data. Changes typical of both TSC (tubers, calcifications and cystic lesions) and focal cortical dysplasia (increased cortical thickness, abnormal gyration, gray/white matter blurring, transmantle changes) were identified. Localization of the findings was compared with the location of the resection cavity on the postoperative MRI. We then compared the occurrence of individual MRI changes inside and outside the resection site in 23 subjects with favorable postsurgical seizure outcome, and analyzed reasons for surgical failures in 8 subjects with unfavorable outcome. Results: MRI information alone correctly localized the resection cavity in all 23 TSC patients with favorable seizure outcomes. Significant MRI features in the resection site of these subjects included: largest tuber (n=21), calcification (n=15), cystic lesions (n=2), increased cortical thickness (n=14), abnormal gyration (n=11), transmantle changes (n=7) and gray/white matter blurring in 19/21 cases (two infants had unmyelinated white matter). Increased cortical thickness and abnormal gyration occurred only in the resection site. The relation of other MRI features to the resection site was as follows: largest tubers 11/10 (ratio of subjects with the finding only in the resection site to patients with the finding also occurring outside the resection); calcifications 12/3; transmantle changes 6/1 and gray/white matter blurring 7/12. The resection site was localized correctly using MRI in five other patients with unfavorable postsurgical outcomes; all had incomplete resections of the epileptogenic zone due to overlap with eloquent cortex. The resection site was not localized using MRI in three patients with unfavorable seizure outcomes. One of these patients had overlap of the epileptogenic zone with eloquent cortex; two subjects had multifocal epileptiform activity identified by intracranial EEG. Conclusions: Thorough MRI evaluation is able to accurately localize the epileptogenic zone in a significant proportion of TSC patients. Epileptogenic regions were characterized by "FCD-like" changes outside cortical tubers, especially increased cortical thickness and abnormal gyration. The findings could have important practical consequences for surgical planning in patients with intractable epilepsy due to TSC

N2 - Objective: Children with severe physical disabilities have high care needs. Consequently they and their families are at risk of restricted opportunities to participate in activities that support their wellbeing, social connections with others, and family cohesion. The child is more likely to rely on family support for their own social participation, rather than on participating in activities with peers, which may further alter the dynamics of the family's social participation. Our objective was to gain an 'insiders' view of family social participation, so as to better understand the enabling and restricting factors involved. Design: Narrative Inquiry. Method: Participants were 10 parents or primary care-givers of youths aged 10-18 years with severe physical disabilities (identified as GMFCS & MACS Levels IV or V) recruited primarily through the Royal Children's Hospital and Specialist schools. Parents were interviewed using the Occupational Performance History Interview-III to elicit accounts of daily life within families as well as changes that had occurred over time with their children's growth. Each interview was audio recorded and transcribed verbatim. Narrative analysis was used to construct a core story from each interview within which key participation issues were identified. Secondly thematic analysis was used to compare themes across participant's stories. Results: Parents characterised daily life as involving highly structured routines that were demanding of their time, energy and resources. Routines were dependent to some extent on service provision that was often described as inflexible and not meeting the needs of the family.

Parents prioritised the needs of their child with a disability. Their other roles, including volunteer or paid employment and maintaining relationships both inside and outside the family, were dependent on the suitability and flexibility of care arrangements that could be made for their child. Participating in activities outside the home required parents to access detailed information and plan carefully to cater for their child's needs, particularly concerning toileting and wheelchair accessibility. The personal and financial resources required, and the physical and attitudinal barriers that families faced, meant that 'going out' relied heavily on parents' energy and resources. Parents therefore considered carefully whether social participation was worth the effort.

Conclusions: Daily life was demanding of parents' time, energy and resources. Participation outside of core routines required planning and the means to overcome environmental barriers. Family social participation relied on parents' resourcefulness in facing these barriers. Being knowledgeable and mindful of these issues will assist planning feasible family centered interventions

N2 - Objective: This study compared the participation patterns of children with physical disabilities (PD) with their peers with typical development (TD) in activities outside of school. The aim was to describe similarities and differences in the extent (number of activities and frequency), context (location and companionship) and experience (enjoyment and satisfaction) of participation. Design: A two-group matched pairs design, using survey methods. Method: Data were extracted for children with PD (e.g. spina bifida or cerebral palsy) who lived in regional or metropolitan Victoria, from a previous participation study of children with disabilities. Children with PD were rated by parents as having mild (n=14), moderate (n=19), and severe (n=12) disabilities. Children with intellectual disability were excluded. Forty-five children with PD (15 girls, 30 boys; median age of 11 years [range: 6-17y]) were matched according to age, gender, socio-economic background and location (regional or metropolitan living situation) to 45 children with TD. Children with TD were recruited through 17 government and private schools selected by stratified random (n=12) and convenience sampling (n=5). Participation was measured using the Children's Assessment of Participation and Enjoyment (CAPE) and the Preferences for Activity of Children (PAC) questionnaires. Data were collected via mail-outs or with the support of a researcher. As the data were not normally distributed, Mann-Whitney U-tests were used to assess between-group differences. Results: There was no evidence that the participation patterns of children with PD were different to those with TD in extent or context of participation in Recreational, Skillbased or Informal activities (all $P > 0.05$). Of the 20 activities in which most children participated, 17 activities were consistent between groups. There was evidence that children with PD participated less frequently in Formal ($P = 0.028$) and Social activities ($P = 0.013$). Although children with PD participated in fewer Physical activities ($P = 0.005$) there was no evidence of a difference in their frequency of Physical participation ($P = 0.066$). Conclusion: Participation patterns of children with PD and children with TD were similar, although community-based participation of children with PD was lower in comparison to children with TD. There are few recommendations about how much participation is optimal, or what dimensions of participation are most important. Working with individual children and families to facilitate activity within the community in enjoyed and preferred activities may assist to develop healthy participation patterns for life. Future research that investigates engagement in activity will enhance knowledge about how to support high quality participation

N2 - Thermographic imaging of the skin can be widely used to assess ongoing processes of the skin surface as well as processes within the subcutaneous tissue. The possibility to apply visual images to thermographic images of skin changes allows to gain additional information which can be of great importance for their clinical interpretation. The role of infrared thermography in the diagnosis of inflammatory processes (abscesses, periodontal infiltrations, inflammatory processes with submandibular lymph node involvement) of the skin and surrounding tissues was previously described. Thermographic imaging is an objective diagnostic tool in the interpretation of skin tests with allergens, especially in cases when the skin is covered with other lesions or has a different color. The purpose of our study is to present new opportunities of using thermographic imaging in the evaluation of ongoing processes of the skin surface and within the subcutaneous tissue. 1 The appearance of skin lesions described as allergic urticaria is characterized by great diversity. Typical lesions (wheals) usually show up a few minutes after contact with the allergen and can resolve in a short period of time. Infrared images

of the lesions show, that they are far more expressed than in the visual assessment. Infrared images can also become valuable clues for clinicians, because they describe the activity of the continuing process and thereby can influence the treatment. (Figure presented) In figure 1 a rectangular area, outside the wheal (A4), was selected. After applying a thermographic image we can see a clearly visible area of increased temperature induced by the wheal, with a far greater range than seen in the visual image. The thermographic image was taken in a standard environment using the infrared camera FLIR T-640, which allows applying visual images to thermographic images 2. Skin carcinomas require careful analysis of the surgical field range to determine appropriate and safe surgical margins. On the other hand the cosmetic effect after surgery is very important, that is why surgeons try to minimize the scar. Infrared thermography allows to precisely determine the range of the neoplastic lesion, which very often has a greater size than primary observed. (Figure presented) A skin lesion in the temporal region (figure 3) represents a squamous cell carcinoma, which was qualified for surgical treatment. The surgical field range is intuitively set by the surgeon during the procedure. A histopathologic section is examined under the microscope to ensure safe surgical margins. Infrared images can be helpful in determining the surgical field range. The clinical presentation of infantile hemangiomas is characterized by great diversity. Their range in spatial dimension can be difficult to assess in routinely performed Doppler ultrasound. Recent studies have shown a good effect in treating infantile hemangiomas with prolonged propranolol therapy. The involution of hemangiomas during propranolol therapy is associated with formation of atrophic foci. Infrared thermography allows to assess the temperature of hemangiomas, their size in metric units (by using special software). Because of the diversity of hemangiomas, their location, the age of children, the progress of the healing process (atrophy of the hemangioma) it seems that the comparison of average temperatures between an area registered within the hemangioma and an area registered within a symmetrical body part is the most reliable method to describe the treatment efficacy. In cases of an unfavorable location of the hemangioma (i.e. nose area, forearm), it is more objective to compare temperatures between the hemangioma and an adjacent, healthy tissue. (Figure presented) In the thermogram of a 12-months old girl with an infantile hemangioma 2 areas were marked: A1 is an area with high blood flow within the hemangioma determined by Doppler ultrasound, A2 is an area with marked atrophy of a highly vascularized region due to propranolol therapy. The average temperature in the area A1= 36.8degreeC, in the area A2 36.2degreeC. Delta of average temperatures (Figures 5,6)= 0,6degreeC (Figure presented) A 7-months old boy with an inflamed and tender infantile hemangioma of the nose, after 4 months of propranolol therapy. The tenderness of the hemangioma limited the use of Doppler ultrasound. Visual and thermographic evaluation allows to fully control the healing process. CONCLUSION: The presented opportunities of using infrared imaging in the evaluation and interpretation of ongoing pathologic processes of the skin surface and the subcutaneous tissue indicate the high value of thermography as a diagnostic method

N2 - Objective: Recurrent headache (RHA) results in socio-economic burden, adversely affects quality of life, school performance, social interaction and sleep patterns. This study aimed to determine the impacts of different types of RHA as this has not been previously reported in Bangladesh. Design: Cross-sectional cohort controlled study. Method: Children from 24 government-run secondary schools in Dhaka, were selected randomly through a structured questionnaires consisting of (1) information on migraine/tension-type headache (TTH) using the International Classification of Headache Disorder II, (2) evaluation of headache disability using PedMIDAS (paediatric migraine disabilities assessment score) for cases and modified PedMIDAS for controls and impact on economic status and sleep patterns. Results: In RHA-cases, mean disability score (DS) for school performance, inability to perform usual home-work including chores, restricted outdoor play and compromised social activities were higher (more disability) than controls (8.3, 2.4, 4.9, 1 vs 2.6, 0.4, 1.1, 0.2 respectively, $P < 0.001$). Average DS was higher (19.57) in RHA than controls (5.63, $P < 0.001$) but was also higher in migraine than TTH (21.02 vs 16.27, $P < 0.001$). Sleep disturbances, such as difficulties in initiation and maintenance of sleep (61% vs 49%, $P < 0.001$), number of awakenings per week (32% vs 19%, $P < 0.001$) and fragmentary sleep (16% vs 8%, $P < 0.001$) were more common in RHA. No significant difference was observed in sleep measures between migraine and TTH. Medication requirement and monthly cost for headache treatment was higher in RHA and medication was higher for those with migraine than with TTH, $P < 0.04$. Conclusion: RHA had greater disability in relation to school performance, home work, social activities, sleep pattern and more treatment cost than controls and disability was higher among migraine than TTH

N2 - Introduction: Motor fitness is considered as an individual health measure. Its impact on human organism is extremely important during the early school years due to the intensive child's growth at that time. Aim: The aim of this study was to assess the relationship between the health behavior of early-school children and their motor fitness. Materials and methods: A group of 60 school children attending I-III classes of a rural school was examined in June 2008. The children's motor fitness was determined by employing motor ability tests and interview questionnaires to categorize the children's lifestyles and nutritional patterns. Results were analyzed statistically. Results and discussion: The majority of these school children presented a medium level of motor fitness. Children's opinions concerning their health status and nutritional patterns did not influence their motor fitness. However, a higher percentage of children with a high level of motor fitness was observed among those children with a positive attitude towards health promoting behaviors. A high level of motor fitness was found in about 50% of children spending their free time outdoors 2-3 times a week and a low level in over 57% of children seldom spending their free time outdoors. A higher percentage of children with a low fitness level was detected among those declaring contact with cigarettes and alcohol. Conclusions: Such factors as physical activities during leisure time, children's opinions on their health status and nutritional patterns had only a slight influence on the levels of motor fitness. 2012 Warminsko-Mazurska Izba Lekarska w Olsztynie

IS - var.pagings

N2 - Background: Hearing loss (HL) is a frequent reason for CT and MR imaging studies performed in children. However, a generic request of neuroimaging studies for "HL" is not sufficient. The radiologist should require the clinician to specify whether HL is unilateral (and which side is involved) or bilateral, and whether it is sensorineural (SNHL), conductive (CHL), or mixed. This will influence the imaging approach, which is primarily based on a combination of CT and MRI for SNHL or mixed HL, and on CT for CHL. Sensorineural hearing loss (SNHL) In SNHL, CT detects only approximately 20% of causes. Thus, MRI is often the first-line imaging study. The MRI protocol should always include thin-slice (1 mm or less), heavily T2-weighted images obtained with adequate techniques (ie T2 DRIVE, CISS, FIESTA), which allow for a superb delineation of the membranous labyrinth of the inner ear, inner acoustic canal (IAC) with the VII/VIII cranial nerve complex, and cerebellopontine angle cistern. These sequences can be reformatted on any plane, but direct inplane acquisition offers significant advantages in terms of spatial resolution. Because the acoustic lemniscus projects to the Heschl's gyrus in the temporal lobe, MRI studies in patient with SNHL should not focus on the inner ear only, but include the whole pathway. Contrast material may be administered where applicable. Unilateral SNHL is usually caused by acoustic schwannomas in adults. However, this lesion is uncommon in children except for bilateral schwannomas in the setting of neurofibromatosis type II. Unilateral enhancing mass lesions involving the pediatric IAC are rare and usually of other histologies, including capillary hemangiomas in PHACE syndrome. Most cases of uni- or bilateral SNHL in children are caused by malformations of the inner ear. These, in turn, depend on the timing of the derangement in the development of the inner ear, which starts at 23 days with the formation of the otic placode, proceeds with the otic pit (24 days) and otic vesicle (27 days) stages, and subsequently with the appearance of the vestibular and cochlear pouches and, finally, of the semicircular canals, of which the lateral is the last one to appear. The adult size and configuration is reached by the middle of the fetal period (20-22 weeks), and any derangement at intermediate stages will result in a different kind of malformation. Early stage derangement, including the Michel aplasia (complete aplasia of the inner ear) and the

common cavity, are relatively rare. Midstage derangements are more common and include the incomplete partition types I (cystic appearance of cochlea and vestibule) and II, formerly known as Mondini malformation (1.5 cochlear turns, dilated vestibule and vestibular aqueduct). Although CT adequately depicts these malformations, MRI has the advantage of the absence of ionizing radiation and the possibility to assess the presence of the cochlear nerve, a critical issue for management planning which cannot be resolved by CT alone. Moreover, MRI must be used to look for associated abnormalities and syndromic complexes, in particular the CHARGE association which it also comprises. Among other abnormalities, orbital colobomas which must be scrutinized during the same MRI study. Among causes of SNHL in children, the large vestibular aqueduct syndrome (LVAS) is the most common. In LVAS, HL is initially mild, worsens stepwise, and deteriorates with trauma or intercurrent disease, CT and MRI show a markedly enlarged vestibular aqueduct, mono-or bilaterally; MRI also shows the dilated endolymphatic sac protruding into the cerebellopontine angle cistern. Conductive hearing loss (CHL) Causes of CHL can be categorized into congenital (i.e. malformations) and acquired (i.e. otitis and otomastoiditis). Congenital aural aplasia (CAA) is the main cause of congenital CHL. It is characterized by stenosis (types 1 and 2) or atresia (types 3 and 4) of the external acoustic canal, and it is very commonly associated with anomalies of the middle ear and mastoid. This is due to the common embryological origin of the anterior part of the external ear, incus and malleus from the first branchial arch, and the posterior part of the external ear and the stapes from the second branchial arch. CAA is unilateral in 70% of cases, and bilateral in the remainder; it can be isolated or syndromic (Goldenhar, Klippel-Feil, Treacher-Collins, and other syndromes). In CAA, CT must be used to carefully scrutinize for associated ossicular anomalies which include incudomalleal fixation and stapes dislocation. The course of the facial nerve must also be carefully evaluated, especially looking for dehiscence courses which may cause problems during otological surgery. Acquired CHL is mainly caused by otitis, otomastoiditis, and related complications. Acute otitis/otomastoiditis is caused by pharyngeal germs which colonize the middle ear through the Eustachian tube. Acute otitis/otomastoiditis is a clinical diagnosis that does not require imaging studies for confirmation; the clinical course is usually short, and the process terminates because of the host's immune system, the infection-resistant properties of the mucosal linings, and antibiotic treatment. However, a small proportion of untreated or inadequately treated patients may experience complications which can be a threatening disease and must be diagnosed promptly. Intratemporal complications include incipient mastoiditis, in which infection is restricted to the mucoperiosteal compartment, and coalescent mastoiditis, in which the bone is involved. From this stage, extratemporal complications may ensue, including Bezold's abscesses, sigmoid sinus thrombophlebitis, cerebellar abscess, and Lemierre syndrome. Contrast-enhanced CT is required in the study of complicated mastoiditis to rule out these potentially life-threatening complications; MRI plays a complementary role for confirmation of the diagnosis. Chronic otomastoiditis is caused by the persistence of inflammation in the middle ear cavity leading to mucosal thickening and occlusion of the Eustachian tube. This, in turn, causes retraction of the tympanic membrane at the pars flaccida with development of chronic inflammation which, eventually, may lead to the formation of a cholesteatoma. The Prussak space at the anterior epitympanic recess is the most common location for acquired cholesteatomas, although other locations in the tympanic cavity and petrous bone cells are also possible. Cholesteatomas are characterized on CT as discrete masses causing bone resorption (typically with amputation of the scutum) and ossicular demineralization. Labrynthine or facial nerve fistulae must be carefully ruled out since they may be the source for recurrent meningitides. In doubtful cases, MRI is useful to discriminate a cholesteatoma from aspecific inflammation; a cholesteatoma gives restricted diffusion and does not enhance with contrast material administration. MRI is also useful in the post-surgical follow-up in operated cases.

Conclusions In conclusion, neuroimaging is a powerful tool for the characterization, management planning, and follow-up of both congenital and acquired petrous bone pathology in children. A careful history-taking and correlation with the clinician are of paramount importance to correctly choose the imaging technique and recognize the various conditions. Profound knowledge of anatomy and embryology is necessary to properly address this difficult, fascinating area

N2 - This review presents a geographic distribution of the three autochthonous venomous snake species, which are the only viperids present in Spain, among the Iberian fauna: *Vipera aspid*; *Vipera seoianei* and *Vipera latasti*. This is followed by a detailed descriptive analysis of hospital care provided to patients admitted into hospital due to venomous bites, in the period from 1997 to 2009, using the data from the Spanish hospital discharge registry database. This analysis reveals that in Spain, during this period, 1649 cases were recorded, which means that hospital care was required for more than one hundred cases per year, of which nearly 1% of the cases resulted in death. Cases were recorded in all the Autonomous communities, but more than half (54, 14%) were concentrated in the following four regions: Catalonia, Castilla and Leon, Galicia and Andalucia. It is notable that this concentration of cases is not associated only with the population demographics of the community, but is also the result of the concurrence of very diverse factors of exposure including: habitat of venomous fauna, volume of rural population, farming activities, and practice of outdoor leisure activities. We

also carried out a gross economic calculation for the use of hospital resources by each snakebite case requiring hospital care in Spain, which provided us with an approximate figure of 2000 per case. 2012 Elsevier Ltd

N2 - A concomitant study was carried out, of the association of positive serology for *Toxocara* spp. in 90 children who played in public squares used for leisure, with the frequency with which each child used these areas, and the presence of eggs of *Toxocara* spp. in the sand or grass in these locations. The sand and grass of their peridomiciles and school playgrounds, as well as the feces of their dogs were also analyzed for *Toxocara*. Serum samples were tested for IgG antibodies to *Toxocara canis* excreted-secreted larval antigens by ELISA, and blood samples for eosinophilia. The water-sedimentation technique was used to evaluate the presence of parasite eggs in the sand and grass turfs, and in feces of the dogs that also frequented these locations. 16/90 (17.8%) of the children were seropositive for *Toxocara* spp. There was a positive association between seropositivity in children who played in the public squares six or seven times a week, with a parasite load above 1.1. eggs/g of sand, as well as with contamination of the peridomicile, even at less than 1.0. egg/g of sand. Eosinophilia, the habit of geophagy, age from one to four years, and the presence of parasitized pet dogs were also positively correlated with seropositivity in the children. Eggs were found in 15/15 (100%) of the public squares, 17/90 (18.9%) of the peridomiciles, 3/13 (23.1%) of the schools, and 12/41 (29.3%) of the dogs living in the peridomiciles investigated. 2012 Elsevier B.V

N2 - Physical inactivity is an important health issue in the U.S. and more children today are overweight or obese than ever before. Reflecting the importance of physical activity (PA) among children and adolescents Healthy People 2020 included several objectives on PA guidelines compliance and screen time reduction. Multiple data sources were used to provide baselines for the specified HP2020 objectives: 2005-08 National Health and Nutrition Examination Survey, 2009 Youth Risk Behavior Survey, and 2007 National Survey of Children's Health. About 18% of adolescents met current Federal PA guidelines in 2009. Males, white adolescents, and 9th grade students were more active than their counterparts. About 33% of adolescents participated in daily school physical education and 9th graders were more likely to participate in it than older students. Among children ages 0-2 40.6% viewed no television or videos on an average weekday, about 76% of children ages 2-5 and 6-14 viewed TV, videos or played videogames for no more than 2 hours a day, among adolescents the percentage of those who did not exceed 2-hour a day limit was 67.2%. More than 90% of children ages 6-14 and 75% of adolescents in grades 9-12 used a computer or played computer games outside of school (for nonschool work) for no more than 2 hours a day. Healthy People 2020 was launched on December 2, 2010. National data for the PA topic area are currently available for public use. The PA objectives will be tracked during the decade to measure their progress toward 2020 targets

N2 - Vitamin D is an integral determinant of musculoskeletal health. Reports from across the world indicate the presence of widespread vitamin D deficiency. A 2009 IOF review of global vitamin D status highlights the prevalence and severity of vitamin D deficiency in Asia. Despite abundant sunshine, populations from many countries in Asian region, in particular in South Asia and possibly China are severely affected by vitamin D deficiency. In India, for example, all ages (newborns, children, adults, pregnant women and elderly) have been shown to be affected. Among factors that have been blamed for this epidemic in Asia is skin pigmentation, cultural practices like avoidance of sun exposure, and traditional clothing that allows limited skin exposure. Fortification of food products with vitamin D is not widely practiced in Asia. The majority of the world's population lives in this region of the world, and, given the diverse nature of the countries in the region, each with their own set of unique issues and problems, it is difficult to envisage a uniform strategy for the region as a whole. However, the approaches can broadly be divided into 3 parts: 1. Increasing awareness about importance of sun exposure and outdoor activities in the population, particularly in children. 2. Designing and implementing vitamin D fortification programs. This requires combined expertise of 'vitamin D' experts, nutritionists, chemists, food technologists and social workers, so that a comprehensive plan can be presented to policy makers. Choice of the appropriate food items to be fortified and monitoring strategies are essential to the success of such a program. 3. Selective and judicious use of vitamin D supplements in populations 'at risk'. Typical examples include schoolchildren and the elderly. The dose required to achieve adequate 25(OH) D levels may be much higher than internationally recommended, due to low baseline levels. Studies from India show that at least 2000 IU of cholecalciferol is required daily to achieve optimum serum 25(OH)D levels. There is an urgent need for Asian countries to formulate strategies for combating this epidemic, based on country specific needs and situations

N2 - Objective: To analyze risk factors and morbidity associated with tics in children. Background: Tics are the most common movement disorders in children. Methods: Ninety-two children (73% boys, mean age 9 years, range 2-17) were prospectively evaluated with a standardized protocol for tics. Yale Global Tic Severity Scale (YGTSS) was applied to 65 patients. Results: Children were classified as follows: Tourette syndrome (56%), chronic motor or phonic tics (24%) and tics of <12-month duration (20%). Overall, 97% of the patients had motor simple tics and 73% had complex tics. Tics were limited to the face/neck in 30% of children and were generalized in the rest. Simple (throatclearing, shouting, nonspecific noises, sniffing and coughing) and complex (coprolalia and palilalia) phonic tics affected 75% and 30% of the cohort, respectively. Motor tics showed an earlier onset than phonic tics (6.2 vs 7.2 yr; $p<.05$). Stressful situations and certain daily-life activities (school exams or homework), but also playing video-games and watching TV, aggravated tics in one-third to one half of patients. As opposite, artistic activities (theatre, dancing, painting, listening to music), playing sports and other

outdoor activities improved them. Throat infections were identified as a trigger factor or as an improving event in 4% and 8% of cases, respectively. Tic-associated pain/thraumatic lesions and disabling tics affected 40% and 20% of patients overtime. The following comorbidities were present in children with tics: obsessions and compulsions (44%), ADHD (36%), anxiety (38%). ADHD was significantly more frequent in boys (44% vs 14%; $p=.01$). YGTSS scores correlated positively with time of evolution ($r=0.273$, $p=.026$), and Tourette patients obtained higher scores than other diagnosis (36.7 vs 16.7; $p<.001$). Poor school performance was associated with higher scores in the YGTSS (37.8 vs 24.5; $p=.018$) and with the diagnosis of Tourette (33% vs 15%; $p=.043$) and ADHD (46% vs 18%; $p=.007$). Conclusions: Several daily-life activities were identified as modifying factors of tic severity and may be important clues for tic management. In a small proportion of children, tics were associated with significant morbidity and poor school performance

N2 - Introduction. Children and adolescents with organ transplants have an increased risk of skin cancer. The cumulative and intermittent UV exposures are considered main carcinogens for the development of skin cancer. Consequently it is very important to increase sun protection knowledge and to decrease UV light exposure in childhood. Objective. To evaluate the technical feasibility and acceptability of short message service (SMS) based sun protection recommendations for adolescents after organ transplantation following a special sun protection program. Methods. Adolescents after organ transplantation were invited to participate in a special sun protection program. Thereafter the participants received sun protection recommendations on a daily basis for 4 weeks sent to their mobile phones via SMS, depending on the regional UV index. Baseline survey consisted of a questionnaire which was carried out before the sun protection program took place. The follow-up survey (telephone interview, questionnaire) was conducted by trained interviewers after text messaging intervention. Results. A total of 25 (female 8, male 17) adolescent organ transplant patients were enrolled. 19 (female 6, male 13) of these 25 patients took part in the text messaging intervention. According to an interim analysis 84% of the participants (16/19) confirmed the daily receipt of sun protection recommendations on their mobile phones. All participants reported that text messages helped them to remember the most important information of the sun protection training. 11 of the 19 participating youth (females 3, males 8) mentioned that both sun protection training and text messages would have changed their sun protection behavior (e.g. increased application of sunscreen, use of fabric UV-light protection, decrease of outdoor activities during the lunch time). Conclusions. This study demonstrates that SMS based sun protection recommendations are technically feasible and accepted by adolescents after organ transplantation. In addition to the sun protection program this intervention may help on one side to increase sun protection knowledge and on the other side also help to reduce UV light exposure. Sex/gender differences and similarities should be taken into account in further investigations

IS - var.pagings

N2 - Background/Purpose: Systemic sclerosis (SSc) is an autoimmune connective tissue disease that affects multiple systems and results in thickening of the skin, vascular insufficiency and fibrotic changes in the muscles, joints and internal organs. SSc is a rare disease primarily affecting women. However, men also have SSc. The mean onset of SSc is between 30-50 years of age which are peak years when men are becoming or being fathers. The role of a father can be impacted in many ways by this chronic illness and its unpredictability. Despite the severity of SSc, little is known about the impact this illness has on parenting especially being a father. Therefore, the purpose of this qualitative study is to describe the impact of scleroderma on the role of a father. Methods: Ten fathers with scleroderma that had children 18 years of age and younger living with them at least 50% of the time, participated in this study. The mean age of the fathers was 44.80 years; mean disease duration was 3.76 years. Ninety percent were married, 60% worked full time, and the mean number of children was two. Fathers completed demographic questionnaires and were interviewed over the telephone. The interviews consisted of questions regarding the aspects of SSc that interfered with their ability to parent, situations in which SSc interfered with their ability to parent, what would make parenting easier, advice for other fathers, and support that makes being a father easier. The interviews were tape-recorded and transcribed verbatim. Content analysis was used to determine the primary codes and a summary statement generated for each code. Working from the summary statements the data was aggregated into two key themes with a single overarching theme. Results: The overarching theme, I'm still Dad described the feelings of the fathers that scleroderma does not negate the fact or importance of parenting. Daily tasks and daily routines change but the fathering role stays constant. The two key themes that emerged from the findings related to the emotional impact of the illness and the day to day realities of the illness. The unpredictability and rareness of the illness lead to ongoing feeling of isolation and the fear of the mortality of the illness. The daily activities fathers participated with their children changed related to fatigue, vascular and musculoskeletal physical changes. Even though the men had physical challenges, support systems in place helped them to complete day to day routines. Conclusion: Being a father with scleroderma has positive and negative influences. The negative effects are the inability of the fathers to participate in all of the physically activities the children enjoyed such as outdoor sports and throwing a ball. Being able to take time to spend quality time with the child was a positive influence of the illness

N2 - Background: NHANES data have revealed important clinical predictors of vitamin D serum level.

However, for preschoolers, significant gaps remain. Objective: To examine the relationship between 25-OH vitamin D serum level and volume of milk, outdoor activity, season, BMI, vitamin D supplementation and skin pigmentation. Our secondary objective was to examine whether biochemical indices of calcium metabolism could define the physiologically normal 25-OH vitamin D level. Design/Methods: A cross-sectional study was performed. Healthy children aged 1-5 years were recruited from TARGet Kids! community-based pediatric practices in Toronto, Canada (43degreeN) during well child visits. The primary analysis examined the direction and magnitude of potential clinical predictors of 25-OH vitamin D level. The secondary analysis examined associations between 25-OH vitamin D level and biochemical measures of calcium metabolism. Results: 849

children were recruited between December 2008 and October 2010. The mean age was 35 months (SD 17), 52% were male, 51% had white skin, and 56% were vitamin D supplemented. Mean 25-OH vitamin D level was 92 nmol/L (SD 33), 31% were below 75 nmol/L and 5% were below 50 nmol/L. Univariable analysis revealed cow's milk intake ($p<0.0001$), vitamin D supplementation ($p<0.0001$), outdoor play ($p=0.0005$) and season ($p<0.0001$) were associated with 25-OH vitamin D level with a trend towards skin pigmentation ($p=0.07$) and BMI ($p=0.09$) but not screen time ($p=0.8$). Multiple linear regression revealed that 25-OH vitamin D level increased by 5 nmol/L (95% CI 3-7) per 250 mL cup of cow's milk per day, 11 nmol/L (95% CI 6-16) in vitamin D supplemented children, 4.5 nmol/L (95% CI 2-7) per hour of outdoor play per day and 10 nmol/L (95% CI 5-15) May through September. Using these 4 variables for predicting 25-OH vitamin D level <75 nmol/L resulted in an area under the receiver operating curve of 0.81. There was no significant association between 25-OH vitamin D level, PTH, phosphate, calcium or alkaline phosphatase. Conclusions: Serum 25-OH vitamin D in urban 1-5 year old children at 43degreeN is influenced by daily volume of cow's milk, vitamin D supplementation, outdoor play and season. Biochemical measures of calcium metabolism, including PTH, are not useful in determining physiologically normal 25-OH vitamin D levels in this population

N2 - Background: Little is known about the relationship between vitamin D serum levels and cardiometabolic risk factors in preschoolers. With a potentially long duration of exposure to low vitamin D levels, identifying whether such relationships exist in preschoolers could have important long-term public health implications. Objective: To examine the relationship between 25-OH vitamin D serum level and cardiometabolic risk factors: total cholesterol, triglycerides, HDL, LDL and non-HDL. Design/Methods: A cross-sectional study was performed. Healthy children aged 1-5 years were recruited from TARGet Kids! participating community-based pediatric practices in Toronto, Canada (43degreeN) during well child visits with concurrent measurement of 25-OH vitamin D and cardio-metabolic factors by blood test as well as anthropometrics and dietary exposures by questionnaire. Our primary analysis examined associations between 25-OH vitamin D level and cardiometabolic risk factors. Our secondary analysis used multiple linear regression to examine whether such relationships were independent of BMI and other known factors which influence 25-OH vitamin D level. Results: 849 children were recruited between December 2008 and October 2010. The mean age of the population was 35 months (SD 17), 52% were male, 51% had white skin, 22% were overweight and 6% were obese. Mean 25-OH vitamin D level was 92 nmol/L (SD 33), 31% were below 75 nmol/L and 5% were below 50 nmol/L. Univariable analysis revealed associations between higher 25-OH vitamin D level and lower total cholesterol ($p=0.002$), lower triglycerides ($p<0.0001$), lower non-HDL ($p=0.02$), and a trend towards higher HDL ($p=0.07$) but not LDL ($p=0.5$). Multiple linear regression adjusted for BMI z-score, age, milk intake, outdoor activity, season, skin pigmentation and vitamin D supplementation revealed that for each 1 nmol/L increase in 25-OH vitamin D, total cholesterol decreased by 0.17 mmol/L (95% CI 0.11-0.39), triglycerides decreased by 0.15 mmol/L (95% CI 0.10-0.30) and non-HDL decreased by 0.19 mmol/L (95% CI 0.11-0.56). Conclusions: Serum 25-OH vitamin D in urban 1-5 year old children at 43degreeN is associated with cardiometabolic risk factors. This association appears to be independent of BMI and other clinical variables that are associated with 25-OH vitamin D level

 N2 - Background: Guidelines for physical activity for preschool children promote at least 60 minutes of daily unstructured physical activity (PA). Reduction of sedentary transportation by stroller is encouraged. Objective: To determine if stroller use in healthy children ages 1-5 is associated with PA levels, and adiposity. Modifiable factors associated with increased stroller use were examined. Design/Methods: A cross-sectional study was performed. Healthy children age 1-5 years were recruited at well-child visits from TARGet Kids! community primary care practices in Toronto, Canada with parent reported measures of child and family characteristics including daily PA, nutritional risk (using the NutriSTEP), and child temperament (using the Child Behaviour Checklist). zBMI (WHO) and z-waist circumference (zWC) were used to measure adiposity. Parents reported the proportion of time per week that their child used a stroller or wagon when going for a walk. Multiple linear regression models were used to estimate effects and adjust for potential confounders. Results: 1070 children 1-5 years old were included. The mean age was 35 months; 51% were male. 18% had a zBMI >1 and 6% had zBMI >2. 80% of children 1-2 years of age, compared to 25% of children 3-5 years of age reported using a stroller at least 50% of the time; odds ratio 12.4 (95% CI 9.2, 16.9). Increased stroller use was associated with decreased unstructured PA per week. Adjusted for daycare use, child temperament, and parent perception of child PA level, always using a stroller, compared to never using a stroller, was associated with a decrease in days per week of unstructured physical activity of almost 1 day; -0.72 (-1.2, -0.3). Factors associated with increased stroller use included younger age (p<0.001), and use of a bottle (p=0.004). High effortful control temperament score (pleasure with low stimulus intensity, high attentional focus) was associated with lower stroller use (p=0.03). When adjusted for age, birth weight, nutritional risk, maternal BMI, and maternal PA, there was no association between stroller use and zBMI (p=0.50) or z-WC (p=0.23). Conclusions: Preschool children are spending a large proportion of their outdoor time inactive in a stroller. Anticipatory guidance for parents on appropriate stroller use may be one strategy to improve PA in this age group

N2 - Introduction: Understanding factors associated with BMI and activity levels in young children can help address the obesity epidemic. An important consideration may be where and with whom children spend time. We explored the relationship between childcare arrangement (CCA) and 1) moderate-to-vigorous physical activity (MVPA), 2) sedentary activity (SED), and 3) BMI in preschoolers. Methods: We assessed CCA at baseline and 1-year later for children (N=229; age 55 months) enrolled in an obesity prevention trial. CCA groups were defined as "mother only" (MO; exclusive mother-care at both timepoints), "outside home" (OH; exclusive care outside the home at both timepoints) and "mixed" (MX; includes part-time care, and multiple CCAs). MVPA/SED was measured via 7-day accelerometry; BMIz-score was calculated from standardized measurements. Results: OH was more likely to be black (29.2% vs. 12.7% in MO, 17.9% in MX), and have income >\$160,000/year (MO: 80% vs. 51.3%, MX: 63.9%). MO was youngest (39.5 months vs. 41 in FC, 46.3 in MX). In unadjusted analysis, MO had significantly lower BMIz (.24) compared to others (MX = .51, p=.05, OH =.58, p=.03), and less SED than FC (369 vs. 395 min/day, p=.05). CCA was not associated with MVPA. After adjusting for child gender, race, and age, MO and OH remained significantly different for BMIz (p=.04). Conclusions: Preschool children cared for exclusively by their mothers may have healthier BMIs and less sedentary time than children in other care. Obesity prevention efforts are important for all preschoolers, and the biggest need may be with arrangements outside of mother-care

N2 - IntroductionReported associations between physical activity (PA) and overweight/obesity in children may be weak due to imprecise measurements and inappropriate cut-offs defining moderate-to-vigorous PA (MVPA). The degree to which children's living environment shapes their PA is unknown.MethodsIn 2007/08, 16,223 children (2-9 years) from 8 European countries participated in extensive examinations including anthropometry

and PA (accelerometry, 60-second epochs, n=7,451). Parents reported socio-demographic, behavioural, medical and nutritional data. Adjusted odds ratios (OR; 95%-confidence intervals [CI]) were estimated by logistic regression. BMI was categorized according to IOTF. We assessed opportunities for PA by a moveability index considering multiple urban forms (footpaths, intersections, playgrounds) which was linked with reported PA (n=460) and MVPA (n=275) in German school children. Using multilevel adjusted regression models, we investigated The impact of The moveability index on PA and travel mode to school. Results MVPA varied dramatically depending on The definition used. Using Evenson's criteria, 9.7% (18.3%) of preschool (school) children spent 60+ minutes in MVPA/day. This percentage varied substantially across Europe. Compared to children with 60+ minutes MVPA/day The risk for overweight/obesity was 1.26 (CI 1.04-1.53) and 1.56 (CI 1.29-1.90) in children with 30-60 minutes and <30 minutes MVPA, respectively. Footpath density was positively associated with walking to school (OR=2.17, p=0.034). Density of recreational facilities (beta=0.22, p=0.002) and The moveability index (beta=0.25, p<0.001) showed a positive effect on MVPA/day. Conclusion MVPA was strongly associated with overweight/obesity in children. The moveability index was a positive predictor of PA, where recreational facilities were The main factor influencing PA

N2 - Introduction: Physical activity (PA) is of high importance for health promotion in young children and child care centers represent ideal settings. To fill the existing gap, we conducted a cluster RCT assessing the effectiveness of Youp'luge, a real-life program in child care centers implemented by governmental agencies. Methods: 58 child care centers were randomly selected and 1:1 assigned to a control and an intervention group. The Youp'luge program supports unstructured PA by providing workshops for educators, adapting the built environment of the child care centers, providing time for PA and involving parents. Motor Skills was the primary and BMI, PA (accelerometers) and Quality of Life secondary outcomes. Results: Of the 1616 children, 1467 (age 3.3 +0.7 yrs, 46% girls) participated in the study. 648 children (BMI 16.2 + 1.2 kg/m², 12% overweight & obese,) were present on the motor test day at baseline (mean attendance at child care 48%). There were no intervention effects in the measured outcomes. However, within the intervention group, associated predictors were identified for improvements in motor skills (free-access movement corner, parental evenings), BMI (motivated and additionally formed educators) and PA (type of equipment). Conclusion: This real-life PA program did not improve motor skills or the secondary outcomes. As many programs have to balance between effectiveness and feasibility outside of a research setting, taking the found predictors into account may improve outcomes in such programs

N2 - Introduction: Childhood obesity is over-represented in socially disadvantaged communities. Families living in these areas in Australia have high proportions of parents with low levels of education, government supported needs, and culturally and linguistically diverse backgrounds. Methods: To understand more about early risk factors for childhood obesity in socially disadvantaged areas, we asked parents (n = 796) and health/education professionals (n=45) of children aged 0 to 8 years about children's nutrition and physical activity practices, and perceptions of their child's weight status. Parents and carers completed questionnaires and a small number of carers also consented to interviews. Local interpreters assisted parents of pre-school children, where appropriate. Results: Despite a national prevalence of childhood overweight and obesity of 20 to 25% among children 4 to 8 years of age, only 5% of parents reported concerns about excessive weight in their child. More carers than parents expressed greater concerns about children's risk of obesity. Approximately three in every four children aged 2-6 years averaged less than two hours of outdoor active play. The recommended one hour of 'screen' time for preschool children was exceeded by 80% of children. In children 6-8 years, television viewing doubled and computer time tripled on weekends. Reports of food insecurity, consumption of take away foods and requests for lower cost healthy foods, indicated complexities facing some families. Conclusion: Early obesity prevention strategies may be a low priority for socially disadvantaged families. Broader base supports and strategies assisting families to translate knowledge into practice are required

N2 - The Childhood obesity surveillance initiative in Greece was carried out from November 2010 to March 2011. 5701 children, 7-8 and 9-10 years old (2nd and 4th elementary school grade) from 150 primary schools randomly selected and nationally representative, participated in the study. Anthropometric measurements were performed by experienced dietitians who also completed the student and school questionnaires. Family questionnaires were completed by the family and returned to schools. In the second grade 23% of the children were overweight (OW) and 13,6% obese (OB) whereas in the fourth grade 28,9% were overweight and 13,4% obese. No differences were found for both grades in the OW and OB prevalence between boys and girls.

Percentage of underweight girls was higher than boys in both age groups. A negative correlation was found between rates of OW and OB and participation in sports. Only 20% of schools reported to provide physical education lessons more than three hours per week. 98% of schools reported to have outside playgrounds or inside play areas where children can play during school breaks and about half schools had organized initiatives/projects to promote a healthy lifestyle. Only 21% of schools had fresh fruits in their canteens and 31% milk. The results showed that childhood overweight and obesity prevalence is very high in Greece. Care should be taken to promote healthy eating and increase physical activity in schools

N2 - **BACKGROUND:** Twenty six percent of Canadian children/youth are overweight/obese. Public perception indicates hospitals should promote health and disease-prevention through institutional policy, long-range planning and resource budgeting. In 2007, we performed a survey of all Canadian Paediatric Academic Health Centres [CAPHC] demonstrating inadequate healthy active living (HAL) policy and practices. Fast food vending and patient sedentary activities were prevalent. A strong policy framework was recommended to create and implement HAL guidelines. **OBJECTIVES:** i) To perform a follow-up survey of all CAPHC to detect changes in HAL policy/practice since 2007. ii) To host a multi-disciplinary, pan-Canadian task force to create a compendium of HAL strategies. **METHODS:** In 2009, a modified HAL survey was completed by all 16 CAPHC. Local CAPHC champions collected and submitted data. A multi-disciplinary, pan-Canadian task force met to share best HAL practices and create novel hospital-based HAL strategies through several small group sessions. **RESULTS :** Survey 2009: Health Promoting Committees were similar at 56%. Although nonsmoking policy prevalence was unchanged, only partial adherence was reported by 93% of CAPHC. A mere 19% of CAPHC have written nutrition policy. Most CAPHC cafeterias had limited hours of operation. Sixty two percent of CAPHC had fast food/coffee franchises. In 81% of centres, the vendor determined vending machine content; 38% of CAPHC increased vending machine numbers. No CAPHC had Physical Activity (PA) promotion policies. Outdoor walking trails increased 27-50%. Thirty eight percent of CAPHC children's playrooms offered Wii fit. Thirty one percent of CAPHC had outpatient Child Life workers. None had incentives for staff PA other than discounted fitness club memberships. **Suggested Strategies from Taskforce:** Unique nutrition initiatives: Dial for dining room service; phase out fast food restaurants; restriction of fast food advertisements; hospital-based farmers markets. Unique PA initiatives: Staff walking challenges; patient treasure hunts; active play in waiting rooms; Active living passports. **CONCLUSIONS:** Canadian paediatric hospitals have demonstrated some improvement in HAL promotion since the first survey in 2007 but considerable effort is required to develop a more comprehensive and systematic approach. Urgent attention must be given to the common practice of fast food kiosks and vending machines with nutrition-poor content. The deficit of Child Life workers and lack of active play areas for children and teens must also be addressed. The

taskforce developed a compendium of HAL strategies that will be published and shared with all Canadian Pediatric Hospital administrators to help facilitate improvements in HAL practice and policy

N2 - Pain is the hallmark symptom of vaso-occlusion in sickle cell disease (SCD), but has not been well studied, particularly in children. Previous studies of pain in very young children with SCD have largely been limited to episodes sufficiently severe as to require acute care visits or hospitalizations. Our previous studies in school-aged children and adolescents (Dampier CD et al. J Pediatr Hematol Oncol 2004), as well as those in adults (Smith W et al Ann Intern Med 2009) suggest that vaso-occlusive pain is frequently managed at home outside of acute care medical settings. We sought to obtain similar data about the home pain experience of infants and young children with SCD as reported by parents or guardians, and to explore the relationship between the pain experience and hematological biomarkers. Enrollment and data collection was conducted from Jan 1999-Mar 2008 at the Marian Anderson Sickle Cell Center as part of the Comprehensive Sickle Cell Centers program. Families with SCD infants identified by newborn screening were first approached about the study after completion of confirmatory diagnosis and initial SCD-related education, usually between 4 to 6 months of age. After informed consent, parents/guardians were trained in pain assessment and daily reporting. When sickle cell related pain events occurred, parents/guardians reported pain occurrence, location, associated symptoms and the treatment that they provided. Daily paper diaries were generally used in the first year of life to familiarize families with pain assessment and reporting. Subsequently a novel daily pager system was used to provide a method allowed daily reporting, but with reduced participant burden. A monthly telephone system in conjunction with a daily calendar was used for those families unable to effectively comply with providing daily reports. All pain reports were adjudicated by consensus of study staff and PI/Co-PI. Children were removed from the study for any period of chronic transfusion for clinical events (splenic sequestration, recurrent acute chest syndrome, surgery). Over the study period, 103 children (58% male) were enrolled beginning at a median age of 7.3 months (range 1.5, 65.2 months). This represented about 50% of SCD children referred to the Center by newborn screening during these time periods; the most common reasons for refusal were inability to complete daily reporting and geographic distance from the Center. An SS genotype was present in 50 children (48.5%), SC in 32 (31.1%), SB0thalassemia in 6 (5.8%), SB+thalassemia in 15 (14.6%). Children were actively followed for a median of 3.8 years (range 0.3-7.6 years). The total number of days children were assessed for pain was 141,197 days with an additional 28,079 days of missing data (16%). The total number of days that children had reported pain was 2,288 days (1.6%), which represented 768 distinct episodes of pain. Over 80% of children reported to have pain in the 0-12 month age interval had pain locations (hands/feet) and characteristics (swelling or tenderness) consistent with dactylitis, which became progressively less prevalent in older age intervals. Significantly more SS/SB0 patients (58%) had >2 days of average dactylitis pain during 0-12 months or 12-24 months (53%) intervals compared to SC/SB+ patients (0%) (p=0.04). The timing of the first reported dactylitis event (<2 years or 2 years) significantly predicted the frequency of SCD pain events per person year, with earlier onset associated with more frequent pain events during the study period (p=0.02), for both the SS/SB0 and SC/SB+ (P=0.03) groups. Our study demonstrates the feasibility of initial recruitment and subsequent daily reporting of clinical events by families of infants and young children with SCD over many years, particularly when careful consideration is given to enhance family support and minimizing respondent burden. The onset of an initial dactylitis episode prior 2 years of age, even if treated at home, was associated with more frequent pain throughout childhood, irrespective of hemoglobinopathy type. Such children may be appropriate for interventions, such as oral hydroxyurea, that reduce excessive pain frequency

N2 - LEF1 is a member of the LEF/TCF family of DNA-binding transcription factors, which interact with beta-catenin in the WNT signaling pathway. N-terminal LEF1 mutations that impair beta-catenin binding are commonly found in human sebaceous skin tumors, and expression of an N-terminal-deleted Lef1 mutant that lacks the beta-catenin binding domain leads to sebaceous skin tumors. The intracellular domain of NOTCH1 has also been shown to function as a co-activator of LEF1, leading to the up-regulation of target genes distinct from those activated by beta-catenin binding. Recently, inactivating mutations of LEF gene have been reported in T-cell acute lymphoblastic leukemia (T-ALL) cases. In this study, we analyzed the frequencies and clinical significance of LEF1 mutations in pediatric T-ALL and T-cell non-Hodgkin's lymphoma (T-NHL). Mutation analysis was performed on 138 of the primary T-ALL and T-NHL patient samples. The clinical data were available for 55 newly diagnosed T-ALL and 14 T-NHL patients. These children, aged under 15 years were enrolled into the Japan Association of Childhood Leukemia Study (JACLS) protocol ALL-97 between 1997-2001 and JACLS trial NHL-T98 between 1998-2002. At the time of diagnosis, bone marrow and/or peripheral blood cells were obtained from T-ALL patients and lymph nodes and/or pleural effusions were obtained from T-NHL patients. A total of 69 patients were included in the present study; 49 were male and 20 female; 55 were children diagnosed with T-ALL (median age of 9.5 years; range: 2.0 - 15.0 years) and 14 with T-NHL (median age of 11.0 years; range: 3.7 - 15.0 years). We performed high-resolution array comparative genomic hybridization (array CGH) and sequencing was performed on the entire coding region of LEF1. High molecular weight genomic DNA was used for microarray analysis using Affymetrix GeneChip 50K XbaI, HindIII or 250K NspI, according to the manufacturer's instructions. Genome-wide detection of allelic imbalances was performed using CNAG/AsCNAR software. We identified mono or biallelic LEF1 deletions in 7.5% (5 of 67) of these primary samples. An additional 11.6% (16 of 138) of the cases harbored sequence alterations of LEF1 gene. Twelve of the single nucleotide alterations were found in exons 1, 2 and 3, and four of the frame-shift mutations were found in exons 3, 7, and 8. Frame-shift mutations were novel LEF1 mutations, and mutations in exons 3 and 8 were positioned outside catalytic domain and DNA binding region. Missense mutations in exon 1 were located highly conservative lesion of beta-catenin binding domain of LEF1. Of the 8 LEF1 alterations detected in 16 cases also had NOTCH1 mutations. Analysis of the available clinical data showed that LEF1 gene alteration was not a significant predictor of event-free survival in children with T-ALL treated in JACLS ALL-97 and NHL-T98 protocol. However, LEF1 inactivation was associated with a younger age at the time of diagnosis, but not with sex, white blood cell count, central nervous system involvement, or the presence of an anterior mediastinal mass at the time of diagnosis. Furthermore, analysis of the T-ALL cell surface immunophenotype obtained at the time of diagnosis showed that all LEF1-altered cases were characterized by developmental arrest at a cortical stage of T-cell differentiation. The clinical significance of these gene alterations and detailed data is discussed

N2 - Background: Tyrosine kinases are widely implicated in the genesis of hematologic malignancies and tyrosine kinase inhibitors have achieved remarkable clinical outcomes. However, most cancer patients are ineligible for this form of therapy because we lack knowledge of the oncogenes driving the growth of their malignant cells. In particular, first-line therapy for T-cell acute lymphoblastic leukemia (T-ALL) fails in 25% of children and more than 50% of adults despite improvements in clinical outcomes due to intensification of therapy, and these relapsed patients have a very poor prognosis. Most current T-ALL therapy regimens lack tyrosine kinase inhibitors suggesting that addition of effective kinase inhibitors to T-ALL therapy may improve clinical outcomes. We report that tyrosine kinase 2 (TYK2), signaling through signal transducer and activator of transcription 1 (STAT1), is vital for the maintenance of T-ALL growth and viability, suggesting that incorporation of TYK2 inhibitors into T-ALL therapy regimens may improve patient outcomes. Methods: T-ALL diagnostic specimens were collected with informed consent and neoplastic cells were isolated on a Ficoll gradient. Cells were treated with an siRNA library that individually silences each member of the tyrosine kinase gene family and cultured for 4 days at which time an MTS assay was used to assess cell viability. DNA was isolated from 16 T-ALL cell lines as well as 50 T-ALL patient specimens. TYK2 was sequenced and identified point mutant were cloned and introduced into Ba/F3 cells for assessment of transformative capacity. Transformed Ba/F3 cells were lysed and immunoblotted with antibodies specific for total or phospho-TYK2, STAT1, STAT3, and ERK1/2. Results: RNAi functional profiling of cells from a T-ALL patient specimen demonstrated dependence on TYK2 for cell viability. Sequence analysis of TYK2 in T-ALL cell lines and patient samples revealed a diversity of TYK2 point mutations. These mutations were located just outside of or within the FERM domain (V15A, G36D, G36R, S47N, R425H), the pseudokinase domain (V731I), and the kinase domain (E957D, and R1027H). Introduction of these point mutants into Ba/F3 cells revealed that 7/8 (all except R425H) transformed these cells to factor-independent growth. Analysis of whole cell extracts from transformed cells revealed constitutive phosphorylation of TYK2, STAT1, STAT3, and ERK1/2. Treatment of transformed cells with JAK Inhibitor I revealed extreme sensitivity of cells to this TYK2 kinase inhibitor as well as reduction of TYK2 AND STAT1 phosphorylation. Conclusions: We demonstrate for the first time that the TYK2-STAT1 pathway is constitutively active and required for viability in the setting of T-ALL, sometimes due to gain-of-function point mutations in TYK2. Small-molecule kinase inhibitors with activity against TYK2 reduce the growth of these TYK2-dependent cells. Hence, we have defined a new, oncogenic signaling pathway in T-ALL cells that can be readily modulated by kinase inhibitors. Interestingly, this pathway has previously been associated with tumor suppression, therefore, our findings indicate that activation of this pathway can have varying effects depending on cellular context. Cumulatively, these data offer new therapeutic options for T-ALL patients while simultaneously providing novel insights into the biology of T-cells and the TYK2-STAT1 signaling cascade

N2 - Background: Septic shock is a highly inflammatory and pro-coagulant state associated with high mortality. In a single randomized controlled clinical trial, recombinant human activated protein C (rhAPC, drotrecogin alfa) reduced mortality in patients with severe sepsis at high risk of death. Further clinical trials in patients with a lower severity of illness and in children have failed to reproduce these results, and the effectiveness of rhAPC remains the subject of ongoing debate. Insufficient data exists regarding the use of rhAPC outside of a clinical trial. Objective: To evaluate the effectiveness of rhAPC on mortality in a cohort of patients with septic shock. Methods: We conducted a retrospective, propensity-matched, multi-center cohort study in 28 academic and community intensive care units in 3 countries. Propensity scores were based more 33 variables that were either known or suspected to be associated with rhAPC use. Our primary outcomes were mortality over 30 days and 30-day mortality stratified by APACHE II quartile. Secondary outcomes were hospital and ICU mortality and length of stay, ventilator free and vasopressor free days, and the use of acute dialysis. Results: Using a propensity matched Cox proportional hazard model we observed a 5.9% absolute reduction in 30-day mortality associated with activated protein C use [115/342 (33.6%) vs. 135/342 (39.5%), HR 0.83, 95% CI 0.65-1.07, p=0.15]; however this reduction failed to reach statistical significance. Similarly, we observed non-significant reductions in mortality among the 3 lowest APACHE II quartiles (APACHE II <20: 12.5% vs. 18.2%, HR 0.66, 95%CI 0.29 - 1.49, p=0.32; APACHE II 21-25: 20% vs 33.3%, HR 0.55, 95% CI 0.30-1.02, p=0.06; and

APACHE II 26-30: 36.7% vs. 48.7%, HR 0.73, 95% CI 0.45 - 1.19, p=0.21). Hospital mortality (40.6% vs. 46.8%, HR 0.83, 95% CI 0.66-1.04, p=0.10) and ICU mortality (31.0 vs. 35.1%, HR 0.87, 95% CI 0.67-1.13, p=0.28) were not significantly reduced among patients who received rhAPC compared to matched controls. The use of rhAPC was not associated with significant differences in ICU or hospital length of stay, ventilator free days, vasopressor free days or the use of acute dialysis. Conclusion: In this retrospective, multi-center propensity matched cohort study, the use of rhAPC in patients with septic shock was not associated with statistically significant reductions in 30-day mortality. However, the absolute reduction in 30-day mortality was similar to that observed in previously published clinical trials. Prospective clinical trials evaluating the efficacy of rhAPC are currently ongoing and will serve to define the role of rhAPC in patients with septic shock

N2 - It has been well established that participation in social activities is essential to children's development and that disability status can affect a child's participation in everyday activities. However, little research has been done on the impact of sensory processing disorders (SPDs) on social participation and play behaviors. This study is part of a larger study examining the social participation of children with SPD and specifically compares the playground play behaviors of children with SPD and those of their typically developing peers. Both groups of children were observed over multiple sessions during unstructured recess activity and their behaviors were coded and analyzed. Statistically, results show that the play patterns of the two groups were generally similar. However, there were qualitative differences in the play behaviors of the two groups, including conflict, social play, access to play opportunities, and awareness of social cues. Implications for practice and future research are discussed. Copyright American Occupational Therapy Foundation

N2 - Background: Stimulant medications are commonly used as first-line pharmacotherapies for attention-deficit/hyperactivity disorder (ADHD), but prescribing practices vary greatly across different countries. Several long-acting methylphenidate-and amphetamine-based products are licensed in the US, but fewer treatment options are available in Europe. Lisdexamfetamine dimesylate (LDX) is the first long-acting, prodrug stimulant approved for the treatment of ADHD. To date, all LDX trials have been conducted outside of Europe.

Objectives: To investigate the efficacy and safety of LDX, compared with placebo in children and adolescents with at least moderately symptomatic ADHD in Europe. This study also included a reference arm of osmotic-release oral-system methylphenidate (OROS-MPH). Methods: Children (6C12 years) and adolescents (13C17 years) with an ADHD Rating Scale IV (ADHD-RS-IV) total score ≥ 28 were randomized to LDX, OROS-MPH or placebo over 7 weeks at 48 European sites. Primary and key secondary efficacy measures were the change from baseline at endpoint in ADHD-RS-IV total score and Clinical Global Impressions-Global Improvement (CGI-I) score, respectively. Endpoint was defined as the last on-treatment, post-randomization visit at which a valid ADHD-RS-IV total score was observed. Safety assessments included treatment-emergent adverse events (TEAEs) and vital signs. Results: Of 336 subjects randomized, 196 completed the study. The least squares mean change from baseline at endpoint (95% confidence intervals [CI]) in ADHD-RS-IV total score was C24.3 (C26.6, C22.0) for LDX, C18.7 (C21.0, C16.5) for OROS-MPH and C5.7 (C7.9, C3.5) for placebo ($p < 0.001$ for each active treatment vs placebo). Effect sizes based on the difference (active -placebo) in LS mean change in ADHD-RS-IV total score from baseline to endpoint were 1.804 for LDX and 1.263 for OROS-MPH. The percentage (95% CI) of subjects showing improvement (CGI-I of 1 or 2) at endpoint was 78% (70, 86) for LDX, 61% (51, 70) for OROS-MPH and 14% (8, 21) for placebo ($p < 0.001$ for each active treatment vs placebo). The most common TEAEs for LDX were decreased appetite (25%), headache (14%) and insomnia (14%). Mean changes in vital signs were small and consistent with the known profile of LDX. Conclusions: LDX was effective and generally well tolerated in children and adolescents with ADHD

N2 - Objectives: To detect and to prevent cardiovascular risk factors as: overweight, obesity and hypertension in school age children and teenagers. Methods: We investigated 3747 pupils, 6-18 yo., from different schools from Timisoara, measuring: weight, height, BMI and blood pressure. A questionnaire regarding nutritional behavior and physical activity was completed. Results: There were 2150 girls and 1532 boys in the study, 2744 (73%) from the city and 1003 (27%) from the village. Overweight was found in 20.66% boys and 17.6% girls. Obesity was found in 16.7% boys and 9.16% girls. Overweight and obese boys were equal in both areas, but obese girls were less in town girls. Hypertension was detected in 399 urban children (10.65%) and only in 40 (3.98%) of rural. From the urban area, 47.6% were girls and 52.4% were boys with hypertension. From the village area, 32.5% were girls and 67.5% were boys with hypertension. Increased BMI was found in 172 hypertensive children from town, and in only 17 hypertensive children from village. Overweight in hypertensive children was found in 61 boys and 35 urban girls, in comparison with only 8 boys and 2 village girls. Obesity was present in 51 hypertensive boys and 25 town girls, in comparison with only 1 hypertensive boy and 6 hypertensive girls from the village. The values of hypertension were analyzed with charts. Fast food eating, sandwiches, snacks and sweet drinks were preferred by children from town. Playing outside the house was more frequent in the village group. PC and static play was more frequent in the town group. Conclusions: Obese boys were dominant in urban boys group. Girls were more interested in better look than boys. Hypertension was detected especially in urban children. Children from village eat healthier and do more physical activity. Risk factors for cardiovascular disease are dramatically high in urban children, especially boys, because of fast food eating, snacks, sweet drinks and sedentariness. After this study, a web site for informing and instructing the children and their families, regarding the cardiovascular risk prevention was promoted by our hospital in the schools from Timisoara

N2 - Background: In a recent randomized international clinical trial (RCT) in high-risk cirrhotic patients with acute variceal bleeding, the early use of TIPS was associated with marked and significant reductions both in treatment failure and in mortality. The aim of the present study was to assess whether these excellent results are reproduced in clinical practice outside RCTs. Methods: Retrospective review of patients admitted after inclusion of the last patient in the RCT for acute variceal bleeding and high risk of treatment failure (Child C <14 or Child B plus active bleeding) at the same centres of the original RCT study. All patients treated with early-TIPS were included (n = 45); patients receiving medical therapy with drugs+EBL were included until the moment when the hospital adopted the strategy of using Early-TIPS for all comers (n = 30). Results: TIPS was done within 24 hours in 28 patients; 24-48 h in 11 and 48-72 h in 6. There were no differences in the baseline characteristics of the patients treated with TIPS or Drug+EBL. Median follow-up was 11.2 months. Patients treated with early-TIPS had a much lower incidence of failure to control bleeding or rebleeding than patients receiving Drug+EBL

(3 vs 15; $p < 0.001$). The 1-year actuarial probability of remaining free of this composite end point was 93% vs 53% ($p < 0.001$). The same was observed in mortality (1-year actuarial survival was 86% vs 70% respectively ($p = 0.056$)). More important, actuarial curves of failure to control bleeding + rebleeding and of survival in this observational study were well within the confidence intervals of those observed in the RCT. Conclusions: In experienced centres, the application of the early use of TIPS in patients with cirrhosis and a high-risk variceal bleeding offers results similar to those previously observed in the RCT, supporting its use in clinical practice

N2 - Introduction: Few data from studies in pediatric samples exploring adherence to the Mediterranean Diet (MD) are available. Children spend approximately half of their waking hours in school. Schools provide 1 to 2 meals daily and are a natural setting for education about healthy food choices. Objectives: The aim of this study was to investigate the association of adherence to the MD with having lunch provided by the school.

Method/Design: A cluster sample of 1740 school children, 8-9 years old, selected in Italy was investigated (ZOOM8 study). Parents were given two self-administered questionnaires: a semi-quantitative FFQ and a questionnaire on their child's lifestyle and physical activity. Body weight and height were measured by standardized personnel. Adherence to the MD was assessed by the KIDMED index. Results: 5.1% of the sample was classified as "high" adherers of MD, while 61.1% and 33.9% had an "average" and a "poor" score respectively. When considering the geographical area a higher frequency of "high" adherence to the MD was observed in the northern regions (6.0%) compared with the central (4.9%) and the southern (4.2%) ones. When children had lunch at school "average" adherence increased up to 63.7% and "poor" adherence decreased to 31.7%. Lunch was provided to 61.4% of the children by the school. Most schools in the southern regions involved in the study did not supply any lunch for lack of facilities. 62.9% of the children eating lunch at school liked it. When associating "like lunch" with adherence a further slight increase of "high" (5.4%) and "average" (65.5%) was noticed, "low" adherence decreased further to 29.0%. Conclusions: Low adherence rates to the MD were observed in Italian children. Schools with the provision of lunch could play an important role in encouraging the adoption of the MD with its benefits so further investigation is desirable

N2 - Functional electrical stimulation can be used to enable spinal cord injured children to participate in cycling training as part of a fitness programme or exercise testing procedure. Exercise can reduce the impact of secondary health conditions due to the injury. Functional electrical stimulation has shown promising results in adults with a spinal cord injury, but additional considerations are needed to realise the method for the child with spinal cord injury, partly owing to their limited force producing capacity. An electric motor provides a practical means of performing cycling at controlled cadences, exercising for longer durations and can also be used for recreational outdoor cycling. Here, a novel real-time control technique is developed for cadence regulation during cycling. A feedback control structure is developed based on an empirical model derived from separate identification tests and pole placement and then verified in a series of reference-tracking tests. The system produced cadence responses in close agreement with reference values in all cases and demonstrated satisfactory robustness of stability characteristics. This approach moves towards the practical application of the technology as a training tool for paediatric spinal cord injured subjects. 2010 Elsevier Ltd. All rights reserved

N2 - Purpose: To evaluate a support and education-based weekend camp for children post heart transplant and their families. The intervention with 60 attendants comprised recreational, social and educational activities for children, youth, parents and siblings. Methods and Materials: Evaluation comprised: (I) pre- and post-camp measures: adapted Children's Inventory of Social Support;evaluating sources and need for support, perceived and available support network, actual or utilized support, and satisfaction with support, and the Adolescent Coping Orientation for Problem Experiences on behaviours used in managing difficult situations and life changes; (II) knowledge and satisfaction assessments (III) post-camp qualitative interviews. Results: Participants consistently appreciated the recreational, supportive and educational components of the camp. On average, participants rated the camp 4.21/5, suggesting that the camp met or exceeded expectations (parents: 4.45; patients: 4.33). Key outcomes include increased social support and transplantrelated knowledge. All teenagers who completed the social support questionnaire showed improvement in all domains of experienced support. All but one noted clinical gains in all social support domains; the remaining adolescent reported gains in 3 of 4. Participants liked the variety of activity choices, the expansion of their transplant-related social network, and having fun in a natural setting. They strongly valued the opportunity to develop relationships with peers and health care providers, and actively engaged in support sharing. All participants are interested in a future camp. Recommendations included increased learning modules, including topics of transition and adolescent motivation, and mentoring opportunities for children by older youth. Conclusions: The transplant family camp was found to be an effective and strongly appreciated intervention. Evaluation triggered various improvements in our program including continuous educational events, a sibling support group, an online parent support network, and annually repeated family camps

N2 - Objectives: to collect relevant, up-to-date, representative, accurate, systematic information, related to foreign bodies (FB) injuries. Methods: The "Susy Safe" registry, a DG SANCO co-funded project gathering data on choking in all EU Countries and beyond, was established in order to create surveillance systems for suffocation injuries able to provide a risk-analysis profile for each of the products causing the injury. Main findings after 4 years of activities are resumed here. Results: 16,878 FB injuries occurred in children aged 0-14 years have been recorded in the SUSY SAFE databases; 8046 cases have been reported from countries outside EU. Almost one quart of the cases involving very young children (less than one year of age) presented a FB located in bronchial tract, thus representing a major threat to their health. Esophageal foreign bodies are still

characterizing injuries occurred to children younger than one year, in older children the most common locations are the ears and the nose. FB type was specified in 10,564 cases. Food objects represented the 26% of the cases, whereas non-food objects were the remaining 74%. Among food objects, the most common were bones, nuts and seed, whereas for the non-food objects pearls, balls and marbles were observed most commonly (29%). Coins were involved in 15% of the non-food injuries and toys represented the 4% of the cases. Conclusions: this data collection system should be taken into consideration for the calculation of the risk of injuries in order to provide the EU Commission with all the relevant estimates on FB injuries. 2012 Elsevier Ireland Ltd

N2 - Introduction: Pragmatic skills, also called social use of language, are among those most frequently affected in brain traumatic injury (TBI) in children. Literature refers that social skills are affected in TBI, but little attention, in respect of rehabilitative intervention, is paid to tasks, contexts, and materials. Professionals involved in rehabilitation of pragmatic skills, meet specific difficulties to structure a "natural" setting that recreates the characteristics of communicative interaction. The small group, with its particular dynamics and communicative interactions, may be regarded as the context closest to natural ones. However, to use it effectively as a rehabilitation tool, there is the need to define its important variables, to assess their progress, and eventually to intervene on them, depending on the targets. Objectives: Monitoring children's and speech therapist's behavior during the interaction in a small group (according to established variables) using a specifically constructed instrument (grid for the analysis of video recordings) Assessing the practical utilization of the evaluation tool and its effectiveness in directing and modulating the rehabilitative intervention Methods: It has been called an evaluation grid of the main communicative, interactive and pragmatic skills that are activated during the small group interaction. Small groups of 3 - 5 children (7.3-10.9 years; mean age 9,1 years) were managed by two speech therapists, one of them leading the activity, while the other serving as a role model to promote imitation of coping strategies. The training was video recorded and subsequently the material was analyzed using the evaluation grid. In some cases the analysis led to change the behavior of the speech therapists and / or to introduce different activities. Inclusion criteria: presence of frontal lobe damage q.i. => 70 The activities have been longitudinally evaluated to notice changes in children's behaviors and their consistency with the objectives of rehabilitative goals. Results: The evaluation of small group activities revealed a positive trend in the interactive behaviors of children. In this sense, we suppose that contextual changes gradually introduced by the speech therapists and based on the analysis of video recordings have had a positive effect on the consistency of children's behaviors. The analysis tool has proved to be useful to check dysfunctional behaviors within the workgroup. It can aid to modify and organize current rehabilitative interventions. An appropriate amount of time is required so that speech therapists get used with it and to analyze

the video recordings. Further studies would be needed in order to longitudinally extend the evaluation methodology and to verify the long-term maintenance of positive changes induced

N2 - Objectives: This is the first study investigating the proportion of risk for TBI in school-age children attending rural and urban public schools in the Republic of Cyprus. The study identified the number of blows to the head and presence of symptoms using the Greek version of the Brain Injury Screening Questionnaire (BISQ). Causes of TBI and persisting symptomatology are also reported. Methods: Primary Research Design: Survey research Setting: Public school facilities, community, research laboratory Participants: The BISQ was sent out to the parents of 2088 children (ages 6-12) attending rural and urban elementary schools from varied socioeconomic backgrounds. Thirty three percent (33.8%) or 706 parents completed and returned the

questionnaires and participated in the study. Main Outcome Measure: The Greek version of the Brain Injury Screening Questionnaire (BISQ) Results: Out of the 706 valid questionnaires, 41 (5.8%) children were identified at risk for TBI. Twenty two were male students and nineteen were female. Children of the ages 11, 7 and 8 were found to match the criteria of TBI diagnosis at a higher rate than the rest of the age groups. Based on the BISQ, students were identified at risk if they have sustained alteration of mental status and had 5 symptoms specific to TBI. Blows to the head were common within this population. Analysis indicates that 34 out of the 41 parents who completed the questionnaire reported a blow to the head. Most common causes of blows to the head were: falling while biking (12.2%), falling down stairs (10.2%), while in playground (9%), during sports (8.2%) and falling from high place (7.3%). Most frequent symptoms reported by the parents of children identified at risk for TBI were: making spelling mistakes (69.2%), feeling angry (59.0%), being easily distracted (56.4%), screaming or yelling, having temper outbursts (51.3%), arguing (48.7%), talking too much (43.2%) and feeling tired (42.1%). Conclusion: A proportion of unidentified children at risk for TBI attend public schools in Cyprus. These children are at risk to sustain the psychosocial and cognitive manifestations of TBI. The Greek version of the BISQ is a useful tool to be used for the identification of children at risk. These children should be followed in order to assess their overall cognitive and academic status, ensure that they reach age-appropriate milestones, and receive appropriate rehabilitation services and support

IS - var.pagings

N2 - Background: Sex work is quasi-legal in Tijuana, with a zone of tolerance (Zona Roja, or Red Light district), and a registration card system whereby female sex workers (FSW) pay an annual cost to cover HIV and STI testing. As healthcare efforts are concentrated in the Zona Roja, we set out to assess the frequency of Pap testing among FSW working outside this zone. Methods: Proyecto Amantes de la Salud (Lovers of Health Project) conducted baseline surveys among 403 FSW working in bars outside of Tijuana's Zona Roja using time-location sampling. Surveys included demographics, sexual and substance use behaviour, sex work characteristics and sexual healthcare practices. Average number of annual Pap tests over the past 5 years was calculated using left censoring for the denominator based on: (1) years sexually active and (2) years in sex trade. Descriptive statistics and logistic regression were used to assess factors associated with Pap testing in the past year. Results: Participants ranged in age from 18 to 55 (Median: 28; IQR: 23-32); all were born in Mexico and 98% reported being registered as an FSW. Sex partners included regular, non-client (25%), regular clients (79%) and non-regular clients (99%). Overall, 85% of women reported a pap test in the past year; however, only 35% of sexually active women and 52% of FSW had an average of at least one Pap test per year over the past 5 years see Abstract P5-S6.31 table 1. A (Table presented) small proportion (4%) indicated they had never had a Pap test. In multivariate models, having a Pap test in the past year was negatively associated with income >3500 pesos/month, more years in the sex trade and having regular clients. Marginal positive associations remained with older age, reporting condom use less than half the time with non-regular clients and having any children. Discussion Prevalence of pap tests in the past year was higher than expected and may be attributed to recent efforts by the Tijuana Municipal Health Services to increase outreach to FSWs in these areas. However, since initiating sex work, only half reported the recommended yearly Pap testing which is concerning given the increased risk for HPV infection and cervical cancer among FSW. Sexual health education, including where access services, is needed to encourage regular cancer screening among this high risk population, especially among younger women and women who have been working in the sex trade for longer durations

N2 - INTRODUCTION AND OBJECTIVES: The epidemiology of pediatric genitourinary injuries in the United States (US) is unknown. We describe the epidemiologic features of genitourinary injuries sustained by children that presented to US emergency departments (EDs). METHODS: We analyzed the National Electronic Injury Surveillance System (NEISS) to identify and characterize genitourinary injuries sustained by children 18 years and younger from 2002 to 2010 (n = 10,130). Estimates and standard errors were calculated using data included in NEISS, which is a stratified probability sample of hospital EDs in the United States and its territories validated to produce national estimates of all patients who present to US EDs with an injury. RESULTS: Between 2002 and 2010, an estimated 252,392 children (95% CI 205,579 - 299,194) presented to US EDs with genitourinary injuries. These children had a mean age of 7.4 years (median 6 years, IQR 4 - 10 years). Forty-five percent of the injured children were boys. The yearly incidence of genitourinary injuries was stable across the time period studied. The most commonly injured organs were female external genitalia (37.7%), penises (21.6%), and testicles (12%). The rates of female external genitalia, penile, and testicular injuries per 1000 person years of follow-up were 0.13, 0.08, and 0.04, respectively. The most common diagnoses were contusions (35.5%) and lacerations (32.9%). Fall was the most common mechanism of injury (n=114,017), accounting for 45.2% of the reported injuries. Genitourinary injuries were most commonly associated with sporting and exercise equipment (35.7%), clothing items (15.5%), and playground equipment (6%). Ninety-one percent of patients were treated in the ED and then discharged. CONCLUSIONS: Genitourinary injuries are an important cause of pediatric morbidity. The stability of the injuries across the time

period studied suggests that potential preventative measures to decrease risk of genitourinary injury have not been identified or implemented. Further studies should be conducted to identify which products pose the greatest hazard to children in hopes of increasing awareness and developing safety mechanisms to decrease risk of traumatic genitourinary injury

N2 - Many studies showed evidence of urban forms being environmental correlates of physical activity (PA). Studies that used geographic information systems (GIS) to objectively assess urban forms are mostly carried out in the US or Australia, but rarely in Europe. Findings from these studies cannot be adopted in a straightforward manner, because the environments in the US and Australia differ from urban areas in many European cities.

Built environments do have a different impact on PA across different countries. We adapted the concept of walkability and included recreational facilities offering possibilities for PA particularly for children to investigate the impact of the built environment on PA of children in Germany. Considering multiple urban forms, e.g. footpaths, intersections, and playgrounds, we used a kernel density approach and combined standardized density measures of urban form to develop a moveability index that assesses the opportunities for PA in the German intervention region of the IDEFICS study. The index was applied to PA data of 344 school children reported in the IDEFICS baseline survey conducted in 2007/08. Using multilevel regression models, odds ratios (OR) and regression parameters with 95% confidence limits were estimated to investigate the impact of the built environment on measures of PA and childrens' travel mode to school. After adjusting for sex, age, parents' education and income, the moveability index showed a significant positive effect ($\beta = 0.18$, $p < 0.005$) on childrens' reported hours of PA per day

N2 - Background: Bronchiolitis is the current leading cause of hospitalization in children. Based on the available literature, waste and unnecessary variation in bronchiolitis care are common. Significant work has gone into developing evidence-based guidelines for inpatient bronchiolitis management, though successful strategies for large-scale dissemination outside of academic medical centers are rarely reported. Methods: We formed a voluntary quality improvement collaborative called the Value in Inpatient Pediatrics Network. Our specific aim was to reduce utilization of nonevidence-based therapies in the inpatient care of bronchiolitis. Using the 2006 AAP bronchiolitis guideline as the basis for determining "unnecessary" therapy, we benchmarked the use of bronchodilators, steroids, chest radiography, chest physiotherapy, and viral testing using administrative data supplied by hospitals for the calendar years 2007 through 2010. Inclusion criteria were all non-ICU hospitalizations for bronchiolitis as the primary code at discharge (specifically including patients in observation status). Exclusion criteria were specific chronic illness codes. We then shared specific resources within the network on a voluntary basis, including protocols, scores, order sets and key bibliographies. We (Table presented) provided coaching and advice to participating centers when requested. We met yearly and honored high performing centers at this meeting. Results: A total of 17 centers completed the three active years of the project and are included in this report (Table 1). Aggregate data on 11,568 hospitalizations for bronchiolitis was analyzed. Demographics of participating centers are provided as Table 1. By 2010, the network achieved a 12% absolute decrease (95% CI, 5%-25%) in the number of patients receiving any dose of bronchodilator. We also saw a 3.4 dose per patient (95% CI, 1.4-5.8) absolute reduction in volume of beta-agonist utilized. Overall CPT usage declined 10% (95% CI, 2.6%-17.8%). Decreases in steroids, chest radiography or viral testing in the network were not statistically significant. The data were also analyzed on an institutional level for intra-institutional change. 88% of institutions achieved significant decreases in any bronchodilator usage and 80% did so for doses per patient. Direct cost savings related to decreased beta-agonist usage alone amount to \$449,000. Conclusions: Real world effectiveness in dissemination of evidence-based guidelines may be achieved with a volunteer, peer group collaborative bridging community and academic institutions

N2 - A common problem in epidemiological studies on air pollution is exposure misclassification, because investigators often assume exposure is equivalent to outdoor concentrations at participants' homes or at the nearest urban monitor. The aims of this study were: (1) to develop a new microenvironmental exposure model (MEEM), combining time-activity data with modelled outdoor and indoor NO₂ concentrations; (2) to evaluate MEEM against data collected with Ogawa personal samplers (OPS); (3) to compare its performance against datasets typically used in epidemiological studies. Schoolchildren wore a personal NO₂ sampler, kept a time-activity diary and completed a questionnaire. This information was used by MEEM to estimate individuals' exposures. These were then compared against concentrations measured by OPS, modelled outdoor concentrations at the children's home (HOME) and concentrations measured at the nearest urban monitoring station (NUM). The mean exposure predicted by MEEM (mean = 19.6 mug m⁻³) was slightly lower than the mean exposure measured by OPS (mean = 20.4 mug m⁻³). The normalised mean bias factor (0.01) and normalised mean absolute error factor (0.25) suggested good agreement. In contrast, the HOME (mean = 31.2 mug m⁻³) and NUM (mean = 28.6 mug m⁻³) methods overpredicted exposure and showed systematic errors. The results indicate that personal exposure can be modelled by MEEM with an acceptable level of agreement, while methods such as HOME and NUM show a poorer performance. 2012 Elsevier Ltd

N2 - Background: School-based interventions hold promise for obesity prevention among youth, with programs implemented via school nutrition services offering a way to both positively influence students' food choices and reinforce nutrition education provided in the classroom. The "Go Slow Whoa" stop light eating pattern is designed to aid students in identifying nutrient-dense food choices and learning moderation for less nutrient-dense foods. Methods: Focus groups were held with 43 cafeteria staff from among eight schools that participated in the "Go Slow Whoa" component of the Winning with Wellness obesity prevention project implemented across rural Central Appalachia. Results: Participants recognized the importance of the role that school nutrition services can play in influencing student choices, yet many indicated that lack of administrative support for cafeteria-based interventions, minimal interaction between staff and teachers and lack of ongoing multi-disciplinary collaboration were barriers to change. Further, the role of family influence on children's food choices was underscored, with a common concern being that students choose less nutritious options due to the patterns learned outside school. Collaboration with teachers and administrators was viewed as a useful mechanism for improved implementation feasibility and overall impact of school-based nutrition programs. According to participants, program effectiveness could also be facilitated by a supportive administrative environment and ongoing technical support. Conclusions: The findings of this qualitative investigation suggest that a primary component of effective school-based nutrition programs is ongoing collaboration between cafeteria staff and school staff and administrators

N2 - Background: One in four children in the United States under age five are overweight/obese, yet little is known about the association between acculturation, parental weight perception, and weight status in young children. Methods: Parents who consented to have their children participate in a randomized-controlled trial among 28 low-income preschools completed a baseline survey measuring mediating factors related to nutrition. BMI data was collected on all participating children (N = 774). Results: The sample consisted of 60% Hispanic, 13.3% Haitian, and 24% non-Hispanic Black/ Mixed race. 34.55% of children were overweight or obese. Children whose parents were born outside of the US were significantly more likely to report their child's weight as normal when they were overweight/obese (OR=0.61, 95% CI, 0.44-0.85, P=0.003). Children whose parents did not speak English at all or spoke very poorly were also significantly less likely to have an accurate perception of their child's weight versus parents who reported they spoke English well (OR=0.54, 95% CI, 0.40-0.73, p<0.0001). Non Hispanic parents were significantly more likely to accurately identify their child's weight versus Hispanic parents (Central American/Mexican in particular), (OR=1.49, 95% CI, 1.10-2.03, p=0.010). Conclusions: Despite the high prevalence of overweight children, few parents of overweight/ obese children recognized that their child was overweight. This was more common in those who did not speak English proficiently, were born outside of the US, and were of Hispanic origin. Methods for increasing parental

awareness of children's overweight status in these populations are needed and may help engage these families in practices related to healthier eating and increased physical activity

N2 - Background: Physical activity was reported decreasing among children and adolescents in the U.S. There is limited longitudinal research on physical activity and its determinants in China. Methods: To explore the trends and determinants of physical activities in Chinese children and adolescents after a government campaign to promote children's physical activity and health, we used a subgroup data of 4,117 children and adolescents in school (aged 6-18 yrs) from four waves of the China Health and Nutrition Survey enrolled in 2000 and followed up through 2009. IOTF standards were used on measured weight and height. Direct interviews recorded detailed activities in and out of school as well as culture-specific activities at home. Both time spent in physical activities and metabolic equivalent task (MET, hours per week) were included. Longitudinal mixed models examined physical activity determinants. Results: Overweight and obesity among Chinese children and adolescents doubled from 7.2% in 2000 to 15.1% in 2009. Time spent in physical activities were stable (~30 minutes per day), while homework time significantly increased from 57 minutes to 98 minutes per day. Students in communities without playgrounds or facilities were less likely to participate in any physical activities compared

to their peers. Doing more homework, being discouraged by mothers to engage in physical activities, and lack of facilities were the major determinants of physical activity levels among students. Conclusions: Decreasing homework time, increasing physical activity classes in schools and building more facilities in neighborhoods may promote physical activities among Chinese children and adolescents

N2 - Background: MEND is a multicomponent, behaviorally-based obesity secondary prevention program developed and trialed in the UK. This pilot study is the first to test the USA adaptation of MEND when delivered in low-income communities in Austin and Houston, TX. The purpose of this study is to evaluate the effects of an adapted 10-wk intervention on obesity-related behaviors and beliefs. Methods: Children (age 7-14yr) and their parents attended MEND classes at YMCAs. The intervention, based on Social Cognitive Theory, consists of two weekly, 2-h sessions: 60-m behavior modification and nutrition sessions for children and parents followed by 60-m of fun skill-based aerobic activities for children and group sessions for parents. Measurements included validated surveys, and multi-level regressions were conducted to test pre- and post-intervention differences. Results: 85 families participated: children were 45% female, 89% Hispanic, mean age 10.2 +1.55y. At post-test, 89% (33/37) of beliefs and behaviors measured changed in the expected directions. Participants reported consuming less soft drinks, watching less TV, and having higher self-efficacy for healthy eating and being physically active ($p < 0.05$). Participants also reported consuming less chips, fried food, punch, and frozen desserts ($p < 0.08$) and consuming more breakfast and wheat bread and playing more outdoors ($p < 0.08$). Conclusions: Preliminary results indicate MEND positively influenced children's obesity-related beliefs and behaviors, with most changing in the anticipated direction. Behaviors that changed in an unexpected direction provide an opportunity to refine the intervention. The adapted MEND program was well received and is feasible to be delivered by non-specialists at YMCA's in low-income, underserved communities

N2 - Background: Exposure to "green" environments may encourage higher levels of physical activity among children. Few studies, however, have explored this association exclusively in preschool-aged children in the US. Methods: In 2009, children aged 2-3 years ($n=365$) were recruited from licensed day care centers located in four

counties in Central Illinois. Neighborhood greenness was measured using National Aeronautics and Space (NASA) satellite imagery of vegetation. Outdoor physical activity levels and behaviors were ascertained from parental survey responses. Linear regression was used to examine the relationship between exposure to neighborhood greenness and overall outdoor physical activity levels among children. Logistic regression was then used to explore associations between physical activity behavior and neighborhood greenness while controlling for other covariates. Results: Children living in neighborhoods with higher levels of neighborhood greenness were significantly more likely to engage in outdoor physical activity. Children whose parents spent more time playing with them or transporting them to sporting activities were also more likely to engage in outdoor physical activity. Conclusions: Neighborhood greenness influences physical activity levels among preschool-aged children. Parental involvement, however, attenuates this relationship

N2 - Background: Children are not achieving sufficient levels of physical activity. We aimed to combine accelerometer and global positioning systems (GPS) use to collect objective information on childhood physical activity (PA). We sought to use these methods to identify the locations where children spend their time and the

locations where children exert the most PA. We tested three different data collection methods to identify the one returning the richest data. Methods: Twenty-four middle-school children from Massachusetts wore accelerometers (ActiGraph GT1M) and GPS units (Garmin Forerunner-201) to quantify and locate childhood PA over 5 weekdays and 2 weekend days. Data were collected in 3 waves (winter, spring, summer) in 2009-2010, each with different study staff (research assistant, teacher, counselor) and collection methods (before-school, after-school, camp). Data points were matched by time, and children's locations throughout the day were mapped using GIS. We mapped the locations where all PA, as well as where moderate-to-vigorous physical activity (MVPA), occurred. Results: A total of 26,406 matched datapoints were collected. Teacher-provided pre-charged equipment yielded the most matched (30.1%, range 10.1-52.3%) and greatest average days (6.1) of data. Children spent most of their time at home, regardless of season. Children spent equal amounts of PA time at home and on streets, and were most likely to be engaged in MVPA on streets. Outdoor use patterns varied by season, with street use increasing in spring, and park and playground use increasing in summer. Conclusions: Using GPS and accelerometers to collect objective information on children's PA locations is feasible. All combined data collection method proved similar data return. Children spent most of their time at home with no or light PA. Children's use of indoor and outdoor spaces may vary by season

N2 - Objective: To determine the pattern of referrals, socio-demographic factors, frequency of psychiatric diagnosis, and help offered to children presenting in Child Psychiatry Department outpatient clinic of a tertiary care hospital in Lahore. Methodology: A cross sectional study of children attending child psychiatry outdoor in a tertiary care hospital in Lahore was conducted. Following informed consent from the parent/ legal guardian, 1000 consecutive new referral to the department were assessed by interviewing the parent and the child. A Structured proforma was used for data collection. ICD-10 criteria were used for the diagnosis of psychiatric illness. Record was made of the interventions offered to the child & family. Results: Total sample size was 1000 children with predominant male gender (65%) and mean age of 8.46 (S.D 4.51). More than half (54.5%) of the children in our sample were not enrolled in school and 19% had family history of psychiatric illness. Among the various sources of referral, self-referral was the highest (84.7%) followed by referral from Pediatrics (8.4%). Psychiatric diagnosis observed were Speech Related Difficulties {including speech delay, articulation problems and specific developmental delays of speech & language} (46.5%), Learning Disability (43.3%), Behavior Problems (26.3), Epilepsy (12.6%), Dissociative Disorders (10.1%), Attention Deficit Hyperactivity Disorder (4.5%), Autism (3.2%), Depression (2.4%), Anxiety (1.7%), Psychosis (1%) and Tics (1%). Co-morbidities were found in 44.7 percent of the children. The various interventions offered included medications, referral to psychologist (for family therapy and individual work), play therapist and speech therapist. Conclusion: Majority of children presenting to the child psychiatry clinic have multiple and complex needs due to high frequency of learning disabilities and co morbidities. The findings illustrate the importance of multidisciplinary approach and to assess the different dimensions of psychopathology in children for future service planning

N2 - To estimate the sustained (>8 weeks) objective response rate in pediatric patients with recurrent or progressive high-grade gliomas (HGG, Stratum A) or brainstem gliomas (BSG, Stratum B) treated with the combination of O⁶-benzylguanine (O6BG) and temozolomide (TMZ). Patients received O6BG 120 mg/m²/d IV followed by TMZ 75 mg/m²/d orally daily for 5 consecutive days of each 28-day course. The target objective response rate to consider the combination active was 17%. A two-stage design was employed. Forty-three patients were enrolled; 41 were evaluable for response, including 25 patients with HGG and 16 patients with BSG. The combination of O6BG and TMZ was tolerable, and the primary toxicities were myelosuppression and gastrointestinal symptoms. One sustained (>8 weeks) partial response was observed in the HGG cohort; no sustained objective responses were observed in the BSG cohort. Long-term (>6 courses) stable disease (SD) was observed in 4 patients in Stratum A and 1 patient in Stratum B. Of the 5 patients with objective response or longterm SD, 3 underwent central review with 2 reclassified as low-grade gliomas. The combination of O6BG and TMZ did not achieve the target response rate for activity in pediatric patients with recurrent or progressive HGG and BSG. 2011 Springer Science+Business Media, LLC. N2 - Aim: The aim of this study was to determine the relationships between physical activity level and demographic characteristics, body mass index and some other health behaviors in Turkish adolescents. Material and Method: The data presented in this study were a part of the Turkish data collected for the cross-sectional and international "Health Behavior in School-aged Children 2005/2006 study" which aimed to evaluate adolescents' health and health behavior around Europe and North America. The data were collected from 3884 11 and 13 years of age (1946 males, 1938 females) students who attended 180 classes of 82 primary schools in 26 cities, and 1668 15 years of age (901 male, 767 female) students who attended 88 classes of 83 high schools

in 26 cities. Statistical analyses were made by using chi square test, factor analysis and logistic regression analysis. Results: Twenty percent of the students reported that they were physically active at least 60 minutes a day every day a week. In logistic regression analysis being 11 and 13 years old, being male, spending four or more evenings with friends outside the home were found to be associated with being physically active. When the "eating both healthy and unhealthy foods less frequently group" was taken as the referans group, the other three groups (healthy foods frequently + unhealthy foods less frequently; unhealthy foods frequently + healthy foods less frequently; eating both healthy and unhealthy foods frequently) were more likely to be physically active than the reference group. Conclusions: The results of this study are important to show that physical inactivity is common among Turkish adolescents especially females. These results are also important to show that both eating habits and time spent with friends are related to physical activity of the adolescents. Effective health promotion programme, should be especially focused on females and emphasize the importance of adolescents' eating habits. It should also be remembered that peers could play an important role to improve adolescents' physical activity level

N2 - Vaccination programs have successfully minimized the risk from many diseases; however, patients with immune deficiencies remain vulnerable to live vaccines. Infections prior to bone marrow transplantation (BMT) increase the risks of the procedure. Case Presentation: The case presented here is a 2- year-old boy who was referred to our institution for BMT for an immune deficiency. He presented to his pediatrician after his first live vaccinations with MMR and VZV at the age of 1 year with a persistent rash still present at the time of our

consultation. On examination, he was playful and well developed with normal growth. Faint violaceous and coalesced papules were apparent on his face, trunk and extremities. He also had small tonsils and no lymphadenopathy but was otherwise unremarkable. His infectious history was significant for hand foot and mouth disease and two episodes of respiratory infections (pneumonia and RSV bronchiolitis) both requiring hospitalization for hypoxia. Three months prior to his diagnosis, he was admitted with failure to thrive and chronic diarrhea. Endoscopy showed lymphocytic infiltration in the duodenum but was otherwise normal. Infectious stool studies were negative and alpha-1- anti-trypsin was normal. An immune work-up revealed low IgG (<60 mg/dL) and IgA (<7 mg/dL) and normal IgM (32 mg/dL) and IgE (0.2 IU/mL). Haemophilus influenzae b, pneumococcal and tetanus titers were low to undetectable. He had reduced T cells (1,340 K/muL) with low CD4+ (80 cells/muL) and CD8+ (123 cells/muL) cells and a reversed CD4: CD8 ratio (0.7), normal CD19+ (880 cells/muL), CD16/56+ (544 cells/muL), and iNKT cells. The percentage of CD45RA+ T cells was reduced. TCR Vbeta repertoire was normal. A hypomorphic severe combined immune deficiency (SCID) was suspected but genetic studies ruled out defects in IL-7R, CD3, IL2R-, PNP, ADA as well as 22q 11.2 deletion. HLADR on his T cells and APCs was undetectable at the outside institution. We determined that his B cells and monocytes were missing HLA-DR by flow cytometry confirming a diagnosis of MHC II deficiency. Because of the persistent rash after live vaccines we sent studies for measles, mumps, rubella and VZV which revealed detectable rubella by PCR on nasal swab and peripheral blood. Other viral studies were negative except for HSV II by PCR. He continued IVIG, atovaquone prophylaxis and started acyclovir to effectively clear HSV prior to BMT. He had an unrelated donor BMT with an uncomplicated course to date despite prior rubella viremia. Rubella is now undetectable in both nasal and serum samples five months post-transplant. He continues on standard infectious and GVHD prophylaxis with 100% engraftment, no serious infections or GVHD. A mild intermittent rash is being treated with topical corticosteroids. Conclusion: This is the first case to describe successful BMT with clearance of prior chronic vaccine-associated rubella viremia in a child with MHC II deficiency. This case demonstrates several important lessons. First, a widely used screening method for primary immune deficiencies, such as evaluating T-cell excision circles (TRECs), is urgently needed to avoid live vaccination in undiagnosed cases. This is of paramount importance for pre- and posttransplant survival. Immune reconstitution and outcomes in patients undergoing BMT with MHC II deficiency are historically worse than in patients with other forms of SCID presumably due to severe infections prior to transplant, graft failure due to the presence of the recipients alloreactive and normal T cell repertoire and the possible impact on T cell reconstitution due to the absence of MHC on thymic epithelium. The long term outcomes for this patient remain to be seen but are optimistic

N2 - Background: Playground environmental interventions that increase children's moderate-to-vigorous physical activity (MVPA) have not been adequately tested among low-income and minority children. Schools are key venues for environmental interventions because they reach children from all socioeconomic groups. Some issues remain unclear: whether these interventions benefit low-income and minority U.S. children; whether increases in MVPA at school are matched by increases outside school; whether benefits last beyond the immediate post-intervention period; and how children's school and neighborhood environments affect their response to the intervention. Methods: Evaluation/study design: quasi-experimental intervention study, using both longitudinal and cross-sectional measurements during seven-day measurement sessions pre-intervention, immediately after intervention inception and every six months thereafter. Intervention: Walking/nature trails enhanced with fixed play equipment designed to stimulate activity directly on playgrounds and indirectly in local parks, trails and neighborhoods. Two schools will receive intervention early (Fall 2011) and two late (Spring 2012). Setting and population: 283 fourth-grade children and their parents (>50% of whom will be from low-income families) from four under-resourced elementary schools in a mid-western, mid-sized city. Measures: Pre- and post-intervention: MVPA measured using geographically-linked accelerometers (indicating location and intensity of MVPA) and cross-sectionally using SOPARC methods to quantify the proportion of 4th graders playing actively on school playgrounds; qualitative interviews with children (cognitive mapping, photo-elicitation); questionnaires including secondary aim outcomes, family socioeconomic data and parent perceptions regarding neighborhood environments; children's height and weight Post-intervention only: focus group discussions with children and parents Analysis: Quantitative outcomes: hierarchical longitudinal data analysis, testing intervention effects as the interaction between study condition and time; Qualitative outcomes: identification and iterative review of codes and themes, using a grounded theory approach to identify cross-cutting concepts that characterize interview and discussion responses. Conclusion: This study will contribute to the prevention of childhood obesity nationally by developing, implementing and documenting an approach to assess the effects of community-developed environmental playground interventions using geographically attributed, longitudinal accelerometer data, cross-sectional SOPARC place-based data and qualitative interview data

N2 - Obesity has become a major epidemic causing serious public health concern and contributes to 2.6 million deaths worldwide every year. In developing countries such as India, especially in urban populations and affluent children, obesity is emerging as a major health problem. Objectives: 1. To study the prevalence of overweight & obesity among school children of an affluent school. 2. To assess the risk factors related to obesity. Materials and methods: The present study was a cross sectional study conducted in an affluent English Medium School of Bhubaneswar during Jan. - Feb. 2011. After getting permission from school authorities, the data was collected from students of Class 1 to 10. One section from each class is randomly selected and all the students present during the survey were screened for overweight and obesity. In this way, data was collected from 468 children. Complete data of each child were collected using a pre-designed, pre-tested questionnaire. Result: Out of total 468 school children, 41.9% were boys and 58.1% were girls. 44.4% children belong to 5-10 years age group while the 55.6% children belong to 10-15 years age group. The overall prevalence of overweight and obesity in school children of 5-15 years was found to be 28.63% (overweight - 14.1% and obesity - 14.53%). Maximum prevalence i.e. 36.54% was found in children of 5-10 years age group and 33.65% in boys. Overweight and Obesity was found significantly higher in Children of 5-10 years age group, with family H/O obesity, not playing outdoor games, not doing regular exercise, watching TV, Computer more than 2 hours daily and consuming junk food regularly. Conclusion: Periodic screening for overweight and obesity should be done in schools followed by counseling of parents of overweight and obese children. Counseling of adolescent children on lifestyle modification should be emphasized

N2 - Introduction: Overweight and obesity during childhood are a matter of growing concern in India. Most individuals develop their eating and activity patterns during childhood. Obesity in children and adolescents is

gradually becoming a major public health problem in many developing countries, including India. The objective of the present study is to estimate the prevalence of overweight and obesity among school children and to identify the factors which influenced childhood overweight and obesity. **Materials and Methods:** A cross-sectional study was carried out from July 2009 to January 2011 on school children who were aged between 5 and 16 years. **Results:** The prevalence of overweight and obesity among children was 9.00% and 5.5% respectively. Overall, the prevalence of overweight/obesity was 14.52%. The risk of overweight/obesity was significantly ($p < 0.0120$) higher among children who belonged to the upper SES and to the age group of > 10 years, who viewed television for > 1 hour, who slept for only > 7 hours ($OR = 1.87$; 95% $CI = 1.87-2.53$) and who used vehicles to go to school ($OR = 1.59$; 95% $CI = 1.14-2.24$). The prevalence of overweight and obesity was significantly ($p < 0.0032$) lower among children who swam, danced regularly ($p < 0.0353$) and played outdoor games ($p < 0.0323$) than their counterparts. Its association was found to be protective against overweight/obesity. The risk of overweight/obesity was significantly higher among children who were non-vegetarians ($OR = 1.88$; 95% $CI = 1.39-2.55$, $p < 0.0001$), who regularly consumed junk food ($OR = 2.54$; 95% $CI = 1.82-3.53$, $p < 0.0001$), and in whom the calorie intake was more than the recommended daily allowances ($OR = 1.88$; 95% $CI = 1.39-2.55$, $p < 0.0001$). **Conclusion:** This study confirmed the findings of earlier studies which were carried out in the other parts of the country and it emphasized that regular physical exercise, regulated television viewing, and a healthy eating behaviour could contribute to control overweight and obesity

N2 - **LEARNING OBJECTIVES:** 1. Recognize malaria as an uncommon underlying cause of pulmonary hypertension. 2. Recognize that treatment of uncomplicated malaria may prevent further sequelae of pulmonary hypertension. **CASE INFORMATION:** A 18 year-old man from Mali with recurrent episodes of malaria initially presented to an outside hospital with three days of fever, vomiting, and diffuse abdominal pain followed by a presyncopal episode. The patient arrived in the United States one month prior to this presentation. Labs were notable for hemoglobin 12 g/dL, platelets 88 K/uL, AST 68 U/L, ALT 104 U/L, LDH 284 U/L, and creatinine 1.3 mg/dL. HIV test was negative. A blood smear on admission was positive for plasmodium falciparum with 0.5% parasitemia. Cat scan of the abdomen and pelvis with contrast showed a splenic lesion consistent with infarction. The patient was treated with a seven day course of doxycycline and quinine for uncomplicated malaria. A transthoracic echocardiogram was performed as part of the presyncopal workup and revealed severe pulmonary hypertension based on decreased pulmonary acceleration time and systolic notching. On hospital day 7, the patient was transferred to the present hospital for further evaluation of his pulmonary hypertension. He denied chest pain, dyspnea, and decreased exercise tolerance. Vital signs were unremarkable. Physical exam was significant for a well appearing male in no acute respiratory distress; elevated jugular venous pressure, a right ventricular heave, a loud P2, and lower extremity edemawere absent.A six minutewalk test revealed oxygen saturations of 98-100% on room air. A repeat transthoracic echocardiogram on hospital day 11 revealed normal pulmonary arterial pressures with a preserved ejection fraction and no chamber enlargement. Two repeat blood smears were negative for plasmodium falciparum. The patient had improved clinically and

was discharged home with scheduled follow up of a serial transthoracic echocardiogram.

IMPLICATIONS/DISCUSSION: Pulmonary hypertension (pHTN) is an elevation in the pulmonary arterial pressure, which if severe enough can lead to right ventricular failure. The World Health Organization proposed a classification of pHTN into five groups based upon pathophysiology. Group 1 describes idiopathic disease and the remaining groups focus on an underlying cause. Although parasites, such as schistosomiasis, have been classified in Group 4 as causing pHTN by embolic disease, little is understood about the mechanism by which malaria causes pHTN. One study proposed that malaria causes pHTN by intravascular hemolysis in a manner similar to sickle cell disease. During the hemolysis process, nitric oxide may be depleted leading to increased pulmonary arterial pressures. [1] In patients living in endemic areas of malaria, repeated infections may aid in the development of partial immunity and subsequently lead to less severe infections but, pulmonary hypertension is an important disease sequela that can contribute to increased mortality. In this case, it seems that prompt treatment of uncomplicated malaria with doxycycline and quinine led to the resolution of pulmonary hypertension and presyncopal symptoms. Further studies are needed to fully understand the relationship between malaria and pHTN. [1] Janka J, et al. Increased Pulmonary Pressures and Myocardial Wall Stress in Children with Severe Malaria. *The Journal of Infectious Disease*. 2010; 202(5):791-800

N2 - **BACKGROUND:** Minority populations are disproportionately affected by the obesity epidemic. In recent years experts in the field have recommended that social and behavioral interventions should be focused on promoting small lifestyle changes that will eliminate or reduce the gradual excess weight gain that occurs in people of all ages over the life span. This "small change" approach is based on analyses that demonstrate that people gradually gain weight over time because of a small average daily difference between energy intake and energy expenditure known as the "energy gap." Based on theory and experimental research on small change strategies we developed a novel behavioral intervention aimed at achieving weight loss among Black and Hispanic adults in two New York City communities through small changes in eating behavior and physical activity. Prior to the implementation of the trial we sought to develop a better understanding of how different experimentally-based small change strategies would translate across different cultural groups. Qualitative group interviews were used to culturally tailor the future intervention. **METHODS:** Black or Hispanic adults > 21 years of age with a BMI > 25 and a previous weight loss attempt were recruited at two clinical and two church sites in Harlem and the South Bronx, New York. Six focus groups, three in Spanish and three in English were conducted by two moderators using a standardized interview guide following informed consent. Participants were asked to describe previous attempts at changing their eating behaviors to lose weight. Participants were then presented with thirteen experimentally-validated small change eating strategies known to reduce the "energy gap" (i.e. using a 10 inch plate for main meal, not eating when the TV is on, eating breakfast everyday, eating dinner at home at least 6 days a week). Participants voted for the top six strategies they felt could be

easily adopted by themselves and their family or social network. Group discussion explored potential advantages and challenges of adopting each of the six strategies. Sessions were tape-recorded and transcribed verbatim. Responses were entered into Ethnograph qualitative software and systematically analyzed using grounded theory methods. Through an iterative process, concepts were grouped into categories based on similar properties and dimensions. Overarching themes were then developed by three trained qualitative experts. Three additional trained corroborators independently reviewed the transcripts, and consensus was reached with the final themes reported here. RESULTS: 67 participants mean age 54 years+13, 72% women and 60% Hispanic were enrolled. More than half of participants had some college education (58%), 30% were employed, 42% were married and had one or more children. 74% described themselves as weighing too much and being advised by a medical provider to lose weight. The mean BMI was 34+7.2. 52% of participants described their general health as fair or poor. Only 36% of participants met the daily recommendations of eating five or more servings of fruit and vegetables. We identified three primary themes: 1) The Wake Up Call- an interaction with a health care provider or their own personal decision-making (based on psychologic or physiologic reasons) would prompt a self-awareness that obesity was negatively impacting their health and that it was time to initiate a behavior change; 2) Taking Control - preferences for a particular weight loss strategy were chosen based on which aspect of the built and/or social environment participants believe they could gain control over ; and 3) Falling Off the Wagon -all participants described the experience of not being able to maintain newly adopted behavior/s long term as a result of either unrealistic weight loss planning and goals or negative environmental influences such as stress. Participants selected the following six small change strategies; 1) Using a smaller plate for the main meal; 2) Making half of the main meal vegetables; 3) Putting snacks out of sight; 4) Eating breakfast everyday; 5) Drinking water instead of sweetened beverages; and 6) Eating dinner at home at least 6 days a week. Common reported advantages of the strategies were: 1) Do not require a sacrifice -"you don't feel like you are giving something up;" 2) Cost-effective -"it's cheaper than eating out all the time"; and 3) Health benefits - "there are lots of health benefits from drinking water". CONCLUSION: Our study demonstrates that among community dwelling African-American and Hispanic adults the need to lose weight is often triggered by outside influences such as a health care provider or change in health status (i.e. new onset diabetes). While individuals are able to select strategies that results in short tem weight loss they reported that they are unable to maintain these efforts long term. Some strategies may conflict with family and cultural meal practices and values, others with daily schedules or household food environments. Participants voted for six out of thirteen small change eating strategies that they believe could be easily adopted and maintained long term by themselves or other members of their family and social network. Our results may also have important implications for translating basic experimental research on small change strategies for diverse cultural groups. The development of obesity interventions utilizing small environmental and behavioral changes may be more sustainable over time in comparison to more robust dieting efforts that yield positive results but cannot be maintained long term. The translation of the small change strategies into more culturally and environmentally relevant forms may also increase the success of interventions. The results of this study will be used to refine and tailor a large scale randomized behavioral intervention targeted at achieving a > 7% within-patient reduction in weight through small sustained changes in eating behavior coupled with sustained increases in lifestyle physical activity

N2 - Introduction: The clinical observations of autistic patients show that they react in an unusual way to unattended changes that appear in the environment. Several studies have investigated novelty active detection in children with autism (CWA) and have highlighted visual atypical change processing. However little is known about the automatic change detection, phenomenon that can be study throughout the analysis of the mismatch negativity (MMN). The aim of the present study was to investigate the visual MMN in CWA. ERPs mapping was used to localize in both time and space the brain activations elicited by unattended visual change. Method: Twelve healthy children (aged 8-14 years) and 12 CWA (aged 8- 14 years) participated in the experiment. We used a visual passive oddball paradigm in which the stimuli consisted in the deformation of a circle into an ellipse in the horizontal direction (standard) or in the vertical (deviant). In order to present the visual stimuli outside the focus of attention, a concurrent task was required in which participants had to stare at the central fixation cross and to respond to its disappearance. Results: Behavioral measures showed that CWA displayed longer reaction time than Controls but did not differ in the number of omissions. ERPs analysis revealed several groups differences. Compared to controls CWA showed a typical morphology of response but with a significantly delayed latency. Moreover vMMN displayed shorter latency and atypical morphology in CWA than in controls. Conclusion: This study allowed to evidence an atypical visual automatic processing of change in CWA. These results suggest that abnormalities in change detection in CWA are independent of the sensory modality and might contribute to explain their characteristic behaviours in response to change

N2 - This study examined relationships between greenness exposure and free-living physical activity behavior of children in smart growth and conventionally designed communities. Normalized Difference Vegetation Index (NDVI) was used to quantify children's (n=208) greenness exposure at 30-s epoch accelerometer and GPS data points. A generalized linear mixed model with a kernel density smoothing term for addressing spatial autocorrelation was fit to analyze residential neighborhood activity data. Excluding activity at home and during school-hours, an epoch-level analysis found momentary greenness exposure was positively associated with the likelihood of contemporaneous moderate-to-vigorous physical activity (MVPA). This association was stronger for smart growth residents who experienced a 39% increase in odds of MVPA for a 10th to 90th percentile increase in exposure to greenness (OR=1.39, 95% CI 1.36-1.44). An individual-level analysis found children who experienced >20. min of daily exposure to greener spaces (>90th percentile) engaged in nearly 5 times the

daily rate of MVPA of children with nearly zero daily exposure to greener spaces (95% CI 3.09-7.20). 2011

N2 - Purpose: 1. To compare and review the spectrum and severity of blunt splenic trauma in children associated with motor vehicle accidents and sports and related activities 2. To assess severity of associated intra-abdominal injuries in both categories. 3. To compare the AAST trauma grading scores and review image based severity grading of blunt pediatric splenic trauma. Materials and methods: 220 consecutive cases of blunt pediatric splenic trauma cases were analysed in a retrospective study. Patients presented to our Level 1 trauma center over a period of 4 years (2004-2008). Splenic Injury was graded according to AAST grading on CECT in all patients. Associated intra and extraabdominal injuries were categorized. Patients were categorized according to mechanism of injury into Motor vehicle related trauma, Outdoor Sports related trauma and biking related trauma. Results: All grades and severity of splenic injuries were seen in all three categories in our population. However the severity of associated intra and extraabdominal injuries was highest in the motor vehicle group as expected. Biking related injuries were found to be more severe in grade than other outdoor

sports. Handle bar injuries to spleen are a serious hazard and constitute a whopping 22% of all blunt splenic trauma. Frequency of associated abdominal solid visceral trauma is low with sports related trauma. Conclusion: Traditionally motor vehicle trauma is considered as the major culprit in pediatric splenic trauma, however in our study we found a far exceeding number of sports related and biking related trauma to the spleen. This is cause for concern and calls for a need for improved safety measures during pediatric recreational activities

N2 - The aim of the study was to describe the prevalence, trends and associated factors of dietary supplements (DS) and anabolic-androgenic steroids (AAS) use among Finnish adolescents. The sample comprised 30 511 adolescents aged 12-18 years, of which 22 519 (74%) answered a questionnaire. We also studied associations between 14 socioeconomic, health and health behavioural variables and DS and AAS use by logistic regression.

The proportion of respondents using DS was 45% during the past year and it increased linearly by age. Vitamins (37%) and herbal products (13%) were the most common DSs. In 1991, 9% of the boys aged 16-18 years reported protein use, while the frequency in 2005 was 17% ($P < 0.001$). AAS use was uncommon; only 53 boys (0.5%) and 20 girls (0.2%) reported AAS use. The strongest factors associated with DS use in multivariate model were physical exercise outside sports clubs (OR 1.9; 95% CI: 1.6-2.2), and in sports clubs (OR 1.7; 95% CI: 1.5-1.9). Recurrent drunkenness (OR 5.8; 95% CI: 1.5-21.6) and peer drug use in boys (OR 2.1; 95% CI: 1.2-3.7) were the risk factors for AAS use, whereas physical exercise outside sports clubs (OR 0.3; 95% CI: 0.1-0.5) was a protecting factor. Although the overall use of DS remained at the same level during the study period, there was a slight trend towards increasing use of vitamin and protein supplements. DS use is associated with frequent sports participation and poorer than average health, while AAS use is associated with health-compromising behaviours

N2 - Rationale: The addition of pictures to health information can improve comprehension, recall and treatment adherence, all of which can lead to improved disease management. Objectives: To evaluate self-drawn illustrations made by chronic asthmatic pediatric patients to identify their perception of somatic symptoms and aspects of asthma management. Secondly, to use the emergent themes to develop child-specific pictograms to be

used as a supplementary aid to improve communication for use in the management of chronic asthma in pediatric patients. Study Design and Methods: Chronic inpatient and outpatient asthmatic children recruited at a Canadian pediatric hospital. Participants were asked to draw how they feel when their asthma is under control and during an attack. A multi-disciplinary team determined key drawing features from each individual picture to incorporate these identified themes as pictogram components of an asthma action plan. Results: Drawings from 53 participants analyzed. When asked to draw how they felt when their symptoms were well controlled, emerging themes included images of clear lungs, happy expressions, sunny skies and children playing sports and other outdoor activities. When asked how the children felt during an asthma attack, images of coughing, lung pain/tightness, sad expressions, and confinement or inability to play were common. No differences in common drawing features found between age groups. Conclusion: The next step will be to validate the pictograms with pediatric patients. This development of a validated easy to use asthma action plan can lead to improved asthma outcomes for asthmatic patients with a wide range of health literacy

N2 - PURPOSE: Vitamin D (VD) plays an important role in inflammatory and immune reactions and may be critical in the human tuberculosis (TB) response. With the increased prevalence of TB in the aboriginal (A) population, especially those residing in Northern Manitoba (NM) we sought to identify how frequently children seen in the TB Clinic were VD deficient (VDD). METHODS: VD levels were drawn (as part of routine baseline blood work as per clinic protocol after few patients failed to exhibit inadequate response to usual treatment) from patients referred to the TB clinic for contact investigation, school/immigration screening or treatment of primary/pulmonary disease from July 1, 2006 to June 30, 2008. The normal reference value used was 75-250nmol/L. VD insufficiency (VDI) was when the level was 25-75nmol/L and VDD was diagnosed in those with levels <25nmol/L. Results were analyzed using chisquare test and one way ANOVA. Data were analyzed by using SAS 9.2 software. Significance level considered at < 0.05. Log 10 transformations were done for the variables that were not Gaussian. RESULTS: 358 children had blood levels drawn during the 24 month period. The prevalence of VDD as to gender, ethnicity (aboriginal population versus other ethnicities) were similar but was significantly higher in the older age group(>14 years), and in those residing outside of Winnipeg. There was marginally significant difference in levels associated with seasonal variation, being more prevalent in the fall to winter. As expected, PTH levels were significantly higher in those with VDD. CONCLUSIONS: VDD is common in the aboriginal and immigrant populations seen in our clinic. What role and contribution genetics, diet and environment play require further study, especially as to whether the prevention of VDD may reduce the risk of developing TB. Analysis of VD levels in patients subsequently found to be tuberculin negative will provide more information. CLINICAL IMPLICATIONS: VD as an addition to anti-TB medications may be indicated to reduce risk and to facilitate treatment response

N2 - Background: Spasticity is a disorder of muscular function causing muscular tightness or spasm which occurs when there is damage to the central nervous system whether it is of spinal cord or brain origin. This insult could be either pathological or traumatic. Method: Thirty-three patients had intrathecal Baclofen pumps implanted for severe spasticity. These patients either did not respond to or tolerate oral medications. Results: All patients showed significant improvement in their spasms following the procedure. Improvement was noted not only in spasticity, but also in pain, management of sleep disturbance, activities of daily living, indoor and outdoor mobility and behavior. Conclusion: The number of complications was acceptable, and generally were not lifethreatening. Infection was the significant complication in two patients and this led to explantation of their pumps. Patient satisfaction was very high and was related to improvement in the quality of life for the patients

 N2 - Purpose: EXPAAH project financed by European Community with LIFE+ funds aims at identifying and quantifying population exposure among children and elderly people to carcinogenic PAHs in particulate matter in highly urbanized areas. The main goal of the project will be the health impact assessment of PAHs. An integrated approach, based on measurements and modeling techniques, will be used to estimate the spatial distribution of population exposure to PAHs, to identify key determinants of high exposures and to estimate potential health effects on the target population. In this paper, we summarize the component of the project consisting of in field campaigns for estimating the actual concentration of PAHs in different areas of the city and for assessing the actual human exposure in different living places (microenvironments).
 Methods: Measurements will be performed by means of low volume PM2.5 sampling devices in stationary outdoor and indoor locations, such as houses and schools, and by means of PM2.5 personal exposure measurements of volunteers selected between children and elderly people. The sampling will be performed in the city of Rome on a daily period during two seasonal weeks. Results of the study: Results of the in field campaigns will be addressed to: develop an outdoor-indoor infiltration model; estimate the mean exposure of the target populations to PAHs using data from the air pollution model, infiltration models and population time-activity patterns through an exposure model; evaluate the extent of outdoor-indoor PAHs infiltration; evaluate the population exposure to PAHs

N2 - CASE: Lucy is a 12-year-old Latina whose mother brought her to the pediatric clinic for help with her anxiety symptoms, "hearing voices," and episodes of "spacing out." Lucy did not cry at birth secondary to vocal cord paralysis and still has the tracheostomy performed at a few days of life. In addition to her neonatal intensive care unit stay, she has been hospitalized for pneumonia. Her mother says she is "sickly" and has a weak immune system due to her asthma symptoms. Lucy also experiences somatic complaints related to gastroesophageal reflux and constipation. Lucy is described as being "in another world" and must be called several times before she responds. Lucy states she is nervous "all the time" and often experiences a fast heartbeat, chest pain, and headache. Her attention and internalizing problems began at age 4 years and have worsened since she entered adolescence. When she is alone in the dark, she sees an unknown person and becomes frightened. She hears the voice of her paternal uncle telling her something will harm her mother and runs crying to "check" on her. Lucy also says she hears voices of paternal family members fighting. She has dreamed that her paternal uncle stabbed her in an alley. Lucy reports experiencing sadness and feelings of wanting to die. She has not tried to harm herself and has no plan to do this. She states that she does not know when she is awake or asleep and "hate people talking in my head." She does not report drug use. Lucy's family is bilingual, English and Spanish. Her mother works part-time as a nutritionist, and her father is a machinist. Her father receives counseling for anger management, and there have been previous unsubstantiated child abuse reports involving Lucy and her younger brother. The maternal uncle has been involved in a gang and attempts to phone Lucy's mother, who does not wish to have contact with him. Lucy's mother expresses strong Christian religious and spiritual beliefs, including demons and spirits that may enter her home and can be cast off with prayer. Recently, the family purchased a "cuadro" (picture) at a yard sale, and Lucy's mother said this resulted in footprints in the bathroom that are disappearing with prayer, guidance from the church minister, and discarding of the "cuadro." The primary pediatrician ordered a home school program, given Lucy's frequent illnesses. She is progressing well with a special education teacher. Her recent psychological evaluation at school showed a below average nonverbal intelligence quotient, with strengths in the areas of perceptual, logical, and abstract relationships. Lucy's mother in the past has been hesitant to follow through with psychiatric evaluation because "it is up to God." In the clinic, she is pale and slender with an ethereal look. She is awake and alert with appropriate affect and mentation. Her tracheostomy is intact without any respiratory distress noted. There are no signs of drug use or active hallucinations. You are left wondering whether these voices need psychiatric management. 2011 Lippincott Williams & Wilkins

N2 - The high prevalence of asthma among school-aged youth places a significant burden on students, families, and communities. Secondhand smoke (SHS) exacerbates asthma symptoms and attacks. Parental smoking is likely the most common and recurring source of SHS exposure among children. School-based asthma management programs can play a major role in educating students and their families about how to reduce, eliminate, and cope with SHS exposure. Between January 2007 and May 2008, a total of 121 middle and 248 elementary school students who participated in school-based asthma management programs in elementary school completed pretest and posttest surveys assessing asthma behaviors and management difficulties. Subgroups of 40 middle and 54 elementary school students participated in 15 focus groups. Quantitative data were analyzed using descriptive statistics and independent sample t tests. Thematic analysis was used to identify and interpret prominent themes within qualitative data. Quantitative analysis of elementary school student data revealed students exposed to SHS had significantly higher asthma management difficulties at pretest (2.79 vs 1.98, respectively; $t = 3.4$, $P = .001$) and posttest (2.56 vs 1.74, respectively; $t = 3.8$, $P < .001$) compared with those without SHS exposure. Qualitative results from elementary and middle school students revealed that many students reported SHS exposure resulting from family members smoking at home or in cars. Students and their families reported using ineffective methods (eg, opening a window, drinking water, holding their breath) for

reducing, eliminating, and coping with SHS exposure. School-based asthma management programs should provide education to students and their families on the lasting effects of SHS on asthma symptoms and effective strategies for reducing, eliminating, and coping with SHS exposure in homes and cars. A focus on parent and community involvement can play a key role in addressing students' asthma management needs outside of school. 2011 The Author(s)

N2 - Results of new research indicate that, contrary to previous thinking, youth do not have less effective thermoregulatory ability, insufficient cardiovascular capacity, or lower physical exertion tolerance compared with adults during exercise in the heat when adequate hydration is maintained. Accordingly, besides poor hydration status, the primary determinants of reduced performance and exertional heat-illness risk in youth during sports and other physical activities in a hot environment include undue physical exertion, insufficient recovery between repeated exercise bouts or closely scheduled same-day training sessions or rounds of sports competition, and inappropriately wearing clothing, uniforms, and protective equipment that play a role in excessive heat retention. Because these known contributing risk factors are modifiable, exertional heat illness is usually preventable. With appropriate preparation, modifications, and monitoring, most healthy children and adolescents can safely participate in outdoor sports and other physical activities through a wide range of challenging warm to hot climatic conditions. N2 - Background. The detrimental effects of excess personal solar ultraviolet (UV) radiation exposure include sunburn, immunosuppression and skin cancer. In South Africa, individuals with minimum natural protection from melanin, including fair-skinned individuals and African albinos, and people spending extended unprotected periods outdoors are at risk of sunburn, a risk factor for skin cancer. Sunburn becomes increasingly likely during the high solar UV radiation hours around midday, and previous studies have shown that children are exposed to potentially high, sunburn-causing solar UV radiation levels while at school. Method. To estimate national potential child sunburn risk patterns, monitored ambient solar UV radiation levels at six sites in South Africa were converted into possible schoolchild solar UV radiation exposures by calculating the theoretical child exposure to 5% of the total daily ambient solar UV radiation as derived from personal child exposure studies. Results. Schoolgoing children with skin types I, II and III were identified as being at greatest risk of sunburn. There were 44 and 99 days in a year when schoolchildren with skin type III (moderately sensitive) living in Durban and De Aar, respectively, would be likely to experience sunburn. Schoolchildren with skin type I (extremely sensitive) were at risk of experiencing sunburn on 166 days in De Aar, and those with skin types I and II were at risk on at least 1 day per year at all six locations. Conclusion. Seasonal patterns show that schoolchildren with sensitive skin types may experience sunburn in spring, summer and autumn months. Differences in child sunburn risk were evident, mainly due to latitude and atmospheric aerosols. Additional factors affecting sunburn risk include schoolchildren's use of sun protection, sun-exposed activity, and timing and duration of exposure. Understanding risk patterns and obtaining locally relevant information will assist South African skin cancer prevention and sun protection awareness

N2 - Background: Dietary recommendations for healthy food intake are an essential part of preventive strategies, food variety might offer one additional approach. Methods: Between January 2005 and September 2009, a total of 2548 persons attended a medical outdoor centre for diagnostic and/or therapeutic interventions. To obtain information on their nutrition behaviour, patients were requested to complete a 51-item semi-quantitative food frequency questionnaire. Frequencies of consumption of food items were reported on a scale between 1 (seldom or never) and 6 (more than once per day). To investigate the impact of nutrition patterns on the probability of cardiovascular event and/or medication we estimated four alternative versions of logistic regressions. Results: Up to the age-decade 51-60 of years, the majority of the patients reported a moderate to high food consumption variety. A low variety was primarily found in the age decades older than 60 years. Within each age cohort, the predicted probability of cardiovascular events and/or medication was lower for patients with higher food variety. Our parameter estimates indicate that, on average, the consumption of one additional food item reduced the probability of a cardiovascular disease by about 0.5%. Adding overall daily intakes of energy or nutrient contents did not change this result. Conclusion: Our study shows that food diversity has a significant impact on the probability to stay healthy. 2011 European Society for Clinical Nutrition and Metabolism

N2 - Clinical gait analysis is the accepted "gold standard" for evaluating an individual's walking pattern. However, in certain conditions such as idiopathic toe walking (ITW), the degree of voluntary control that a subject may elicit upon their walking pattern in a gait laboratory may not truly reflect their gait during daily activities. Therefore, a battery-powered, wireless data acquisition system was developed to record daily walking patterns to assist in the assessment of treatment outcomes in this patient population. The device was developed to be small (30x50x12 mm³), light-weight (15 g), easy to install, reliable, and consumed little power. It could be mounted across the laces of the shoe, while forces and walking activities were recorded to investigate the percentage of toe walking during the assessment. Laboratory tests were performed and preliminary clinical trials at a gait laboratory were done on six normal gait walkers. These volunteers also try to walk on their toes to simulate the toe walking at the gait laboratory. The system was able to track the gait pattern and determine the percentage of toe walking relative to normal gait. Three boys and one girl were diagnosed with ITW then participated into this study. A total of 4 sets thirty-three 10 min data sessions (5.5 h) were collected outside the laboratory. The results showed that the test subjects walked on their toes 70+4% of the total walking time, which was higher than that they performed 64+5% at the gait laboratory. This preliminary study shows promising results that the system should be able to use for clinical assessment and evaluation of children with ITW. 2011 American Society of Mechanical Engineers

N2 - Objective: To investigate virological and immunological response to antiretroviral therapy (ART), and predictors of switching and interrupting treatment among infants starting ART across Europe. Design: Cohort study. Methods: Nine cohorts from 13 European countries contributed data on HIV-infected infants born 1996-2008 and starting ART before age 12 months. Logistic and linear regression, and competing risks methods were used to assess predictors of virological (viral load <400copies/ml) and immunological (change in CD4 Z-score) response, switching to second-line ART and treatment interruptions with viral load less than 400copies/ml. Results: A total of 437 infants were followed for median 5.9 (interquartile range 2.3-7.6) years after starting ART; 30% had an AIDS diagnosis prior to ART initiation. 53% had suppressed viral load <400copies/ml at 12 months in 1996-1999, increasing to 77% in 2004-2008. Virological and immunological responses at 12 months varied by initial ART type (P<0.001 and P=0.03, respectively), with four-drug nonnucleoside reverse transcriptase inhibitor (NNRTI)-based regimens being superior [virological response <400copies/ml adjusted odds ratio=3.00, 95% confidence interval (CI) 1.24-7.23; mean increase in CD4 Z-score coefficient=0.64, 95% CI 0.10-1.17] to both three-drug NNRTI-based (reference) and boosted protease inhibitor regimens which were similar. Rates of switching to second-line ART were lower among children starting four-drug NNRTI-based and boosted protease inhibitor-based regimens compared with three-drug NNRTI regimens (P=0.03). Sixty five percent of infants remained on first-line ART without treatment interruption after 5 years. Conclusion: Effective and prolonged responses to first-line ART can now be achieved in infants starting early ART outside trial settings. Superior responses to four-drug NNRTI compared with boosted protease inhibitor or three-drug NNRTI regimens need further evaluation, as does treatment interruption following early ART. 2011 Wolters Kluwer Health | Lippincott Williams & Wilkins

N2 - Individuals with autism spectrum disorder (ASD) demonstrate intact or superior local processing of visual-spatial tasks. We investigated the hypothesis that in a disembedding task, autistic individuals exhibit a more local processing style than controls, which is reflected by altered electromagnetic brain activity in response to embedded stimuli and enhanced activity of early visual areas. Ten autistic and ten matched control participants underwent 151-channel whole-head magnetoencephalography. Participants were presented with 400 embedded or isolated letters ('S' or 'H') and asked to indicate which of the two letters was shown. Performance was equal in both groups, but event-related magnetic fields differed between groups in an early (100-150. ms) and a later (350-400. ms) time window. In the early time window, autistic individuals differed from control participants in the embedded, but not in the isolated condition, reflecting reduced processing of the irrelevant context in autistic individuals. In the later time window, amplitude differences between the embedded and isolated conditions were measured in control participants only, suggesting that "disembedding" processes were not required in autistic individuals. Source localisation indicated that activity in individuals with ASD peaked in the primary visual cortex in both conditions and time windows indicating an effortless (automatic, bottom-up) local process, whereas activity in controls peaked outside the visual cortex. 2011 Elsevier Ltd

 N2 - Current national and international publications describe a suboptimal vitamin D intake or an inadequate vitamin D status in all age groups. The aim of this statement is to summarize the available literature and evidence for reference values of vitamin D intake and vitamin D supply as well as for the current consumption. On this basis, recommendations for infants, children, and adolescents living in Germany were developed. Reasonable measures for achieving an improved vitamin D status are: protected sunlight exposure, intensive physical activity (at least 1 h daily) outside, and increase of vitamin D intake via supplements. Special attention is given to risk groups (children nourished on a vegetarian diet, migrants, persons with limited sunlight exposure, and chronically ill persons) for which regular control of serum 25-hydroxyvitamin D levels has to be considered. A systematic supervision of vitamin D supply in childhood and adolescence and a cost-benefit analysis of recommended or conducted measures should be performed. In the following an abbreviated version of the statement of the Nutrition Committee of the German Society of Pediatrics and Adolescent Medicine (DGKJ) is printed. The full version is published under <http://www.dgkj.de>. 2011 Springer-Verlag

N2 - Objective: Hyper-IgE syndrome (HIES) is a rare primary immunodeficiency caused by autosomal dominant STAT3 mutations resulting in recurrent infections and connective tissue abnormalities. Coronary artery abnormalities have been reported infrequently. We aimed to determine the frequency and characteristics of coronary artery abnormalities. Design: STAT3-mutated HIES patients (n = 38), ranging in age from 8 to 57 years, underwent coronary artery imaging by computed tomography or magnetic resonance imaging. Images were evaluated for tortuosity, dilation, and aneurysm. Charts were reviewed for cardiac risk factors. To allow blinded image interpretation, an age- and gender-matched non-HIES group was also evaluated (n = 33). Results: Coronary artery tortuosity or dilation occurred in 70% of HIES patients, with aneurysms present in 37%, incidences much higher than in the literature and in our non-HIES group, in which 21% had tortuosity or dilation and 3% had aneurysms. Hypertension was more common in the HIES group than in the general population and was associated with vessel abnormalities. Atherosclerosis was uncommon and mild. Conclusions: Coronary artery aneurysms and tortuosity are common in HIES, despite a paucity of

atherosclerosis, suggesting that STAT3 plays an integral role in human vascular remodeling and atherosclerosis. 2011 Springer Science+Business Media, LLC (outside the USA)

N2 - In general terms a mand is a requesting response. Teaching children with autism to mand for information is often a difficult task given their language deficits. The present study examined a procedure consisting of contrived motivating operations, prompt fading, manded consequences, error correction, and a brief preference assessment for teaching the mand "What is it?" A modified multiple-baseline design across situations was used to evaluate the teaching procedure. Each of three children with Autism Spectrum Disorder learned the mands and generalized to situations, activities, scripts, the natural environment, and over time. 2011 Elsevier Ltd. N2 - School recess is an opportunity to include students with autism spectrum disorders (ASD) with their typically developing peers and is a setting in which instruction can occur. However, the educational opportunities for children with ASD within recess are often overlooked and recess time is being reduced or eliminated in the United States. This review involved a systematic search and analysis of 15 studies that utilized recess to implement academic, social, or behavioral interventions for students with ASD. Each identified study that met pre-determined inclusion criteria was analyzed and summarized in terms of: (a) participant characteristics, (b) intervention procedures, (c) dependent variables, and (d) intervention outcomes. This review has three main aims: (a) to evaluate and synthesize the evidence-base, (b) to inform and guide teachers interested in utilizing recess time for educational purposes, and (c) to stimulate and guide future research in this area. Results demonstrate that recess time can indeed be used to teach target behaviors to students with ASD.

N2 - Objective: To study the impact of preschool outdoor environments on children's physical activity and solar ultraviolet (UV) exposure at different latitudes and countries.Methods. Outdoor environments of 11 preschools

(two in Raleigh NC, USA, Lat.36degreeN, nine in Malmo, Sweden, Lat.55degreeN) were scored (OPEC) regarding space, vegetation, hilly terrain and level of integration between open spaces, vegetation and play structures. Free sky (%) was determined by imaging. Physical activity was measured by pedometers and solar UV-exposure by polysulphone dosimeters during 5 days in spring 2009, and individual background data gathered by questionnaires and anthropometric measurements. Global UV radiation was measured and available individual UV radiation (%) computed. Results: In Malmo, mean step count/minute was 21.2 in preschools with high-scored environment vs. 17.6 in low-scored environments, and UV-exposure lower, 26% vs. 43% of available UV during outdoor stay. In Raleigh, step count/minute was 12.3 and UV-exposure of available UV 27% during outdoor stay. Conclusions: Step count/minute was lower in Raleigh than in Malmo, but in Malmo children at low-scored environments ran a higher risk of sunburn than in Raleigh. Trees and shrubbery integrated in children's playscape trigger both physical activity and sun-protective behaviour in Sweden, and previous measurements in Stockholm were confirmed. Such outdoor environment should be recommended, but the role of season and climate needs to be further explored. 2011 Elsevier Masson SAS

N2 - After the completion of a double-blind placebo-controlled trial, tacrolimus (TAC) was approved for the treatment of lupus nephritis (LN) in Japan. However, the approved maximal dose, 3 mg/day, is almost half the dose used for induction therapy outside Japan. In this study, we retrospectively evaluated the efficacy and safety of low-dose TAC (<3 mg/day) for induction therapy in 13 adult patients (2 men and 11 women) with active LN. Eight patients were treated for LN flares. Twelve patients underwent renal biopsies: 8 with class IV, 2 with class III + V, 1 with class IV + V, and 1 with class V renal histology, according to the International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification. The mean initial doses of prednisone and TAC were 34.6 + 14.5 and 2.7 + 0.6 mg/day, respectively. All the patients achieved a complete remission (CR) at 7.7 + 6.7 months (mean + SD) after the last administration of TAC, except for 2 patients who discontinued TAC treatment; 1 because of worsening systemic lupus erythematosus and 1 because of hypertension. Two patients experienced a flare-up after achieving CR. The mean blood TAC concentration 12 h after the last administration (C12) was significantly lower among the patients with flare-ups than among those with a sustained CR (1.5 + 1.5 vs. 5.1 + 1.9 ng/mL, $P = 0.034$). These data showed that low-dose TAC was effective for induction therapy in patients with active LN, although a lower TAC concentration may be associated with a poor outcome. 2010 Japan College of Rheumatology

N2 - We explored how developing neural artifact and animal representations in the dorsal and ventral stream play a role in children's increasingly more proficient interactions with objects. In thirty-three 6- to 10-year-old children and 11 adults, we used fMRI to track the development of (1) the cortical category preference for tools compared to animals and (2) the response to complex objects (as compared to scrambled objects) during a passive viewing task. In addition, we related a cognitive skill that improved substantially from age 6 to 10, namely the ability to recognize tools from unusual viewpoints, to the development of cortical object processing. In multiple complementary analyses we showed that those children who were better at recognizing tools from unusual viewpoints outside the scanner showed a reduced cortical response to tools and animals when viewed inside the scanner, bilaterally in intraparietal and inferotemporal cortex. In contrast, the cortical preference for tools in the dorsal and ventral visual stream did not predict object recognition performance, and was organized in an adult-like manner at six. While cortical tool preference did not change with age, the findings suggest that animal-preferring regions in the ventral visual stream may develop later, concordant with previous reports of a protracted development in similar regions for faces. We thus conclude that intraparietal and inferotemporal cortical networks that support aspects of object processing irrespective of tool or animal category, continue to develop during the school-age years and contribute to the development of object recognition skills during this period. 2010 Elsevier Inc

N2 - Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Public awareness of the risk is not optimal, overall compliance

with sun protection is inconsistent, and melanoma rates continue to rise. The risk of skin cancer increases when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Yet, people continue to sunburn, and teenagers and adults alike remain frequent visitors to tanning parlors. Pediatricians should provide advice about UVR exposure during health-supervision visits and at other relevant times. Advice includes avoiding sunburning, wearing clothing and hats, timing activities (when possible) before or after periods of peak sun exposure, wearing protective sunglasses, and applying and reapplying sunscreen. Advice should be framed in the context of promoting outdoor physical activity. Adolescents should be strongly discouraged from visiting tanning parlors. Sun exposure and vitamin D status are intertwined. Cutaneous vitamin D production requires sunlight exposure, and many factors, such as skin pigmentation, season, and time of day, complicate efficiency of cutaneous vitamin D production that results from sun exposure. Adequate vitamin D is needed for bone health. Accumulating information suggests a beneficial influence of vitamin D on many health conditions. Although vitamin D is available through the diet, supplements, and incidental sun exposure, many children have low vitamin D concentrations. Ensuring vitamin D adequacy while promoting sun-protection strategies will require renewed attention to children's use of dietary and supplemental vitamin D.

N2 - In the early part of the rainy season in 1988, an outbreak of beriberi occurred in free-living adults in a relatively small area in the North Bank region of The Gambia. In 1995 we selected two compounds in a village called Chilla situated within the affected district to retrospectively examine dietary factors potentially contributing to the outbreak. There had previously been cases of beriberi in one compound (BBC) but not in the other (NBC). We measured energy and thiamin intakes for four days on six occasions during the year. We calculated energy and thiamin intakes of people living in the two compounds and foods were collected for thiamin analysis through the year. Thiamin:Energy ratios only met international recommendations in the immediate post-harvest season when energy and thiamin intakes were highest and then fell through the year. In the rainy season when food was short and labour was heaviest, energy intakes were lower in the NBC but thiamin:energy ratios were lower in BBC. Records of rainfall in 1988 collected near the village indicated that the amount in August was twice the average. We suggest the heavy rainfall may have increased farm workload and reduced income from outside-village work activity. The lower energy intakes in the NBC may have forced adults to rest thus sparing thiamin demands and delaying onset of beriberi. In contrast, the higher energy intake of adults in the BBC may have enabled them to continue working, thus increasing demands for thiamin and inducing the earlier onset of beriberi. 2011 by the authors; licensee MDPI, Basel, Switzerland

N2 - Video self-modeling (VSM) has accumulated a relatively impressive track record in the research literature across behaviors, ages, and types of disabilities. Using only positive imagery, VSM gives individuals the opportunity to view themselves performing a task just beyond their present functioning level via creative editing of videos using VCRs or video software. In this study, the authors used a single-subject multiple-baseline design across four preschool children on the autism spectrum to determine if self-modeling would facilitate their social initiations during playground time. The results were mostly positive, with two children exhibiting major treatment effects, one with questionable results, and one child being unaffected. Discussion of the results, the practicality of VSM, and suggestions for continued research are provided. 2011 Hammill Institute on Disabilities

N2 - Context: In humans, the prevalence, mass, and glucose-uptake activity of ¹⁸F-fluorodeoxyglucose (¹⁸F-FDG)-detected brown adipose tissue (BAT), which are expectedly enhanced by a cold stimulus, also appear modulated by other factors that still have to be disentangled. Objective: The objective of the study was to investigate the factors determining the prevalence, mass, and glucose-uptake activity of ¹⁸F-FDG-detected BAT in humans. Research Design and Methods: We retrospectively analyzed all ¹⁸F-FDG positron emission tomography/computed tomography examinations performed between January 2007 and December 2008 at our institution for ¹⁸F-FDG uptake within the cervical/supraclavicular, mediastinal, paravertebral, and perirenal fat areas. The influence of outdoor temperature, sex, age, body mass index (BMI), plasma glucose level, diabetes diagnosis, day length, and cancer status on the prevalence, mass, and glucose-uptake activity of ¹⁸F-FDG-detected BAT depots was investigated. Results: Three hundred twenty-eight of the 4842 patients (6.8%) had ¹⁸F-FDG-detected BAT. The prevalence of ¹⁸F-FDG BAT was negatively associated with outdoor temperature ($P < 0.0001$), age ($P < 0.0001$), BMI ($P < 0.0001$), and diabetes status ($P = 0.0003$). Moreover, there was a significant age x sex interaction for the prevalence of ¹⁸F-FDG BAT (the younger the subjects, the greater the sex difference). The mass and glucose-uptake activity of ¹⁸F-FDG-detected BAT also decreased with increasing outdoor temperature ($P < 0.0001$), age ($P < 0.0001$), and BMI ($P < 0.0001$). They were lower in men than in women ($P < 0.001$) and lower in diabetic than in nondiabetic patients ($P = 0.0002$). Conclusions: The present study identifies outdoor temperature, age, sex, BMI, and diabetes status as determinants of the prevalence, mass, and glucose-uptake activity of ¹⁸F-FDG-detected BAT. N2 - Background: Extensive epidemiological studies have provided evidence of an association between elevated outdoor particulate air pollution and adverse health effects. However, while people typically spend majority of time indoors, there is limited knowledge on airborne indoor particles and on the correlation between the concentrations of indoor particles and health effects. Even insights into the influence of differently sized indoor particles on human health are still rare. Objective: The association between differentially sized indoor air particles and the development of respiratory diseases was studied for three year aged children. Methods: Short-term measurements of particle mass and number concentrations were carried out in children's rooms. Information on possible particle sources (smoking habits, type of heating, and traffic) and respiratory outcomes were obtained from questionnaires. Measured indoor particle concentrations were correlated with possible sources of indoor particles and with respiratory health impacts. Results: Daily smoking, smoking more than 5 cigarettes per day at home and traffic density in front of the window of children's room were found to be related to indoor exposure by particles of different diameters. High indoor particle exposures were associated with an increased risk for the development of obstructive bronchitis and in some extent of non-obstructive bronchitis. The strongest impact was observed for the mass concentration of particles $< 1 \mu\text{m}$ and the number concentration of particles $> 0.5 \mu\text{m}$. The risk increases still remain significant if tested for stability changing the number of adjustment variables or omitting randomly selected cases, respectively. Conclusion: Our results show significant associations between indoor particle concentrations and the risks for respiratory diseases in young children. The applied short-term measurements can help to assess the health risks of indoor particles with different sizes within epidemiological studies. 2010 Elsevier B.V

N2 - The duration of protection of hepatitis B vaccine remains incompletely understood. To assess the long-term protection provided by a primary vaccine series, the current study again recruited all subjects of a previous randomized placebo-controlled trial cohort 23 years after vaccination. Two hundred and sixty-one healthy children aged 5-9 years living in a highly HBV-endemic country were enrolled in the primary trial and received three doses of plasma-derived vaccine or placebo. The primary placebo receivers who did not receive any immunization against hepatitis B were used as non-vaccinated controls in the current study. After eliminating the interference of an early booster dose and vaccines outside the study, 48.1% (39/81) vaccinees still maintained anti-HBs titers >10. mIU/mL at Year 23, higher than 34.7% (26/75) in non-vaccinated controls (P=0.088). 75-100% of vaccinees with anti-HBs titer <10. mIU/mL at Year 23 in different sub-groups divided according to early immune backgrounds developed a rapid and robust antibody anamnestic response after a booster dose, highly significantly different from non-vaccinated controls who received the same dose of vaccine (7.5%, P<0.01). No case of clinically significant HBV infection was found in the primary cohort during the whole 23 years, but 10 transient HBsAg seroconversions in the primary placebo group and one in the primary vaccine group were determined. Anti-HBc positive rate obviously tended to be lower in vaccinees compared with non-vaccinated controls at Year 23. These results suggest a persisting immune memory and certain protection for 23 years after primary vaccination in children living in highly HBV-endemic areas. Clinically insignificant infections, which cannot be avoided and may often occur in vaccinees, play a positive role in the maintaining of immunity to HBV. Booster doses should be unnecessary for more than 20 years after a full primary immunization in children (as catch-up vaccination) and, also likely, in newborns living in highly HBV-endemic areas. 2011 Elsevier Ltd

N2 - Background: An environmental challenge chamber (ECC) is a useful tool to expose allergic patients to relevant allergens in a controlled indoor setting and to test anti-allergic treatment. Hitherto, ECC studies with grass pollen are conducted primarily outside of the pollen season to avoid the influence of natural pollen exposure. Objective: To investigate whether an established anti-allergic treatment, a combination of cetirizine (CET) and pseudoephedrine (PSE), shows an equivalent treatment effect within and outside of the grass pollen season when tested in an ECC. Methods: In a randomized, placebo-controlled, double-blind, four-way crossover study, the effect of a combination of 10 mg CET and 120 mg PSE compared with placebo on nasal symptoms, nasal flow, and nasal secretion was investigated in 70 patients with seasonal allergic rhinitis. Subjects underwent four 6-hour pollen challenges in an ECC with administration of the drugs after 2 hours. Two challenges were conducted within the grass pollen season and two out of the grass pollen season. Results: The active treatment significantly improved nasal symptoms and nasal flow and significantly reduced the amount of nasal secretion compared with placebo both within and outside of the pollen season ($P < .0001$ each). The treatment effect was not different between the seasons ($P > .05$). Conclusion: Controlled allergen provocation in an ECC can be used to test anti-allergic treatment both within and outside of the grass pollen season. 2011 American College of Allergy, Asthma & Immunology

N2 - To examine age-related physical activity (PA) patterns between- and within-day in elementary school-aged children with autism spectrum disorders (ASD). PA was recorded every 5-s by uniaxial accelerometry in 35 children (grades 1-2, n = 13; grades 3-4, n = 13; grades 5-6, n = 9) for up to five weekdays and two weekend days. Younger children were more active during weekend days compared with weekdays, while the opposite was observed in older children. Age variation also exists in children's PA levels within a weekday, with this effect being most evident during recess and after school. Weekend days and free time within school days seem appropriate targets when promoting PA in older children with ASD. 2010 Elsevier Ltd. All rights reserved

N2 - The aim of this review is to explore the methodologies employed to assess the exposure of children to air pollutants, in particular traffic emissions, at school, and how these methodologies influence the assessment of the impact of this exposure on the children's health. This involves four main steps: the measurement of air quality at school level, the association between measured air quality and children's exposure, the association between children's exposure and health; and source identification. The comparative advantages and disadvantages of the methods used at each of these steps are discussed. Air quality in schools can be measured at three scales: broad scale, across several city blocks using remote monitors; school-based scale, through ground-level monitors installed within the schools or their immediate surroundings (i.e. only a few metres outside the school); and personal exposure scale using portable monitors attached to a sample of children. Although studies have reported high exposure to PAHs (polycyclic aromatic hydrocarbons), submicrometre (<1.0 µm) and ultrafine particles (<100. nm) at school, no study has investigated the formation of new particles in school facilities and only a handful of studies have analysed children's exposure at school. Associating air quality measurements at the broad and medium scale with children's exposure is challenging: there is spatial and temporal heterogeneity in the distribution of air quality within a school, indoor measurements can often exceed outdoor measurements; and exposure in the classroom is affected by the penetration of outdoor pollutants, wall absorption, emissions from furniture and other materials, level and length of occupancy, and quality of ventilation. This is further exacerbated by the fact that children move around during their school day. Quantifying the contribution of school exposure with observed health symptoms presents further challenges. In addition to ascertaining the impact of non-school-based exposures and co-morbidities, the air pollutant dose intake is affected by daily patterns of physical and traffic activity during and outside school hours which make it difficult to compare the contribution of school-based and non-school-based exposures to the health effect under investigation. Finally, there is strong evidence that low socioeconomic level is highly correlated with the proximity of the school to pollution sources, yet this area of socioeconomic research has been largely unexplored in the assessment of traffic emission exposure. 2010 Elsevier Ltd

N2 - Microdeletions of 1q41q42 have recently been classified as a syndrome. Features include significant developmental delay and characteristic dysmorphic features as well as cleft palate, clubfeet, seizures, and short stature in some individuals, with a clinical diagnosis of Fryns syndrome in two individuals with congenital diaphragmatic hernia at the severe end of the spectrum. The gene *DISP1*, which is involved in sonic hedgehog signaling, has been proposed as a candidate for the midline defects in this syndrome. We undertook a genotype-phenotype analysis of seven previously unreported individuals with deletions of 1q41q42 that range from 777 kb to 6.87 Mb. Three of the individuals in our cohort do not display the major features of the syndrome and have more proximal deletions that only overlap with the previously described 1q41q42 smallest region of overlap (SRO) at *DISP1*. One individual with several features of the syndrome has a more distal deletion that excludes *DISP1*. The three remaining individuals have larger deletions that include the entire SRO and demonstrate features of the microdeletion syndrome. Confounding genotype-phenotype correlations, one of the small deletions involving *DISP1* was inherited from a phenotypically normal parent. *DISP1* haploinsufficiency may not be solely responsible for the major features of 1q41q42 microdeletion syndrome, and other genes in the SRO likely play a role in the phenotype. Additionally, some features present in a minority of individuals, such as Pelger-Huet anomaly, may be attributed to deletions of genes outside of the SRO. 2010 Elsevier Masson SAS

 N2 - Hemolytic-uremic syndrome (HUS) often follows intestinal infection with Shiga-toxin producing Escherichia coli (STEC). STEC affects 73,000 US patients annually and is the leading cause of acute renal failure in otherwise healthy children < 5 years. It is believed that developing therapeutic that acts intracellularly is the priority, because the toxin would have translocated from outside to inside the cells, by the time the disease develops. Objective: Evaluate efficacy of a novel cell-permeable tetravalent peptide (TVP) that binds to Stx2 beta subunit, in nonhuman primate models of Stx2 toxemia. Methods: Baboons were challenged with a lethal dose of Stx2 (50 ng/ kg); TVP was given i.v. at T (0) with toxin (prevention) or at 6 or 24 h after toxin with daily supplements up to day 4 (rescue). A comprehensive array of clinical and inflammatory indicators was monitored up to 28 days after challenge. Results: Peptide delivered with toxin (prevention) or after toxin (rescue) resulted in either complete absence of clinical signs of acute kidney injury and normal urine output, or delayed and reduced BUN and creatinine levels. Delayed peptide administration reduced thrombocytopenia and inflammatory cytokine responses, but surprisingly did not alter anemia even when monitored for 28 days in rescued survivors. Plasma VEGF levels were undetectable, whereas urine VEGF increased to 400 pg/mL after toxin, and were reduced to baseline by TVP. Conclusions: A cell-permeable peptide designed to counteract Stx2 activity within susceptible cells rescued baboons from an otherwise lethal dose of toxin. Even when delayed by 24 h, the survival rate was substantial and significant. Bedside measure of urinary VEGF levels may provide a non-invasive way to monitor treatment efficacy and clinical course. This is the first successful intracellular

therapeutic that counteracts Stx2 lethality in a nonhuman primate model which recapitulates many of the human responses to enteric infection

N2 - Background: The prevention and treatment of overeating and obesity continues to be a major challenge. While the ease of availability of highly palatable foods is a major factor in this regard, not all individuals overeat or become obese in this environment. The current project examines individual differences in palatable food intake at a critical time in human development. The current analysis studies the relationship between dopamine genes and eating behaviour in children from 4 to 6 years of age. A particular focus is the hypo-functional 7-repeat (7R) allele of the dopamine-4 receptor gene (DRD4), which associates with overeating and obesity in several female overeater populations (e.g. Levitan et al., 2004, 2006, 2010). Recent imaging work suggests that weaker activation of the brain's reward circuitry may play a role in these associations (Stice et al., 2010). Methods: The current sample consists of children taking part in a longitudinal cohort study (Maternal Adversity, Vulnerability and Neurodevelopment) based in Canada. The mothers of the children, oversampled based on maternal depression and low SES, were recruited at 13-120 weeks of pregnancy, and the children have been followed intensively since birth. Key outcome measures include: 1. A laboratory-based snack test at 48 months of age which provides an objective measure of food preferences and overall caloric intake. 2. A food frequency questionnaire at 48 and 72 months, based on maternal report, which assesses naturalistic food intake and feeding behavior. 3. The childhood eating behaviour questionnaire (CEBQ; Wardle et al., 2001) which measures eating styles likely to promote over- or under- weight. Results: To date, 118 children have completed the 48 month snack test in the lab. Of these, 47 (39.8%) carry the 7R allele, while 71 (60.2%) do not. Controlling for total caloric intake, there is a significant gender X genotype interaction in predicting fat intake during the snack test ($F=7.16$, $df=4$, 113 , $p=.009$). Girls who carry the 7R variant are consuming 31.2 % more fat during this snack than are non-carriers (mean=12.2 vs. 9.3 grams respectively) while in boys, 7R carriers are eating 19.2% less fat than are non-carriers (mean=11.3 vs. 13.5 grams respectively). This suggests that the 7R allele increases objective fat intake in girls but not boys by four years of age. Strikingly, when intake is measured using the 48 and 72 month food diaries, which were completed two years apart, the gender X 7R interaction is even more robust, accounting for 21 % of the variance in fat intake ($F=11.3$, $df=3$, 42 ; $p=.002$; $N=46$). Based on these diaries, girls who carry the 7R allele are consuming 39.8% more fat in their natural environments at 48 months than are non-7R carrier girls (820.5 vs. 587.0 calories/day respectively). Importantly, this difference remains robust at 72 months of age (881.5 calories as fat in 7R carriers vs. 609.2 calories as fat in non-carriers, a 44.7 % difference). In boys, 7R carriers are consuming 40.1 % less calories from fat than are non-carriers at 48 months, and 25.4 less calories from fat at 72 months based on these diaries. The consistency of these data across both laboratory based measures and food diaries, and the consistency of the food diary data over a two year time span, adds greatly to these findings. These findings are also highly consistent with earlier work in female adult overeater populations (see above). Discussion: These converging results show a highly robust association between the hypo-functional 7R allele of DRD4 and fat intake in girls, but not boys. The consistency of these findings across different outcome measures and across a two year age

span adds greatly to their validity and potential impact. Pending replication and detailed anthropomorphic outcomes later in childhood, these results may identify a significant subgroup of young girls at higher risk for childhood obesity and/or eating disorders. If so, this could inform novel prevention strategies implemented as early as birth in this subgroup

N2 - Introduction: This study was designed to determine the association of obesity with certain risk factors in children and to evaluate the associates of obesity and overweight in children. Methods: Data were collected from parents of 983 children by dietetic students. A questionnaire form consisting of the child's anthropometric measurements (weight, height, waist), physical activity patterns, eating and lifestyle habits were constructed by reviewing literature. There were also questions in the questionnaire form about the parents' anthropometric measurements (weight, height, waist) and level of education. Results: Mother's BMI were found as statistically

significant between obese and nonobese children ($P < 0.05$). In obese children, both values for parents were found greater than nonobese children ($P < 0.05$). In obese groups, mothers' waist circumference was found as different from nonobese group ($P < 0.05$). Number of fast food eatings was also a significant variable between groups ($P < 0.05$). Eating in view of TV, doing regularly breakfast everyday and performing physical activity were found as significant variables in the analysis ($P < 0.05$). Conclusions: The results of this study support previous work indicating that both family responsibility. Parents should be helped to recognise their child's overweight, and educational strategies should be targeted at both children and their parents. In the preventing and controlling childhood obesity will require multifaceted and community- wide programs and policies, with parents having a critical role to play. Successful intervention efforts, they argue, must involve and work directly with parents from the earliest stages of child development to support healthful practices both in and outside of the home

N2 - Introduction: Accurate objective methods for the assessment of sedentary behavior are crucial for population monitoring and evaluation of public health strategies for preventing childhood obesity. Actigraph accelerometers are a commonly used objective physical activity measurement tool. It is hypothesized that accelerometers may also provide a valid method for assessing children's sedentary time. However, there is considerable variation in published accelerometer cut-off points for measuring sedentary time in children. The objective of this study is therefore to compare different accelerometer sedentary cut points with observation of

children performing specific sedentary behaviors in free-living conditions. Methods: Direct observation and Actigraph uniaxial accelerometers were used to measure children's activity intensity while playing computer games, non-electronic sedentary games, watching television and playing outdoors. Direct observation was the criterion for assessing the validity of four different previously published sedentary cutpoints: i.e., 100, 300, 800, and 1100 counts per minute (cpm). Results: The median cpm were lowest for computer games (30 cpm), followed by television viewing (109 cpm) and non-electronic sedentary games (172 cpm) and highest for outdoor play (1452 cpm). The median counts during all sedentary behaviors were below the lowest cut-point of 100 cpm. The 75th percentile values for the sedentary behaviors were always below the cut-point of 300 cpm. Conclusion: Our results suggest that the Actigraph accelerometry cut-point of <100 cpm is the most appropriate, if not too high, for quantifying the time children spend sedentary

N2 - Regular physical activity during childhood is associated with improvements in numerous physiological and psychological variables and is being promoted as an objective for obesity prevention. Although it is frequently assumed that physical activity is an integral part of growing up, numerous studies show that children are often physically inactive. All young people should participate in physical activity of at least moderate intensity for one hour per day. In most nations schools are the primary societal institution with responsibility for promoting physical activity in young people. PE classes, school-related physical activity outside PE and information to parents and other educational team members can contribute to the development of an active lifestyle. Moreover, through schoolcommunity partnerships schools can work together with local sport providers

to increase after school sports participation. Recent research focuses on environmental physical activity correlates. Also in children modifiable environmental factors were found to associate with physical activity, as well for neighborhoods (e.g. presence of sports fields, cycle track) as for school playgrounds (e.g. adequate space, diverse play opportunities, interaction with natural elements). However it is still unclear if changing the environment is enough to increase children's physical activity levels. Socio-ecological approaches to health promotion, consider children's PA levels as the result of transactions among multiple levels of influence and recommend to target intervention strategies at multiple settings. Moreover, the results of some intervention studies show that targeting both behavioural and environmental changes to promote PA is an effective strategy to target children's physical activity behaviour

IS - var.pagings

N2 - Purpose: "Floor the Pain" is an initiative to provide prompt pain management to children experiencing acute, uncomplicated episodes of sickle cell pain bypassing the Emergency Department (ED). Background: Pain crisis the hallmark of sickle cell disease. Frequently, systems of care in the emergency room and hospital are barriers to appropriate care. Dedicated day hospitals or infusion centers are an effective but potentially expensive option. While specialized, dedicated teams may be able to improve the care of these patients, such approaches typically leave out the regular nursing and resident staff, further limiting the spread of expertise in the care of patients with sickle cell disease. Emergency departments can improve care by following pain protocols and individualized pain plans. However, they are frequently overwhelmed by seasonal epidemics or trauma cases and are not able to consistently meet the needs of patients with SCD presenting with VOC. Further, in patients presenting with severe pain, sometimes it is evident that the pain is unlikely to be relieved by interventions offered in the ED and in-patient hospitalization is inevitable. In such cases the ED visit becomes an avoidable expense. Moreover, patients who receive some relief in the ED may have worsening of pain when there are delays in the institution of appropriate pain management in the transition to the in-patient floor. Aims: To develop an approach that eliminates avoidable ED visits, eliminates loss of pain control during transitions and involves a multidisciplinary in-patient team in order to improve the management of vasoocclusive pain crises. Methods/Implementation Strategy: Collaborative of multi-disciplinary team has been developed to improve patient outcomes. The team includes floor nurses, residents, pharmacists, facilities management and sickle cell staff. The goal of this multidisciplinary team is to immediately assess and treat pain by immediately initiating pain management with intravenous opioids according to an individualized pain plan within 10 minutes of arrival on the floor and transition to a patient controlled analgesia, our standard of care within 30 minutes of arrival to floor. This service is available to clients triaged by the Sickle Cell Team and considered to be experiencing an uncomplicated vasoocclusive pain crisis. As soon as a patient is identified as a candidate for 'Floor the Pain, a group page alerts the multidisciplinary team. This initiative will improve pain management by assuring prompt, aggressive treatment for acute pain crises, comprehensive treatment delivery outside of the ED, Support and expertise of a highly knowledgeable staff with prior knowledge of the patient, Care in a quiet, comfortable setting on a patient care unit. All of this is achieved with no additional investment in physical plant or dedicated staff. Evaluation: This process began on June 21, 2010. Thus far we have applied this intervention to 18 patients. We have reached the goal of initiating intravenous opioids within 10 minutes of arrival on the floor and initiation of PCA within 30 minutes of arrival to the patient care unit in 15 of these patients. Three patients had intravenous opioids started within 30 minutes and PCA's started within 1 hour of arrival on the floor. Prior to initiation of this program these patients had received a PCA between 130min to 365 min after arrival on the floor. Implication for Practice: Floor the Pain promotes a new model for improved care which empowers members of interdisciplinary team to improve the quality of life of a child with SCD. This improvement actively involves staff nurses in pain management of complex patient's based on clear pathways as well as prior knowledge of the patients. Future plans are to continue this improvement 24 hours a day, 7 days a week, via phone triage by the clinical leader

N2 - Background and Objectives: Pediatric constraint-induced movement therapy (CIMT) is a promising intervention for children with unilateral cerebral palsy (CP). Recent systematic reviews have found moderate effects but intervention dose has varied from 6 to 126 total hours, without compelling evidence defining optimal CIMT dosage. This multisite randomized controlled trial (RCT) applied continuous casting of the less involved arm for 18 days of intervention with 3 additional days without constraint. We tested the hypothesis that 6 hours versus 3 hours/day for 21 days would produce greater maintenance of gains 6 months post-treatment. Design: Our study was a multisite randomized controlled trial. Participants and Setting: Three sites recruited 18 children (six per site) ($\mu=48.75$ [SD=12.19] months) with unilateral CP. Children were randomly assigned to 3 or 6 hours/day of CIMT for 21 days, wearing a cast on the unaffected extremity the first 18 days. Occupational therapists applied a standardized pediatric CIMT protocol in the child's natural environment. Materials and Methods: Evaluators, blinded to condition, administered the Assisted Hand Assessment and the Quality of Upper Extremity Skills Test, and parents completed the Pediatric Motor Activity Log pre- and post-treatment (1wk, 1mo, and 6mo.) Results: Both CIMT dosage groups showed significant gains on all assessments with no significant group differences at 6 months post intervention. Effect sizes (partial η^2) ranged from 0.34 to 0.63 for the Assisted Hand Assessment (AHA) and the Quality of Upper Extremity Skills Test, with continual improvement on the AHA at the three post intervention measurement times (post, 1mo and 6mo post). The parents rated their children's use of their affected arm as more frequent ($F=20.7$, $p=0.001$, effect size=0.78) and with higher quality ($F=14.7$, $p<0.001$, effect size 0.71) across intervention measurement times. Conclusions and Significance: This multisite RCT of pediatric CIMT using continuous casting and intervention in the child's natural environment affirms maintenance of positive effects at 6 months follow up, across multiple functional performance measures. The hypothesis that maintenance of effects would differ for children who received 6 versus 3 hours per day of CIMT (63 vs 126 total h) was not supported

N2 - Background and objective Developing countries have double burden of malnutrition and obesity in children. The present study was conducted to determine the risk factors for childhood obesity in children with reference to their dietary pattern, physical activity and body mass index (BMI) levels. Subjects and methods 64 obese children and 40 healthy children were enrolled for the study. Subjects were evaluated for demographic details, anthropometry, general physical examination and clinical investigation (blood sugar, hemoglobin, liver function tests, renal function tests, ultrasound abdomen, lipid profile, thyroid profile). Dietary assessment was

done by one day recall method. Physical activity was assessed by one day activity recall. Results Prevalence of obesity was more among urban nuclear upper and lower middle income families. The mean calorie (2772.6 + 345.2 kcal/ day), protein (70.45 + 9.9 g/day) and fat (94.14 + 14.9 g/day) intake was higher among obese children compared to control, however their calorie and protein intake per kg of body weight was low. Mean calorie, protein, and fat consumption showed significant direct correlation with body mass index (BMI). However, an inverse correlation was found between BMI with calorie intake per kg body weight, serum lipids. 92% of obese children spent less than one hour per day on outdoor activities, more than 45% spent time 2 hours or more on sedentary activities. Conclusion Childhood obesity is associated with high calorie and low protein intake. Physical activity was grossly inadequate among 92% of obese children. Excess sedentary habits remained the most important determinant of childhood obesity

N2 - AIM: Discovery of a "hot" nodule is usually comforting due to the presumption that the nodule represents a benign toxic adenoma. Here, we present an adolescent with a hot nodule turned out to be a papillary cancer. PATIENT: A 15-year-old girl was referred to our Endocrine Unit, complaining of a painless mass in the right side of the neck that had appeared a few months earlier. Her family history was significant for benign nodular goiter (mother). RESULTS: Thyroid US showed a 25mm hypoechoic, non-homogenous nodule in the right lobe. Serum TSH was 0.26 mU/L (n.v. 0.27-4.2), with normal values of FT3 and FT4. ¹³¹I thyroid scintigraphy was consistent with an autonomous thyroid nodule. Six months later, the girl returned complaining of fatigue, weight loss and palpitations of 1-month duration. Physical examination revealed warm, moist skin; tremors of the extremities; hyperreflexia. The patient's weight was 42.5 kg. Her pulse rate was 94 /min. At endocrine evaluation, TSH was 0.001 mU/L, and FT3 (7.68 pml/L; n.v. 3.0-6.7) and FT4 (26 pml/L; n.v. 12.0-22.0) were elevated. Thyroid US revealed an increase in the size of the nodule, that measured 35x30x21mm and displayed an abnormal intranodular blood flow. Treatment with MMI (20mg/day) was started, with normalization of FT3 and FT4 values. Subsequently, the patient underwent near-total thyroidectomy. Pathological examination revealed a papillary carcinoma, follicular variant. The excised nodule was examined for activating mutations of TSH receptor and Galphas genes by direct sequencing. No mutations were detected. Nevertheless, two combined non-functioning mutations were detected. The first mutation is a known single nucleotide polymorphism (SNP), in the transmembrane region of the TSHR gene, at codon 187 (AAC->AAT, both encoding asparagines). The second mutation is within exon 8 of Gsalpha gene, at codon 185, (ATC->ATT, both encoding isoleucine). Search for mutations in BRAF gene was negative. Few months later, patient underwent: Radioiodine thyroid uptake measurement (RTU=3%) after oral administration of ¹³¹I (1.85 MBq) and ¹³¹I ablation therapy (1850 MBq) (at this time: TSH: 45 mIU/L and Tg <1.6 ng/ml). ¹³¹I post-dose WBS did not reveal areas of radioiodine uptake outside the thyroid bed. At one year-follow-up, the patient is on levo-thyroxine therapy, with TSH values <0.2 mIU/ml and both basal and rhTSH-stimulated serum Tg <1.6 ng/mL, and neck US is negative. CONCLUSION: This case demonstrated that

the presence of hyperfunctioning thyroid nodule(s) does not preclude malignancy and warrants careful evaluation, especially in children and adolescents

N2 - Background: Author's previous study on breastfeeding dyads demonstrates that nursing facilitates the development of intricate interactions, contributing to sensitive mothering styles and healthy psychological growth. Systems theory indicates that interchanges in dyads affect the family and vice versa. Objective: To broaden earlier research and investigate the reverberating impact of nursing on the family system. Methods: Observations, interviews, audio and videotape of families actively involved in physiological breastfeeding in natural settings over time and interviews with carefully selected key informants were organized into case studies and categories and analyzed. Results: Families engaging in physiological breastfeeding patterns display unique behaviors and interactions associated with evolving and reverberating themes related to breastfeeding. Themes facilitate interaction based on infant and child cues. Parents' attuned responses to cues for nursing and proximity evolve into an overall sensitive parenting and family style extending beyond nursing and early childhood. The circulation of themes associated with the development of sensitivity through nursing is influenced by complementary parenting task allocation, open communication and tutoring. Unresolved couple discord and closed communication interfere with these processes and is expressed through distancing, the use of artificial pacifiers, and naming nursing as feeding. Conclusions: The study concludes that interaction in the nursing sub-

system affects and is influenced by overall systemic interchanges, and facilitates the development of parental and family sensitivity extending beyond nursing. The conclusions have important implications for child outcome, including for children in families with multiple risk factors, due to the importance of parental sensitivity for healthy socio-emotional development. Funding Sources: None. The author has published the findings in a book and receives intermittent royalties

N2 - Background: Vitamin D has recently been shown to have a role outside of its well known effect on mineral metabolism. An immunological role for VitD in pediatric infections is being increasingly recognized. Toll like receptors (TLRs) are part of the innate immune system and function as sentinels of the immune system. Activation of TLRs is associated with production of antimicrobial peptides such as cathelicidin and others which are regulated by VitD. Serum from individuals with low VitD has poor cathelicidin induction which can be normalized by correction of serum VitD levels. Children with CF are vulnerable to VitD deficiency from malabsorption of fat soluble vitamins and are at risk for recurrent/chronic respiratory infections. We hypothesized that CF patients with low levels of VitD are at risk for increased respiratory infections, worse severity score, and lower pulmonary function. Methods: With Institutional Review Board (IRB) approval, data was collected over a one year period on 79 children with CF aged 6 to 17 years. We analyzed the prevalence of VitD deficiency (<15 ng/mL) or insufficiency (15-30 ng/mL), and compared these vitamin levels to the frequency of antibiotic use, severity score per CF Pulmonary Guidelines, and forced expiratory volume in one second (FEV₁). We also analyzed the data using the new recommended VitD cut-off level of 20 ng/mL from Institute of Medicine (IOM). Statistical analysis was performed using SAS software. Results: There was significant correlation between serum VitD level and treatment with intravenous antibiotics (IVAbx) (p=0.036), worse severity scores (p=0.005) and lower FEV₁ measurements (p=0.02). In the 3 group comparison using Kruskal-Wallis test between deficient, insufficient and normal VitD levels, children with CF and VitD deficiency were more likely to receive IVAbx (p=0.016), have worse respiratory severity scores (p=0.006) and lower FEV₁ measurements (p=0.038). In 2 group analysis using Wilcoxon Rank Sum test with IOM cut-off of 20 ng/mL for VitD, children with CF and VitD deficiency had higher IVAbx use (p=0.009), worse respiratory severity scores (p=0.037) and lower FEV₁ measurements (p=0.05). Conclusions: The results suggest that VitD may have a role in infectious and pulmonary complications in children with CF. Additional studies are needed to confirm our preliminary observations from this retrospective analysis. Until further literature becomes available, we must strive to maintain normal serum VitD levels in children with CF

N2 - It is clear that regular, intentional, physical activity (PA) should be part of a healthy lifestyle, including for patients with cystic fibrosis. There are both disease specific, e.g., improved airway clearance, improved lung function, better control of CF-related diabetes, etc., as well as more general, e.g., cardiovascular and musculoskeletal health, benefits of PA. It is equally clear that there is no "one-size-fits-all" target for PA. The following is intended to provide a general guide for PA recommendations followed by suggestions for children. PA recommendations of any kind should be based on knowledge of the clinical status, including pulmonary function, and of the exercise response, including whether desaturation occurs and at what level of exercise. PA targets can be attained using a combination of both formal, e.g., exercise prescription and leisure-time activity recommendations, and informal, but no less intentional, habitual or lifestyle PA recommendations. In any case the recommendation should be based on the patient's response to three critical questions: "What kinds of activities do you like to do?," "Who is going to be your partner?" and "What sorts of things keep you from being physically active?" Success in meeting PA targets will be improved if participants can select from a variety of favorite activities and participate in these activities on an "as desired" basis. Success is further enhanced by making a commitment with an activity partner. For children and young adults, promoting activity with best friends significantly increases time spent in moderate-to-vigorous activity while adults benefit from the accountability associated with a committed partner. Finally, PA is more easily integrated into a lifestyle with the identification of, and removal or minimization of barriers - excuses, in many cases. Making PA a regular part of one's daily routine is difficult for most people, particularly if they are currently sedentary. It is therefore best to start the exercise recommendation with advice and encouragement as to how to become a regular exerciser. For some the first step is to find ways to incorporate activity into one's daily routine. These lifestyle changes might include changing one's commute or shopping habits to include walking or riding a bicycle for all or part of the distance or simply parking the car at the far side of the parking lot and walking, taking the stairs instead of the

elevator, walking during work breaks, etc. An initial goal should be to accumulate 30 minutes of this kind of activity 5 days a week. The use of a pedometer can enhance motivation for lifestyle PA. Recognizing that less than 5,000 steps per day represents a sedentary lifestyle the initial goal should be to increase the daily step count to >10,000 per day over a period of time. As the individual approaches the goal of 30 minutes, 5 days a week or 10,000 steps the recommendation should include advice on increasing exercise intensity to moderate to vigorous levels. Moderate exercise intensity should allow the person to maintain a conversation without becoming breathless while vigorous intensity would involve a sense of breathlessness. Once a person has become accustomed to an increase in habitual, lifestyle PA it becomes easier to move to leisure-time PA or more formal exercise recommendations. The compendium of physical activities (1-3) provides a listing of hundreds of activities and their energy cost. Energy cost is listed in terms of METS (Metabolic Equivalents, with 1 MET = 3 mL O₂/kg/min) allowing one to recommend a variety of specific PA at moderate (3-6 METs) or vigorous (>6 METs) activity intensities. For instance, encouraging activities such as general carpentry or sweeping floors or bicycling with light effort would fulfill a recommendation for moderate activity while encouraging jogging at 6 mph, shoveling snow or higher intensity bicycling would fulfill a recommendation for vigorous activity. In this way a variety of activities can be combined to attain the goal of a minimum of 30 minutes of moderate-vigorous activity 5 days a week. Some patients will require a more formal exercise prescription to be carried out in an inpatient or outpatient rehabilitation setting; some may find that specific exercise prescriptions make it easier to attain the above-described goals outside of a rehabilitation setting. This more specific prescription approach also allows for safe recommendations for strength training activities. The prescription for aerobic exercise will use heart rate as the marker for exercise intensity and a target of >60% of Heart Rate Reserve calculated from a peak/maximal exercise test ($HRR = (Peak\ HR - Rest\ HR)\% \text{ intensity} + Rest\ HR$). The most effective way to involve children in regular activities that will meet the recommendation is to engage family and friends in an active lifestyle, including leisure activities and sports. Children can be effectively disengaged from sedentary activities by providing rewards for reducing those activities, allowing them to select their own alternatives. Similarly, connecting children with active friends is effective in increasing the amount of time spent in moderate to vigorous activity on a daily basis

N2 - Recent controversy regarding how anaesthetists outside major teaching hospitals can maintain their skills prompted us to develop an in-house half-day update [1]. Advanced Paediatric Life Support (APLS) and European Paediatric Life Support (EPLS) courses cover all aspects of paediatric resuscitation but are time consuming, expensive and not specifically designed for anaesthetists. The Association of Paediatric Anaesthetists (APA) suggest a list of core skills and knowledge, which they recommend are tailored to local requirements [2]. In addition, there is a national requirement for all anaesthetists who have contact with children to attend regular level 2 child protection training [3]. Methods We developed a scenario based update course designed specifically for the local anaesthetic department. The session was lead by anaesthetists who are trained APLS instructors and was based on recent APA recommendations, endorsed by the Royal College of Anaesthetists [2]. We ran five 25 minute sessions in small groups during a protected teaching half day. These sessions covered the following: a question and answer session on departmental guidelines and protocols, three scenarios incorporating all aspects of resuscitation training and intraosseous needle insertion practical session. Level 2 child protection training update was also included. We further supported clinicians by providing written information, designed as a small booklet, outlining local relevant and approved hospital guidelines and resuscitation algorithms. Feedback was actively promoted and has led to significant further changes to course design and structure. Results Feedback forms were received from 17 candidates, with 16/17 (94%) scoring all stations as excellent and 1/17 (6%) as adequate. The course was recommended by 100% of candidates. Other comments commended the effective learning atmosphere, and the useful forum to discuss local guidelines and policies. Estimated course costs were low and included those of protected departmental teaching time.

Discussion This house paediatric anaesthetic update covered all aspects recommended by the APA. It was well received by local clinicians, and positive feedback confirmed suitability and effectiveness of the course format. Using local APLS expertise and resuscitation equipment kept costs to a minimum

N2 - Background: Vitamin D is an important biochemical marker of bone metabolism and immunity. In recent years the exposure of children to sunlight decreased due to weather conditions and more time spent on the internet. Moreover they have also lower outdoor physical activity. We decided to study vitamin D status as serum levels of 25-OH vitamin D₃ in a group of obese children in the city of Prague. Methods: We measured serum 25-OH vitamin D₃ in the period between October and November 2010 in a group of overweight and obese children (BMI more than the 90th percentile, or 97th percentile respectively, of Czech population according the age and sex, [http:// www.szu.cz/publikace/data/rustove-grafy](http://www.szu.cz/publikace/data/rustove-grafy)), 53 boys aged 4-18 years and 60 girls aged 4-18 years. We used ECLIA method, cobas e411 (Roche Diagnostics). There is consensus opinion, that the minimal 25- OH vitamin D level for bone health is 50 nmol/L. Results: The median level of 25-OH vitaminD₃ in boys (n=53) was 25.9 nmol/L, 32 of them had levels below 30 nmol/L, and 20 boys had levels between 31 and 50 nmol/L. The median level of vitamin D₃ in girls (n=60) was 31.3 nmol/L, 26 of them had values below 30 nmol/L, 26 girls had levels between 31 and 50 nmol/L, and only 8 girls had values over 51 nmol/L. Conclusion: 98.1% of overweight and obese boys and 86.7% of overweight and obese girls had serum levels of 25-OH vitamin D₃ in autumn (October-November) less than recommended value, so less than 50 nmol/L

N2 - Introduction Critical values are a concept introduced by Lundberg in 1972, defined as "pathophysiologic derangements of such variance with normal as to be life-threatening if therapy is not instituted immediately" [1]. Physician notification of critical values is currently a standard of practice in laboratory medicine. The definition of critical values must be a collaborative process between services and the clinical laboratory, which balances clinical needs and resource utilization. Periodic revision is recommended by the College of American Pathologists. The laboratory's critical value reporting practices should reflect activities critical to patient outcome [2]. The position of the American Academy of Pediatrics is that kernicterus is preventable. The AAP

focus is to reduce the incidence of severe hyperbilirubinemia and its sequelae of severe bilirubin encephalopathy, which begins with appropriate and timely evaluation of bilirubin levels. Specifically, a bilirubin level is recommended on every jaundiced infant in the first 24 h of life and if the jaundice appears excessive for the patient's age [3]. Bilirubin critical value reporting is a tool for the prevention of kernicterus and bilirubin-induced neurological damage. A bilirubin value elevated outside the range expected at a given age (in hours) has been demonstrated to represent high risk for kernicterus. In particular, values obtained during the hours of life, which represent the steepest slope of the curve for onset of physiologic jaundice [4], must be interpreted relative to age. Since bilirubin carries a uniquely pediatric impact as a critical value, and kernicterus is a devastating clinical outcome of global scope, an investigation of bilirubin critical value reporting practices in North American children's hospitals was undertaken, in the context of current theory and practice of critical value reporting. Methods A comprehensive review of current literature regarding critical value result reporting in the pediatric age group, including the fetus, neonate, child and adolescent, was performed. Evidence base for risks and benefits of analytes frequently chosen for critical value reporting was analyzed. Critical values for bilirubin were investigated in representative children's hospitals throughout the fifty United States, and two provinces of Canada. Bilirubin critical value reporting was surveyed in children's hospitals, if a children's hospital was available, in the fifty United States and three provinces of Canada. Performance characteristics (risks and benefits) for various critical value reporting strategies, as reported in the survey, were analyzed. Results The literature highlights that critical values are generally from inpatients, intensive care unit cases are overrepresented, and most are chemistries. Overall, they represent 0.25% of all tests and 0.75% of tests eligible to be critical values, based on broad-based survey [5]. Centralization of critical call notification is linked to standardization, fewer misses and a decrease in turnaround time [6]. The most recent comprehensive survey on pediatric critical values in fourteen Canadian laboratories reported only four analytes (sodium, glucose, potassium and calcium) eligible for critical value reporting in at least 90% of the laboratories. Considerable variability among these laboratories for thresholds—such as high critical glucose, high critical magnesium, and low critical O_2 —was reported, and few laboratories could identify a source for their critical values [7]. Preliminary data and analysis of the frequency distribution of numerical values defined as critical for bilirubin in neonates from 93 children's hospitals in the United States and Canada is represented in Fig. 1 (including the number of children's hospitals that fail to define 1 critical value for bilirubin, and those institutions that offer age-related critical values for bilirubin). (Figure presented) Critical values for bilirubin that are age-related and based on the natural history of physiologic jaundice, as reported at Stanford University Hospitals and Clinics are presented (Table 1). Discussion The current landscape of pediatric critical values, as represented in the literature and this original data set, is characterized by a wide variety in analytes for which a critical value is chosen, whether or not the values are age-related, based on ontogeny of biochemical and hematological development, and in the numerical level chosen to alert the physician. Outcome-based studies are required to optimize this critically important laboratory activity: to define best practice in bilirubin reporting; insure relevance to patient care and clinical decision-making; and an appropriate balance of laboratory resource utilization and patient safety. Variability in practices of notification and thresholds across countries (e.g. the United States and Italy) has been recently described, and this topic is of global interest and import [8]. For the first time we have defined the practice pattern for bilirubin critical value definition and reporting at representative children's hospitals over the United States and Canada. These data demonstrate 1 high degree of variability in three variables: whether or not bilirubin is defined as a critical value; the numerical level at which the critical value, if existing, is defined; and whether the value is age-related in accordance with current knowledge of the natural history of physiologic jaundice in healthy newborns. Some hospitals do not define any value as a critical value for bilirubin, which may represent 1 missed opportunity in the course of prevention of severe hyperbilirubinemia and its sequelae. There are a small number of hospitals that offer bilirubin critical values that are age-related, which have the (Table presented) potential to offer greater safety and earlier manifestation of pathological elevation, and perhaps earlier intervention for neonates at risk for severe hyperbilirubinemia

N2 - Introduction and Aim of the Study: Bladder re-training with behavioural approach is normally adopted in children affected by lower urinary tract symptoms (LUTS). For children with an intellectual disability, instructed method based on behavioural principles are likely to succeed in order to teach new skills and reduce dysfunctional habits, such as voiding behaviours. Children with ID have more frequent medical problems than age-matched peers without ID. Despite the higher rates of health problems, research has highlighted lower rates of health care use among children with ID. Less frequent approach to these patients may be related to environmental, behavioural and social barriers. Parents describe diverse barriers to access to care, in particular a lack of care in coordination services between providers. The possibility to improve the quality of health care services for children with ID is to organize individualized and specialized intervention programs, on the basis of the children specific needs. The aim of our study was to analyse the effect of a behavioural urotherapy in reducing LUTS in children with ID, compared with typical controls. Materials and Methods: This study included 10 patients (5 children with normal intelligence aged 6-12 years and 5 mildly mentally retarded children with IQ > 70 of the same age) with non-neurogenic voiding dysfunction, referred to our hospital

between March 2004 and April 2010. Of a total of 10 patients, 4 had recurrent urinary tract infections (3 of the group with normal intelligence and 1 of the group of children with ID). In the course of the first tests the patients are checked by a psychologist and a paediatric urologist, to continue with the evaluation and collection of information and definition of objectives. The two groups were treated with a behavioural urotherapy program, that is a self-management programme on actual voiding behaviour using the Frequency-Volume Chart (FVC). Frequency-volume charts (FVCs) is a non-invasive tool that allows the assessment of LUTS outside the setting of a clinical interview but it's been used in this study also as a selfmanagement tool to re-educate the children to adopt a normal voiding behaviour. By using the behavioural approach it is possible to rectify bad urinary habits of their children. A careful history and general examination was performed on all patients. Therefore a programme of voiding re-education was proposed, with a system of incentives. Patients are thus trained to use FVC frequently. In the first 15 days the FVC was without restriction therefore without influencing the patient's urinary behaviour. In the subsequent period, timed urination was advised, recommended children following FVC with their own cooperation. All children have been evaluated every 20 days in the first 6 months of observation and later every 40 days. All the participants were monitored for voiding frequency for 12 months with monthly evaluations. After the end of the therapeutic program, all parents received a phone interview every six months for 5 years, to know urinary habits of the children. Results: Among the 10 children considered in this study, 9 (90%) had a improvement of symptoms during the application of the FVC. Of the 4 children with recurrent UTI, 3 had a complete lack of UTI in 1 year follow-up. The behavioural urotherapy program was successful for both groups, meaning that the children reached a normal habit of voiding behaviour after 7 or 8 months of treatment. The results were stable at 12 months and all patients got a normal voiding behaviour during the five years follow-up. Interpretation of Results: The use of an incentive system in mildly mentally retarded children and in children with normal intelligence, allows the strengthening of the children in a positive way to avoid regression in the acquired behaviour and the FVC showed an improvement in voiding behaviour in both categories of patients. Analyzing in detailed the pattern of voiding behaviour at base-line, it seems that children with ID learn adaptive voiding behaviours at the same rate of typical children. This might be due to the fact that behavioural principles used in our urotherapy program are particularly suitable for them in order to learn new habits and new behaviours. Moreover, the collaboration of the parents have been critical for the program to succeed. Conclusions: We showed that even in mildly mentally retarded children with LUTS it is possible to obtain the same results in terms of quality and quantity as compared to other children with normal intelligence of the same age. The results obtained generate confidence and self-esteem as well as better quality relationships in the child, giving support and reassurance when difficulties arise during the educational course. Medical activity together with psychological advice which is applied the cognitive technical of behaviour supported of FVC, it reveals a efficacious, economical method, and non invasive in the treatment of LUTS in children

N2 - Case Report: Case Presentation: A previously healthy 6 month old white male was transferred from outside hospital with uncontrolled fever and rash. Before being transferred, the patient was twice admitted and treated with IV antibiotics. Both the times, the septic workup including LP was negative. When transferred, the patient had a fever of 104 F and physical examination revealed a reddish tongue and peeling of the skin at the extremities. Detailed history revealed the progression of symptoms: fever followed by conjunctivitis, reddish discoloration of the tongue and finally peeling of the skin. Suspecting Kawasaki disease, a 2D echo was done which showed dilated coronaries. Patient immediately received Aspirin and 2 doses IV IGG. However, symptoms persisted and repeat echo showed worsening of coronary dilatation. Patient was then started on high dose of solumedrol. After 3 doses, a repeat 2D showed further worsening of coronaries with RCA measuring 8 mm in diameter. The patient's platelets continued to increase from 300 K to 1200 K. At this time, anti-TNF (Infliximab) and Lovenox were started and patient was put on list for evaluation of cardiac transplantation. Post-Infliximab, echo showed improvement. Discussion: 'The contribution of genetics to disease predisposition is clear but the mechanisms involved in regulating the predisposition and the impact are not clearly understood. Two recent independent studies have identified regulation of T-cell activation as the critical factor in determining the susceptibility and severity of Kawasaki disease. In one study, genetic analysis of affected Japanese children identified ITPKC, 1,4,5-triphosphate 3-kinase C, a kinase involved in regulation of T-cell activation, to be significantly associated with Kawasaki disease. The other study also found that regulating T-cell activation is strongly correlated to the susceptibility and severity of the disease. The study demonstrated a central role for TNF-alpha in Kawasaki's pathogenesis. Controlled, randomized clinical trials are warranted to determine the role of anti-TNF-alpha therapy for treating this disease

N2 - Aims: To determine whether parental stress factors are present in a significant proportion of a community paediatric caseload. Methods: Analysis of routinely collected service activity data using parental factors codes defined in the national Child and Adolescent Mental Health Services dataset (CAMHS), that is, parental sensory impairment, physical illness, mental illness, drugs and alcohol problems, learning disability, history of being in care or the victim of abuse as a child, history of known violence or child abuse as an adult and other unspecified parenting difficulties. These data relates to cases seen generically, that is, outside dedicated child protection and LAC sessions. Results: Over the financial year 2009/2010 the service had 2230 new and 4802 follow-up successful contacts. A total of 1519 separate instances of parental factors were identified in 436 new (19.55%) and 747(15.55%)of follow-up contacts. Specific factors (each contact may have more than one & up to four factors could be coded for each contact) were identified as follows: mental illness in 364, known history of violence in 208, learning disability in 159, physical illness in 157, problem drinking/ drugs in 132, known history of child abuse in 40,period of care in childhood in 30,childhood abuse in 24, sensory impairment in 18 and physical disability in 13.Unspecified parenting difficulties which could not be included in the previous categories were identified in another 374 instances. Conclusion: This study identifies for the first time the

frequent presence of both specific and unspecified parenting difficulties, most often reflecting adverse aspects of adult mental health, in this generic community paediatric caseload; this is another dimension of case mix complexity which has implications for training as well as planning and funding of services; it also illustrates the need for coordinated working across agencies as well as across services for vulnerable children and vulnerable adults & demonstrates the increasing overlap between CAMHS and community paediatrics. In our view the forthcoming child health dataset should therefore also include the CAMHS dataset parental stress factors codes SN - 0003-9888

N2 - Aims: The purpose of this study was to investigate how families who have multiple autistic children function. Methods: 11 families were recruited and included in the study. The number of children per family varied between two and six, with up to four autistic children in a family. Married, single parent, and non married partnerships were sampled. 44 semi-structured interviews were undertaken with mothers, fathers, children with autism and their siblings. These were transcribed and analysed using Grounded Theory. A selection of transcripts was read by another researcher and the findings were sent to families for checking. Results: A variety of themes emerged from the data, including the use of practical strategies to reduce behavioural problems, the place of emotions in coping, the use of statutory and other services and the views of verbal autistic children and their siblings. A theoretical model encompassing the families' views of their children as normal was developed and highlighted that families dislike being pitied and pathologised by the non-autistic world. A surprising finding was that families with several autistic children in large families found coping easier, as they were more able to normalise the autistic children. Although several different types of emotions were expressed at the time of the diagnosis, there was also an overwhelming sense of relief. All of the families found there were several positive attributes to caring for autistic children. A small minority of families had very negative experiences and the reasons for these are discussed in my presentation. Conclusions Families rely mainly on their own internal family members for support, including grandparents, rather than on outside services. The Early Bird parent support scheme received high praise, with more criticism for education, social care and some health services. The main advice for newly diagnosed families was to treat your children as normal as much as possible, and to plan your day and activities ahead

N2 - Objective: To assess the effectiveness of a novel neurocognitive prevention intervention for preschoolers with ADHD that was designed to enhance brain development and yield enduring reductions in ADHD symptom severity. Participants and Methods: 29 4 and 5 year-old children with ADHD and their parents participated in concurrently-run child (3-5 children/ group) and parent groups. Child groups focused on an array of games targeting distinct neurocognitive domains including inhibitory control, working memory, motor control, set-shifting and planning/organization. Parents received education about ADHD coupled with instruction, modeling, and a description of the cognitive constructs tapped by each of the children's game. Parents were directed to spend at least 30 min. per day playing these games with their children and were instructed in how to individualize (i.e., scaffold) the games to their child's level of proficiency and progressively increase the cognitive/behavioral load of each game as their child achieved mastery of the requisite skill. Daily diaries were collected to measure time engaged in activities outside of sessions. Treatment palatability was evaluated, and parent and teacher ratings on the ADHD-RS-IV were assessed pre-treatment, posttreatment and at 1- and 3-month follow-up. Data are reported for 7 child groups. Results: Only one child failed to complete the intervention, and session attendance was very high (92.7%). Mean daily playing at home was 35.3 min/day, and parent satisfaction ratings were quite high. Parent and teacher ratings on the ADHD-RS-IV significantly improved from pre- to post-treatment (both $p < .01$), and behavioral gains reported by parents ($p < .01$) and teachers ($p < .05$) persisted 1- and 3-months post-treatment. Conclusions: These data indicate that a structured play-based approach to neurocognitive training may be an effective treatment for preschoolers with ADHD. Double-blind, randomized controlled trials are beginning

N2 - Objective: To find a possible relationship between presence of OCD symptoms thematically unrelated with weight or appearance and level and characteristics of physical activity AN. Method: 76 female patients, aged 14.76 ± 1.78 years met the DSM-IV criteria for AN at the time of admission, with no comorbid psychiatric diagnosis, completed the Polish version of the 20-item self-report version of Leyton Obsessional Inventory-Child Version (LOI-CV). Two groups, high-risk (HR) and no high-risk (nHR), were defined according to the cut-off score of LOI-CV. Physical Activity Index (KAF) was used to assess the intensity and type of physical activity. The information obtained allowed to measure the frequency and type physical activity as well as the change of behaviors and habits before and during anorectic episode and absence of AN symptoms (activities not controlled by parents). Results: 35 subjects (46%) were qualified to HR group and 41(54%) to nHR group. Compared to high-risk group no high risk subjects spent much less time outside in the winter ($U = 5,760, p = 0.029$), spent less time studying while standing ($U = 10,371, p = 0.005$), used elevators more often than stairs ($U = 7,391, p = 0.015$). Differences between patient-perceived Activity Index ($U = 3,578, p = 0.061$) and the total score on Activity Index ($U = 3,334, p = 0.071$) were on the tendency level. Patients in nHR group scored less on both indexes compared to HR patients. Negative correlation was found ($t = -0,572; p = 0,026$) between the number of YES answers in LOI-CV inventory and the time spent studying at school. Negative correlation on tendency level was found between the number of hours spent watching TV or playing computer and LOI-CV Interference Score ($t = -0,458; p = 0.063$). Positive correlation was found between the time spent on physical activities weekly and the number of YES answers. Conclusions: Results of the study showed that obsessiveness may be involved in the development of hyperactivity in AN patients

N2 - Background: It has been shown that subjects with ASD have altered visuospatial processing and memory processing capabilities. The purpose of the present study was to examine both behaviorally and with neuroimaging methods the difference between adolescent ASD and TD controls during working memory task. Materials and methods: 30 adolescent ASD cases and 30 age and gender matched controls was assessed with multiple tests (DSM-IV). Resting and activation scans were imaged with GE 1.5 T, ASSET x 2, TR 1800 ms, TE 40 ms, flip angle 90, 64 x 64 matrix, FOV 25.6 cm, 28 4 mm slices. We investigated whether attentional processing (0-back) or more stronger task load (2-back) during working memory (WM) task is altered in ASD. Results: The memory load and task effects (2-back vs. 0-back) areas are in the right temporal regions S1 and insula. The power of deactivations, i.e. task <baseline activity, outside the default mode network during 0-back task was stronger in the ASD group and the activations were reduced compared to TD controls. There were deactivation during 0-back task in the right precentral and postcentral gyrus in ASD group. Activated areas were observed in the right Rolandic operculum, supramarginal gyrus and superior temporal gyrus. Conclusion: Our results show the differences between groups were largest in the cerebellum and they dominated compared to the differences in cerebral cortex. The cerebellum was the only area which had alterations in both 2-back and 0-back tasks in comparison to baseline. This was thought to be due to altered salience processing in the right insular/frontal region. In 0-back condition, the controls activated the cerebellum more strongly in the cerebellum lobules I, VII, VIIIb and in lobule IX. During 0-back task the brain is already de-activated and activated in excess and during the higher task load there is no reserve to take from and then the system overrides and gives un-controlled motor responses

N2 - A healthy diet is the key to normal growth and development in infancy and childhood and is the foundation to adulthood. Communities have absorbed these children in extended families with the desire to help them. The responsibility of raising these children is not easy and provision of food and other basic needs is a daily predicament in Soweto slums and most parts of Uganda at large. Purpose of study: This paper will discuss the risks that children encounter in their daily struggle and that of their families to provide food in Soweto slums in Kampala Uganda. Methods: Direct observation of the daily activities revolving around the children in Soweto slums were observed for fourteen consecutive days of the week. Cluster and simple random sampling methods were used to select 40 willing participants. Questionnaires were administered to adults and children. Study design: cross-sectional descriptive study. Results: Observation results showed that major activities in Soweto were driven by the dire need to provide at least a meal at the end of each day. In the daily struggle to provide food children were directly exposed to hunger, diseases, injuries, child labour, neglect, drug abuse, sexual abuse and child sacrifice. The residents used water from tunnels and Nakivubo channel for daily domestic use. The interview showed that hunger, injuries and diseases were the greatest risks. Neglect and child labour was the second greatest risk followed by drug abuse, sexual abuse and child sacrifice. Conclusion: Majority of children

are at a high risk of contracting diseases, injuries, child labour, neglect, drug abuse, sexual abuse, and child sacrifice. These risks are as a result of the struggle to earn daily living. Recommendations: Collaborative approach in provision of safe water, food and community safe playgrounds. Strengthen Advocacy for the rights of children, draw attention to the possibility of a safe childhood in Soweto slums

N2 - Hali-Berni started in Finland in 1999. Who can be Hali-Berni dog? It does not depend on the breed but of the character of the dog. Dogs are trained pet dogs. The most important feature is that the dog likes people, comes actively to strangers, loves to be scratched and enjoys proximity. Dogs visit homes for elderly, mentally retarded, disabled people, mental health patients, children's homes, daycare centers. They give joy and pleasure just by their presence. They accept you as you are. Touching is very important. Hali-Berni holder must be committed to do this voluntary work, willing to give joy and good experiences to elderly, children and disabled and willing to share their own dog. Visits can be made from once a month to once a week. Amount of hugging portions (=one visit of a dog and a holder) has grown very rapidly from 72 in 2007 to 883 in 2010 in Turku and

to 1250 in Finland. Visits are free of charge. A dog and its holder are tested. The new holder must make some visits first without the dog and then with a dog with experienced Hali-Berni. Puppies are also accepted and they are welcome everywhere. In Finland Hali-Berni has taken part in many studies. In Turku area: how dogs can effectively be used in child welfare (Kallio and Rintamaa 2008). Newest is Luetaan koiralle-study. In Helsinki area there have been studies how they affect mental health patients (Tuunanen 2008) and elderly people (Lang in print). In Tampere area Hali-Berni dogs visit adolescent psychiatric department with very severe behavior disturbances (Reini in print). Studies have shown the same type of influence as other studies: positive results were related to behavior and affect, social skills, self-esteem, control and decreases in aggression and hostility especially in children and adolescents (Fine 2000; Kruger and Trachtenberg; Serpell 2004). You all are welcome to meet and feel our Haliberni dogs outside Finlandia Hall. They are waiting for you

N2 - Art work has been shown to be beneficial in health care. It can be used as a channel for communication. Art activity can bring to consciousness that which is unconscious. It is particularly helpful where individuals are unable to express feelings, due to cognitive impairment, dysphasia or because the person does not have the vocabulary to express their feelings. It addresses the existential dimension, in that it can also help in the search for meaning. This is especially important when one is faced with a health issue or life threatening condition. Art can improve one's sense of self-worth as creativity is enhanced. Examples of art work produced by those who have faced illness and its consequences clearly demonstrate some of the feelings and emotions they experienced. Art is very important in helping the brain reach its full potential. It introduces the brain to diverse cognitive skills that help us unravel intricate problems. It activates the creative part of our brain - the part that works without words and can only express itself non-verbally; the intuitive side of the brain. This is why art so important. It benefits the brain by training it to think outside the box. It helps children understand concepts more easily. It helps them to be greater achievers. In practice development of the artistic side of the brain helps in problem solving. It guides individuals to create solutions. It helps individuals to think beyond linear and logical thinking (Eckert accessed online 16-10-2010). Semir Zeki, a former professor of neurobiology at the University College, London detailed the relationship between the development of cognitive abilities and the creative process. He asserted that artistic expression is the key to comprehending ourselves. He also considered art and its expression as an expansion of brain function. In other words, art helps the brain in its search for knowledge. So what are the benefits of art on the brain? When individuals create art and reflect on it, the processes, increase self-awareness, initiate awareness of others and helps individuals cope with stressful, and traumatic experiences. Art enhances cognitive abilities and provides individuals with the ability to enjoy the life-affirming pleasures of making art (Zeki, 2001). In relation to cancer Fallowfield (2003) asserts that it is necessary to use modes of expression other than language to capture what cancer really means to those affected by it. The power of the arts as a channel for communication has been clearly demonstrated through Michele Angelo Petrone's (a professional artist) paintings of his cancer journey (Fallowfield, 2003; Richards, 2003). Health care must be holistic with emphasis on giving attention to the physical, social, emotional and spiritual domains of the individual. Art work helps address all domains. The emphasis on maintaining the quality of life for individuals in our current health care philosophy and mission statements is partly met through art work intervention. Qualitative findings through case studies of patients involved in art work demonstrate that clients regained a sense of control in their lives, after being given the opportunity to explore personal issues and emotions (Pratt, 1998). Art work may be completed alone or in groups. Completed alone it allows time for reflection; in groups it can be therapeutic for those with similar problems; for example a group who are experiencing grief through death or the thought of a loved one dying; or the losses individuals experience when faced with life threatening illness. Bonding can develop with individual group members helping, not only themselves but each other too as they identify and externalise common feelings. Facilitators of art work must be aware of the potential power of the art medium; just as any image, sound or smell can evoke a powerful reaction. It is important to highlight that it is the process of the art work that is important, not the artistic skill of the individual (Dalley, 1981). The environment must be psychologically safe. "Found images" may be used as a "safety net" that is, an image on a postcard or photograph which evokes some feeling for the individual. This is particularly helpful if art work seems threatening initially. It is important that a creative space is made in order to

assist with the process of the art work, that is a space that is physically comfortable and aesthetically appealing with the appropriate lighting. Breige Devlin MSc Health Promotion University of Ulster; Advanced Diploma in Teaching Studies University of Ulster RN N. Ireland SAA (The Society For All Artists) Member UK Dalley, T (1998) Assessing the therapeutic effects of art: an illustrated case study - Art Psychotherapy 7 (1) 11-17 Eckert, G <http://www.self-help-healing-arts-journal.com/art-benefits-brain.html> accessed 16-12-2010 Fallowfield, L (2003) Forward. IS - var.pagings

N2 - ISSUE: The staggering rates of HIV infection among Canadian Aboriginal women are connected to the legacy of colonization and the enduring effects of the residential school system, entrenched poverty and cultural genocide. Aboriginal women who are living with HIV (AWLWH) often contend with sexual stigma and stereotypes, dispossession of their rights, multiple family roles, gendered violence, unequal economic power, fear of rejection when seeking services, an unsympathetic medical system and invisibility in HIV/AIDS research and policy. Consequently, AWLWH frequently experience social isolation, poor health, and barriers to accessing HIV support services. DESCRIPTION: Since 1993, Positive Women's Network (PWN), a women-exclusive AIDS Service Organization in British Columbia, has organized weekend wellness retreats, allowing women living with HIV to come together safely. Given the number of Aboriginal women who are living with HIV and make up PWN membership, PWN has held an Aboriginal Women's Wellness Retreat every other year since 2004. Applicants who identify as having Aboriginal ancestry are prioritized. All costs, including transportation, are covered by PWN. Through workshops and activities facilitated by Aboriginal elders and diverse staff, there are opportunities to develop social support networks, discover personal strengths, health practices and coping skills, learn about HIV, and engage with Aboriginal history and culture. LESSONS LEARNED: To date, PWN has organized 4 Aboriginal Women's Wellness Retreats, 1 retreat included participants' children. On average, 16 women attend each retreat, 40% have not attended a retreat before, 35% are from outside city centre, and 95% have Aboriginal ancestry. During the evaluation phase, participants continually report the retreat serves as a catalyst to begin, maintain or enhance their healing journey. NExT STEPS: Our results indicate a retreat program focused on culturally sensitive gender specific healthcare strategies, traditional practices and peer support significantly improves quality of life for AWLWH

N2 - Background: Poor compliance with prophylactic penicillin administration and good compliance with hydroxyurea has been reported in children with sickle cell disease. This difference could be because the effects of hydroxyurea are tangible whereas the effects of penicillin are not evident to the caregiver. The concept of "locus of control" (LOC) deals with the extent to which a person expects that the outcomes in life are under the control of one's own actions (internal LOC) in contrast to being controlled by outside factors such as chance (external LOC). The multidimensional health locus of control (MHLC) measure is a modification of this concept applicable to health behavior. A person's health locus of control has three categories: internal, chance and powerful others (outside influences such as health care professionals.) Objectives: We wanted to study the difference in the adherence rate between penicillin and hydroxyurea; and the relationship of LOC to medication adherence, to see if we can identify which caregivers are more likely to be non-adherent and thus might need more intervention. Design/Method: The Multidimensional Health Locus of Control Scale (MHLC), an 18-item questionnaire, a self-reported 8-item scale for medication adherence developed by Morisky, were administered to caregivers of patients. Results: 30 caregivers of children taking penicillin and 15 caregivers of children taking hydroxyurea. 1. Medication adherence was high in 45% of patients taking penicillin and 46% of patients taking HU. 2. The Pearson correlation coefficients of penicillin adherence with LOC subscales: internal LOC: 0.024143; chance: >0.5976208; powerful others: >0.46023241. 3. The Pearson correlation coefficients of HU adherence with LOC subscales: internal LOC: 0.147447; chance: >0.7444194; powerful others: >0.2308007. Conclusion: There was no difference between adherence to penicillin and adherence to hydroxyurea in our patients. There is a very strong (inverse) correlations between chance/powerful others and adherence. MHLC could be used as a screening instrument to identify a subgroup of people who believe that neither they nor the providers play a role in the health of a person and are at greater risk for non-adherence. We can design studies to see if interventions can be developed to improve adherence in this group

N2 - Background: Survivors of leukemia are at an educational disadvantage compared to siblings as a direct result of both medical treatment and school days missed. For patients treated at the Columbia University Medical Center, this is of great concern as many attend NYC public schools where overall four year high school graduation rates are 63%, (51% for Hispanic students and 54% for African American students). Objectives: Define the educational experiences of patients with ALL focusing on minority patients compared with white patients. Design/Method: Educational experiences were assessed using a semi-structured IRB approved survey. Eighteen patients (11 female/7 male; mean age 12.7 years, range 7- 19) and/or their caregivers were interviewed by a single researcher. Thirteen patients were on therapy, five off. Twelve patients were Hispanic, two African American, and four Caucasian. Thirteen/fourteen (93%) of minority patients attended NYC public schools; whereas three/four (75%) of white patients attended schools outside of NYC. Results: Seventeen of eighteen (94%) patients received home schooling during therapy. All white patients had home schooling established by school while nine minority patients had home schooling set up by the hospital and four by a parent or school. All cited individual attention as a positive aspect of being home schooled and lack of social interaction as a negative aspect. All white patients reported home schooling to be effective in keeping them on pace in school while one-third of minority patients did not. All white patients reported successful re-entry into school while on treatment. Four minority patients have or will have received home schooling for the entire duration of medical therapy. White parents were more likely to know about 504 plans while minority parents were more likely to be aware of Individual Education Plans. Conclusion: Minority students had less support from the school system in setting up home schooling and establishing a re-entry plan than non-minority students. It is unclear from this sample what role race, ethnicity and language played in this discrepancy. Further studies will be conducted in a larger patient sample to assess the best way to enhance the educational experience of all children with cancer in our population

N2 - Introduction: Preschoolers spend a substantial portion of their day in child care; therefore, these facilities are an ideal venue to encourage healthy active behaviours. It is important that provinces'/territories' child care legislation encourages physical activity (PA) opportunities. The purpose of this study was to review Canadian provincial/territorial child care legislation regarding PA participation. Specifically, this review sought to: 1) appraise each provincial/territorial child care regulation for PA requirements; 2) compare such regulations with the NASPE PA guideline; and 3) appraise these regulations concerning required PA infrastructure. Methods: A systematic review of all provincial/territorial child care legislation was performed. Each document was reviewed separately by two researchers, and the PA regulations were coded and summarized. The specific provincial/territorial PA requirements (e.g., type/frequency of activity) were compared with the NASPE guideline. Results: PA legislation for Canadian child care centres varies greatly. Eight of the 13 provinces/territories provide PA recommendations; however, none provided specific time requirements for daily PA. All provinces/territories did require access to an outdoor play space. Conclusion: All Canadian provinces/territories lack specific PA guidelines for child care centres. The development and implementation of national PA legislation for child care centres may aid in tackling the childhood obesity epidemic and assist child care staff in facilitating PA participation

N2 - Case Presentation: A 63-year-old white woman with a medical history of hypothyroidism, hypertension, hypercholesterolemia, and recent deep vein thrombosis on Coumadin presented to the emergency department with dehydration because of intractable diarrhea and intermittent emesis. She had a 6-month history of daily greenish watery diarrhea with abdominal cramps. She also lost about 100 pounds. Her family history was remarkable for colon cancer in her mother and fatal pulmonary embolism in her daughter. She had a 30-pack-year smoking history. Her prior workup at an outside hospital included a CT of the abdomen and pelvis, which showed no definite inflammatory changes. Her esophagogastroduodenoscopy (EGD) showed a small hiatal hernia and gastritis. Her duodenal biopsy showed duodenitis with villous atrophy. She also underwent a colonoscopy, which showed some erythema in the sigmoid and descending colon with a normal terminal ileum. Random biopsies throughout the colon were negative for active chronic colitis. Physical exam revealed very dry skin with decreased turgor, occasional expiratory wheezes, and mild left lower quadrant tenderness. Laboratory was significant for white blood cell count of 15, INR of 1.8, normal thyroid-stimulating hormone, erythrocyte sedimentation rate, and C-reactive protein, negative stool infectious workup, and negative celiac disease serologies. Her repeated EGD showed diffuse mildly scalloped mucosa in the entire duodenum, which was suspicious of celiac disease. Yet duodenum biopsy revealed intense active chronic enteritis with loss of Goblet and Paneth cells, which was suggestive of autoimmune enteropathy (AE). Her symptoms improved significantly after prednisone was started. Subsequently she was transitioned to azathioprine as an outpatient. Discussion: AE is a rare cause of intractable diarrhea in adults associated with circulating gut autoantibodies and a predisposition to autoimmunity. In children it can be a part of IPEX (immunodysregulation, polyendocrinopathy, enteropathy, and X-linked) and APS-1 (autoimmune polyglandular syndrome 1). The prevalence and incidence is unknown because of limited epidemiological data. The diagnosis of this disorder is based on proposed Mayo criteria: chronic diarrhea (>6 weeks), malabsorption, exclusion of similar disorders, the presence of specific antibodies such as antienterocyte and anti-Goblet cell antibodies, and specific histological findings including partial/complete villous atrophy, increased crypt apoptotic bodies, deep crypt lymphocytosis, and minimal intraepithelial lymphocytosis. It is caused by dysregulation of CD4/ CD25 T cells, whereas the presence of antienterocyte autoantibodies seems to be secondary. Immunosuppressive agents such as corticosteroids, azathioprine, cyclosporine, tacrolimus, and mycophenolate have been used with apparent benefits. In refractory cases, infliximab, intravenous immunoglobulin, and cyclophosphamide can be used. Conclusions: Hospitalists should consider AE in the differential diagnosis of chronic intractable diarrhea. Because of its many similarities with celiac disease, small-bowel biopsy is a cornerstone of investigation

N2 - Case Presentation: A 20-year-old African American man with a history of MSM (having sex with men) and previously treated for syphilis was admitted with 3 weeks of watery nonbloody diarrhea. Two weeks after symptoms started, the patient went to an outside hospital emergency room. At that time the patient was empirically started on ciprofloxacin and metronidazole and discharged home without stool cultures. The patient's symptoms did not improve, and subsequently he came to our institution. At that time the patient denied fever, nausea, vomiting, or abdominal pain. The patient also denied any international travel, water park activities, or consumption of well water. The patient's current partner was HIV+. Physical exam was unremarkable. Patient's laboratory analysis was significant for leukopenia ($3.4 \times 10^3/\mu\text{L}$), hyponatremia (131 mmol/L), and renal insufficiency (1.62 mg/dL). Stool studies including stool cultures and *Clostridium difficile* assays were negative. Stool for ova and parasites revealed *Cryptosporidium* by Ziehl-Neelsen stain. The patient reported that he and his partner routinely use tap water enemas prior to unprotected anal intercourse. HIV antibody was negative. The HIV RNA polymerase chain reaction was $>500,000$ copies/mL, and CD4 count was 399 cells/mL. The patient was prescribed nitazoxanide 1 g twice daily for a total of 14 days. Patient's diarrheal symptoms improved from 20 episodes down to 3-4 episodes of diarrhea per day at the time of discharge. Patient was sent home with plans for follow-up in the hospital's HIV clinic. Discussion: *Cryptosporidium* infection is responsible for causing persistent watery diarrhea in children as well as in immunocompromised patients, including HIV+ patients, but also causes self-limited disease in healthy exposed persons. Patients are usually infected via ingestion of oocytes from a contaminated water source. Common sources of *Cryptosporidium* ingestion are usually attributed to unpurified water or from swallowing recreational water despite chlorination. The incidence of *Cryptosporidium* infection has fluctuated over the years because of various outbreaks; however, it generally presents at an average rate of 2-3 cases per 100,000 per year. These rates may be underreported, as the diarrhea is generally self-limited in immunocompetent individuals. The introduction of highly active retroviral therapy has seen a decrease in HIV-associated cryptosporidiosis. It should be noted that cryptosporidial disease in AIDS patients with low CD4 cell counts has a high mortality. The literature of a possible association between tap water enema and *Cryptosporidium* infection is limited. Conclusions: Providers should remember to evaluate stool for cryptosporidia in acute diarrheal illness, especially with known risk factors and in immunocompromised patients. *Cryptosporidium* infection may be associated with the use of tap water enema and may be the initial presenting illness in acute HIV infection

N2 - Aim: To verify the possibility of auditory habilitation and to present audiological outcomes in four children with aplasia of the cochlear nerve, by direct stimulation of the cochlear nuclei (CN) using an Auditory Brainstem Implant (ABI). Material and Methods: Four children with cochlear nerve aplasia underwent retro sigmoid approach for placement of the ABI into the lateral recess. The correct positioning of the electrodes was monitored through the EABR. Results: No surgical or postoperative complications were observed. Auditory sensations were produced with the activation of the ABI. Patients have achieved speech detection and environmental sound awareness. They are showing auditory improvement in the MAIS Scale through the parents' opinion. All patients use the ABI in a permanent way. Active electrodes, audiological outcomes, free field and speech perception tests, will be reported separately. Conclusions: This study suggests that ABI in children with cochlear nerve aplasia is feasible, with variable results

N2 - Aim: The aim of the study was to specify the indications for cochlear implantation in patients with rare genetic syndromes: Goldenhar and BOF and assess the results obtained after surgical treatment. Material and Methods: Two children with Goldenhar syndrome and one with BOF syndrome were operated on in our Clinic. Various cochlear implant systems were used to each of these patients. The technique of cochlear implantation was in all cases facial recess. Results: In all cases we achieved satisfactory hearing level. No early or late surgical complications were observed. Conclusions: We point that even in cases with very complicated anatomy and congenital malformations there is possibility to improve hearing using implantable devices. It is of crucial importance to focus on hearing improvement to maintain appropriate hearing level and to give chance for those children to be active society members

N2 - Objectives: Our 20 bedded PICU attempts to provide supra-regional services as well as intensive care for the majority of a local catchment (1.3 million children). We sought to model demand because of high refusal rates. Methods: A conventional method based upon local catchment, using average length of stay and incidence and assuming a Poisson distribution, was used to find the number of beds required to cover 95% of the time. This was compared to the Monte Carlo method justified because: - supra regional referrals come from outside the catchment area - length of stay is a right skew distribution - refused admissions (exclusively referrals from other hospitals) would stay longer. Our data also shows marked increase in length of stay during winter. Using activity (admissions) and the refused admissions, we created 1,000 randomly sampled scenarios (with replacement) from 2 years data. Custom software established how many beds were occupied each minute. The maximum number of beds per calendar day under the worst scenario was compared to the percentage of time where this number of beds would accommodate all patients (i.e. percentage compliance). Results: Poisson suggested 27 beds covers 95% of the time. Monte Carlo showed 95% compliance with 35 beds. Conclusion: Methods using average length of stay for refused admissions underestimate required capacity compared to the Monte Carlo method. No additional capacity (required to meet the year on year increase in demand) was included

N2 - Aim: To examine the activity and impact of a new combined acute neonatal and paediatric transfer service, Embrace, on the Yorkshire and Humber region and to describe the evolution of a new service.

Background: Embrace is the result of a 3-year effort between Sheffield Children's Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Leeds Teaching Hospital Trust and regional commissioners of children's

services to provide a combined neonatal and paediatric transport service, aid in finding delivery suite and neonatal cots for in utero transfers and act as bed bureau for children's critical care. Methods: Retrospective analysis of transport database from Dec 2009-June 2010 to determine service activity, levels of care required, resources use within and from outside the service. Results and Discussion: Yorkshire and Humber is the largest of nine English regions, population 5.1 million, covering 15,413 sq miles. Embrace supports 23 hospitals within the Strategic Health Authority (SHA). Embrace started in a phased manner with paediatrics retrievals going online first followed by neonatal retrievals in April 2010. Table 1 shows the activity breakdown since Embrace's start. (Table presented) 2000 retrievals are predicted for the first full year of operation. As the service is now fully staffed and operates 24 hours a day, there is a decreasing reliance on assistance from outside services except in the case of time critical transfers. Transport teams of the tertiary NICUs and PICUs within the Yorkshire and Humber SHA no longer formally exist thereby allowing hospital staff of these units to concentrate on in-patients and not be called away for retrievals

N2 - My tasks and experiences as a paediatric nurse caring for a rehabilitation camp for children and teenagers after cancer treatment Since 25 years I am qualified as paediatric nurse at the St. Anna Children Hospital stem cell transplantation-unit. An exciting but challenging profession. Everyone who works in it, has announced that after a hospital stay-of the daily life of patients is still far away from commonplace. Although we often expect that children return quickly to their normal life after successful treatment, the way back is quite stony for the whole familie. They are fare beyond their expectations and the burden of late effects is still present. The "national organization for children's cancer care" aims to assist patients and their families with reintegration. The "rehabilitation camps" play a centrale role and offer tailord programs for the needs of various age groups. The professional team of educators, psychologists, psychotherapist, and a paediatric nurse offer the children a platform of a well-prepared 10-day-game history to exchange experiences and disease specific. For this purpose I was trained as a leisure educator for one year to accompany these camps. My duties at the camp are medical treatment, supervizing and supporting the children with nursing measures. (e.c. subcutane application of growth hormones) Minor "accidents" are first aided from me, and I indicate a doctor's visit. The work outside the hospital is much joy and motivation for me. It's nice to see how they make their own progressions during the post-care-camp after a long and serious illness by making experiences to handle a change in living conditions. We trie to show them possibilities of ways back from the daily routine to self-determination. One of the majorgoals is not only but also teamwork within the peer group handling the daily routine. I want to point of the importance and effectiveness of aftercare camps, and aware of all concerned groups of professionals. For me, working in a rehabilitation camp is a very satisfactory enrichment and it influenced my personal attention in the stationary everyday anew

N2 - Children and adolescents with cancer may be hospitalised for long periods of time, leading to isolation from their family, home, school and peers. The protracted nature of some treatments can impact negatively on educational outcomes, including progress in the classroom, socialisation and acceptance by peers. Treatments such as Bone Marrow Transplant (BMT) require the child to be isolated from weeks to months, thus imposing another layer of separation from the outside world. It is more important than ever, with available technology, that patients remain connected with their school for both school work and socialisation, yet there is a dearth of literature evaluating the impact of the use of interactive technology in this context. As part of a pilot program at Sydney Children's Hospital, a small cohort of patients "dialled in for lessons" at their home school and remained in contact with their school friends using Skype. The hospital school teacher was able to be present during the sessions, using either Skype or a video conferencing facility at the hospital school called 'Connected Classroom'. The aim of the program was to assist students to overcome the negative impact of prolonged absence and to assist their re-integration into the classroom post BMT. Teachers and parents both evaluated the program positively. Patients were able to join in lesson activities, teachers were able to successfully integrate the patient into the classroom from their bed and parents viewed the program as facilitating increased normality for their child. Classmates were able to see the physical changes in the patient as they occurred and being able to see the patient assisted with demystifying what was happening at the hospital. After discharge from the BMT unit but while still in isolation, patients continued with the program from their home. Data from a formal retrospective evaluation by patients, parents and teachers will be presented

N2 - Objectives: This study aims to describe vitamin D status of Belgian children assessed by blood samples taken during winter and spring 2010 and to examine the influence of non-nutritional factors on the outcome observed. Materials/Methods: Participating children (n=357; 51.5% male, 4-11 years) were drawn from the Belgian control region (Aalter) of the EU 6th FP IDEFICS cohort. Blood was sampled between February and June 2010. 25(OH)D was measured using radioimmunoassay I125 (INCSTAR 25 (OH)D-¹²⁵ IRIA kit, Stillwater, MN, USA). Vitamin D status was categorized as deficient (25(OH)D<25 nmol/l), insufficient (25-50 nmol/l), sufficient (50-75 nmol/l) and optimal (>75 nmol/l). Height and weight were measured with standard clinical stadiometer and balance. The BMI zscore was determined using the LMS method (with British reference population). Skinfold thickness (triceps and subscapular) was measured using Holtain Tanner/Whitehouse skinfold calipers. Ethical approval was granted by the Ethical Committee of the Ghent University Hospital. Results: Serum 25(OH)D ranged from 13.6 nmol/l to 123.5 nmol/l (mean 47.2+14.6 nmol/l). Within the group, 5% was deficient, 53.1% insufficient, 39.7% sufficient and 2.2% optimal. No significant difference in vitamin D status was found between boys and girls and no significant correlation with age. However, a significant difference in 25(OH)D concentration between the months of sampling was found, as well as a significant correlation with the number of h playing outside (r=0.14) and the sum of skinfolds (r=-0.11). Two different multivariate models (ANCOVA) indicated that 68% of the variability of the 25 (OH)D concentration was explained by the month of sampling, the number of h playing outside and the BMI z-score or sum of skinfolds, respectively. Conclusions: The majority of Belgian children have a suboptimal vitamin D status, with more than half having an insufficient status in winter and spring. Month of the year, number of h playing outside as well as body composition (BMI or sum of skinfolds) were identified as important determinants of vitamin D status in this group of children

N2 - Background: Obesity, a natural consequence of over-nutrition and sedentary lifestyle, is increasing rapidly in children and adolescents of developing countries including India. This is leading to an increased risk of

morbidity and mortality due to various metabolic problems such as diabetes, and cardio vascular diseases. Objectives: To assess the prevalence of childhood overweight/obesity among 9-18 year old school children and to assess impact of educative intervention on them. Materials and methods: Project MARG is a school based intervention program for school children aged 9-18 years initiated in 8 cities (Agra, Allahabad, Dehradun, Delhi, Jaipur, Lucknow, Mumbai, and Pantnagar of India. Each city enrolled 10 schools with a 50-50 split in the type of schools. The Ethics Committee of the Institution, Diabetes Foundation (India), approved the study. Informed consent from the principals of the schools, and parents of the students were procured before initiating the study. Students not willing to participate were excluded from the study. Results: A total of 57 225 school children participated in the study. Prevalence of overweight/obesity was 24.1 and 7.0 percent in private and public schools, respectively across 8 cities in India. This data increased to 32.9 and 9.2 percent in private and public schools, respectively when calculated for children between 14-18 years of age (n=25 738). Dietary intake pattern among schoolchildren revealed that 1 in every 3 eats out once or more in a week, with 22-50 percent of the children eating calorie dense foods at least once in a week, coupled with spending less time in outdoor activities (68%). Baseline knowledge and behaviours indicated better scores in private as compared to public schools. Educative interventions utilising locally appropriate innovative strategies showed improvements irrespective of the schools type. The percent increase in the score levels across all topics of assessment (health, nutrition, disease, physical activity, cooking practices) varied from 3.5 to 43 and 3.4 to 34.8 percent in private and public schools, respectively. Following intervention, more percent of children from public schools now identified chips as junk food (23.8%) and more than 80% of all children had improved knowledge in regards to cereals and fruits. Knowledge in regards to type-1 diabetes improved in 30 and 23.9 percent children from both schools, respectively. Dietary intake among children and young adults revealed a high total fat and saturated fat intake with a low intake of MUFAs and -3 PUFAs, predisposing them to an increased prevalence of obesity and insulin resistance. Biochemical parameters showed improvements as in decrease in fasting blood glucose levels and hs-CRP levels post educative intervention. Sustainability is being ensured by training volunteers for the initiative. Conclusion: Reports on educative interventions directed towards children and their parents show encouraging results, but large scale country wide programs need to be initiated

N2 - Objective: To investigate the association between adiposity and urbanisation level in a sample of schoolchildren of the Italian cohort of the IDEFICS Project. Materials and methods: The sample was composed of 2256 children (boys=1167; girls=1089; age=6.1+1.7 yrs).The degree of adiposity was estimated as the sum of the four measured skinfold (SST): biceps, triceps, suprailiac and subscapular. Lifestyles were investigated by a questionnaire filled in by parents. The sample was divided in three categories of urbanisation level, estimated according to the population density in each municipality: rural n=716; suburban n=600; urban n=940.The analysis was performed separately for kindergartens (KG) and primary schools (PS). Data are mean (95% CI). Results: A statistically significant -linear- increase in SST was observed going up across urbanisation categories (KG: rural=28.5 (23.5-33.5) mm; suburban=33.3 (28.8-37.9) mm; urban=37.1 (34.1-40.1) mm; PS: rural=46.1 (41.5-50.6) mm; suburban=48.6 (45.0-52.2) mm; urban=51.5 (48.6-54.2) mm; ANOVA P<0.0001).Children who lived in rural zone reported to spend significantly more time in outdoor activities (KG: rural=165 (149-181); suburban=96 (85-108); urban= 89 (80-97) minutes/day; PS: rural=160 (149-171); suburban=98 (89-107); urban=93 (84-100) minutes/day; ANOVA P<0.001) but on the contrary they practiced less structured physical activity (% of children regularly practicing structured physical activity; KG: rural=24%; suburban=24%; urban=52%; PS: rural=21%; suburban=30%; urban=49%; P<0.001). Multivariate analysis showed that sex, education level of parents and urbanisation level were independent determinants of the degree of adiposity in KG children (P<0.001). In PS children, age and time spent in outdoor activities were other statistically significant determinants of adiposity (P<0.01). Conclusions: Our data show that children living in an urban area had a higher degree of adiposity in comparison to the peers living in suburban and rural areas. Differences in lifestyle, in particular in physical activity patterns, could explain these results and may have implications for paediatric obesity prevention

N2 - Objectives: A growing body of evidence is documenting the positive relationship between the built environment and physical activity. The aim of this presentation is to report on the evidence of this relationship and its impact upon obesity in children, adolescents, and adults, and to give a critical analysis on its similarities and differences. Material and methods: Several key studies from Europe are presented. For adults, the Belgian Environmental Physical Activity Study (BEPAS) will be presented. In this study 24 neighbourhoods in Ghent were selected based on GIS-based walkability and SES; 1166 adults (aged 20-65) participated in this study. In adult research, high-walkable neighbourhoods are defined by high street connectivity, residential density and land use mix. For adolescents, a small pilot study in 2 neighbourhoods and the Youth BEPAS will be presented in which 32 neighbourhoods were used based on walkability, and 509 adolescents (aged 13-15) were included. In children, the contribution of preschool playground factors in explaining children's physical activity was analysed in 39 randomly selected preschools (415 boys and 368 girls; 5.3+0.4 years old). Physical activity levels were assessed using accelerometers (7 days) or pedometers, supplemented with self-reports. Results: A clear association was found in adults between the built environment and physical activity. Adults living in a high-walkable neighbourhood reported more active transport and more leisure time walking than adults living in a low walkable neighbourhood. Physical activity mediated the associations of neighbourhood walkability with BMI. In adolescents, the relationship was less univocal. A first pilot study showed that, in contrast with results

in adults, lower walkability and larger distance to school were associated with more physical activity. However, the second study, which was larger, did show some positive relationships between the built environment and physical activity, but no relationship with overweight. In preschool children physical activity during outdoor play was associated with some modifiable playground factors, but not with others. Conclusion: The strength and the characteristics of the relationship between the built environment and physical activity are different across the life cycle

N2 - Topic: Expanded inpatient and outpatient services Description: The American Academy of Pediatrics (AAP) and the World Health Organization (WHO), in their respective definitions of pediatric palliative care (PPC), suggest that services should commence at the time of diagnosis of a child with a life limiting condition.

Despite these definitions, pediatric palliative care has traditionally been reserved for children nearing the end-of-life; those who are transitioning from curative treatment to hospice care. In the Department of Pediatrics at the University of Kansas Medical Center, a unique program is working to ensure that palliative supports begin at the time of diagnosis, and continues through cure, transition to adult care, or end-of-life care. The KU Kids Healing Place provides care for the physical, psychological, social, spiritual and educational needs of children with life limiting conditions, as well as traditional palliative care for youngsters nearing the end of life. The program initiates services within the hospital, and extends them into the natural environments of the youngster. As health care providers partner with schools, child care programs, extracurricular activities, athletics, places of worship and more, a system of support is developed that enables young people, regardless of health status, to continue to grow and develop normally. School professionals, peers, child care providers, coaches, clergy and other community members receive education and training which enables them to provide 'palliative care' in every facet of the youngster's world. This poster presentation will chart the development of this innovative model of pediatric palliative care, from inception to implementation

N2 - RATIONALE: This study evaluated the impact of exercise-related respiratory symptoms on physical activities of children with asthma. METHODS: A national survey was conducted with parents of 516 children (4-17 years) with asthma or taking medications for asthma in the prior year. Responses assessed whether up to 6 exercise-related respiratory symptoms influenced participation in exercise and school activities. Subgroup analyses (4-12 and 13-17 years) were also conducted. RESULTS: Majority (80%) of parents with children with asthma reported that their child experienced >1 and almost half (47.4%) experienced >4 exercise-related respiratory symptoms. Most commonly reported symptoms were coughing, shortness of breath, and wheezing. Older children were more likely to avoid activities because of exercise-related respiratory symptoms compared with younger children (31.9% vs 22.9%, respectively). Respondents felt that asthma limited their children's ability to participate either "a lot" or "some" in sports/recreation (30%), normal physical exertion (20.9%), and other outdoor activities (26.3%). A higher percentage of older children were reported to be limited "a lot" in sports participation compared with younger children (12.4% vs 6.4%, respectively). Only 22.2% of children with asthma took bronchodilators such as albuterol "always" or "most of the time" before exercise. CONCLUSIONS: Exercise-related respiratory symptoms substantially limit ability of children to participate normally and perform optimally in physical activities, with adolescents compromised to a greater extent than younger children. Many children are not using short-acting bronchodilators before exercise as recommended in national guidelines. Adherence to controller therapy and prevention with short-acting bronchodilators should be optimized per current treatment guidelines

N2 - Sunscreens formulated with exclusively inorganic UV filters are ideal for baby and sensitive skin. The combinations of titanium dioxide and zinc oxide can provide excellent and balanced UVA and UVB protection with a high skin tolerance. Until recently, high protection levels of inorganic sunscreens were typically accompanied by undesirable aesthetic properties, such as skin whitening and poor skin-feel. Formulation advances have overcome these aesthetic challenges as indicated by sensory testing and consumer in use testing. A comprehensive assessment of an SPF 60 sunscreen containing only titanium dioxide and zinc oxide was conducted, including in vivo UVA (UVAPF) assessment, critical wavelength measure to assess the breadth of the protection, clinical and in use studies. A double-blind, crossover clinical in infants and young children at Rady Children's Hospital was conducted to compare the efficacy and tolerability of the inorganic sunscreen with a conventional organic sunscreen. A home use study involving about 200 babies and infants evaluated the aesthetic features and acceptability of the inorganic sunscreen. Finally, a double-blinded, randomized clinical eye-sting test was performed to assess the ocular irritation potential of a sunscreen product relative to the conventional organic filter product. The SPF 60 inorganic sunscreen had a PFA value of 20.8, higher than all other inorganic sunscreens tested, and a critical wavelength above 370 nm, indicating broad-spectrum protection. The SPF 60 sunscreen showed statistically better sunburn protection on the body and comparable sunburn protection on the face when compared to the organic sunscreen of SPF 50 in the baby clinical study with no adverse events. The majority of the mothers in the home usage study found the inorganic sunscreen nongreasy, nonwhitening, and easy to apply. The eye-sting evaluation showed that the inorganic sunscreen did not irritate the delicate tissue of the eyes or induce tearing in subjects after 30 minutes of outdoor activities during a hot summer day. The SPF 60 inorganic sunscreen demonstrates high protection and consumer acceptance, and has been clinically shown to be gentle and efficacious for use on babies and young children

N2 - Background: The social and economic impact of asthma is substantial worldwide. Although current therapies targeting both airway inflammation and airway hyperresponsiveness (AHR) effectively relieve and prevent clinical symptoms in the majority of asthmatic children, some patients experience persistent symptoms and a progressive decline in lung function from early childhood. To date, there are many unanswered questions about the role of many factors in asthma progression and persistence. Purpose: This study was focused on finding possible risk factors for persistent asthma to allow better control of the illness from infancy to late childhood. Material and method: Sixty-eight children with persistent mild-to-moderate asthma: 23 early-onset (<2 years of age) and 45 late-onset (>2 years), according to GINA Guideline. Detailed information included personal or family history of atopy, breastfeeding, parental smoking, recent use of inhaled corticosteroid, and laboratory tests such as spirometry, body mass index, skin prick test, allergen-specific IgE, PB eosinophils and serum ECP. All the asthmatics were performed bronchial challenge by methacholine inhalation (BCM) and outdoor free running (ET). Results: Risk factors such as eczema and frequent wheezing were more common in early-onset asthmatics than in the late-onset ($P < 0.05$). On the other hand, there were no differences in overall incidence of AHR induced either by methacholine or by exercise as well as PC20 and postexercise decrease of FEV1 ($P > 0.05$) in both study groups. For the appropriate management, early-onset asthmatics required more frequent use of inhaled corticosteroid than the late-onset ($P < 0.0001$). Author also found a reciprocal relationship between FEV1/FVC and days of asthma in the study groups of persistent asthma ($n = 68$, $r = -0.380$, $P = 0.004$). Conclusion: One of the important risk factors for asthma persistence and lung function decline from early to late childhood was atopic dermatitis and frequent wheezing. In persistent asthmatics with AHR, early and proper treatment with inhaled corticosteroids is required for the support of better pulmonary function

N2 - Background: Detrimental effects of pollution on children pulmonary function have been described, but few data relates the characteristics of air near and into schools. Methods: We selected two primary schools in Milan, one located near a large park (school 1) and the other downtown (school 2). For each school, from September 23th to October 3rd 2008, we sampled every 5 min in- and outdoor fine particles (PM1, PM2.5 and PM10, $\mu\text{g}/\text{m}^3$) by Optical Particle Counters (OPC 1.107 environcheck and OPC 1.108 dustcheck). We compared the mean concentration during schooltime (7:30 am-18:30 pm) and during the rest of the hours (school empty). In the meantime we enrolled 232 children, mean age 8 years; 149 attending the first school, 83 the second school. All children underwent clinical evaluation, spirometry and exhaled fraction of nitric oxide (FeNO) dosage. Results: The mean concentrations of measured particles (SD) are summarized in the table. Fine particles are significantly higher in school 2 except PM10 indoor, during schooltime, which is higher in school 1. In both schools the concentration of indoor PM10 drastically increases during school activities. This increase is not observed for PM2.5 and PM1. Respiratory function measures were normal in all children. There are significant differences between the percentage values [mean (SD)] of FEV1, FVC and PEF in the two schools [106.1 (11.85) versus 102.1 (12.87) $P = 0.007$; 100.4 (10.77) versus 95.84 (11.45) $P = 0.011$; 92.8 (14.62) versus 88.6 (13.63) $P = 0.31$]. Mean (SD) concentration of FeNO (ppb) was normal in both school [14.5 (9.16) versus 17.1 (12.7) $P = 0.456$]. Conclusion: The higher value of PM10 in school 1 and its increase at the beginning of school activities show that the coarse fraction of particles depends on the location of the school but also on the presence/absence of children. PM10 could be not the most useful indicator of air quality and its effects on children pulmonary health. Further studies are needed to analyze the chemical composition of PM in schools

N2 - Zagreb Children's Hospital is the institution in which most children with burns are treated in Croatia. Analysis over a six-year period revealed that on average one child with a severe burn is treated per month in the intensive care unit (ICU). Here we present the distribution of patients according to age, sex, cause of burn, surface area and regions of the body affected, as well as some indicators of how demanding intensive care and surgical treatment of these patients is. Within the timeframe analysed, over 60% of children were in the age group up to 5 years old and were most frequently scalded by boiling water in their family home in the presence of adults, but lacking their supervision. In the group over 10 years of age, boys were more frequently burned than girls and it would occur while playing outdoors. Burns were equally distributed among all regions of the body in severely burned patients. Over 60% of children had burns covering 10%-30% of their body surface. There were 4 children (5.6%) with burns covering over 70% of their body surface. The average length of stay in

the ICU was 0.61 days per percent of affected body surface, while the overall average length of stay in the hospital was 2.05 days per percent of affected body surface. The purpose of this study is to warn about the relatively high number of children receiving severe burns in the earliest period of life and in the family home, and to discuss the complexities and demands of treating these patients in the ICU and on the ward

N2 - General practice is a suitable and natural environment for educating children on the issues of nutrition and physical activity. The aim of the study is to research the main difficulties in prevention of overweight and obesity encountered in general practice. 34 general practitioners are encompassed in the study. Interviews with general practitioners have been made as well as a direct open observation of the preventive measures organization has been applied. The insufficient funding, lack of materials in appropriate form on the obesity in children as well as the written documentation are the main barriers the general practitioners meet in the prevention of obesity in children. At this stage of the reform in Bulgaria there are substantial organizational difficulties with regard to the insufficient volume and quality of preventive measures on the problem with obesity in children. 2010 Duzce Medical Journal

N2 - There is a growing understanding that chronic respiratory diseases in adults have their origins in early life. Adverse environmental exposures occurring in vulnerable periods during lung growth and development in the fetal period and in early childhood that alter lung structure and limit the growth in lung function may have lifelong consequences. Evidence is increasing that exposure to the ambient environment, including air pollutants, persistent toxic substances, water pollutants and respiratory viral infections, can inhibit lung function growth and predispose to chronic non-malignant lung diseases. These exposures generally interact with a genetic predisposition, and gene-environment interactions and epigenetic phenomena are attracting considerable study. An understanding of how ambient exposures impact on normal lung growth and development will aid in understanding of how chronic respiratory diseases of adults develop and may lead to new preventative strategies. 2010 The Author(s)

N2 - Few studies report a protective role of childhood solar exposure to multiple sclerosis. Our objective was to confirm the protective role of childhood solar exposure in multiple sclerosis in Cuba, Martinique and Sicily. This was a matched case- control study, and cases met Poser criteria for clinically, laboratory (definite, probable) multiple sclerosis. Controls were resident population, without neurological disorder, living close to cases (within 100 km), matched for sex, age (+5 years), residence before age 15. We recruited 551 subjects during a 1-year period (193 cases, Cuba n = 95, Sicily n = 50, Martinique n = 48; 358 controls). Some (89%) met definite clinical multiple sclerosis criteria (relapsing remitting form (with and without sequel) (74%), secondary progressive (21%), primary progressive (5%)). Odds ratios in a uni-variate analysis were: family history of multiple sclerosis (5.1) and autoimmune disorder (4.0); wearing shirt (3.5), hat (2.7), pants (2.4); sun exposure causing sunburn (1.8); sun exposure duration (1 h more/day; weekends 0.91, weekdays 0.86); bare-chested (0.6); water sports (0.2). Independent factors in the multivariate analysis were family history of multiple sclerosis (4.8 (1.50-15.10)), wearing pants under sunlight (1.9 (1.10-3.20)), sun exposure duration (1 h more/day, weekdays 0.90 (0.85-0.98), weekends 0.93 (0.87-0.99)), water sports (0.23 (0.13-0.40)). We conclude that outdoor leisure activities in addition to sun exposure reports are associated with a reduced multiple sclerosis risk, with evidence of dose response. 2010 The Author(s)

N2 - This study characterized the time-location pattern of 107 residents living in air pollution hotspots, the Waterfront South and Copewood/Davis Streets communities in Camden, NJ. Most residents in the two communities are minority and impoverished individuals. Results showed that employment status played the fundamental role in determining time-location patterns of this study population, and the variations of time-location pattern by season and by day-type were partially attributed to employment status. Compared to the National Human Activity Pattern Survey, the Camden cohort spent significantly more time outdoors (3.8 hours versus 1.8 hours) and less time indoors (19.4 hours versus 20.9 hours) than the general US population, indicating a higher risk of exposure to ambient air pollution for the Camden cohort. The findings of the study are important for understanding exposure routes and sources for the socioeconomically disadvantaged subgroup and ultimately help develop effective strategies to reduce community exposure to ambient air pollution in hotspots. N2 - Objective: To identify the prevalence of overweight and obesity and associated factors among six to ten-year-old students from public county schools in the urban area of Marialva in Parana, Brazil. Methods: Cross-sectional study that used a stratified random sample of 356 students. The following variables were evaluated: body mass index, gender, age, number of siblings, physical activity and sedentary activities. Descriptive statistics was used to verify the distribution of the sample in the strata. The chi-square test was used in order to verify the differences between the distribution of the sample for each category of variables. The association between variables was tested by univariate analysis. Results: Prevalence of overweight was 20% and obesity, 7%. Most students (72%) did not practice physical activity outside school and about half of them (53%) spent more than four hours a day in sedentary activities. The number of siblings was the only variable associated with excessive weight for those who had only one sibling (PR=1.64; 95%CI=1.10-2.45) and for those who had no siblings (PR=1.70; 95%CI=1.02-2.84), compared to those who had two or more siblings. Conclusions: There was a high prevalence of overweight and obesity in this sample. Further studies are needed in order to investigate the prevalence of this disease in children living in small Brazilian municipalities, as well as for research and actions to prevent and/or treat obesity

N2 - Objective: The aim of the study was to investigate the pedometer-assessed physical activity of Singaporean youths using an objective measurement of physical activity. Methods and results: Pedometer step count was monitored over the entire week in 877 participants aged 9-18. years in three schooling cohorts [primary (age, 9-12. years; n= 150 males; 156 females), secondary (age, 13-16. years; n= 137 males; 138 females) and junior college (age, 17-18. years; n= 140 males; 156 females)] in Singapore during July to September 2009. Analyses identified significant main effects for step count taken outside of school compared to within school (mean (SD): 5568 (4796) vs. 3881 (3149), $p < 0.05$). However, no significant difference was found for steps accumulated within or outside school in boys and girls across the schooling levels (steps x sex x level interaction, $p > 0.05$). Step counts were not significantly different between weekdays or weekends (9719 (6063) vs. 9483 (8056), $p > 0.05$), across schooling levels and between male and female participants (sex x level and steps x level x sex interactions, all $p > 0.05$). Conclusion: Step count decline is drastic for male adolescents after primary school but remains low across the schooling levels for female participants. Aggregated daily step count fell short by up to 35% of the 16,000 and 13,000 steps recommended respectively for male and female youths.

N2 - Background: Infections are the most commonly reported health problems in children. Younger age and day care outside the home are two factors of importance for infectious morbidity. The influence of siblings on infectious symptoms is not clear. Objectives: To compare families with one child and families with more than one child in terms of reported infectious symptoms, physician consultations and antibiotic prescriptions.

Methods: A prospective population-based survey was performed. During 1 month, all infectious symptoms, physician consultations and antibiotic prescriptions for 18-month-old children were noted by the parents. The 789 families also answered questions about socio-economic factors, numbers of siblings in the family and type of day care. Results: No difference in number of symptom days was found between children with and without older siblings. Neither could we find any significance in terms of having older siblings in relation to physician consultations and antibiotic prescriptions. Conclusions: The results of our study indicate that having older siblings not was important in relation to number of symptoms days, physician consultations or antibiotic prescriptions for 18-month-old children in Sweden today. Changes in social activities and attitudes towards antibiotic prescription may explain our different findings as compared with previous Swedish studies and studies from other countries. N2 - * Translation projects (implementation of evidence-based strategies) are desperately needed to get schools up to speed on what we already know about bullying. * School personnel can take numerous simple steps to make schools safer, such as increasing supervision in restrooms and on playgrounds. * Both students and teachers need to be taught the difference between tattling (telling an adult about bad behavior to get someone in trouble) and reporting (telling an adult about bad behavior to get help and stay safe). * Social-emotional education should be incorporated into the daily routine of all children both at home and at school. * Schools must be careful not to reward bad behavior by giving time off or special time with an adult to the bully, which inadvertently can reinforce bullying. * Some emotionally disturbed children are served best in special classrooms designed to meet their specific needs. * Adult indifference to bullying must end because it may be teaching young people to tolerate coercive and abusive behavior. * Parents, school personnel, and pediatricians can educate themselves by reading evidence-based literature on bullying. * Openness to feedback and discarding stereotypes about bullying may enable parents to respond constructively when their child has a behavior problem. * Parents can use community resources (eg, social skills and etiquette classes for children) to improve their children's social skills. * Pediatricians should advocate for parents with school personnel to make changes to stop bullying and should be open to supporting legal action if no change occurs

N2 - Background: Few studies have used longitudinal ultrasound measurements to assess the effect of traffic-related air pollution on fetal growth. Objective: We examined the relationship between exposure to nitrogen dioxide (NO₂) and aromatic hydrocarbons [benzene, toluene, ethylbenzene, m/p-xylene, and o-xylene (BTEX)] on fetal growth assessed by 1,692 ultrasound measurements among 562 pregnant women from the Sabadell cohort of the Spanish INMA (Environment and Childhood) study. Methods: We used temporally adjusted land-use regression models to estimate exposures to NO₂ and BTEX. We fitted mixed-effects models to estimate longitudinal growth curves for femur length (FL), head circumference (HC), abdominal circumference (AC), biparietal diameter (BPD), and estimated fetal weight (EFW). Unconditional and conditional SD scores were calculated at 12, 20, and 32 weeks of gestation. Sensitivity analyses were performed considering time-activity patterns during pregnancy. Results: Exposure to BTEX from early pregnancy was negatively associated with growth in BPD during weeks 20-32. None of the other fetal growth parameters were associated with exposure to air pollution during pregnancy. When considering only women who spent < 2 hr/day in nonresidential outdoor locations, effect estimates were stronger and statistically significant for the association between NO₂ and growth in HC during weeks 12-20 and growth in AC, BPD, and EFW during weeks 20-32. Conclusions: Our results lend some support to an effect of exposure to traffic-related air pollutants from early pregnancy on fetal growth during mid-pregnancy

N2 - Bottari C, Dassa C, Rainville C, Dutil E. A generalizability study of the Instrumental Activities of Daily Living Profile. Objective: To establish generalizability estimates of the Instrumental Activities of Daily Living (IADL) Profile when administered to persons with a moderate or severe traumatic brain injury (TBI) within their home and community environment. Design: Generalizability theory was used to estimate generalizability and dependability coefficients as well as the relative contribution of identified sources of measurement error to total measurement error. Decision studies were used to enable the investigators to determine the optimal measurement design. Setting: The IADL Profile was administered in subjects' homes and community environments. Participants: Convenience sample of adults with a moderate or severe TBI (N=30, aged 16-65y). Interventions: Not applicable. Main Outcome Measures: IADL Profile scores include 6 factor scores (going to the grocery store/shopping for groceries, having a meal with guests/cleaning up, putting on outdoor clothing, obtaining information, making a budget, and preparing a hot meal) and 1 total score. Results: The greatest sources of measurement error were the subject-item interactions (3-random-facet design) and the subject-rater interactions (2-random-facet design). One hundred percent of generalizability coefficients of factor scores indicated acceptable to excellent reliability. Indices of dependability confirmed that 1 evaluator could reliably score the tool on a single occasion after having received a 3-day training workshop. Conclusions: The IADL Profile administered to persons with a moderate or severe TBI provides occupational therapists with a reliable set of measures of IADL independence capable of both capturing and analyzing the complex interactions between personal and environmental factors. 2010 American Congress of Rehabilitation Medicine

N2 - In several campaigns we investigated the respiratory health of schoolchildren using questionnaires, clinical examinations and spirometry. The latter proved especially sensitive. The influence both of the outdoor air pollution and its improvement over time could be demonstrated. Among the indoor factors living in a smokers household as well as damp and mouldy homes were important as was the location of the home near a busy street. As protective factors we found breast feeding and sports activities of the children. 2010 Dusti-Verlag Dr. Karl Feistle

N2 - Background & Aims: We aimed to characterize the genetic susceptibility to primary sclerosing cholangitis (PSC) by means of a genome-wide association analysis of single nucleotide polymorphism (SNP) markers.

Methods: A total of 443,816 SNPs on the Affymetrix SNP Array 5.0 (Affymetrix, Santa Clara, CA) were genotyped in 285 Norwegian PSC patients and 298 healthy controls. Associations detected in this discovery

panel were re-examined in independent case-control panels from Scandinavia (137 PSC cases and 368 controls), Belgium/The Netherlands (229 PSC cases and 735 controls), and Germany (400 cases and 1832 controls). Results: The strongest associations were detected near HLA-B at chromosome 6p21 (rs3099844: odds ratio [OR], 4.8; 95% confidence interval [CI], 3.6-6.5; $P = 2.6 \times 10^{-26}$; and rs2844559: OR, 4.7; 95% CI, 3.5-6.4; $P = 4.2 \times 10^{-26}$ in the discovery panel). Outside the HLA complex, rs9524260 at chromosome 13q31 showed significant associations in 3 of 4 study panels. Lentiviral silencing of glypican 6, encoded at this locus, led to the up-regulation of proinflammatory markers in a cholangiocyte cell line. Of 15 established ulcerative colitis susceptibility loci, significant replication was obtained at chromosomes 2q35 and 3p21 (rs12612347: OR, 1.26; 95% CI, 1.06-1.50; and rs3197999: OR, 1.22; 95% CI, 1.02-1.47, respectively), with circumstantial evidence supporting the G-protein-coupled bile acid receptor 1 and macrophage-stimulating 1, respectively, as the likely disease genes. Conclusions: Strong HLA associations and a subset of genes involved in bile homeostasis and other inflammatory conditions constitute key components of the genetic architecture of PSC. 2010 AGA Institute

N2 - Injury rates in youth soccer, known as football outside the United States, are higher than in many other contact/collision sports and have greater relative numbers in younger, preadolescent players. With regard to musculoskeletal injuries, young females tend to suffer more knee injuries, and young males suffer more ankle injuries. Concussions are fairly prevalent in soccer as a result of contact/collision rather than purposeful attempts at heading the ball. Appropriate rule enforcement and emphasis on safe play can reduce the risk of soccer-related injuries. This report serves as a basis for encouraging safe participation in soccer for children and adolescents. Copyright 2010 by the American Academy of Pediatrics

N2 - Objective: To study the effectiveness of planning and management interventions for ensuring children in India are immunized at the appropriate age. Methods: The study involved children aged less than 18 months recruited from Haryana, India, in 2005-2006: 4336 in a pre-intervention cohort and 5213 in a post-intervention cohort. In addition, immunization of 814 hospitalized children from outside the study area was also assessed. Operational barriers to age-appropriate immunization with diphtheria, pertussis and tetanus (DPT) vaccine were investigated by monitoring vaccination coverage, observing immunization sessions and interviewing parents and health-care providers. An intervention package was developed, with community volunteers playing a pivotal role. Its effectiveness was assessed by monitoring the ages at which the three DPT doses were administered. Findings: The main reasons for delayed immunization were staff shortages, non-adherence to plans and vaccine being out of stock. In the post-intervention cohort, 70% received a third DPT dose before the age of 6 months, significantly more than in the pre-intervention cohort (62%; $P = 0.002$). In addition, the mean age at which the first, second and third DPT doses were administered decreased by 17, 21 and 34 days, respectively, in the study area over a period of 18 months (P for trend < 0.0001). No change was observed in hospitalized children from outside the study area. Conclusion: An intervention package involving community volunteers significantly improved age-appropriate DPT immunization in India. The Indian Government's intention to recruit village-based volunteers as part of a health sector reform aimed at decentralizing administration could help increase timely immunization

N2 - Objective: Research has shown an association between depression and functional limitations in older adults. Our aim was to explore the latent traits of trajectories of limitations in mobility and instrumental activities of daily living (IADL) tasks in a sample of older adults diagnosed with major depression. Methods: Participants were 248 patients enrolled in a naturalistic depression treatment study. Mobility/IADL tasks included walking one-fourth mile, going up/down stairs, getting around the neighborhood, shopping, handling money, taking care of children, cleaning house, preparing meals and doing yardwork/gardening. Latent class trajectory analysis was used to identify classes of mobility/IADL function over a 4-year period. Class membership was then used to predict functional status over time. Results: Using time as the only predictor, three latent class trajectories were identified: (1) Patients with few mobility/IADL limitations (42%), (2) Patients with considerable mobility/IADL limitations (37%) and (3) Patients with basically no limitations (21%). The classes differed primarily in their initial functional status, with some immediate improvement followed by no further change for patients in Classes 1 and 2 and a stable course for patients in Class 3. In a repeated measures mixed model controlling for potential confounders, class was a significant predictor of functional status. The effect of baseline depression score, cognitive status, self-perceived health and sex on mobility/IADL score differed by class. Conclusions: These findings show systematic variability in functional status over time among older patients with major depression, indicating that a single trajectory may not reflect the pattern for all patients.

N2 - Equine-assisted therapy is used beside therapies realised at the Child Psychiatry Center and included into individualised therapeutic program. The goals are to adapt therapeutic principles outside hospital and with pony as mediator in order to exercise adjustment and control systems: Communication and relationships with others, cognitive regulation (attention, mental representation, understanding causality, anticipation), motor regulation (tonus, body consciousness, postural adjustment, balance, coordination), emotional regulation (self-esteem, relaxation, pleasure, coping emotionally with problems, expressing and sharing emotions), adjusting to change. Varied activities with tranquil and easy-going ponies were realised in a calm secure environment by three therapists with experience in horseback riding for a group of four children. An individual plan targeting specific goals was worked out for each child. Results were evaluated with standardized tools (Behavior Function Inventory and Behavior Summarized Evaluation Scale) for six children with autistic spectrum treated at the day-care hospital, which participated to equine-assisted therapy. Improvements are obtained since the first session and concerns all developmental functions, especially communication, imitation, perceptual, emotional and motor adjustment. With his/her pony the child is stable, calms down, adjusts his/her interactions, is more aware of the effects of his/her actions, and optimal sensory integration can take place. So, equine-assisted therapy is an

efficient remediation of the neurophysiologic functions involved in developing communication and social skills, and cognitivo-emotional regulation. 2010 Elsevier Masson SAS

N2 - In developed nations people spend about 90% of their time indoors. The relationship between indoor and outdoor air pollution levels is important for the understanding of the health effects of outdoor air pollution. Although other studies describe both the outdoor and indoor atmospheric environment, few excluded a priori major indoor sources, measured the air exchange rate, included more than one micro-environment and included the presence of human activity. PM_{2.5}, soot, NO₂ and the air exchange rate were measured during winter and summer indoors and outdoors at 18 homes (mostly apartments) of 18 children (6-11-years-old) and also at the six schools and 10 pre-schools that the children attended. The three types of indoor

environments were free of environmental tobacco smoke and gas appliances, as the aim was to assess to what extent PM_{2.5}, soot and NO₂ infiltrate from outdoors to indoors. The median indoor and outdoor PM_{2.5} levels were 8.4 µg m⁻³ and 9.3 µg m⁻³, respectively. The median indoor levels for soot and NO₂ were 0.66 m⁻¹ x 10⁻⁵ and 10.0 µg m⁻³, respectively. The respective outdoor levels were 0.96 m⁻¹ x 10⁻⁵ and 12.4 µg m⁻³. The median indoor/outdoor (I/O) ratios were 0.93, 0.76 and 0.92 for PM_{2.5}, soot and NO₂, respectively. Their infiltration factors were influenced by the micro-environment, ventilation type and air exchange rate, with aggregated values of 0.25, 0.55 and 0.64, respectively. Indoor and outdoor NO₂ levels were strongly associated (R² = 0.71), followed by soot (R² = 0.50) and PM_{2.5} (R² = 0.16). In Stockholm, the three major indoor environments occupied by children offer little protection against combustion-related particles and gases in the outdoor air. Outdoor PM_{2.5} seems to infiltrate less, but indoor sources compensate. 2010 Elsevier Ltd

N2 - We examined the association between perceived neighborhood characteristics and transport and 2-year changes in accelerometer-determined nonschool MET-weighted moderate-to-vigorous physical activity (MW-

MVPA) and sedentary behavior of adolescent girls. Reporting that children do not play outdoors in their neighborhood, that their neighborhood was well lit, and that there were trails in their neighborhood were each associated with significant decreases in nonschool MW-MVPA. None of the neighborhood or transportation measures was associated with changes in nonschool sedentary behavior. Further work is needed to understand the determinants of the decline in physical activity and the increase in sedentary behavior among adolescent girls. 2010 Elsevier Ltd

N2 - Active travel (walking or cycling for transport) is an important contributor to adolescents overall physical activity (PA). This study examines associations between personal, social and environmental variables and active travel to and from school using data from a large observational study to examine active travel in 2961 year 6 and 8 students (48.7% male), aged 10-14 years (M = 11.4, SD = 0.8. yrs) from 231 schools. Participants completed an on-line survey and all reported living within 2. km of school. Data collected included mode of travel to and from school, self-reported health, and PA variables. Social environmental variables included having playgrounds, parks or gyms close by, feeling safe to walk alone, barriers to walking in the neighbourhood (e.g. traffic, no footpaths), peer and family support for PA, existence of sports teams/scout groups, community disorder and perceived neighbourhood safety. Results showed that while more girls (44.3%) than boys (37.4%) walked to school, lower proportions rode bikes (8.3% vs 22.4%) and hence fewer were active travellers overall. Logistic regression models, adjusted for age, location and socio-economic status were conducted for active travel to/from school, separately for boys and girls. Predictors for boys and girls being 'active travellers' to/from school included recreational facilities close to home, higher perceived safety of the neighbourhood and higher community disorder. For boys, social support from friends, scout groups available and higher enjoyment of physical activity was also important. These findings suggest areas for future research and may be used to guide strategies to increase active travel to and from school. 2010 Sports Medicine Australia

N2 - During firework season in the UK (October-January), many patients present to emergency departments across the country with firework-related injuries. These seasonal injuries can vary from minor skin trauma to major burns, inhalation injuries and even death in some cases. Governments have tried to improve public awareness and safety with education using multi-million pound national safety campaigns as well as clamping down on fireworks both from within and outside of the EU which fail to meet safety standards. Despite these measures, firework-related injuries are increasing (2005 census Royal Society of Prevention of Accidents (RoSPA)). Reasons for this have been cited as new variations in firework design, antisocial behaviour and readily available cheap fireworks. The author conducted a retrospective study in the emergency department in Exeter from October 2006 to January 2007 highlighting 18 firework-related injuries. Of those, four patients needed referral to local burns centres and five needed admission for supportive treatment and specialty management. Prevention of firework injuries to the hand is of the utmost importance. It is hoped that an increase in public awareness will concentrate attention on precautionary measures to prevent these avoidable 'recreational' accidents. If and when accidents do occur, hand surgeons and therapists attempt to provide patients with the best possible return of hand function with a minimum disability and disfigurement. Further research together with national awareness is suggested to reduce these injuries, all for a tradition which can cost millions in healthcare and loss of earnings, but ultimately, it can cost peoples' lives. 2010 Springer-Verlag

N2 - The aim of the present study was to investigate, using exhaled nitric oxide (FeNO) as a marker of bronchial inflammation, the inflammatory effects of air-borne particles in children in the general population and to examine the role of asthma and atopy on any observed associations. FeNO was measured in 149 children at school in central Clermont-Ferrand participating in the Six Cities Study. Exposure to particles with a dimension of less than 2.5 micrometres (PM_{2.5}) was evaluated with a pump placed for one week in the classes and in the playground used by the children. Heavy exposure to PM_{2.5} was associated with a greater amount of exhaled FeNO in both asthmatic and non-asthmatic children. The non-asthmatic children who were heavily exposed in class exhaled 18.3ppb (95 % CI 14.5-23.2), against 11.3ppb (95 % CI 10.0-12.2) for those weakly exposed. In this same population, the difference in the FeNO between the non-atopic children weakly exposed and those heavily exposed (8.9ppb vs. 12.9ppb) was significantly less than it was between the weakly and the heavily exposed atopic children (11.1ppb vs. 27.4ppb). Our study confirms the inflammatory effect of air-borne particles on children with respiratory allergies, not only in asthmatic children but equally in those without pre-existing bronchial inflammation. The results obtained in non-asthmatic atopics confirm the existence of the known adjuvant effect of certain PM_{2.5} components on the intensity of the allergic inflammatory response. 2010 Elsevier Masson SAS

N2 - Japanese encephalitis (JE) has been found to be endemic in Bali, Indonesia. A case-control study was conducted to identify factors associated with JE infection. All 94 serologically confirmed JE cases (cases) and 163 cases of encephalitis or aseptic meningitis without JE (controls) identified in Bali during 2001-2004 were included in the study. Potential risk factors were surveyed at hospital admission. Univariate analyses revealed the following factors to be associated with JE: older age, referral from sub-district health centre or private hospital, playing outdoors after dinner, use of mosquito repellent or spraying, proximity of the residence to rice fields, and pig ownership by the family or next-door neighbours. Multivariate analysis identified proximity to rice fields (OR 293, 95% CI 157-545), pig ownership (OR 224, 95% CI 117-426), and older age (OR 121, 95% CI 109-133) as being independently associated with the risk of JE. Because rice cultivation and pig rearing are essential to the economy of Bali, JE immunization is the best intervention for prevention of JE in Bali.

N2 - Little is known about the prevalence of *Balamuthia mandrillaris* amoebae and *Balamuthia* amoebic encephalitis in Africa. As an approach, relative concentrations of amoebae-binding serum antibodies (Ab) were assessed by flow cytometry using formaldehyde-fixed *B. mandrillaris*, *Acanthamoeba lenticulata* 72-2 and *Acanthamoeba castellanii* 1BU amoebae for specific Ab capture (B.m.-Ab, A.l.-Ab, A.c.-Ab). One hundred and ninety-two sera from West African (Cote d'Ivoire) donors aged 11-95. years (mean 38 a; 51% males), and living in villages surrounded by rainforest near the Liberian border, were tested and related to reference sera from Berlin. While B.m.-Ab tended to increase with donor age, A.l.-Ab and A.c.-Ab did not. Accordingly, B.m.-Ab correlated only weakly with A.l.-Ab or A.c.-Ab. Of the nine individuals with the highest B.m.-Ab

concentrations, most were elderly (mean 58 a), male (78%), and professed intensive outdoor activity (hunting, farming). Only three of these sera also showed elevated A.i.-Ab, and none elevated A.c.-Ab. 2009

N2 - We determined the efficacy of a Southwest Ohio state-sponsored intervention to promote nutrition (Nu) and physical activity (PA) in preschool child care. We conducted baseline (7/08-4/09) and follow-up (9/09-12/09) phone interviews with child care center directors on Nu and PA environments of centers in an intervention (I, N=108 centers, Dayton area) and a demographically similar control (C, N=162 centers, Cincinnati area) county. A self-assessment was sent to the 108 I centers; 28 [active intervention (AI)] returned the application and received a Targeted Action Plan to address self identified deficiencies in Nu and PA environments. The 6mo (mean+SD) in global Nu (eg, meal environment, milk, juice, snacks, etc) and PA (eg, TV, outdoor play & muscle room features, etc) scores trended higher in AI than inactive intervention (II, N=80 centers) for Nu (0.86+1.71 v 0.10+2.74 p=0.21) and PA (0.96+3.74 v 0.00+3.35 p=0.18), but not C (Nu: 0.45+2.60, p=0.4; PA: 0.80+3.78, p=0.8). The trend in differences between AI and II remained after adjustment for race (25% and 27% primarily black in AI and II respectively) or % of children receiving meal subsidy (>75% of children for 39% of AI and 32% of II). These pilot data suggest the intervention could be effective as an annual state-wide public health initiative, but a larger study is needed

N2 - Inhalation of DPM has been reported to shorten the life of 70,000 Americans each year and to increase the risk of developing brain tumors in children. Environmental radon progeny (ERnP) have been measured in human brain tissues, but how they entered the brain remains uncertain. We hypothesize ERnP may be incorporated in DPM during combustion and enter the body through inhalation. Therefore, we captured DPM on 30 nm filters. The DPM, containing polonium-210 (Po-210) came from a variety of diesel engines operating in normal outdoor atmospheres with radon concentrations from 7 to 33 Bq/m³. Initially, the Po-210 alpha emissions were measured directly from the nanofilters. However, the activity dropped dramatically, presumably due to the volatility of the DPM particles. Therefore, immediately after loading the nanofilters were soaked for approximately 12 hours in nitric acid. Po-210 from this solution was deposited onto silver disks and counted. The observed Po-210 activities were dependent upon the type of diesel engine and the atmospheric ERn concentration

N2 - Background: A positive association between acetaminophen use and allergic diseases is suggested with impaired respiratory oxidant/antioxidant balance and promotion of atopy as proposed underlying mechanisms. The aim of the study was to explore the impact of frequent acetaminophen use on asthma and hay fever. Methods: Self-reported data obtained through the International Study of Asthma and Allergies in Childhood (ISAAC) Phase Three written questionnaires of 5507 children aged 12/16 years from eight cities in The Republic of Macedonia were used for the analysis. The frequency of current acetaminophen use was correlated to current and ever-diagnosed asthma and hay fever. Current intake of fruit, vegetables, cereals and fish as dietary antioxidants and truck passage through the residential street, second-hand tobacco smoke, gas/wood cooking and wood/coal/oil heating at home as parameters of outdoor oxidant exposure were all employed as confounders for acetaminophen use adjustment. The data were statistically analyzed by odds ratios (OR, 95%

CI) in binary logistic regression. Results: Current acetaminophen use at least once monthly, compared to its use at least once yearly/never, was associated with an increased risk of current wheeze (OR: 1.53; 95% CI: 1.21-1.94; P = 0.000), current speech-limiting wheeze (OR: 2.06; 1.36-3.12; P = 0.001), current sleep-disturbing wheeze (OR: 1.69; 1.26-2.28; P = 0.001), current night dry cough apart from chest infection (OR: 1.82; 1.55-2.15; P = 0.000), current rhinoconjunctivitis symptoms (OR: 1.80; 1.46-2.23; P = 0.000), interference of current rhinitis symptoms with daily activities (OR: 1.66; 1.41-1.96; P = 0.000) and ever-diagnosed hay fever (OR: 1.55; 1.21-1.98; P = 0.000). Conclusion: The findings suggest an increased risk of asthma and hay fever associated with frequent acetaminophen use in early adolescence. Until further epi-demiological and biological research results come, acetaminophen should be used only if it is physician-recommended, within therapeutic doses and not frequently

N2 - Background: Historically, the safety and efficacy of specific immunotherapy (SIT) has been demonstrated in (mainly small-scale) studies and confirmed in meta-analyses. However, the inherent sources of heterogeneity (patient selection outside the pollen season, pollen count variations, long evaluation periods) observed in recent, large-scale studies of sublingual immunotherapy (SLIT) tablets mean that highly susceptible patients may not exhibit uniformly a sufficient level of symptoms during the study period to assess the efficacy of SIT. Methods: We performed randomized, double-blind, placebo-controlled, multinational clinical trials of a 300IR pre- and co-seasonally administered 5-grass pollen SLIT tablet in adults and children with allergic rhinitis. The primary efficacy criterion was the mean average rhinoconjunctivitis total symptom score (ARTSS) over the pollen season, during which daily grass pollen counts were measured locally. To evaluate the potential relationship between disease severity and the treatment effect, investigating centres were divided in tertiles according to their mean placebo group ARTSS. Results: Pre-seasonal inclusion of patients on the basis of retrospectively severe symptoms in the previous pollen season did not produce such a severely affected population in the study season. The apparent treatment effect of SLIT tablet was partially masked by the highly variable severity of symptoms during the whole pollen season (mean ARTSS in the adult placebo group: 4.93 ± 3.229). For the adult trial, the mean active versus placebo ARTSSs and the relative difference versus placebo (%) were 15%, 26% and 37% for the low, moderate- and high-disease severity tertiles, respectively. In the paediatric trial, these values were 10%, 33% and 34%, respectively. Linear regression of individual daily RTSS scores and pollen counts in active and placebo groups also showed that the more severe the disease, the greater the treatment effect of SLIT tablet. Conclusion: Inherent sources of heterogeneity must be taken into account when interpreting the results of natural-exposure immunotherapy trials but none obscured the statistically significant treatment effect of SLIT. In a subgroup analysis, SLIT tablets' beneficial effect increased with disease severity

N2 - Background and research objective: In the recent years the essential role of IL-5 and eotaxin in eosinophilia occurrence in patients with allergic diseases has been raised. The goal of this study was to evaluate the importance of IL-5 and eotaxin in blood serum in children with allergic diseases and coexisting eosinophilia. Materials and methods: We have studied a cohort of 27 patients from 3 to 17 years of age with allergic diseases (atopic dermatitis, allergic rhinitis and asthma) with a relative and absolute eosinophilia. IL-5 and eotaxin in blood serum has been detected using IFA method: Bender Medsy Stem (Austria) and Biosource immunoassay kit (USA) (sensitivity 0-1000 and 0-500 pg/ml accordingly). Results: Average value of relative quantity of eosinocytes was $7.65 \pm 0.1\%$, absolute - $0.65 \pm 0.08 \times 10^9$. In all patients we have detected eotaxin, and IL-5 in 11 children. Average level of IL-5 was 5.9 ± 3.1 pg/ml, eotaxin - 84.1 ± 7.8 pg/ml. Cytokines level depended on eosinophilia degree, in patients with the absolute eosinophils level <0.4 , IL-5 level was 1.3 ± 1.06 , and eotaxin level was 77.7 ± 19.76 , in those patients with absolute eosinophilia >0.4 ($n = 17$) it was detected as 8.9 ± 4.96 and 84.7 ± 6.6 accordingly, at higher eosinophilia >0.8 ($n = 10$) - 13.45 ± 7.66 and 89.3 ± 6.66 accordingly. We have found a positive correlation between eotaxin level and absolute quantity of eosinophils ($r = 0.47$, $P > 0.05$). In patients diagnosed with hay fever and coexisting eosinophilia IL-5 level was 2.07 ± 1.05 , and eotaxin - 82.1 ± 8.6 . Outside the pollen season ($n = 8$) IL-5 level was 1.92 ± 1.06 , and eotaxin - 67.6 ± 8.8 while during the pollen season ($n = 10$) IL-5 level was 2.1 ± 1.05 , eotaxin - 88.9 ± 13.8 . Eotaxin level depended on a particular month: in February average eotaxin level was 82.9, while in May - 107.1. In patients sensitized to house dust mite and coexisting eosinophilia has been detected a higher level of IL-5 (10.8 ± 7.02) compared to those patients who had a pollen sensitization, eotaxin level was 77.3 ± 6.7 . We haven't found any difference depending on the allergic disease. Conclusion: To summarise, IL-5 and eotaxin definitely play an important role in eosinophilia development in children with allergic diseases. Level of these cytokines depends on the type of sensitization and allergen exposure but it's requires further research

N2 - Background: Related to the suggested different prevalence rates of allergic diseases in different nationalities living in the same country, the study was aimed to explore the impact of the nationality on asthma in R. Macedonia. Methods: The self-reported data obtained through the ISAAC phase three questionnaire from 5507 adolescents aged 12/ 16 years from eight cities in R. Macedonia in 2006 were analysed. Chi-square test and odds ratios (OR, 95%CI) in logistic regression were performed for statistic analysis of the data. Results: In Macedonian in contrast to Albanian respondents significantly higher prevalence rates of current wheeze (W) and current sleep-disturbing W ($P = 0.000$ for both of them), nonsignificantly higher prevalence rates of current exercise-induced W and inhalant corticosteroids use ($P > 0.05$) and nonsignificantly lower prevalence of ever-diagnosed asthma ($P > 0.05$) were established. In Macedonian nationality a positive association of frequent fast food and paracetamol intake, dog at home, >3 hrs daily TV watching with current W (OR 1.49, 1.11-2.00 $P = 0.009$, OR 1.39, 1.03-1.87 $P = 0.033$, OR 1.38, 1.03-1.86 $P = 0.031$ and OR 1.56, 1.17-2.08 $P = 0.002$, respectively) and of frequent paracetamol intake, trucks passage through the residential street with current sleep-disturbing W (OR 1.72, 1.17-2.52 $P = 0.005$ and OR 1.52, 1.05-2.20 $P = 0.025$, respectively) were determined. In Albanian nationality a negative association only of fruit intake with current W and sleep-disturbing W (OR 0.26, 0.09-0.69 $P = 0.007$ and OR 0.16, 0.05-0.57 $P = 0.004$, respectively) and of cereal intake with current W (OR 0.37, 0.14-0.97 $P = 0.043$) were documented. Conclusion: It seems that the different lifestyle i.e. sedentary regimen, pets at home, frequent paracetamol and fast food intake and outdoor airpollution in Macedonian contrary to Albanian nationality may be responsible for frequent and more severe wheeze attacks

N2 - Background: Air pollution may exercise a detrimental effect on respiratory system, also influencing the allergic sensitization. Methods: We enrolled 228 children (127 boys, 101 girls; mean age 8, range 7-10 years) from two primary schools in different sites for pollution exposure in Milan: the first located downtown (74 children; 47 boys, 27 girls), the second in a large park (154 children; 80 boys, 74 girls). One hundred ninety three children (73 in downtown school and 120 in park school) agreed to undergo skin prick tests to common inhalant allergens: grass, ragweed, birch, olive tree pollens, dust mites, dog and cat dander and alternaria. Written informed consent was obtained from parents. Daily in- and outdoor levels of PM_{2.5} and PM₁ (diameter <2.5 µm and 1 µm respectively) were measured by two detection units for a week during the study (October 2008). Children underwent spirometry, dosage of exhaled nitric oxide fraction (FeNO), skin prick tests and were administered the ISAAC questionnaire. Results: Mean (SD) values of indoor particulates (µg/m³) were significantly (P < 0.01) higher in the downtown than park school: PM₁ 48 (17.3) versus 21 (5.29), PM_{2.5} 62.7 (20.5) versus 43.3 (17.9). The mean values of FEV₁ (SD) and FVC (SD) were significantly lower in downtown school: 102.2 (12.8) versus 106.1 (11.8) (P = 0.02, t-test) and 95.8 (11.4) versus 100.4 (10.7) (P = 0.003). Mean (SD) concentration of FeNO (ppb) was 17 (12) in downtown school and 14.4 (9) in the park school (P = 0.456). Prevalence of sensitization to inhalant allergens did not differ between the two schools, both as a whole (downtown school 32.8% versus park school 27.5%; P = 0.427) and for any specific allergen. The prevalence of asthma exacerbations reported in the previous 12 months was higher in children from downtown school (8.4% in downtown school, 2.5% in park school; P = 0.05); in children allergic to grass pollen (16.4% in downtown school, 22.5% in park school), the prevalence of allergic rhinitis was higher in park school (30.8% in downtown school, 69.2% in park school P = 0.03) with more activity limitation due to rhinitis and associated conjunctivitis (0% in downtown school, 29.6% in park school; P = 0.03). Conclusion: Exposure to higher indoor levels of fine particulates could negatively affect respiratory function. The higher prevalence of allergic rhinitis and consequent activity limitation in the previous 12 months observed in park school might be related to allergen exposure

N2 - The cingulate cortex is a key region involved in the understanding of consequences and in the selection of appropriate behaviour. We have previously shown that a single binge exposure to ethanol during early neonatal life results in the acute death of neurons in the cingulate cortex via apoptosis. This study investigated the long-term consequences of ethanol-induced cell death on the structure of the mature cingulate cortex and on play fighting behaviour during adolescence. On postnatal day (PN) 6, Long-Evans rat pups were randomly assigned to either an alcohol exposure group (E); with daily doses of either 6.0, 5.25 or 4.5 g/kg ethanol via intragastric intubation as two feeds two hours apart; a sham intubation (IC) or a suckle control (SC) group. For one cohort, beginning on PN30, play fighting in pairs (an SC or dose matched E rat) was video recorded for 20 minutes a day on 3 consecutive days. Data was then manually scored. For a second cohort, animals were deeply anaesthetised (sodium pentobarbital 100 mg/kg i.p.) and perfused (4% paraformaldehyde) on PN365. Brains were removed, cryo-protected, frozen and sectioned in the coronal plane at 60 μ m. A random systematic set of sections was stained with thionin and unbiased stereological methods used to determine the number of neurons in the anterior cingulate cortex (Acc). The 6.0 and 5.25 g/kg E groups showed a 39.6 and 30.8% ($p < 0.05$) mean decrease respectively in Acc cells relative to the IC group. The 6.0 g/kg E group also had significantly less Acc neurons than the 4.5 g/kg E group ($p < 0.05$). Preliminary data indicates that alcohol exposed animals differ in their rate of initiation of attack and in their response to attack compared to control animals. Alterations in play-fighting behaviour, that is characteristic of adolescent rats, may have implications for the playground behaviour of alcohol-affected children. For children that have been exposed intermittently to alcohol during fetal life, altered social skills that are used in typical playground interactions, may be the result of neuropathology in the cingulate cortex

N2 - Objective: Prenatal Alcohol Exposure (PAE) often leads to Fetal Alcohol Spectrum Disorder (FASD). Children diagnosed with FASD frequently display symptoms of hyperactivity and deficits in attention span associated with Attention-Deficit Hyperactivity Disorder (ADHD). Rodent animal models have been used to study biological and behavioral consequences of PAE. In the present study, we tested the hypothesis that PAE rats would exhibit hyperactivity when placed in an open field environment. Methods: Pregnant Sprague-Dawley dams (Alc) were intragastrically intubated with ethanol (6 g/kg/day) on gestational days 1-20 and compared to chow-fed (CF) and pair-fed (PF) controls. At sixteen weeks of age, rats were individually placed in a cylindrical gray open field arena (8 ft in diameter and 3 ft high) surrounded on the outside by white sheet curtains. Video tracking software recorded the coordinates of the rat's movements within the arena. SEE (Software for Exploring Exploration) was used to analyze these coordinates. Results: Alc rats had significantly larger average ($p > .05$) (i) total distance traveled [26,631.221 cm] than PF [19,959.641 cm] and CF [20,674.931 cm] controls, (ii) Median Segment Acceleration to Max Speed (the median of a movement segment's maximum speed divided by its duration) [17.5198 cm/sec²] than PF [12.469 cm/sec²] and CF [13.274 cm/sec²] controls, (iii) Median of Move Segment Max Speed (the median of the maximum speed in progression segments taken over all progression segments) [48.831 cm/s] than PF [36.674 cm/s] and CF [41.708 cm/s] controls, and (iv) Quantile 95 of Move Segment Max Speed (the 95th quantile of the maximum speed in progression segments taken over all progression segments) [83.729 cm/s] than PF [58.877 cm/s] and CF [66.164 cm/s] controls. Alc rats also covered more distance in the arena center than the controls, which usually stayed near the arena's edge. Percent activity levels during lingering segments were significantly greater ($p > .05$) in CF [11.3% activity] and PF [12.0%] rats than Alc rats [7.9%]. Conclusion: These results suggest that Alc rats moved more rapidly, accelerated more quickly, covered a greater amount of distance, were less active in lingering segments, and were less confined to the arena's walls than the controls. We conclude that PAE greatly alters open field behavior in adult rats, and may reflect deficits in cognition and/or motor control

N2 - Objective: The safety of Crotalidae polyvalent immune Fab (Crofab) for copperhead envenomations has not been studied in pediatric patients. This report documents the safety of high dose Crofab in a toddler bitten by a copperhead. Case report: A 28-month-old female was bitten on her right knee by a copperhead while playing in her backyard. Her father positively identified the snake, and the patient was transferred to an academic medical center (AMC) after brief evaluation in an outside hospital. On initial evaluation at the AMC (about 4.5 hours after the bite), the patient's right leg was noted to be ecchymotic and swollen from the ankle to the hip, with a right thigh circumference roughly three times greater than the left. Peripheral pulses were diminished and capillary refill was delayed. She was immediately treated with four vials of Crofab and the leg was elevated. Her vital signs and initial laboratory studies were normal, with exception of fibrinogen (149 mg/dL) and WBC (19,800 u/L). She was admitted to the ICU where swelling of her right lower extremity progressed to her umbilicus and both labia. The patient received an additional 18 vials over 24 hours to impede swelling and improve right lower extremity perfusion. Her edema significantly decreased by day three and she was discharged on day seven. No adverse reactions to Crofab were identified. Conclusion: Crofab is effective in treating copperhead envenomation in adults. Limited data is available on Crofab use in children. This case

demonstrates uncomplicated use of high dose Crofab in a pediatric patient with progressive edema following copperhead envenomation

Conference Publication:

IS - var.pagings

N2 - Background: The birth rate for teenagers aged 15-19 years rose 3% in 2006, interrupting the long-term decline from 1991 through 2005. There are many risks associated with pregnancies among adolescents,

including increased maternal morbidity-mortality, infant morbidity, psychosocial and economical factors. In Puerto Rico, the birth rate to adolescent mothers 15 to 19 y/o, in 2000, (67 per 1,000) is higher than in the United States (49 per 1,000). The repeat births reported were 22% of a second child and 6% were of a third child. Adolescents that have repeat pregnancies have been through the health care system. The objectives of this research are to describe the profile of a group of Puerto Rican adolescents with a repeat pregnancy, identify the prevalence of psycho-social factors related to their repeat pregnancies and illustrate observed associations with psychosocial factors. Methods: An IRB approval, #9090109, was obtained for a cross sectional survey of adolescents younger than 21 years of age with a repeat pregnancy attending a prenatal clinic between November 2008 and February 2009. The questionnaire given included information related to: demographics, education, and socioeconomic status; support system; pregnancy history and reasons for not using contraception. The data was then gathered and analyzed using χ^2 Yates Correction with a significance of $p < 0.05$. Results: The total participants recruited were seventy (70). The ages of the participants were from 12 to 19 (12, 1%; 16, 12%; 17, 11%; 18, 27%; 19, 46%). Their partner's ages ranged from 16 to 38, with a mode of 19 and 21, while 33% are between 21 and 23, 23% between 24 and 29, and 11% between 31 and 38. Their main activity at the time of the study was house work (36%), studying (26%), not working in or out of the house nor studying (23%) and working outside the home (16%). Among all of them, 63% had left school before becoming pregnant and 60% received government help. Only 3% of the participants live alone, while 56% lives with their partner and 41% lived with their family, some including their partners. Of all the participants, only 10% were legally married. The use of contraceptives was significantly ($p < 0.05$) associated to older partners. Partners wanted the pregnancy in 49% and adolescent wanted the pregnancy in 48% of the cases. Other results will be presented. Conclusions: Psychosocial factors are associated with failure to use contraception among adolescents with repeat pregnancies in Puerto Rico. The factor that was found that influenced the most was a partner over 20 years of age. It is important to take into account the age of the partner, the level of education and the motivation in pregnancy postponement programs

IS - var.pagings

N2 - Background: Schizophrenia (SZ) occurs throughout the world with a prevalence of 1%. As much as 80% can be attributed to genetic factors. Individuals with SZ reproduce at a lower rate: females produce 50% as many children as normal; males 25%. Genetic factors accounting for SZ should therefore behave like highly lethal genes. Laws of Hardy-Weinberg equilibrium predict that SZ should disappear from the human gene pool. How can we explain the persistence of SZ at a constant frequency of 1%? Methods: Clinicians appreciate that the natural course of SZ varies widely from patient to patient and cannot be predicted. The Clinical Antipsychotic Trial of Intervention Effectiveness (CATIE) concluded that the response of any individual with SZ to treatment with 2nd generation antipsychotic agents cannot be predicted: either the effectiveness of the treatment or the myriad of possible side effects. Each clinical intervention is a clinical trial. More than 50 candidate genes have been identified within kindreds with high frequencies of SZ. There is no identified candidate gene common to all afflicted patients. The development of nucleic acid hybridization technology has revised our understanding of the structure and function of the human genome. Several recent publications have identified chromosomal rearrangements of large coding and non-coding regions including certain candidate or neurodevelopmental genes. Structural variations such as microdeletions and/or duplications range from 100 KB to 15 MB. Microduplications may include copy number variants. Importantly, these chromosomal variants were not found in parental genomes. They are post fertilization or in vivo mutations. In vivo mutations are found in control DNA at a frequency of 5%, in SZ DNA at a frequency of 15%, and among children with the most severe childhood-onset SZ (COS) a rate of 22%. Results: Balanced polymorphism is the hypothesis explaining how non-adaptive genetic factors are maintained in natural populations in combination with other genes to confer increased fitness to the entire population, thus insuring their preservation in the gene pool. Diverse evidence suggests a neurodevelopmental model of SZ, the autism spectrum, Asperger's Syndrome, and others. A family of genes has been identified that are activated by diverse extracellular mechanisms. They are the interface between the organism and its environment, at the cellular and organismic level. An example of such a regulatory gene is Disrupted in Schizophrenia (DISC-1). Neurodevelopmental genes account for the organization of complex neuronal networks that are analogous to organogenesis. In vivo mutations are a normal part of the development of the brain but occur more frequently in patients with SZ and most frequently among

patients with COS. In vivo mutations are not passed on to the next generation. Discussion: Genetic elements which are adaptive must exist to account for the persistence of SZ as well as its familial pattern of inheritance. A different class of neurodevelopmental genes in SZ, must exist to increase the rate of in vivo mutations within the CNS and must, in combination with other genetic elements, be adaptive to account for their preservation in the human gene pool. Such a gene, operating outside the CNS, would be expected to be highly lethal by generating oncogenes. These hypotheses, in conjunction with the findings of CATIE raise the possibility that each patient with SZ may be genetically unique, a phenocopy

N2 - Background and Aims: Autoimmune Hepatitis (AIH) is a hepatocellular inflammatory disease characterized by interface hepatitis, portal lymphocyte infiltration, circulating autoantibodies, and hypergammaglobulinemia. In Brazilian patients HLA-DRB1^{*}13 has been identified as the major susceptibility gene variant associated with the disease. Additional genes located outside of the MHC region may contribute to overall disease susceptibility. The cytotoxic T lymphocyte antigen-4 (CTLA-4) protein is an inhibitory receptor expressed on the surface of activated CD4 T helper cells playing a key role in the downregulation of T-cell activation, and has been associated with several different autoimmune diseases. At least three polymorphisms (SNPs) have been described for CTLA-4. The G allele called CT60 in the 3'UT portion of the CTLA4 gene is associated to lower mRNA CTLA4 levels, and consequently to decreased CTLA-4 protein levels, which would result in defective modulation of T cell-mediated inflammatory responses. This study looked for the association of CTLA4-318C/T, +49A/G and CT60A SNPs, and CTLA4 haplotypes, with AIH-1 in Brazilian children. Methods: SNPs were analyzed in 105 Type 1 AIH Brazilian children (AIH1) and in 228 healthy subjects (CTRL) by the polymerase chain reaction restriction-fragment length method (PCR-RFLP). Results: The G allele at CTLA4 CT60 and the corresponding GG genotype showed slightly higher frequencies in AIH1 compared to CTRL, with borderline p values ($p = 0.0540$ and $p = 0.0508$). The CT60 G allele is also part of the CTLA4-318C, +49A, CT60G haplotype, which exhibited a significant association with AIH1 compared with CTRL (23% vs 15%, $p = 0.0166$). The other SNPs had similar distribution in the two groups, suggesting that CT60 is the primary susceptibility variant marking this gene. Conclusions: The CT60G CTLA4 allele and the CTLA4-318C, +49A, CT60G haplotype are associated with AHI-1 in a pediatric sample of Brazilian patients. Supported by FAPESP

N2 - Background: The use of stimulant drugs for attention-deficit/hyperactivity disorder (ADHD) has raised questions about the possibility of overtreatment. It is necessary to develop biologically-based criteria to adjust treatment appropriately. Near-infrared spectroscopy (NIRS) is a noninvasive neuroimaging method that can measure relative changes in the concentration of oxygenated hemoglobin ([Oxy-Hb]) in cortical tissue in natural settings. The stop signal task is suitable for detecting the dysfunction of response inhibition in ADHD. The aims of our study were to examine the bilateral prefrontal activation associated with response inhibition by using multi-channel NIRS in children with ADHD, and to develop a neurophysiological index which predicts the effect of continuous administration of methylphenidate hydrochloride (MPH) on the cognitive function evaluated by Das-Naglieri Cognitive Assessment System (DN-CAS). Methods: Participants were 14 children with ADHD and 20 typically developing children. We defined the children with ADHD whose total score or subscale score of DN-CAS was improved after administration of MPH as responder (ADHD-R) and the children with ADHD whose score was not improved as non-responder (ADHD-NR). Results: ADHD-NR showed the lower [Oxy-Hb] increase than ADHD-R and typically developing children during the activation task in right dorsolateral prefrontal cortex (DLPFC) ($p < 0.01$). Conclusions: The activation of [Oxy-Hb] in right DLPFC represented the difference of the frontal lobe function between responder and non-responder before administration of MPH. These results suggest that NIRS might be potentially useful as a neurophysiological index which predicts the effect of MPH in children with ADHD. Graph Presented

N2 - Introduction: School closure is often recommended for mitigating the impact of an influenza pandemic. Little is known, however, about the impact of school closures on students and families. Aim: To describe the behaviour of students excluded from school due to school closures and parental opinions of school closure as a pandemic influenza control strategy. Methods: Parents/guardians of all students at the three schools excluded from school attendance due to school closure were surveyed seven days after the closure ended to ascertain their child's age and illness status, childcare arrangements, whether the child went out of the home during the school closure, and parental opinions of school closure. Results: Surveys were returned for 233 (58%) of the 402 students (range 5- 13 years, median = 11) affected by school closure. Twelve (5%) of the 233 responses were from confirmed cases, 143 (61%) from contacts and 78 (34%) from student peers (neither a case nor contact). Fourteen contacts (10%) and five peers (6%) developed respiratory symptoms during the closure. A total of 172 (74%) students went outside the home on >1 occasion during the week of closure, including 42% and 66% of cases and contacts. The mean number of outings was 3.7 (range: 0-24). Less than half the parents (47%) thought that school closure was appropriate. Cases and contacts, and children of parents who thought school closure was appropriate were less likely to report activities outside the home. Forty-five percent of parents of asymptomatic students reported taking time off work (range: 1-5 days; median = 3) to care for their child and 71 (35%) had to make additional special childcare arrangements. Conclusion: Nearly three-quarters of students undertook out-of-home activities during school closure. These findings can be used to predict more accurately the effectiveness of school closure as a disease control strategy

N2 - Introduction: Cryoablation is an alternative to radiofrequency ablation of cardiac arrhythmias. In some circumstances it may be the treatment of choice, e.g in small children. Temporary effects during cryoablation such as increases in effective refractory period and AV nodal block have been observed clinically but have so far not been explained. Methods: Hearts from healthy Yorkshire pigs (40-60 kg) pigs were isolated, Langendorff perfused and optically mapped with a voltage sensitive dye (di-4-ANNEPS). Cryoablation was performed with a 5 mm tip at -120degreeC at three endocardial ventricular locations for 8 min. Optical voltage mapping data was obtained using two high-speed CCD cameras and a custom 520nm light source. Epicardial temperature profile was imaged via an infrared camera at 1 frame/s. Both voltage and thermal mapping were performed during and for 15 min following cryoablation. Maps of activation time, signal magnitude, APD90, and conduction velocity were generated. Correlation between epicardial temperature and signal parameters was performed. Loss of tissue function was defined as regions where voltage magnitude was below 10% of baseline level. Results: Regions outside the visible ice ball experienced temporary conduction changes such as reduced action potential magnitude, reduced conduction velocity, slower de- and repolarization, and an increase in APD90. As a result, late activation of epicardium was observed located proximal of the permanent lesion in relation to the pacing site, and disappeared after tissue warmed back to body temperature. APD90 increased from 262.1+/-12.2 ms at 36 degreeC to 295.0+/-7.1 ms at 22 degreeC, with no further increase at lower temperatures. Conduction velocity slowed by a factor of ~2.4 for every 10degreeC, and regions of slow conduction correlated with locations of reduced epicardial surface tissue temperature. These changes were completely reversible and disappeared upon rewarming, approximately 4 min after the end of cryoablation. Conclusions: Temporary changes in cardiac conduction were observed surrounding the permanent cryo lesion and may explain temporary effects observed during clinical cryoablation procedures

N2 - Objective. To compare a 6 week, recess-based, active video game intervention with traditional recess activity. Methods. Thirty, 10-11 year old children (12 boys, 18 girls, 16% overweight; 6% obese) were randomly allocated to intervention (N =15) or control (N =15) groups. The intervention group undertook twice weekly sessions of active video gaming during school lunch breaks. The control group took part in traditional' recess activity. Height and body mass (from which BMI was derived) were assessed pre and post the intervention period. Heart rate and pedometer data, assessed during the first, third and sixth weeks, were used to quantify physical activity over time and between groups. The children also participated in focus group interviews pre and post the intervention to determine their lived experiences of active video gaming as a physical activity tool. Results. Repeated measures ANOVA indicated a significant steps by group interaction ($F_{2, 56} = 3.88, P = 0.02$) with number of steps/min being greater for the intervention group on the first week of the intervention period but lower than the control group at the mid and end points of the 6-week period. The percentage of time spent in moderate and vigorous physical activity ($F_{1, 28} = 15.6, P = .0001$) was significantly lower in the intervention group across the intervention period. BMI was not significantly different across time or group ($P > 0.05$). Conclusions. These findings suggest active video gaming may not be a sufficient stimulus to enhance children's recessbased physical activity in the long term

N2 - Objective. Assessment of physical activity habits and factors that can promote or inhibit activity in kindergarten age children. Methods. Self-administered questionnaires were filled in by the parents of 1063 children attending kindergarten in Italy, Poland and Denmark. Statistical analysis: χ^2 test. Results. 50% of Italian parents as compared with 99% of Danish parents and 96% of Polish parents stated that, in the area where they lived, children could play outside their home. The most frequently reported obstacles were heavy traffic (52%), and the absence of a park/house yard (24.7%). On weekdays, only 19.8% of Italian children and 19.5% of Danish children spent more than one hour playing outside per day as compared with 35% of Polish children. 11% of Italian children never played outside ($p > 0.0001$). On weekends, 91% of Polish children and 86.7% of Danish children, but only 50% of Italian children played outside for more than one hour. 8.4% of Italian children never play outside ($p > 0.0001$). Conclusions. The urban environment in Italy, even in small towns, is not built according to children's needs or Italian parents perception of risk is higher than in other countries. For 3-6 years old children the most natural way to be active and to develop healthy and positive attitudes to physical activity is to play freely. Low levels of PA in Italian children can partially explain their higher rate of being overweight. Grants: Periscope (AN 2006341) EU Public Health Programme framework SN - 1747-7166

IS - var.pagings

N2 - Early Intervention: E. Poskitt: When one looks at policy and legislation it's relevant to make note that obesity is well established by the time the child gets to school. Research has indicated some of the things that happen in pregnancy or in the first weeks of life (rapid weight gain and fatness) are the things that contribute to the obesity later on. It is physiologically normal for a baby to be fat. In the past (30 years ago) 80-90% of fat babies slimmed down to normal five-year old children. We have to get the environment at weaning and beyond right so that we can go back to this natural slimming down before they start school at age five. Audience-T. Wilkin: It is important to remember that once children get to five they are set on a trajectory. Therefore the opportunity for intervention by implication lies before age five. M. Flynn: Recent work by our group found that in Ireland, by the time an infant is six-months they have already tasted chips, salty bacon, crisps and chocolate pudding. The fact that chocolate pudding exists for babies at 4-6 months raises questions regarding the type of message this gives parents. E. Roche: We need to intervene with education and advice on primary prevention before children are born and then at every healthcare meeting thereafter. M. Lordon Dunphy: In Ireland we have a national nutrition policy that specifically targets those less than five years. On the parental side, our national campaign looks at parents as role models for their children. We have seen a shift in parents' ability to identify their important role as role models to their children. E. Poskitt: Children need to be taught that "no" means "no" and that though the child is important in the family, he/she does not rule the family. Another important aspect is having a regular bedtime, which may be very important in the development of obesity. Finally, we must not send the message that parents of children who are obese are bad parents. R. Malina: We need to monitor day-care and pre-school more closely. Some centres want the child to sit and be quiet throughout the day. As such, we need to educate those people who take care of the child and this will require major changes. Activity: R. Malina: Physical activity peaks at ten-eleven years and then declines. If we look at the participation of children in youth sport, it increases in general from six to eleven years and then declines. Kids define physical activity as sport. As such, one strategy is to get local organisation to modify sport to meet the needs of our children. It might contribute to increased physical activity levels and may contribute to the prevention of obesity. Regarding research in the area of physical activity, papers focus on group means and the cult of significance. We need to be aware of individual differences, as some youngsters may gain weight and some lose weight. We need to do

our statistics carefully and not overlook variability as not all will respond to conditions in the same manner.

Audience-T. Wilkin: There are two different aspects to physical activity. One is that physical activity is effective at improving cardiorespiratory and metabolic fitness. The other is whether we can indeed use physical activity to improve body mass. If we can, does it have a meaningful impact? These distinctions are important and at the moment they are being confused. If we use body mass as an outcome measure of physical activity intervention we may not see any change. We may need to shift our focus away from body mass and instead move toward the use of fitness testing or blood sampling to test the effect of physical activity interventions.

Audience-ML. Frelut: When asking why people escape moving and choose sedentary pursuits we must remember that children live now in a world of major permanent constraint at school and elsewhere. Sedentary games at home are their space for freedom. Also, many children are lonely and competition is only another way for them to be lonely, while using the internet, watching TV and playing video games are ways to be with the others.

Audience: It's vital to link these children with activities that they enjoy.

M. Lordan Dunphy: Ireland's Participation Strategy aims to engage children at all levels with their local sports partnerships and there is a special focus on teenage girls.

E. Roche: Girls are falling out of exercise early and these are the future mothers of future generations. Sport is very oriented toward team games and the Irish sports council has made the attempt to broaden this definition.

Policy: T. Lobstein: If we are to think outside the box we need to think on a public health level rather than the individual level. Once the environment is altered then we can work on individual behaviour. Some environmental changes are very simple like providing healthy school meals and bicycle lanes. We need to make the opportunity to be active more secure and safe and also food policy and taxing need to be discussed.

M. Flynn: Indeed laws on marketing exist as does good legislation from the EU on the regulation of health claims. However, having been involved in the legislation workshops since 2006, I'm dismayed to have seen this legislation picked apart. I do not know where the consumer group-voice is. It appears we are tiny and that the industry lobby are winning.

Audience-A. Vazeou: It is clear that if we improve the eating habits of the masses then we will have better results on the individual level.

Audience-H. Thibault: In France, there is a law since 2004 that vending machines must be banned in middle and high schools. It has been effective. At the same time morning snacks in primary school are not recommended. We are for individual liberty but sometime we need to recognise that law can be useful.

Audience: Regarding that point, the schools are not happy that vending machines are forbidden as they usually yield a lot of money for the schools.

Audience: We know that structural prevention by imposing rules works, and that influencing the individual's behaviour change is difficult as we are talking to archaic feelings within us. For example in the STOP programme in Sweden, bringing candy and unhealthy foods to school was banned. It is evident now that children are bringing this message home to their parents who in turn can modify the home environment with less resistance.

E. Poskitt: We have to think hard about how we get people to do healthy things as imposing rules may not be successful. Sometimes coming sideways at these issues by removing poverty and deprivation might be effective though this method is slow. In addition, similar to the case in developing countries, non-governmental organisations work in parallel rather than together. This leads to duplication of materials and wasted resources.

M. lordon Dunphy: I think that joint business planning across the various governmental departments is imperative as there is a lot of duplication of information, which can confuse the public and uses up resources.

Industry: M. Caroli: Ted Kennedy once said "who is responsible for the control of advertising, marketing and promotional activities which market products in spite of public health consideration ". If we are honest that responsibility lies with everybody.

C. Faenza: I work in the product's quality control department of COOP, the most important Italian retailer, and I can say that formulating recipes with fats and sugars is easier and cheaper from a technical point of view. Coop's actions are the concrete demonstration that it is really possible to find innovative solutions in terms of healthier product- formulation and still keeping in mind the need to achieve a positive budget at the end of the year. COOP is an ethical company and believes in social values; thus, with the aim to facilitate our consumer in making healthy choices, COOP has reformulated its children's products. We have developed a new specific range of healthy products for children. These have an increased fibre content, a lower content of sugar, sodium, and fats and use only natural flavourings. Secondly for all our existing products which cannot be feasibly re-formulated we have decided to discontinue their production altogether. This policy is very different from one which only adds a healthier line of products to an existing unhealthy one.

J. Waligora: Regarding health regulation, the final legislation that we have for industry is not perfect. We have to realise that so many differences exist between each member state of the EU and what each would like to achieve. As such, it's difficult to find consensus. Secondly, we need to have dialogue with both the member states and industry if we want to achieve our aims

N2 - In this presentation I shall focus on the issue of protecting children from commercially-led persuasions to purchase and consume unhealthy foods. This immediately raises a question - what foods are unhealthy? I shall return to that issue shortly. Before discussing how to protect children, we need to consider what is currently happening - what is the nature and extent of commercial persuasion. When we have an understanding of this, we can discuss what measures would be appropriate to protect children. The forms of persuasion are many: I can only show a few in this presentation. They range from the familiar, such as TV commercials and advertising in cinemas, through to more unusual techniques, including internet sites, branded toys, packaging and the compositions of the foods themselves. Text messages to phones, viral marketing messages on Facebook, product placements in computer games, plus for younger children, product placement in story books and counting books. Free gifts with products, games and puzzles on product labels, and I would argue that the addition of colours and artificial flavours are really marketing methods, to make an object more appealing to children. The extent of marketing can be considered in terms of the amount of spending by industry on promoting their products. This is not easy to identify, especially as the available figures do not distinguish child-oriented and non-child-oriented commercial promotions. Further, the figures available do not include all the activities used by companies, such as internet sites, product labelling, and product composition. We can also get some feel for the problem by asking how many advertisements children are exposed to on TV, for example. The figures vary across countries and interestingly the variation matches to some extent the variation in obesity levels among children in those countries (Lobstein and Dobb, 2005). Advocacy organisations have been arguing for many years that children should not be exposed to junk food marketing messages. The Sydney Principles launched at the ICO in 2006 made a clear statement of the need to protect children. In Europe, the WHO organised a meeting on the issue in 2006 and launched a Network of governments sympathetic to the protection of children from marketing in 2007, chaired by Norway. The World Health Assembly in Geneva in 2007 called for its officials to prepare a draft set of recommendations on the issue, to be presented in 2010. IASO, with Consumers International, launched a set of recommendations in the form of an International Code in 2008 (see www.iosf.org/documents/Consumers-InternationalMarketingCode.pdf) and has contributed to the WHO consultation on the issue. The Network chaired by Norway has also drafted an international code (in press), with some very similar recommendations to the IASO-CI code. The European Commission has made some bold statements about the need to control marketing to children, but has been slow to take any solid action, preferring a voluntary model. Meanwhile there have been moves at Member State government level to exert some control over the types of ads and the numbers of ads seen by children. Ireland has banned specific techniques - such as the use of celebrities - and is considering further controls. Both Sweden and Norway have general restrictions on marketing of any products to children under age 12. France requires health messages to be included on any food product advertisement on TV or in print. The UK has perhaps gone the furthest, by banning ads in children's programmes or directed to children under age 16, and the UK has specified what it means by junk food: using a 'nutrient profile' model based on positive and negative aspects of the nutritional quality of a product. It is now possible to say what is 'healthy' and what is not, and to get industry to comply with this distinction, even if they dislike it. I believe this could not have happened if we had relied on a voluntary approach. I do accept that some food companies have taken steps towards recognising the need to restrict marketing to children, and have offered some new thinking in just the last year or two, including some 'nutrient profiling' of their own (but this differs between different companies). Companies have also offered a higher age threshold, increasing it from 6 years to 12 years and in some examples 14 years. Companies have promised not to market to children in primary school settings. They have also promised not to advertise in programmes where children are over 50% of the audience (and some companies have strengthened this to 35% and even 30% of the audience). But big questions remain: what about the companies that do not join in the agreement? What happens to voluntary agreements after a few years when we have stopped making such a fuss? What penalties are there for a company if it breaks the rules it made? And what about all the loopholes in the voluntary agreements that allow a wide range of techniques to continue? The problems with a statutory approach are that legislation would have to be very detailed to cover all the possible methods for marketing to children. TV controls are relatively straightforward, but writing the same sort of legislation for all the different possible media would be extremely difficult. The other issue is the cross-border problem, where marketing is coming in from outside the jurisdiction of a country, through internet, satellite, and imported media such as Olympic Games broadcasting, computer games and so on. A compromise approach being tried in some countries is 'co-regulation' which can take various

forms, but could include a tough set of standards set by government to which industry signs up. There has to be some persuasion to get industry agreement, such as the threat of tough legislation. Then the standards are monitored and enforced by a body including industry and non-industry stakeholders. There are problems with this model, and there will be loopholes that industry will exploit. But it may represent the best available compromise when large multinational corporations have advertising budgets greater than the economies of several countries, and in a political climate that is strongly pro-free market

N2 - Several etiologies have been postulated for the childhood obesity epidemic, including genetics (e.g. "thrifty gene" theory), the "weight set point", and "low metabolism." Sedentary lifestyle (e.g. playing on the computer instead of the playground), less nutritious food at school, "supersized" portions, and consumption of soda and junk food' all contribute. However, none of these theories or factors adequately explains the meteoric rise in childhood obesity or why treatment is only marginally successful, with dismal long-term results. What does explain it? Kids do! This presentation will reveal what tens of thousands of overweight children say in nearly 130,000 bulletin board posts on an open access website for overweight teens and preteens over a nine-year period. Children come to the site mainly on their own via search engines, links on other sites, and links in books. Many children are from Europe, as well as the U.S. With stunning honesty, these children share their difficult lives, their shame and secrecy, and their struggles and successes. Most say they're too embarrassed to talk to their friends, parents, or even their doctor. Numerous messages express a striking struggle to lose weight. Many explicitly describe using the pleasure of food and the displacement activity of eating to cope with depression, stress, anger, loneliness, anxiety, and boredom. Even grief is described from giving up "my best friend", i.e. food. The majority of messages ask, "How do I lose weight?" If a child posts any degree of success, multiple replies immediately ask, "How'd you do it?" Success stories typically describe distractions from food, improvement in the happiness level of the child as a predecessor for losing weight, and tolerating withdrawal-type symptoms. These children use food to cope with life. They become hooked on this behavior and are unable to stop. They struggle to resist cravings for pleasurable food, particularly junk food,' in spite of full awareness of the negative impact that overweight has on their lives and the dreadful effects of further weight gain. Many say that their eating is "out of control. " This is suggestive of an addictive quality, or psychological food dependence, which is further supported by the many explicit descriptions of using food as: 1) a stress coping mechanism (displacement activity similar to nail biting); 2) selfmedication for depression, loneliness, and anxiety (comfort eating); and 3) entertainment (to combat boredom). Some children explicitly state that they use food "like a drug." The professional community generally offers healthy diet and exercise as the solution to the overweight problem, however these children say that information is often unhelpful. A new paradigm will be explored in regard to what is really causing the childhood obesity epidemic and what should be done about it from a treatment, prevention, and policy standpoint. The perfect storm' of increasing youth stress levels combined with the rise of the Comfort Food' industry will be examined. Perhaps overweight and obesity in childhood should be treated similarly to forms of substance dependence, by: 1) sequential weaning from each abused food or excessive portion size; 2) management of resulting withdrawal' symptoms; 3) coping skill training; and 4) long-term support to prevent relapse. Public policy would control exposure of children to highly abused foods. Proposed weight loss techniques to combat psychological food dependence will be presented, e.g. getting through withdrawal -type cravings, substituting non-food ways to cope, combating stress, and generating healthy self-esteem and joy in living. The session also will include multiple, compelling video and audio clips.

Learning Objectives: a) Appreciate what the lives of overweight children are like and why they struggle to lose weight. b) Learn what overweight kids say about their parents and health professionals. c) Understand why the current theories on the causes of the childhood obesity epidemic do not fit. d) Realize the role of the "comfort food" industry in the childhood obesity epidemic. e) Comprehend what may be a little understood but substantial component of the childhood obesity epidemic, including fresh ideas on treatment and prevention

N2 - Purpose: Urban communities with high sexually transmitted infection (STI) prevalence often have disparities in unplanned pregnancies among young women. Research using single measures of pregnancy desire and/or intention has not yielded guidance on dual prevention strategies. Exploring childbearing motivation (CBM), the first step in the psychological sequence to childbearing behavior, may enable us to better understand reproductive decisions. The objective of this study is to examine the relationship between CBM and use of hormonal contraception, condoms, and dual contraception. Methods: A cross-sectional household study was conducted from 2004-2007. Data was collected from 297 sexually active females 15-25 years in age residing in high STI- prevalent neighborhoods in Baltimore, Maryland. Participants completed audio-computerized assisted self- interviews eliciting demographic, reproductive history and behaviors, and CBM. CBM was measured using a youth-specific adaptation of Miller's childbearing questionnaire. Positive (P)CBM subscales included measures of satisfaction from raising a child, feeling needed/connected, value of children/ parenthood, and positive aspects of pregnancy, birth, and infancy ($\alpha = .94$). Negative (N) CBM subscales included discomforts of pregnancy and childbirth, fears/worries/stressors of parenthood, and negatives of caring for child ($\alpha = .85$). The highest and lowest quartiles from each subscale were combined to create overall positive (high PCBM/low NCBM) and negative (low PCBM/high NCBM). Data outside of these groups was characterized as intermediate (I). Data were evaluated using multivariable regression analyses. Results: Participants were 90% African American with a mean age of 19.4 (SD 2.8). More than half (55%) had a history of pregnancy and 42% had children. 35% had a history of STIs. Using the quartile-based groups (21%; $n = 64$) were in the positive CBM group, 39.3 were in the negative group, and 39.7% ($n = 118$) were in the ICBM group. Those in the ICBM group were less likely to use condoms at last sex with main partner compared to the NCBM group (AOR: .54; 95% CI: .32-.93), controlling for STI history, pregnancy history, and age. Those in the PCBM group were 2.8 times more likely to use hormonal contraception (AOR: 2.75; 95% CI: 1.35, 5.62), and 3.3 times more likely to use dual contraception (consistent condom use with hormonal contraception) with their main partner (AOR: 3.31; 95% CI: 1.46, 7.50) compared with those in the NCBM group, controlling for STI history, pregnancy history, and age. Conclusions: Young women with overall positive attitudes about parenting are more likely to engage in simultaneous family planning and STI/HIV prevention behaviors than those with NCBM. Those in the intermediate group who appear to be ambivalent or indifferent about parenting are at highest risk for STIs due to inconsistent condom use compared with those in NCBM group. Given the health disparities associated with early childbearing and STIs, additional research exploring how CBM evolves over adolescence and the potential role of CBM in the prevention of STIs and unplanned pregnancy is warranted

 N2 - Aim: Previous studies have shown a relationship between Inflammatory Bowel Disease (IBD) and psychological stress (PS); there is increasing evidence that PS can adversely affect the course of IBD in children and young adults. Emerging trials tend to demonstrate that psychological intervention is necessary as well as conventional therapy. Medical literature is not so rich about the role of psyche in biogenesis and maintenance of IBD in pediatric patients. Studies of Psycho-Neuro-Endocrine-Immunology (PNEI) have pointed out how stress can become disease, giving a scientific dignity to assumptions that in the past were only scientific speculation. PNEI studies have shown in gastrointestinal tract the presence of about 100,000 neurons secreting peptides, independent of Central Nervous System (CNS), that are however linked to CNS through the Autonomic Nervous System, today better known as Gut-Brain. Thus, our gut must be considered as a potent neuro-endocrine-immune complex, autonomous and in continuous contact with the outside (food) and the internal

(brain, emotion, disorders, diseases) world. Objectives: Our observation started from the relief of a high number of relapses in IBD patients already receiving medical therapy, after the devastating earthquake interesting Abruzzo (a region of Central Italy) in April 2009. Our study started with the objective of capturing the correlation between stress (triggering event) and relapse or first manifestation of the disease. We are also in charge of studying the relational dynamics of families with a child affected by IBD, to highlight any common relational mode. Another important objective was to motivate willing families to a path of individual or family psychotherapy and therefore to assess the evolution of the disease after a certain period. Material and methods: 70 families of children with IBD and treated in our Centre have been called for a psycho-diagnostic interview lasting 60-120 minutes (in any case all the necessary time to collect relevant information). The interviews were conducted by a doctor specialist in psychotherapy and a psychologist. Results: 80% of cases showed distrust and skepticism toward the initiative, a 10% refused the interview. There were no significance differences in the relationship of families of patients with Crohn Disease (CD) or Ulcerative Colitis (UC). It was always revealed a relationship between perceived stressful event and the onset of symptoms. The following transactional characteristics were common to 90% of households: 1. enmeshment; 2. hyper-protectiveness; 3. rigidity; 4. lack of conflict resolution. Particularly, three patterns of involvement have emerged, giving the impression to prevent the emotional disabling: a. triangulation; b. coalition; c. deviation. We were able to motivate 50% of households to undertake psychotherapy. Preliminary data are suggestive of hypothesis that relapses can be reduced by psychotherapy. Conclusion: It seems clear that in those families with a child affected by CD or UC, the family system is characterized by rigid and poor transactions and that the patient plays a major role in interactive models of avoidance of family conflict and of maintenance of family homeostasis. It seems also evident that this role is a source of reinforcement for his own symptoms. The study is still ongoing, rather we are just beginning: we intend to review the evolution of the disease after an appropriate psychotherapy path

N2 - Introduction: Cardiac 31P-MRS is the only non-invasive in vivo technique for the determination of cardiac high energy phosphate metabolism. Changes in cardiac phosphocreatine to adenosine triphosphate ratios (PCr/ATP) occur in common cardiac pathologies and have diagnostic, prognostic and therapeutic utility. However, long acquisition times (20 minutes or more, depending on heart rate) required to achieve sufficient signal to noise ratios for reliable interpretation have limited the clinical utility of 31P-MRS studies in patients with severe cardiac disease. We have developed an 8 minute 31P-MRS protocol and demonstrate the validity of this 'short' acquisition by comparison with a 'long' (at least 20 minutes) method of published reproducibility (Tyler, NMR Biomed:2008). Purpose: To design a robust, 'short' cardiac 31P-magnetic resonance spectroscopy (31P-MRS) protocol which facilitates acquisition within a clinically acceptable timeframe. Methods: Protocol development This 'short' protocol essentially incorporates a larger voxel (93 mls compared to 39 mls for 'long' protocol) but eliminates extra myocardial contamination by: * active suppression of chest wall muscle and liver signals, * raw data acquisition weighted to reduce contamination arising from outside the nominal voxel. The accuracy of the data and its interpretation is improved by: * optimised radio frequency () pulse, * flip angle calibration (at voxel of interest) used during postprocessing to calculate and correct for subject variation to coil loading. * calibrated signal enhancement (Nuclear Overhauser Enhancement (NOE)), * rapid repetition time (with calibrated saturation correction). Validity: 22 healthy volunteers (age 42 + 16.5; 13 males, 9 females), were scanned (3 T Siemens Trio) with both the 'long' and 'short' acquisitions. Acquisition parameters for both protocols are summarised and compared in Table 1. (Table Presented) Results: There was no difference of derived PCr/ATP ratios for both methods ('short' 1.83 + 0.32; 'long' 1.78 + 0.27). Bland-Altman analysis demonstrates excellent agreement between the two methods (Figure 1) confirming equivalence for clinical purposes. Figure 2 shows an example of spectra acquired from one subject, using both methods. Conclusion: We have developed a novel 'short' cardiac 31P-MRS protocol of high data quality. This protocol allows cardiac spectroscopy to be measured in patients who are often intolerant of long acquisition times, such as those with severe cardiac disease and children. Hence this work provides a useful tool for the routine clinical assessment of cardiac 31P-MRS. (Figure Presented) (Figure Presented)

N2 - Background: Studies have questioned swimming, especially total hours swam in a life time (THS), and swimming in indoor chlorinated pools (ICP), to the development or worsening of asthma (A), based on chlorine chemical exposure. This study explored the frequency of active asthma (AA) among swimmers(S)based on:(1) THS;(2)and the frequency of AA versus THS of S using ICP compared to chlorinated outdoor (OCP) pool facilities. Methods: IRB approval was obtained from Children's Mercy Hospital in Kansas City. 1500 surveys were distributed by coaches to the parents of S ages 5-18y/o participating in a variety of Kansas City competitive swimming programs. Responses were collected by the study investigators. Each survey queried THS in ICP and OCP. Estimations of swimming hours spent in swim venues were given. THS were categorized as follows. 0-99(A);100-249(B);250-499(C);500-999(D);1000-1499(E);>1500(F) for each type of facility. Queried was whether S have health care provider diagnosed A and if A meds were used in the last year (criteria for AA). S gender and age were also noted. S were age bracketed by std USA swimming divisions. Results: An independent samplest test was used. For AA, there was a marginal difference overall between S in groups (grp) A-F t=1.73 (301), p=.085, and S in ICP in groups A-F t=1.68(209), p=.094. There was a sig differences between S in OCP grp A-F t=2.48(287), p=.014. There was no difference of AA between male S in ICP, OPC or overall in grp A-F. In female S, AA was significant in hours spend in OCP t=2.45(139), p=.016 and ICP t=2.15(104), p=.034. AA frequency by age bracket had a significant correlation between 9-10 y/o S in OCP t=2.039(69), p=.045 (primarily driven by females at this age), and 11-12 y/o in OPC t=2.55(60), p=.013. No differences in AA noted between age groups for A-F overall and ICP. Conclusion: Our study supports the notion that

increased hours of swimming may contribute to the persistence of AA in both ICP and OCP and female S may be more at risk for persistence of AA than males as THS increases. S ages 9-12y/o appeared to have an increased frequency of AA, particularly in females. Although the results are interesting, as swimming is often recommended as a sport for AA, further results are needed to validate the above conclusions. This study is ongoing. The specific role of inhaled chlorine products being responsible for the persistence of AA in S is yet to be determined

N2 - Introduction and objective: Fluctuations in ADHD symptoms are theoretically explained by variations in arousal, a factor influenced by circadian rhythms. This study investigates whether 24-h patterns of heart rate (HR), an arousal-related marker, support differential circadian processes in children with ADHD. Mediating effects of physical activity, chronotypology and sleep-wake problems are explored. Methods: 30 children with ADHD and 30 sex-matched normal classmates, aged 6-12, were examined in their naturalistic setting during 5 days: HR and activity (24/24 h), chronotypology and sleep-wake problems. Results: Both activity and HR analyses showed significant group differences, with higher levels in the ADHD group, and significant day-night differences. Only for activity an interaction effect was detected, with no group differences during night but marked differences in the afternoon. Subjective evaluation revealed a later time-ofday preference in the ADHD group. Discussion: Raised HR in ADHD during night could not be explained by nighttime activity levels as these were only higher during day. Daytime HR levels did not follow daytime activity peaks in ADHD.

Conclusion: Results revealed differential autonomic functioning in children with ADHD compared to controls

N2 - Background and objective Adverse drug reactions (ADRs) occur frequently in paediatric patients.

Information about ADRs in children are often lacking or are insufficient. Frequently, they are not supplied by drug administration authorities or pharmaceutical industry. Many drugs used are unlicensed for the treatment of children or are prescribed outside the terms of the product license (off-label use). Occurrence especially of the preventable ADRs can be reduced by a monitoring performed by health care professionals (physicians, pharmacist and nurses). The ADRs are recorded and analysed by a physician and a clinical pharmacist. Design Spontaneous adverse reactions (ADRs) reporting in paediatric patients. Setting Paediatric Wards, Department of Pharmacy, Paediatric University Hospital. Main outcome measures Side effect monitoring and reporting. Case reporting to The State Institute for Drug Control. Results A 4 years survey of spontaneous ADRs is given. Among them one very serious-resulting in death (amphotericin B) and one world's first published adverse event (growth hormone somatotropine). Conclusions Number of adverse drug reactions reported by our paediatrics wards was influenced by several factors. First, usually only severe or rare events were spontaneously reported by physicians. Second, the prolonged hospital stay, the pharmaco-therapeutic groups of drugs, and the

polypharmacy also play a significant role. More ever, the reports are provided spontaneously. To increase detection of adverse reactions or events questionnaires and chart reviews should by implemented

IS - var.pagings

N2 - Introduction and Aims: Several studies have described an hypoactivity in the inferior frontal gyrus in children with autism during the observation of facial expressions^{1,2,3}. This hypoactivation has been interpreted as evidence for a deficit of the mirror neuron system. The deficit is thought to have serious consequences on the ability to simulate and understand the feelings of others⁴. We examined the outcome of the motor simulation deficits in a large sample of adults with autism. In addition, we investigated the relationship between inferior frontal gyrus activity and social functioning outside the laboratory. Patients and Methods: Twenty-one adult males with autism spectrum disorders and 21 typically developing subjects matched for age, gender, and IQ were scanned in three conditions: observing short movies showing emotional facial expressions, performing a facial movement, and experiencing a disgusting taste. Symptom severity and level of social adjustment were measured with the Autism Diagnostic Observation Schedule and the Social Functioning Scale. Results: Activity

triggered in the inferior frontal gyrus by the observation of facial expressions increased with age in autism, but not in controls. This age-related increase of activity was associated with changes in gaze behaviour, and improvements in social functioning, but not with the remission of autistic symptoms. Conclusions: The results suggest that activity in the mirror neuron system normalizes with age in autism, and this normalization is accompanied by changes in gaze behaviour and improved social functioning. Better simulation of facial expressions in the inferior frontal gyrus may contribute to the amelioration in social functioning commonly observed throughout adolescence and adulthood. It is the first demonstration of an age-related neurocognitive improvement in autism. This finding should encourage the development of new therapeutic interventions aimed at augmenting motor simulation of emotional facial expressions in children with autism

N2 - The antifolates sulfadoxine-pyrimethamine (SP) and trimethoprim-sulfamethoxazole (TMP/SMX) have potent activity against wild type *Plasmodium falciparum*, but activity is decreased due to resistance mediating mutations in many areas. However, SP remains the drug of choice for intermittent preventive therapy in pregnant women and children, and TMP/SMX is widely used to prevent opportunistic infections in those with HIV infection. Resistance to antifolates is mediated by a series of mutations in the target enzymes dihydrofolate reductase (DHFR) and dihydropteroate synthase (DHPS), key enzymes in the folic acid biosynthetic pathway. In East Africa, parasites commonly harbor 3 DHFR mutations (S108N, N51I and C59R) and 2 DHPS mutations (A437G and K540E) that mediate an intermediate level of resistance. Additional point mutations, seen more commonly outside Africa, mediate higher-level resistance. We are studying the impact of various resistance mediating mutations in DHFR and DHPS on the relative fitness of *P. falciparum*. To this aim, we are exploring the growth of parasites under different conditions and in competition assays. We are studying D10-strain parasites engineered to express DHPS with 1-3 mutations. In initial competition experiments, D10 wild-type and single mutant (A437G) strains outcompeted parasites with 2 (A437G + A581G or S436A + A437G) or 3 (S436A + A437G + K540E) mutations over 2 months of culture, as assessed by strain-specific PCR. Experiments to more stringently characterize relative growth of these strains utilizing folate-limiting culture conditions and quantitative PCR and to evaluate parasites with mutations in DHFR are underway. Our preliminary results suggest that resistance mediating mutations in DHPS engender a loss of fitness compared to that of wild type strains of *P. falciparum*

IS - var.pagings

N2 - Introduction: High frequency oscillations (HFO) ranging between 80 and 500Hz recorded with intracranial electrodes have been linked to epileptogenic regions in patients with epilepsy. The removal of HFO-generating areas correlates with a good postsurgical outcome. Most studies have been performed with microelectrodes or custom made macroelectrodes. Data on children and different pathologies is limited. We here investigate HFOs in children with Focal Cortical Dysplasia (FCD) during a routine investigation with commercially available grid electrodes. Methods: Patients under the age of 18 recorded in our centre between 2005 and 2009 and with pathologically confirmed FCD were included in this study. EEG was filtered at 450Hz and sampled at 1024Hz. HFOs (Ripples 80-200Hz, Fast Ripples 200-450Hz) were visually identified on bipolar montage in a five-minute segment of slow wave sleep using high-pass filters at 80Hz and 200Hz. Rates of HFOs in areas inside and outside the seizure onset zone (SOZ) were calculated for each channel and compared using ANOVA ($p < 0.05$). Results: Six children were included (mean age 13.6 years), four had FCD type 2a and two type 1b (Palmini classification). Rates of ripples (19.1/min) and fast ripples (2.5/min) were similar to those described before. They were significantly higher inside the SOZ (R: 29.1/min; FR: 4.7/min) than outside (R: 15.8/min, FR: 1.8/min, $p < 0.001$). Two patterns of HFO occurrence were seen: in pattern 1, channels had a flat baseline without high frequency activity and intermittent very high voltage HFOs. Pattern 2 was defined as channels with a continuously oscillating baseline with intermittently occurring higher voltage HFOs. Of the SOZ channels 71.1% showed pattern 1 and 17.1% showed pattern 2. Of non-SOZ channels, 20.5% showed pattern 1 and 17.5% pattern 2. The remaining channels showed few or no HFO activity; nevertheless HFOs were generated in a large number of channels. Conclusion: Children with FCDs showed a large extent of areas generating HFOs. Rates of HFOs could distinguish between channels inside and outside the SOZ. Therefore, HFOs recorded during only 5 minutes in a routine clinical setting in children may help to further delineate epileptogenic areas. Two patterns of HFOs were distinguished, of which pattern 1 consisting of single high voltage HFOs may show a closer link to the SOZ. Whether these neocortical HFO patterns can be linked to FCD or its subtypes will have to be evaluated in larger studies

N2 - Purpose of the study: The EPILS is a one day course and is aimed at the training attendee to recognise and manage critically ill children and children in cardio-respiratory arrest whilst awaiting the arrival of the Medical Emergency Team (MET) (1-5 min). The course also trained the candidate to work as a member of the Resuscitation team. In this paper we describe our experience of teaching EPILS to nurses and physicians of a Paediatric Unit. We have also measured the impact that EPILS has on the resuscitation knowledge. Methods: The EPILS course materials were translated by Italian EPLS instructors. From April to June 2010 nurses and physicians attended the Italian EPILS course. Candidate feedback was collected using an evaluation form. The change in knowledge of candidates was measured using a pre- and post-course test. Variables associated with candidate performance on course papers were investigated. Results: A total of 49 participants attended five EPILS courses. All candidates completed the course successfully and gave high evaluation scores. EPILS produced a significant increase from pre- to post-course test score (87.8+5.8 to 95+4.2, p<0.001). Only 8.1% of the participants obtain a post-test score under 90% (in contrast with 67.5% in pre-test). The pre-course score was higher for nurses and physicians working in Paediatric Emergency Unit compared with those coming from Paediatric unit, but this difference disappeared in the post-course evaluation. A detailed analysis of question evidenced the difficulty to understand when activate MET (limited availability in Italian actuality). Conclusions: This local Italian experience shows that the EPILS course format can be applied successfully outside the UK, and adapted to local needs. Better attention must be focalized to MET alert. The course improves knowledge scores and abolishes knowledge differences due to different working backgrounds of candidates

N2 - Introduction and Aim of the Study: Retropubic tension-free vaginal tape (TVT) has become the gold standard in the surgical treatment of female stress urinary incontinence (SUI), with good clinical results and limited complications. Nevertheless, some severe complications have been reported, among which bladder and bowel perforation and vessel damages. For this reason, a novel route for the introduction of polypropylene sling has been proposed via the obturator foramen, both from the outside to the inside and from the inside to the outside, with similar cure rates.¹ Finally, to further reduce invasiveness and complications (such as groin pain and urinary retention), single incision devices were produced. This continuous reduction of invasiveness leads to an increase of younger women suffering from SUI requesting surgical resolution of incontinence. Hence, a number of case reports on pregnancies after suburethral sling positioning. We here report on two cases of pregnancy after suburethral sling for SUI, one after TVT-O and one after the single incision TVT-Secur device - with different management of delivery. Materials and Methods: A 34-year old woman (gravida 2, para 2) was referred on January 2007 to our Urogynecology Clinic with symptoms of SUI, appeared after her second delivery. After unsuccessful pelvic floor training, on May 2007 she underwent VT-O procedure as described by de Leval.² After the procedure, the patient was continent, as well as at the sixth month follow-up visit. Soon after that follow-up visit, a third unplanned pregnancy occurred. After a thorough discussion of the mode of delivery, considering the pros and cons of vaginal delivery as opposed to cesarean section, the patient decided for the latter. A 41-year old woman (gravida 3, para 3), suffering of SUI symptoms after her second vaginal delivery, on February 2008, underwent TVT-Secur after confirmation of SUI diagnosis with clinical evaluation and urodynamic testing. After the procedure she was continent, as well as at the three-month follow-up visit. Eight months after the procedure, the patient returned with a positive pregnancy test. Since no data on pregnancy after TVT-Secur positioning, and considering the presence of absorbable fixation tips instead of the tape passing out from the obturator foramen, the patient was advised to undergo a cesarean section. Ten days

before the planned cesarean section, the patient was admitted to our Obstetric Ward with strong contractions, a 5 cm cervical opening, a complete effacement of the cervix and fetal index at the ischiatic spine level. Considering the favourable obstetric conditions, after receiving an informed consent by the patients, it was decided to let her complete her labour. Thus, a spontaneous vaginal delivery of a newborn weighing 3,250 g followed one hour later, without episiotomy. Results: During pregnancy, the first patient was continent and delivered a child with a birthweight of 3,560 g at 38 1 week gestation by means of cesarean section. One year after delivery, the patient is still continent as shown both by QoL questionnaires, clinical evaluation and urodynamic testing. After three months, the second patient did not show any incontinence symptoms. Clinical stress test, post-voidal residue and urodynamic findings were negative. Interpretation of Results: Reports of pregnancies following retropubic and transobturator TVT show successful outcomes both in case of cesarean section and vaginal delivery.³ The first reports are on deliveries managed with cesarean section due to the lack of information on the correct modality of delivery following TVT. Nevertheless, reports of vaginal delivery after TVT indicate that, at least in the short term, continence is not altered, as well as the tape position.³ We here report on two women, treated with two different types of slings, delivering with two different modalities. Both women were continent before, during and after delivery. In the case of TVT-O we have a follow-up at one year with no incontinence symptoms, both objectively and subjectively. In that case, the choice of the type of delivery was left to the patients, after having discussed all pros and cons. Our patient treated with TVT-Secur is, to our knowledge, the first case of a pregnancy and a delivery following single incision device positioning. For this patient, vaginal delivery was not planned, since too few information is available on the novel single incision device. The fixation system of this device is different from both retropubic and transobturator TVTs, thus the safest advice would have been to deliver by cesarean section. Nevertheless, she delivered vaginally with no recurrence of SUI. Follow-up of this patient is quite short, so that no conclusions can be drawn from this case, even though it seems that no immediate harm to the urethra has been caused by vaginal delivery and, apparently, function of the tape was preserved. Unfortunately, we did not manage to perform ultrasonography to confirm tape positioning, but we can hypothesize that, since continence was preserved, tape positioning should have been preserved as well. Conclusions: In conclusion, primary treatment for SUI in younger patients should be conservative, but women suffering from persistent SUI and desiring further pregnancies should be offered TVT procedures, since pregnancy seems not to alter TVT-induced continence. The mode of delivery should be thoroughly discussed with the patients, and should be customized for each of them, not precluding vaginal delivery, at least for retropubic and transobturator TVTs. More data on the mode of delivery in case of the presence of a TVT-Secur device are needed to better counsel patients and thus cesarean section should be advised, at least for the moment

N2 - Background: High RA disease activity during pregnancy is associated with lower birth weight. Lower birth weight, even within the normal range, has been linked with cardiovascular diseases and metabolic syndromes later in life. Outside pregnancy, active RA is associated with high levels of circulating cytokines. Purpose: To assess the levels of IL-10, IL-6 and TNF α in pregnant women with RA and to evaluate correlations between these levels, disease activity, and birth weight. Methods: Current study is embedded in the PARA-study, a prospective study on RA and pregnancy. 134 pregnant RA patients are enrolled in first and 168 in third trimester. 33 healthy pregnant women served as control. We analyse data using birth weight standard deviation scores (bwsds), a measure for birth weight adjusting for gestational age and sex of the child. Maternal disease activity is based on DAS28. IL-10, IL-6 and TNF α are determined by Immulite 1000. Results: Levels of IL-10, IL-6 and TNF α decrease during pregnancy. Strong correlations are found between these cytokines in first and third trimester and between DAS28 and IL-10, IL-6. First trimester patients with detectable IL-10 ($n=12$) show a higher disease activity than the IL-10 negative patients, a mean DAS28 4.4 (SD 1.2) and 3.6 (SD 1.1) respectively. To diminish the influence of disease activity on birth weight we match the IL-10 positive to an IL-10 negative group. Matching is on disease activity, parity and prednisone use. Mean bwsds is significantly higher ($p=0.02$) in the IL-10 positive group 0.92 (SD 0.7), than in the IL-10 negative match, 0.15 (SD 0.7). No such association is found in third trimester. To determine the additional effect of IL-6 to disease activity on bwsds stratification is done. In first trimester we stratify IL-6 and DAS28 in high and low group based on their median, resulting in 4 groups. In the two high DAS28 groups (defined median over 3.8), bwsds is significantly lower in high IL-6 than in low IL-6 ($p<0.05$). In the high IL-6 group bwsds is -0.19 (SD 1.12) in the low IL-6 group bwsds is 0.36 (SD 0.93). No such association is found in third trimester. TNF α is stratified the same way. In third trimester, only in patients with low disease activity, bwsds is lower in the low TNF α group than in the high TNF α group, bwsds of 0.05 (SD 0.97) and 0.52 (SD 0.96) respectively ($p<0.05$). Same trend is seen in the healthy cohort group, although not significant. No such association is found in first trimester or in patients with high RA disease activity. Conclusion: Circulating cytokines influence fetal growth in pregnant women with RA. In first trimester elevated IL-10 seems to protect against the negative influence of RA disease activity on birth weight, IL-6 seems to amplify this negative influence. Both cytokines create a bwsds deviation of more than 0.50 which is considered clinically relevant. In third trimester there is no influence suggesting an early critical window. Finally, our data might indicate a physiological role of TNF α in fetal growth during third trimester in healthy controls and patients with low disease activity. Underscoring that TNF-blockers should be used with caution during pregnancy

N2 - Introduction: Cerebellum is not only involved in motor and articulatory control but also in higher cognitive functions. Studies with functional MRI in right-handed healthy volunteers show that cerebellar activation during language tasks is mainly localized in the right hemisphere, contralateral to the dominant cerebral hemisphere. Our purpose was to evaluate cerebellar lateralization of language by functional MRI in healthy children and to study the functional reorganization in children after cerebellar pilocytic astrocytoma resection. Subjects and methods: We performed fMRI studies in 12 healthy right handers children (mean 11.3, range 8-16) and 6 patients (mean 11.6, range 9-17), 5 right handers, 1 left, with surgical resection of vermal (3) and right

cerebellar hemisphere (3). The tasks chosen for the healthy subjects were: overt verbal fluency (OVF), silent verbal fluency (SVF) and silent verb generation (SVG). Patients underwent OVF and SVG tasks. All subjects were trained outside the scanner before the MRI exam. During the fMRI sessions also morphological T1 and T2 imaging was done for each subject. All acquisitions were performed using a 1.5T Siemens Avanto scanner. Imaging processing and statistical analysis were conducted using the Brain Voyager (Brain Innovation) and SPM (Statistical Parametric Mapping) software. Results: Both in OVF and in SVF 11 volunteers presented fronto-parietal activations lateralized in the left cerebral hemisphere, while the cerebellar activations were lateralized in the right hemisphere. In one healthy subject where the activations were right lateralized, the cerebellar activations were localized in the left hemisphere. In SVG, all subjects presented left fronto-parietal and left temporal activations, while the cerebellar activations were lateralized in the right hemisphere. Also a II level study group has been performed on the healthy subjects for all tasks. The random effect analysis gave the localization of the tasks in the right cerebellar hemisphere. The 6 patients presented slightly more bilateral cerebral activations if compared with healthy subjects. Among these, 3 presented bilateral cerebellar activation, 3 more localized activations in the right cerebellar hemisphere. Discussion: Assessment of cerebellar fMRI lateralization of language is feasible in children, even with mild cognitive deficits. According to literature, both VF and VG are associated with significant activation in the cerebellar hemisphere, contralateral to the dominant cerebral hemisphere. The calculated cerebellar Asymmetry Indexes seem to anti-correlate with the frontal lobe Asymmetry Indexes and activations are significantly lateralized for silent tasks, probably due to the bilateral contribution of the mouth movements in overt tasks. Children with right cerebellar resections, especially of the lateral part and for wide lesions, present the most significant language deficits and bilateral cerebellar activations. This activation pattern is likely to be an attempt of compensatory reorganization. However the reorganization takes place also in the right damaged cerebellar hemisphere. Future analysis of correlation between cerebellar lateralization and language performance will disclose if this reorganization is successful to compensate the language deficit. The random effect analysis (study group) conducted on the healthy subjects gave the topology of the cerebellar activations, showing the differences between VF and VG

 N2 - Background: The aim was to compare the energy intake (EI), dietary habits (DH) and physical activity (PA) of mothers of children with obesity with mothers of children with healthy weight. Methods: Design: Case-control (cases: mothers of obese children, n=63; controls: mothers of healthy weight children, n=62). Setting: An elementary school at Guadalajara Mexico, 2009. EI was evaluated by a 24-hour recall questionnaire; HA and PA were evaluated with an ad hoc questionnaire. Analyses: OR, CI95%, logistic regression. Results: Overweight and obesity were significantly more frequent in the mothers of the obese children. They ingested a higher amount of energy and protein and with a significant higher frequency had lunch or dinner at work and watched TV at mealtimes. Their PA differed from controls mothers PA in outdoors or indoors moderate PA, less time of transportation to school and work and longer periods of sedentary activity. The regression models included the variables of the energy equation (energy and protein intake, active plus sedentary PA) plus specific DH and some socio-demographic characteristics (as families with one son and fathers job as independent professionals). Conclusions: The obese children's mothers' lifestyle seems to be obesogenic in variables related to energy intake and consumption -both as a part of the energy equation- as well as in dietary habits and the socio-demographic condition, underlining the multifactorial condition of childhood obesity

N2 - Objectives: Regular physical activity (PA) decreases adiposity in children and benefit cardiopulmonary system. Aim of this study: To estimate frequency, duration and intensity of PA and the sedentary time outside school in Belarusian school children from urban area and to analyze their correlation with body mass index (BMI) and percent of body fat mass (%FM). Methods: The study was conducted in two randomly selected schools. Body weight and %FM were measured using foot-to-foot bioimpedance analyser Tanita. The level of PA and sedentary time outside school was assessed by a selfadministered questionnaire. General sedentary time was estimated as screen time (spent at TV, computer) and time for home work and other sedentary activities. Results: Three hundred and eighty-five children and adolescents aged 10-17 years, M/F 165/220 with completed anthropometric data and questionnaires were included in analysis. Mean age (13.1 + 1.85 years) and mean BMI (19.89 + 3.34 kg/m²) were not statistically different between males and females, males had significantly lower %FM (P = 0.02). Th13% of children reported undertaking PA every day, males more often than females (17% vs. 10%). 25% of children exercised more than 60 minutes per section (38% males vs. 16% females). Totally 6% of children reported recommended level of PA: every day and more than 60 minutes per section (11% males vs. 2% females). 33% of children had screen time more than 3 hours per day (35% males vs. 31% females) and 63% reported general sedentary time more than 4 hours per day. BMI and %FM showed weak positive correlation with screen time (r = 0.151, P = 0.003 and r = 0.104, P = 0.041, respectively), %FM in addition demonstrated weak negative correlation with frequency (r =)0.112, P = 0.028) and duration (r =)0.144, P = 0.005) of PA. Conclusion: Our study showed that level of PA did not influence BMI, however higher frequency and duration of PA decreased adiposity (%FM) in children. Generally Belarusian school children, especially girls, reported low levels of PA

N2 - Background/Objectives: Children with developmental coordination disorder (DCD) struggle to learn new motor skills and demonstrate more variable motor performance than their typically-developing (TD) peers. Because no neuroimaging studies have been conducted to examine the mechanisms underlying motor learning deficits in children with DCD, the objective of this pilot study was to determine if patterns of brain activity differed between children with and without DCD while learning a motor task. We expected that children with DCD would demonstrate more accurate tracing of our trail-tracing task from early practice to retention, but that they would be significantly less accurate on the task as compared to TD children. We predicted that children with DCD would under-activate the cerebellum when tracing, and that they would show a compensatory pattern of brain activity in the prefrontal and posterior parietal cortices when compared with typical peers. Design: Behavioral and functional magnetic resonance imaging (fMRI) blocked design. Participants and Setting: A volunteer sample of seven children with DCD (ages 8-12 y) and seven age-matched TD children in the Brain Behavioral Laboratory and UBC MRI Research Centre. Materials/Methods: Using fMRI, we mapped brain activity associated with learning of a trail-tracing task in children with and without DCD. We indexed motor

learning as a reduction of tracing error from early practice to retention on our experimental task. We assessed changes in brain activation across two fMRI sessions. Early task practice (Day 1) and a retention test (Day 5) took place inside a 3-Tesla Phillips MRI scanner. Three days (Days 2-4) of behavioral practice (tracing outside the fMRI) occurred in between the scanning sessions. Brain activity was represented by using fMRI as a summed-weighted threshold of percent signal change. Results: Consistent with their clinical presentation, children with DCD did not show an improvement in motor accuracy with equivalent practice to TD children. They also showed less blood oxygen level dependent response than TD children in a broad network of brain regions associated with motor learning and performance, including the right inferior parietal lobule, bilateral dorsolateral prefrontal cortices, right middle occipitotemporal area, lobule VI of the cerebellum, bilateral posterior cingulate, and left thalamus. In contrast, significantly greater activation of the caudate and putamen was apparent in children with DCD as compared to control children. Conclusions/Significance: Our results indicate that differences in motor learning may be related to differences in brain activation. Compared to TD peers, the DCD group demonstrated under-activation in the cerebellum and in brain areas associated with the cerebello-thalamo-cortical network. Findings suggest that children with DCD may have a deficit in updating internal models of movement and use the cortico-striatal network to support their motor performance

N2 - Obesity is the new age epidemic and a slow killer with its roots predominantly in our lifestyle and behaviour. MATERIAL AND METHODS: Thirty overweight children who met inclusion criteria were evaluated over a period of 1 year. A detailed history physical examination was done in all. Body Mass Index Percentile (BMI % tile) for their age and sex as per the NCHS/CDC charts was used for classification. Relevant investigations to assess metabolic parameters were done. RESULTS: Thirteen of 30 patients had onset of obesity before one year of age, with 10 being obese and 3 overweight (P=0.036). No correlation was found between parental obesity and BMI of children. Fourteen of the obese children belonged to nuclear families (66.7%) as compared to 9 (100%) who stayed in a joint family (P=0.048). Poor level of motivation was observed in 22/30 children and average level in 8/30 (P=0.037). Excess carbohydrates and fats consumed and the decrease in protein intake by the children correlated significantly with the BMI (P values of 0.001, 0.002, and 0.003 respectively). Amount of protein consumed by those children who were overweight was significantly more than those who were obese (P value 0.001). 93.3% consumed food prepared using saturated fat as compared to 2 (6.7%) who used unsaturated fat (P=0.008). Sedentary hours spent correlated significantly with the BMI (P=0.01), with statistically significant hours spent outdoors by overweight group than in the obese group (P=0.007). Children with high BMI had increased Left ventricular mass index (LVMI). LV Mass showed a positive correlation with systolic and diastolic blood pressure readings. Total Chol/HDL ratio was found to be statistically significant in relation to BMI (P=0.032). CONCLUSION: Grade of obesity statistically correlates with age of onset, type of family, degree of physical activity, diet and raised total Cholesterol/HDL ratio and motivational level. Childhood obesity definitely has a significant correlation with the lifestyle factors

N2 - Extension of the mobile phone technology raises concern about the implications of electromagnetic radiation (EMR) on the central nervous system (CNS). Children are more sensitive to EMR due to developing phase of their brain. Generally Mobile phone radiates an average power of 0.2-0.6 watts when hand-held and operated close to the head, background levels are sharply distorted, with likely 40- 50 percent of radiated phone energy absorbed into the brain. Our previous study has concluded that the extensive users, they hold cell phone for a period above 3 years, were more attentive for 'headache' symptom in comparison to normal users. In this study we assessed the spontaneous locomotors activity (SLA) of the mice after the acute exposure of cellular telephone (CDMA). 10 mice of the 30 days old (average weight 30gm) were grouped as control and EMR and they were habituated for one week prior to start the experiment in well designed circular cellphone exposure (CCPE) cage. CCPE cage was specially designed for EMR exposure through the cellular phone over the mice in the natural environment and it was placed inside the exposure room where no electric appliances were exist. In the cage, cellular phone was placed in the center and mice were allowed to move around the device within 10 cm. radius. 3 hours/day exposure was applied to the mice of EMR group by the cellular phone in CCPE cage. Locomotor activity was assessed using computerized Optovarimax animal activity monitor, following the method Ali et. al., (1990). In this study Distance traveled, Time resting, Time moving and Stereotypic Time was measured with the help of the activity monitor. No significant changes were found in the EMR exposed mice in comparison of control mice. More laboratory research is essential to clarify the contradictions

N2 - **BACKGROUND:** Obesity has risen dramatically in young people over the past two decades; this trend is especially prominent among minority populations, including African American (AA) youth. Schools represent a key venue in which to address the problem of obesity, through creative combination of curricular and environmental interventions. Given parental work demands and schedules and the need for safe and structured after-school opportunities for youth, Chicago Public Schools (CPS) has developed an extensive after-school program that provides an ideal potential setting for a healthy nutrition and physical activity intervention for children and families. **METHODS:** Using Community Based Participatory Research (CBPR) principles, we developed a partnership with Woodlawn Community School (WCS) on Chicago's South Side to implement and assess the feasibility of integrating into the after-school environment a behavioral intervention designed to decrease overweight and risk of obesity among AA youth and their parents. The Power-Up intervention, which comprises 14 interactive weekly sessions for children on various topics concerning nutrition and physical activity, was led by CPS teachers in the after school setting. Children were grouped by age, with approximately 15 children per group. Weekly parent discussion sessions held at pick-up time addressed similar topics in a discussion format, and families practiced Power-Up skills at home throughout the week by completing Power-Up 'homework' assignments. Data for participating families were collected pre- and post-intervention. Parent and child measures included BMI (BMI z-scores for children), blood pressure, self reported dietary intake and levels of physical activity, and health knowledge, beliefs and attitudes. **RESULTS:** 40 AA children (16 boys and 24 girls) and their 28 parents/guardians (all women) consented to participate in the Power-Up study. Children's ages ranged from 5 - 12 years (mean= 8). At baseline, over half of the children were either overweight (26%, 85th-95th %ile) or obese (28%, > 95th %ile). Post-intervention, children significantly reduced their mean BMI z-score from 1.05 to 0.81 ($p<0.0001$). Changes were more pronounced in the overweight children than in the obese category. **CONCLUSIONS:** Children, parents, teachers and school personnel enjoyed the Power-Up program, which was effectively integrated into school activities and culture through support of the Principal and other school leaders, presentations at Parent-Teacher events, and

participation in the annual All School Festival at the end of the school year. The after-school setting proved to be a feasible venue with promising pilot results for this obesity prevention program for children and families. Using CBPR principles in the development and implementation of the program was crucial to the success of this pilot project, and has led to long-term, sustainable impact in the environmental context at WCS; the school is working to install a green house to encourage healthier eating habits and new playground equipment to promote physical activity. Plans are underway for a larger, randomized trial to continue the Power-Up study in additional schools

N2 - Introduction: Vitamin D insufficiency (VID) may result in autoimmune diseases such as diabetes and multiple sclerosis. There is a lack of data on the relative importance of childhood VID predictors. Purpose: To evaluate predictors of childhood VID by undertaking a secondary analysis of the Great Britain National Diet and Nutrition Survey (NDNS) of young people (YP) dataset. Material: One thousand one hundred and two YP aged 4-18 years (999 white, 570 male). Methods: Design: nationally representative survey of YP living in private households in Great Britain. Fieldwork covered 12 months (January 1997-1998). Interventions: interview and record providing information about; dietary habits; physical activity; lifestyle and socio-demographics; and blood sample. Outcomes: Vitamin D deficiency (<25 nmol/L) and VID (<50 nmol/L). Results: Vitamin D levels (mean = 62.1 nmol/L, 95% CI 60.4-63.7) showed deficiency = 7.4% and insufficiency = 35.1%. Levels were higher for those living between 53 and 59 degree latitude (compared with 50-53, P = 0.045). Dietary intake had no effect on vitamin D status. A logistic regression model showed the following significant (P < 0.05) associations for VID: (Table presented) Conclusion: We report the high prevalence of childhood VID and a previously under-recognised risk of VID in adolescents. The marked higher odds for VID in non-white children and those on income support suggest these groups should be targeted in preventative strategies. Marked seasonal differences and the association of higher risk of VID amongst children who exercised less outdoors and watched more TV highlights potentially modifiable risk factors. Clearer guidelines for safe sunlight exposure and an increased awareness are needed as there are no recommendations for supplementation in YP

 N2 - Introduction: New mothers are often seeking professional advice about restarting or beginning a fitness program. Purpose: The aim of this study was to compare cardiorespiratory responses and energy expenditure of various walking speeds while pushing a baby stroller outdoors. Design: Descriptive (Observational) study. Methods: Eleven female volunteers (mean age 24 yrs; range 22 - 41) completed a treadmill VO₂ max test to determine their aerobic capacity. Approximately one week later a portable gas analyzer was used to measure oxygen consumption while subjects performed 3 exercise sessions in random order pushing a baby stroller at 3.0, 4.0 mph and a selfselected speed to simulate the speed they considered walking for exercise. The stroller included an additional 35 pounds of weight to simulate the weight of a one-year old child plus a diaper bag. Oxygen consumption (V_{O2}), heart rate (HR) and walking speed (GPS watch) were measured. Data were analyzed by one-way analysis of variance (ANOVA) for each factor and pairwise comparisons were performed. Results: At steady state there was a difference ($p < .001$) between V_{O2} (ml · kg⁻¹ · min⁻¹) for walk speed. Post hoc comparisons revealed differences between 3.0 mph (19.3 + 4.4 ml · kg⁻¹ · min⁻¹; 43% of max) and both 4.0 mph (25.1 + 2.4 ml · kg⁻¹ · min⁻¹; 55% of max) and self-select (26.6 + 1.6 ml · kg⁻¹ · min⁻¹; 58% of max). Similar differences were observed for HR ($p < .002$) between 3.0 mph (103.2 + 18.1 bpm) and 4.0 mph (121.6 + 12.6 bpm) and self-select (128.7 + 16.2 bpm). Total caloric expenditure was also significantly greater during the 4.0 mph (7.5 + 0.6 kcal/min) and self-select (8.4 + 1.0 kcal/min) conditions compared to the slower walk (5.7 + 1.0 kcal/min). Pushing a weighted stroller at 4.0 mph and at a self-selected speed (mean speed 4.3 mph) was sufficient to meet the American College of Sports Medicine's threshold for improving cardiorespiratory fitness. Conclusions: These data suggest that walking at least 4.0 mph outdoors while pushing a baby stroller can be an effective way to obtain health and fitness benefits

N2 - Adolescence is defined as a period of biological, psychological, and social transition from a dependent child into an independent autonomous adult (1). It commonly occurs in the teenage years, but may extend well into the early twenties. During adolescence additional challenges emerge as the body and mind undergo rapid changes and care is transitioned from parents to the adolescent. The wishes of the young adult begin to surface and must be addressed. While adolescence can be difficult for healthy teens, the trials associated with having cystic fibrosis (CF) can magnify the struggles. Chronic health issues influence perception of body image and this is no less important in young women with CF. Few studies have addressed the impact of chronic diseases on sexual health in women with cystic fibrosis. What studies are available suggest that social and sexual development is delayed. The delay of puberty may be 2 years or more depending on nutritional status and results in a female (or male) of shorter stature with decreased bone density (2,3). Zeitlin suggests that the onset of menarche in CF women may predispose them to impaired lung function as a result of the monthly menses; this may account for some of the gender differences in morbidity/mortality (4). Roberts and Green report that 60% of CF adolescents want to know about sexual health before the age of 16 years (5). CF adolescents engage in sexual activity at the same age as their unaffected peers. Lung function impairment may require alternative positions for sexual activity. Coughing during sexual intercourse can be particularly disturbing for teens. Even though the cervical mucus is thicker, sexually transmitted diseases (STD) and unplanned pregnancy can occur. The incidence of STD and the response to therapy are unknown in this population. Contraception as part of a comprehensive sexual health program should be addressed early in CF affected women as many believe that they cannot get pregnant, but there are no guidelines to suggest an optimal method for all CF women. In addition, CF women who choose hormonal birth control pills must be cautioned about the interaction of antibiotics and oral contraceptives and the risk of venous thromboembolism which can further affect lung function. On another front is the social development of the young CF woman. Illnesses may restrict attendance at common social functions like sports events, homecoming and prom. Sometimes parents are overprotective and limit involvement of CF daughters. Exacerbations of coughing may occur at outdoor events in cooler weather or in smoke filled rooms. Recurrent sinus or lung infections causing coughing or foul breath may affect social intimacy like kissing and result in rejection by boyfriends. Changes in the physical appearance of CF women (such as clubbing, underweight, barrel chested, moon faces, small breasts) cause feelings of inadequacy and result in adjusting hair or clothing styles to hide inadequacies (6). Gastrointestinal disturbances, especially flatus, are particularly embarrassing for CF women, but may be a source of bravado for CF men. Adolescence is also a time of choosing a career path. Adolescents must be guided to choose appropriately. CF women should be steered toward careers in clean environments that pose minimal or no hazard to them or to the people they are around. Healthcare and child care may not be appropriate choices for many reasons (7,8). The treatment of adolescent girls with CF poses specific challenges for promoting health and treating CF related diseases. At this point the relationship between the health care provider and the patient, not the parents, becomes more important. A safe environment separate from the parents to discuss confidential issues of importance to teens is required and can result in improved adherence at a difficult time

N2 - Neurological abnormalities are complained by the cellular users from the corners of the globe in last few years. Our previous study has concluded that the extensive users, they hold cell phone for a period above 3 years, were more attentive for 'headache' symptom in comparison to normal users. Children are more sensitive to EMR due to developing phase of their brain. Generally cellular phone radiates an average power of 0.2-0.6 watts when hand-held and operated close to the head, background levels are sharply distorted, with likely 40-50% of radiated phone energy absorbed into the brain. In this study we assessed the spontaneous locomotor activity (SLA) of the mice after the acute exposure of cellular telephone (CDMA). 10 mice of the 30 days old (average weight 30 gm) were grouped as control and EMR and they were habituated for 1 week prior to start the experiment in well designed circular cellphone exposure (CCPE) cage. CCPE cage was specially designed for EMR exposure through the cellular phone over the mice in the natural environment and it placed inside the exposure room where other electric appliances were not exist. In the cage, cellular phone was placed in the center and mice were allowed to move around the device within 10 cm. radius. 3 h/day exposure was applied to the mice of EMR group by the cellular phone in CCPE cage. Locomotor activity was assessed using computerized Optovarimax animal activity monitor, following the method Ali et al., (1990). In this study sub parameters such as Distance traveled, Time resting, Time moving and Stereotypic time was measured with the help of the activity monitor. No significant changes were found in the EMR exposed mice in comparison of control mice. More laboratory research is essential to clarify the contradictions

N2 - Background: Suspected mass sociogenic illness (MSI) initially attributed to carbon monoxide (CO) poisoning. Case series: Over 100 people at church on hot day when child fainted followed by another. No seizure activity and awoke normal and removed. Others then had various complaints and building evacuated. The fire department evaluated patients including: COHb and O2 sat with Masimo oximeter, several COHb reported up to 19%. Paramedics and Haz Mat to scene. After ambulances more children and two adults became symptomatic outside. No cyanosis at any time. Seventeen of twentytwo taken to tertiary hospital with HBO chamber and other five to local ED. All other attendees asymptomatic. All asymptomatic in ED after 15 min transport time with normal exams. Majority not treated with O2 en route. Mean age 13-year-old (7-50), seven males, complaints at scene: nine dizziness, six headache, three paresthesia, three loss of consciousness, seven nausea. All treated in ED 100% O2 at 15 L/min. VBG COHb immediately sent and different Masimo oximeter repeated. Mean blood COHb 0.6 (0.2-1.2), O2 sat 99.8 (99-100), Masimo COHb 0.2 (0-3), MetHb 1.5 (0-0.4). Discussion: MSI challenging diagnosis. Primarily seen in children, rapid onset and resolution, visual cues trigger, no illness in other persons sharing environment, no clinical or laboratory evidence of illness, hyperventilation and syncope common. None had elevated COHb. Haz Mat did not measure CO or other toxic

gases. No heater or air conditioner on at time. Haz Mat reproduced scenario, including running heater, over several hours and no toxic gases. Heater evaluated and operating normally. Other potential etiology includes simple asphyxiant. Unlikely as affected persons sitting in various areas and majority unaffected sitting near affected persons. Furthermore, several became symptomatic after leaving church. Escalation and increased persons affected with increasing ambulance presence is common in MSI. We suspect field COHb aberrant from inexperienced operator error. Conclusion: Clinicians should consider MSI following mass outbreaks of illness, particularly with the rapid onset and rapid resolution of symptoms coupled with normal physical examination and laboratory analysis. However, MSI should only be entertained after potential toxicologic etiologies have been excluded

N2 - Hypothesis / aims of study Laxity of the vaginal introitus may occur following vaginal delivery. However, this condition is infrequently discussed between patients and physicians, likely due to a paucity of evidence-based treatment options. We hypothesized that introital laxity leads to loss of physical sensation and the development of sexual dissatisfaction during vaginal intercourse. Therefore, a survey was conducted with two primary aims: 1) to better quantify the prevalence of vaginal laxity among parous women ages 25-55 years of age and 2) to explore the association between vaginal laxity and changes in physical sensation or sexual dissatisfaction. Study design, materials and methods A cross-sectional survey was conducted utilizing focus groups and a national database of on-line registrants for women ages 25-55 who had experienced at least one vaginal delivery. This survey was conducted in two phases; a qualitative assessment survey utilizing focus groups from which directional information was collected followed by the second phase, a quantitative survey. For the qualitative phase, nine focus groups were conducted each comprised of six to eight women per group. Three groups per city were organized in Portland, Cleveland and Atlanta. Discussions were lead by a female moderator using a standardized script to explore perceptions and concerns of women presenting with vaginal laxity after vaginal childbirth and their attitudes toward resolution of this medical condition. Key areas for discussion included physical changes experienced since vaginal childbirth, confidence and relationship with partner, physical and psychological consequences specifically related to vaginal laxity, and barriers to discussion of vaginal laxity with health care providers, friends and family. Each focus group lasted approximately two hours; participants received \$100 for attending. The second phase of the survey utilized a national database of on-line registrants of women aged 25-55 who had experienced at least one vaginal delivery. The survey consisted of five parts, namely (i) demographic data, e.g., age, ethnicity, education, employment status, household income, marital status and number of vaginal births, plans for future children, (ii) interaction with her obstetrician/gynecologist (OB/GYN) regarding sexual function, (iii) 16 questions on body image and sexuality following childbirth, (iv) body image procedures contemplated or had, and (v) potential benefits to improving vaginal laxity. Results A total of 50 women participated in the focus groups. In the pre-selected age range of 25 to 45, slightly more than half were 25- 35 years of age, predominantly college graduates, and evenly distributed amongst household incomes. Participants included a mix of women working outside the home or homemakers. They candidly described body image changes following childbirth and the complexity of physical and emotional consequences due to vaginal laxity (e.g., reduced vaginal sensation, difficulty reaching orgasm). Vaginal changes were equated with loss of sexuality, burdensome sexual performance, and a yearning for intimacy and sexual confidence experienced before having children. The participants acknowledged the impediments to discussing sexual concerns with their physicians. In the second, quantitative phase of the survey, 421 (69.8%) of the 635 women who received on-line questionnaires completed the survey. Surveys were collected from women in every state in the continental US (14% of all responses were from CA, 5-6% from NY, MI, TX and FL). The respondents were predominately white (81%), college graduates (55%), employed full or part time (59%), suburban living (57%), income \$70K or greater (71%), and married (90%), and a median of two childbirths. Some of the survey responses related to concerns about self-image, sexuality and sexual satisfaction are presented in Table 1. (Table presented). Interpretation of results Approximately half of the women in all age groups expressed a diminished interest in sex after having children, initiated sex less frequently and felt like it was more of an effort. However, half of the respondents also indicated satisfaction

with their sex life. Laxity of the vaginal introitus was expressed as a concern ("some" or "a little" or "a lot") by 48% (201 of 421) of respondents. Eighty percent of respondents (335 of 421) had not discussed the topic with their OB/GYN. Eighty-five percent (357 of 421) of women knew how to perform the Kegel exercises, 76% (318) had done them, 48% (204) thought they were effective in tightening the vagina, 15% (65) indicated they were not effective and 36% (152) did not know if the Kegel exercises were effective in improving their vaginal tone. Approximately 50% or more of women felt that improving the tightness of their vaginal introitus would have a positive effect on the relationship with their partner, both their sexual confidence and overall confidence, the orgasmic experience of both them and their partner, and sexual satisfaction. Concluding message The results from this cross-sectional survey on sexual health after vaginal birth provide a new focus on laxity of the vaginal introitus as an important medical concern after vaginal childbirth, one that is infrequently discussed between patients and physicians, and under reported in the literature. The surveys are unique in assessing women's attitudes about their body image, sexual health, and sexual relationships. Among the respondents who represented a 30-year age range from 25 to 55, approximately half expressed some degree of concern for "looseness" of the vaginal introitus. Potential treatment to tighten the vaginal introitus was considered to be positive for personal renewal, to improve orgasms and benefit the sexual relationship for both partners. (Table presented)

N2 - Background To identify the epidemiologic characteristics of HIV and AIDS in SETIF during the period between 1986, and 2009. Methods This report presents a descriptive analysis of HIV and AIDS surveillance data. The subjects of this study were all notified HIV and AIDS cases in SETIF diagnosed by ELISA and confirmatory Western blot, we worked with epi info 3.5.2. Results The HIV epidemic started in SETIF in 1986 with the first diagnosed AIDS cases. The number of cases slowly but steadily increased, to reach, by 2009, 152 cases. The median age of infected persons was 39,77 years. 40.8% were WOMEN; The most frequent mode of transmission is sexual (76,9% of all cases; with mainly heterosexual transmission 77.9 percent; with a strong correlation to travel and migration 37.20%). the proportion of persons diagnosed late (within 12 months before AIDS diagnosis) was 82,3%; 91.4% of married men (36) have sexual relationships outside marriage as compared to 0.0% of married women(27). We report also 13.60% discordant couples among married patients, Among documented HIV-positive mothers (36), their children were screened in 61.10%, and 95.5% of them were seronegatif, 55,9% of all cases were treated with ARV. HIV/ AIDS deaths 36,2% decreased markedly from 2002, associated with the advent of HAART. Discussion Gender distribution and distribution by mode of transmission among HIV-infected revealed an equal gender distribution of infection wich contrary to sub-Saharan Africa, where women are more affected. a higher female prevalence of HIV infection might be expected in algeria since heterosexuality is the prevailing mode of sexual transmission. Non-marital sex is the main risk factor, as it is worldwide for several reasons: Our data might be explained by u the large number of males who travel to other countries, especially to areas with a high prevalence of HIV infection. Travel and tourism enhance the probability of having casual sex, a fact that increases the risk of exposure to sexually transmitted infections u The ever-decreasing religious values Adults 23- to 45-years old were found to constitute 65,8% of all cases, a fact that points to the serious social and economical impact of the disease The trend of mode of transmission by blood transfusion shows that most of the cases infected through contaminated blood were registered before 1995. These patients most probably received blood unscreened for HIV in the 1980s before blood safety measures were undertaken. However, the incidence of this type of transmission significantly declined after implementation of blood safety policies. 32,90% of infected had died, This high percentage can be explained by the fact that: most infections are detected among patients, who already have a bad prognosis 66,40% 68,6% of death occurs before 1996 it means before the introduction of highly active antiretroviral therapy

N2 - The purpose of the current study was to examine whether asthmatic children using multiple types of inhalers demonstrate poor inhalation technique scores in comparison to those patients using only one type of inhaler. The DPI inhalers investigated were Turbuhaler (TH; AstraZeneca), Diskus (DK; GlaxoWellcome), and Diskhaler. Subjects used one of these DPI inhalers alone or in combination with MDIS. The inhalation technique was evaluated during the clinic visit and scored using a modified inhaler-specific checklist adapted from the Dutch Asthma Foundation technique score. The total score was obtained by multiplication of all the scores then multiplying the total by 100 to get a percent score. This system incorporates the relative importance of each step in the inhalation technique. For each inhaler, items essential to the delivery of active drug into the lungs were identified. These key items involve preparing or loading the device prior to inhalation, which is performed differently for MDI and DPI, and the inspiration maneuver. In 97 asthmatic children (mean age 11.59+SD 3.9 years) inhalation technique was assessed. Of these, 59 (60.8%) were males and 76 (78.4%) received instruction in the asthma clinic. Those who received teaching from outside the clinic (21 children) had asthma for a mean of 4.5 years. Twenty-eight patients (25 from within the asthma clinic and 3 from outside) used the Turbuhaler, with 12 of these 28 patients using it in combination with MDIS. Meanwhile, 40 children used the Diskus inhaler (35 from within the asthma clinic and 5 from outside), with 26 of these users combining the Diskus device with MDIS. Overall, there were 30 patients (30.9%) in the DPI treatment group and 38 patients (39.2%) using both DPI and MDI inhalers. The DPI alone group exhibited a significantly higher inhalation technique score (85.7% vs. 61.9%; $p < 0.05$). The inhalation technique scores associated with both the Diskus and Turbuhaler were significantly reduced when used in combination with MDIS. The mean of the Turbuhaler technique score was 87% when used alone, which decreased to 61.3% when used in combination with MDIS ($p < 0.05$). Similarly, the mean of the Diskus technique score was also significantly reduced (83.4% to 62%) under these same conditions ($p < 0.05$). We conclude that the use of DPI inhalers in conjunction with MDIS inhalers confuses patients and reduces the likelihood of proper inhalation technique. When prescribing asthma therapy for patients, we advise physicians to consider similar devices to reduce inhalation technique errors, which may improve the drug deposition and lead to better asthma control

IS - var.pagings

N2 - What is PBB? PBB, long been recognized by pediatric pulmonologists worldwide, was only adequately characterized (clinically and BAL) recently [1-3]. PBB's original description was derived from a prospective study that evaluated the aetiology of chronic cough in children using a research protocol. The study [1] used a priori defined criteria and validated cough diaries to assess response with a clear time period relating to when medications were given. In the 108 young children with chronic cough in the study, bacterial infection of the airways (defined as growth of single pathogens of $>10^5$ cfu/ml) was the most common (40% of children) finding [1]. Airway neutrophilia was also present and the respiratory pathogens found in the endobronchial infection were *H. influenzae*, *S. pneumoniae* and *M. catarrhalis* [1,3]. The criteria for PBB in the research study were; (1) history of chronic moist cough, (2) positive BAL culture, and (3) response to antibiotic treatment with resolution of the cough within two weeks. Outside of research protocols, bronchoscopies cannot be routinely undertaken for uncomplicated chronic wet cough in clinical practice. Thus PBB, sometimes truncated to protracted bronchitis (PB) is clinically defined as (a) the presence of isolated chronic (>4 weeks) wet/moist cough, (b) resolution of cough with antibiotic treatment and (c) absence of pointers suggestive of an alternative specific cause of cough [2]. Hence while the diagnosis of PB can be suspected at the time of consultation, it can only be made down the track on review. PB has been officially recognized by the Thoracic Society of New Zealand and Australia and the British Thoracic Society [2]. The clinical profile of children with PB: Children with PB are typically young (<5 years of age, median age - 3 years [1,3]), do not have any other systemic symptoms including the absence of clinical sinusitis and ear disease. Some parents may report a 'wheeze' but it usually represents a misinterpretation of the sound [3]. Many of these children have been misdiagnosed as having asthma [1,3]. Their chest x-rays usually show peribronchiolar changes or may be reported as 'normal' [1,3]. Like children with chronic cough, children with PB have significant morbidity; parents typically have seen multiple medical practitioners for their child's chronic cough in the last 12 months. In PB the child's cough resolves only after a prolonged course of appropriate antibiotics (12-14 days). When a typical course (5 days) of antibiotics is used, the cough either relapses within 2-3 days, or slightly subsides but does not resolve completely. This is in contrast to the short course of antibiotics (5-7 days) required to treat community acquired pneumonia in otherwise well children. Children with PB also have higher Canadian Acute Respiratory Infection Scale (CARIFS) scores in subsequent respiratory illness. When compared with children with acute asthma and normal controls, children with PB, there was no difference between groups on day-1.

However days 7, 10 and 14 later, children with PB had significantly ($p < 0.0001$ for all) higher CARIFS scores [2]. Pathogenesis of PBB: PBB is associated with persistent bacterial infection in the airways [1,3] and it is widely accepted that persistent bacteria infection (with accompanying inflammation) is harmful to the airways. PBB is likely non-homogenous with neutrophilic airway inflammation developing by a variety of mechanisms. It is likely that an innate immune dysfunction or immature adaptive immunity is present, at least in a subgroup of these children. A group of children with bacterial colonisation, airway neutrophilia and protracted cough that was unrelated to the presence or absence of oesophagitis, was identified from 150 children undergoing gastroscopy [4]. In children without lung disease, cough was more likely to result from airway bacterial infection and not to esophagitis [4]. The abnormal microbiology of the airways in children with cough, was not reflected in the microbiology of gastric juices. In a subset of these children ($n = 69$), bacterial colonisation of the lower airways was associated with neutrophilic inflammation and reduced expression of both the toll-like receptor (TLR) -4 and the preprotachykinin gene, TAC1, that encodes substance P [5]. Substance P has a defensin-like function which may explain the association between reduced TAC1 and persistent bacterial infection. In order to provide additional evidence for a dysfunctional host response to bacterial infection, chemokine receptor expression was assessed. Elevated gene expression for neutrophil chemo-attractant chemokine IL-8 cellular receptor, CXCR1, was detected, while the chemokine receptors (CCR3, CCR5) were similar between groups. In another cohort of children with established chronic cough who presented to respiratory physicians and had PBB, intense neutrophilic airway inflammation with marked inflammatory mediator response (IL-8, active matrix metalloproteinase 9 [MMP-9]) was present, compared to controls [6]. The median levels of IL-8 (0.69, IQR 0.30, 1.72 ng/ml) in the BAL was similar to those found in other studies that examined chronic airway inflammation in cystic fibrosis and other forms of chronic suppurative lung disease [6]. In contrast to above data, TLR-2 and TLR-4mRNA expression were significantly elevated in this cohort when compared to the control group [6]. However when corrected for neutrophil numbers (it remains unclear if values should be corrected), TLR-2 and -4 were reduced [6]. Furthermore when followed up those with recurrent PBB has significantly reduced TLR-2 and 4mRNA expression (adjusted values) compared to those who had did not have recurrent PBB in the 12-mo follow-up period (unpublished). Nevertheless there were other differences between these cohorts that include age (innate immunity is age-dependent), duration of cough and key presentation history. Thus the nature and duration of innate immune dysfunction remain undefined, nor is it clear whether the dysfunction is specific to the lower airways or is more generalised (ie systemic). Only a long term study will elucidate the pathogenesis and evolution of PB in children. Treatment and follow-up of children with PB: Both the Australian and UK groups have described the response of the wet cough to a prolonged (at least 2 weeks) course of antibiotics [1-3]. In a Cochrane review (albeit consisting of 2 limited studies with total number of 140 children), chronic wet cough in children responded to antibiotics with a number needed to treat of 3 (95% CI 2, 4) and the progression of illness, defined by requirement for further antibiotics, was significantly lower in the antibiotic group with a number needed to treat for benefit of 4 (95% CI 3, 5) [2]. However until a double blinded randomized control trial that specifically addresses this question is performed, it remains indefinite which children with wet cough should receive antibiotics. Children with PB may have recurrent episodes. In the Brisbane cohort's preliminary study, approximately 35% of children have recurrent (>2 episodes a year) PB. Also whether PB is antecedent to chronic suppurative lung disease and bronchiectasis in some children is unknown and important to evaluate. It is likely that, at least in a small but significant number of children, PBB is an early spectrum of the same process leading to chronic suppurative lung disease and bronchiectasis [2]. Children with PB do not have established bronchiectasis as those with established bronchiectasis usually have a different clinical profile and are unlikely to recover after 12-14 days of oral antibiotics. It is suggested that children with recurrent PB (>2 episodes per year) are evaluated like a child with bronchiectasis. Summary: In summary, chronic wet cough in young children is common and causes considerable morbidity and health care costs. A clinical diagnostic entity called PBB is the most common cause of chronic wet cough on young children. Even though many children with PBB get better with 2 weeks of antibiotics, the long term consequences in young children whose pulmonary system are still developing, remains undefined. In published preliminary studies, reduced levels of receptors involved in innate immune recognition in the BAL cells of children with PBB and airway infection were described. It is likely that, at least some if not many, children with recurrent PBB have innate immune dysfunction and are at risk of chronic suppurative lung disease, which has been lately recognised to be not as rare as previously thought. Studies elucidating the determinants of chronic airway inflammation and bacterial colonisation in children, in particular the role of innate immunity dysfunction in children with recurrent PBB and their clinical outcomes are required

N2 - The frequency of late preterm births has generally increased in the United States over the past 2 decades [1]. Infants 34-36 weeks gestational age (wGA) comprise approximately 71% of all preterm births (in 2007 approximately 390,000 live births) [1]. Infants of this gestational age termed "late preterm" are often considered to be as physiologically and metabolically mature as term infants, and therefore at low risk for morbidity and mortality. The resulting early discharge from hospital may be a factor in an increased overall risk of re-hospitalization [2]. A growing body of literature has documented the broad range of complications that late preterm infants may experience [3]. They have a higher risk of developing a large array of medical complications, and mortality rate for late preterm infants are 3-5 fold higher than that for term infants. Each weekly reduction in estimated gestational age at birth was found to be associated with increased morbidity before hospital discharge and higher rates of hospital readmission in the first months of life [2]. A study involving 377,638 term and 26,170 late preterm (34-36 wGA) infants showed that 22.2% of the late preterm vs. 3.0% of term infants had newborn morbidity during their birth hospitalization. Preterm infants born at 34 wGA had 20-fold (relative risk [RR]: 20.6) and at 35wGA had 10-fold (RR: 10.2) higher risk of morbidity compared with infants born at 40wGA. Relative morbidity increased approximately 2-fold with every week of decreasing gestational age earlier than 38wGA [4]. A recent review on the respiratory consequences of preterm birth suggests that many adverse respiratory consequences of preterm birth are likely the result of persistent pulmonary structural abnormalities [5]. Retrospective analyses of records of infants born to US residents showed higher infant mortality rates in 34-36wGA infants compared with term infants [6]. All forms of respiratory morbidity affect late preterm infants at a higher rate than infants of more advanced gestational age, but in particular preterm infants (33-36wGA) who are outside of the typical bronchopulmonary dysplasia (BPD) age range are highly susceptible to infection by such pathogens as respiratory syncytial virus (RSV). Boyce et al. [7] showed that infants born at 33-36wGA had similar rates of admission to the hospital for RSV infection as infants <33wGA, and that there were substantially higher rates of admission in these 2 populations compared with term infants. In other studies infants 33-35wGA had hospital outcomes that were similar to or worse than those of infants <32wGA, whether RSV infection was confirmed or they were hospitalized for nonspecific bronchiolitis. After RSV-hospitalization infants 32-36wGA experienced rehospitalization rates twice as high,

hospital stays 3 times as long, and outpatient visits twice as frequent as infants of similar gestational age who were not hospitalized for RSV [8]. Prematurity was also associated with an increased risk of bronchiolitis-associated death. The odds ratio for death related to RSV in 32-35wGA compared with full-term infants was approximately 5 [9]. The mechanisms explaining the morbidity in infants 34-36wGA are at least in part related to physiologic deficiencies related to their stage of lung development. Stages of lung development: Early growth and development of the human lung is a continuous process that is highly variable between individuals and has traditionally been divided into 5 stages. Premature infants are predominantly born in the saccular stage (28-36wGA) that precedes the final alveolar stage [10]. The saccular period, is a transitional phase before full maturation of alveoli occurs characterized by an increased number of primitive alveoli (sacculi) that become gradually more effective as gas exchangers and may be sufficient in number and quality to sustain life in the preterm infant. The alveolar walls are more compact and thick than the final thin walls of alveoli and include an immature capillary system that is capable of carrying out the function of gas exchange and also fully matures in the alveolar phase. Mature alveoli are not uniformly present until 36wGA [10]. These structural changes not only affect gas exchange but have profound effects on the mechanical properties of the lung and hence the respiratory system as a whole. Impaired maintenance of FRC due to chest wall compliance, deficient airway tethering, and small lung volumes: The physiologic consequences of this early birth are that maintenance of a stable and adequate functional residual capacity (FRC) that secures stable gas exchange is impaired. FRC is determined by the balance between the opposing forces of the chest wall and lung and is thus a direct function of their respective mechanical properties. In early life, a compliant chest wall offers little outward recoil to the respiratory system and thus the elastic characteristics of the respiratory system approximate those of the lung with a tendency to decrease to lower lung volumes. Only within the first 2 years of life is this vulnerability corrected as the chest wall stiffens. To circumvent this limitation, infants actively elevate their FRC by modulating expiratory flow using laryngeal braking during tidal expiration and by maintaining inspiratory muscle activity into the expiratory phase. In addition they initiate inspiration early within the expiratory phase. Thus it is reasonable to assume that breathing with an overly compliant chest wall, high lung compliance, and reduced number of air-containing units is a challenge for infants delivered before term. The challenge of maintaining an FRC that permits stable gas exchange is likely compounded in the premature infant by apneic events, which have been shown to drive the system to critically low lung volumes and result in rapid desaturation. An additional crucial mechanism that secures airway patency and thus adequate maintenance of FRC is airway tethering. Tethering depends on a complex mesh-like elastic network within the alveolar walls that transmits tension from the pleural surface and exerts a circumferential pull on individual bronchi. Thus, tethering couples lung volume changes with airway caliber. Tethering of airways is less effective in infants born prematurely because alveolarization and the associated development of the parenchymal elastic network are still in the saccular stage of development at 32-36 wGA. The effect of reduced tethering is decreased airway stability, increased tendency to closure, increased airway resistance, and, ultimately, a tendency to collapse alveolar units in the lung periphery. Total lung volume undergoes rapid changes during the last trimester of gestation. At 30wGA, the lung volume is only 34% of the ultimate volume at mature birth, and at 34 weeks only reaches 47% of the final volume at maturity. This change parallels a marked thinning of air space walls associated with a dramatic increases in air space surface area from 1.0-2.0m² at 30-32wGA, to 3.0-4.0m² at term. These volume changes likely have direct mechanical implications in reducing the vulnerability caused by a low and unstable FRC. Altered lung development and function in association with preterm (30-36 wGA) birth: It is now recognized that postnatal hyperoxia plays a key role in the development of BPD. Premature birth interrupts normal in utero lung development and results in an early transition from the hypoxic intrauterine environment to a comparatively hyperoxic atmospheric environment. There is increasing evidence to support the hypothesis that preterm delivery, even in the absence of any neonatal respiratory disease, may have adverse effects on subsequent lung growth and development, and that these alterations may persist during the first 5 years of life and possibly beyond. Using pulmonary function testing a number of studies have shown a direct association between premature birth and altered pulmonary function. These studies demonstrated reduced expiratory flows in premature infants of varying gestational ages, but born without clinical lung disease. Most convincing was a recent study using the raised volume rapid thoracic compression technique [11]. In this study healthy preterm infants (mean, 33.4wGA) were studied at 8 weeks and had reduced airway flows in the presence of normal forced vital capacity compared with term infants. In a follow-up analysis, the reduced flows did not normalize in these children by 16 months of age, thus demonstrating a lack of "catch-up" growth in airway function [12]. The long-term significance of reduced airway function early in life has recently been emphasized in a longitudinal study involving a large group of non-selected infants who had participated in the Tucson Children's Respiratory study [13]. In this study Stern et al. showed that infants whose pulmonary function was in the lowest quartile also had pulmonary function in the lowest quartile through

the years of follow-up until early adulthood. These findings in a normal unselected population, suggest that the level of pulmonary function in early life tracks and changes little with growth. Weiss and Ware [14] suggest that deficits in lung function during early life, especially if associated with lower respiratory illnesses, increase the risk of chronic obstructive pulmonary disease (COPD) in late adult life. Of particular importance in this context may be the role played by RSV, which affects most children during their first year of life. Conclusions: Long term prospective data are needed to elucidate the lifetime impact of birth in the late preterm stage and the consequences of the morbidities associated with such birth

N2 - Introduction: Recent evidence suggests that the nutrition and physical activity behaviours learnt early in life are subsequently carried into adulthood. The aim of this study was to examine the nutrition and physical activity behaviours of elementary (primary) and secondary school students in schools across Victoria, Australia. Methods: Students from 27 primary and 24 secondary schools (n = 1213 and n = 1413 students, respectively) completed a questionnaire regarding nutrition- and physical activity-related behaviours. Results: Compared to primary school students, on average in one day, secondary school students consumed less serves of fruit (mean + SE; 1.68 + 0.03 vs. 2.00 + 0.03; P < 0.001); more soft drink (249.30 mL + 12.71 mL vs. 203.46 ml + 13.47 mL; P = 0.014), more cordial/fruit juice/fruit drinks/sports drinks (385.07 mL + 12.63 mL vs. 310.84 ml + 13.38 mL; P < 0.001), watched more television (1.78 hour + 0.03 hour vs. 1.47 hour + 0.04 hour; P < 0.001) and spent more time playing electronic games or the computer (not for homework; 1.08 hour + 0.03 hour vs. 0.85 hour + 0.03 hour; P < 0.001). The amount of outside play after school was similar (2.09 hour + 0.04 hour vs. 2.19 hour + 0.04 hour). Additionally, there was an increased proportion of secondary school students whom missed breakfast 'yesterday' (15.1% vs. 6.3%; P < 0.001) and reported having a tv in their bedroom (42.5% vs. 38.5%; P = 0.034). Conclusion: Obesogenic behaviours are frequent in both primary and secondary students however they appear to be more prevalent in the older students. Creating consistent health promoting environments for children as they move from preschool, through primary and then into secondary school is an important strategy for reducing obesity both in childhood and in later life

N2 - Introduction: The Kid's - 'Go for your life' (KGFYL) intervention program aims to reduce the risk of childhood obesity by improving children's environments and promoting healthy eating and physical activity related behaviours. The program involves an award scheme whereby elementary and pre-schools join as 'members' and then implement health promotion initiatives to meet the KGFYL criteria and become 'awarded'. The aim of this study is to examine differences in the environment between member and awarded preschools. Methods: Teachers from 36 KGFYL preschools in Victoria, Australia (RR: 65%) completed a 244-item questionnaire examining the nutrition and physical activity environment (socio-cultural, policy and physical) of their preschool. Results: Compared to member preschools, a greater proportion of awarded preschools had written physical activity policies (7% vs. 76%; $P < 0.001$); provided parents with a copy of their nutrition policy (64% vs. 95%; $P < 0.05$); had nutrition policies restricting sweet drinks and packaged snacks (73%, vs. 100%; 64% vs. 100%; $P < 0.05$) and promoting fruit and vegetables (64% vs. 100%; $P < 0.05$). A significantly smaller proportion of awarded preschools reported lack of equipment (53% vs. 19%; $P < 0.05$) and lack of alternatives when weather prevents outdoor play (60% vs. 29%; $P < 0.01$) as barriers to physical activity. There was also a higher proportion of children who brought water for snack time ($P < 0.05$). Conclusion: There is strong evidence that major differences exist between the nutrition and physical activity environments of KGFYL member and awarded preschools. KGFYL appears to be a positive, enabling and motivating program for making the preschool setting more health promoting

N2 - Introduction: The purpose of this study was to assess the association among free time activities, body image perception and obesity. Methods: The sample included 588 children (269 girls and 319 boys) from elementary and secondary school. Obesity was estimated by BMI and the cut off points of Cole et al. A questionnaire was completed by parents and children to provide information about age, hours spent per week and weekend in screen activities (TV, electronic games, internet), playing, studying, doing physical activity, the use of public spaces (playground, gymnasium, swimming pool, gardens) and body image perception (Stunkard's silhouettes). Results: The results from binary logistic regression were only significant for age (OR=0.807; 95% CI 0.714-0.911), playing at weekend (OR=0.678; 95% CI 0.461-0.997) and body image perception (OR=11.219; 95% CI 6.988-18.010). The odds ratio of being obese were 0.678 times less for children that play more at weekend, and 0.807 times less for older children. In other hand body image is a risk factor for obesity and the odds ratio were 11,219 times more for children that have the perception of a more obese image. Conclusions: Age and playing at weekend are preventive factors; meanwhile, the perception of body image is a risk factor for obesity. These results are very important to take into account in programs designed to combat obesity

N2 - Objective: To identify at risk social and behaviours factors linked to obesity in Algerian school children living in an urban environment. Methods: A retrospective study was conducted in a random sample of 810 children (girls = 421, boys = 389) aged 6 to 12 years old, attending 9 schools of the city of Constantine, between April and November 2006. Data included anthropometric measurements, questionnaires about socio economic factors (SES), birth weight (BW), early feeding practices, eating habits, physical activity. IOTF criteria were used to assess overweight including obesity (OB). Statistics were performed using Statview software with statistical significance set at $P = 0.05$. The study was approved by the local ethical committee. Results: RR for OB is increased by parental OB (RR: 2.5, 95% CI[1.66-3.76]). Obese children have higher BW ($3.51 + 0.59$ vs $3.31 + 0.55$ kg, $P = 0.0008$), are less breastfed (16 vs 20%, $P = 0.0004$). BMI is negatively correlated to time spent to outdoor activities ($P = 0.002$) and positively to energy intakes ($P = 0.0003$). Less OB children eat breakfast (69 vs 83%, $P = 0.0004$). Junk foods snacking is more common in OB children than in non OB ones (65% vs 56 %, $P < 0.05$). SES status does not differ among OB and non OB children. Conclusion: Recent changes in urban lifestyle in Algeria, but not SES, favour at risk behaviours leading to OB, starting from early childhood onward. Urgent preventive actions need to be undertaken

N2 - Background: Romp & Chomp (R&C) was an intervention conducted in Geelong, Australia (2004-2008) which aimed to prevent childhood obesity and promote healthy eating and active play in 0-5-year old children through community capacity-building and environmental (policy, socio-cultural, physical) interventions in earlychildhood settings. This paper presents the intervention impacts in family day care (FDC); a government funded and accredited homebased childcare service. Methods: Evaluation of R&C was cross-sectional and quasi-experimental with a comparison sample. An environmental questionnaire was completed by FDC providers at follow-up in intervention (n = 28) and comparison (n = 347) samples. The 45-item survey captured information about the nutrition and physical activity environment. Results: Post intervention, children in the intervention sample spent significantly less time watching television (P < 0.001) and using computer/ electronic games (P < 0.05). Intervention children spent significantly less time in organised active play (P < 0.001), and free inside play (P < 0.001), but were taken more often for active play at another location (P < 0.001) and minimum time in outside play was higher (P < 0.05) compared to the comparison sample. Related to healthy eating, FDC providers in the intervention area had significantly higher odds of: written guidelines related to appropriate foods/drinks for parents to send to care (OR:2.49, 95%CI:1.61-3.86), rules related to healthy eating (OR:1.46, 1.14-1.88) and, taking action if foods provided do not meet guidelines (OR:3.63, 2.63-4.99). Conclusions: The improvements made in the FDC service through the R&C intervention have created more opportunities for children to be physically active and eat more nutritious foods during their time in care

N2 - Introduction: Recombinant activated coagulation factor VII (rFVIIa) is currently a firstline treatment of bleeding episodes in patients with haemophilia A and B with inhibitors. Several studies have been published showing a new dosing schedule of a single dose of 270 ug/kg to be as effective and safe as the standard 90 ug/kg every 2-3 hours. Objective: To evaluate, outside the setting of a clinical trial, the efficacy and safety of single dose rFVIIa treatment in mild/moderate bleeding episodes. Methods: We reviewed 24 mild/moderate bleeds from 10 severe HA patients with inhibitors from our institution. Mean age was 9 years old (4-24), mean inhibitor title was 50.6 BU/mL (5-450). All patients received treatment with single dose rFVIIa and response was evaluated every three hours. If bleeding persisted, further doses were administered. Efficacy was evaluated according to the need of additional doses and re-bleeding within five days of the original episode. Results: The mean dose administered was 217.77 ug/kg (177-309). 20/24 patients (84%) responded to the initial dose, with only 4 (16%) requiring additional doses. Only 1 patient required a new treatment with rFVIIa 3 days after the original episode. No thromboembolic events were registered. Conclusions: Single dose rFVIIa proved to be an efficacious treatment for mild/moderate bleeding episodes in inhibitor patients. The efficacy showed in our patients (84%) was similar to that reported in the literature (81-92%). This treatment provided rapid bleeding control and could be a convenient option, especially for younger children and those with poor venous access

N2 - Introduction: There is limited research on the use of exercise tests outside the clinical laboratory setting in children with CF. Aims: To assess reliability and acceptability of (a) cycle ergometry tests, and (b) using the LifeShirt to record cardiorespiratory responses during cycle ergometry tests, in children with CF. Methods: Children with CF and stable lung disease wore the LifeShirt during 2 cycle ergometry tests (intermittent sprint test (IST) measuring muscle power; continuous incremental test (CIT) measuring cardiorespiratory fitness) on 2 occasions 7-8 days apart. Acceptability data were collected by questionnaire. Results: 10 children with CF completed the study: (5M:5F), 9(2) y, FEV₁: 83(14)%. Peak power (IST) and peak work capacity (CIT) were reliable (bias $p > 0.05$, CV $< 10\%$). Tidal volume, ventilation, respiratory rate, fractional inspiratory time, heart rate and SpO₂ recorded by the LifeShirt demonstrated no significant bias ($p > 0.05$). Respiratory rate, fractional inspiratory time, heart rate and SpO₂ demonstrated acceptable CVs ($< 10\%$). Acceptability questions indicated that cycle ergometer tests and the LifeShirt were mainly acceptable to the children. Conclusion: This is the first study to report reliability of cycle ergometry in children with CF. The LifeShirt may be useful for simultaneous measurement of respiratory rate, fractional inspiratory time, heart rate and SpO₂ outside the normal clinical laboratory setting, however, there is concern over volume components of breathing in children with CF

N2 - OBJECTIVES: The aims of this pilot study were to test effectiveness of a supplemental curriculum intervention in nutrition and physical education in a summer Midwest MEP with the children of migrant farmworkers (MFWs), and to evaluate the study feasibility. Outcomes were: changes in body mass index (BMI), BMI percentile, weight, and knowledge. We hypothesize that students assigned to the intervention group will show greater improvement in outcomes in contrast to the comparison site. METHODS AND POPULATION: Two summer MEPs that support MFW children in remedial education were study sites: intervention group n = 138, comparison group n = 33. Students had 4 interventions a week (2 of each) and structured recess. Curriculum was ethnically-tailored with subject oriented, Latino themed children's trade books, cooking classes and a field day. RESULTS: Bivariate analysis showed that more MEP days attended, the larger change in wt ($r = .24$, $p = .03$, $n = 78$), and larger change in BMI ($r = .27$, $p = .01$, $n = 78$); the means of change in BMI and change in BMI % were negative ($n = 110$). The intervention site had marginal significance with change in BMI (Kendall Tau's, $r = -0.16$, $p = 0.07$, $n = 110$). In the nonparametric Wilcoxon 2 sample test, the intervention site was significant for change in wt ($p = .05$) with the comparison group being heavier in wt. When looking at change in BMI, the intervention group had a greater than 4-fold decrease in change in BMI (-.14 vs. -.03) with marginal significant (Wilcoxon 2 sample test, $p = .06$, $n = 110$). Increases in age-appropriate knowledge scores from baseline to intervention conclusion were seen in 2 assessments by 70% ($n = 47$) and 63% ($n = 46$) of the students. SIGNIFICANCE OF STUDY: Summer MEPs can provide opportunities to instruct MFW children on healthy eating and activity with positive results

IS - var.pagings

N2 - Objective: This study investigated the impact of transition to high school on the range, frequency, enjoyment of, and preferences for participation in activities outside school. We hypothesised that activity preferences would be stable across the period that included transition to high school but that the range of activities adolescents with cerebral palsy engaged in would be reduced. Design: A component of a longitudinal (3 waves, 12mo apart), population-based study of children born in Victoria Australia in 1994 or 1995 who had cerebral palsy. Method: Participants were 26 boys (53%) and 23 girls (47%), classified at Manual Ability Classification System levels I (22%), II (45%), III (19%), IV (8%) and V (6%) and Gross Motor Function Classification System levels I (35%), II (41%), III (6%), IV (10%) and V (8%). All 49 participants contributed wave-1 data in 2006 [mean age 11y 10mo (SD: 6mo)], and wave-2 data in 2007 when n=19 of the 49 had transitioned to high school [mean age 12y10mo (SD: 6mo)]. 30 participants contributed wave-3 data after transitioning to high school in 2008 [mean age 13y9mo (SD: 6mo)]. Participation in recreational, active-physical, social, skill-based and self-improvement activities outside of school was measured using the Children's Assessment of Participation and Enjoyment (CAPE) and the Preferences for Activity of Children (PAC).¹ Changes in diversity (number of activities) intensity (relative frequency), enjoyment and preference were assessed using paired t-tests between assessments conducted 12 months apart (before and after transition). Results: There was some evidence that participation in recreational activities (e.g. crafts, puzzles, pet play, computer games) was reduced after transition to high school in diversity ($t_{48}=-2.47$, $P=0.017$; average reduction of one activity), intensity ($t_{48}=-1.97$, $P=0.055$), and preference ($t_{48}=-3.06$, $P=0.004$). There was no evidence that diversity or intensity of participation in active-physical, social, skill-based or self-improvement activities were different following transition (all $P>0.05$). Apart from changes in recreational preferences, preferences and enjoyment for all other activity types were stable (all $P>0.05$). Conclusion: In this study, participation in activities outside school was predominantly stable across the transition to high school. The slight reduction in participation in recreational activities more suited to younger children was similar to that shown previously,² but was not balanced by an increase in participation in social activities as is expected in typically developing adolescents.³

N2 - Objectives: To identify the source of a protracted Salmonella Paratyphi B biovar Java (S. Java) outbreak localized to a single local government area within metropolitan Sydney, Australia. Methods: From 2007 to 2009 S. Java cases notified under public health legislation to the Northern Sydney Central Coast Area Health Service were interviewed to collect clinical information and to identify likely sources of infection. Human isolates were classified by phage typing and Multi-locus Variable number tandem repeat Analysis (MLVA). Environmental samples were collected from various sources and isolates classified using both phage typing and MLVA. Contaminated sand from one playground was tested second monthly to assess environmental persistence of the bacterium. An age-matched case control study was conducted for outbreak cases identified in the first half of 2008 to test the hypothesis that close contact with playground sand was the source of outbreak. Results: A total of 69 cases of S. Java were notified among residents in a single local government area (population 57,000) between 2007 and 2009 with 41% aged less than 2yrs. Most cases had significant gastrointestinal symptoms (including bloody diarrhoea) lasting a median of 7 days. Of the 65 human isolates for which phage typing was available 72% were reported as Dundee with remainder typed as reacts does not conform (RDNC). MLVA typing identified a specific outbreak strain with no variation at the first and fifth loci and only minor variation at the second locus. Case interviews implicated playground sand as a possible source and subsequent environmental testing isolated S. Java with the outbreak MLVA pattern from 5 of 13 playgrounds tested. Second monthly testing of sand from one playground left undisturbed and closed to public access demonstrated that the organism could survive for at least 6 months in sand. The case control study confirmed playground sand exposure as the source of the outbreak with cases being significantly more likely to have played with sand in known contaminated playgrounds (odds ratio 3.7, 95% ci 1.1 to 12.1). Conclusion: This research demonstrates that S. Java can survive in sand for a prolonged period and lead to a sustained community outbreak of human disease. The use of sand in playgrounds can pose a microbiological hazard especially to young children

IS - var.pagings

N2 - Attention deficit/hyperactivity disorder (ADHD) is one of the most common childhood disorders characterized by three clusters of age inappropriate symptoms: inattention, hyperactivity and impulsivity, with a high worldwide prevalence (around 5%). Several authors have hypothesized that deficits in executive function, behavioral inhibition, and working memory (WM) are considered as one of the key neuropsychological features in children and adolescents with ADHD. Although there is a strong evidence suggesting that frontostriatal dysfunctions is central to the pathophysiology of ADHD, there is now growing evidence in the most recent studies, of dysfunctions outside the frontostriatal circuitry, including the cerebellum and the temporoparietal lobes. The purpose of the present study was to investigate in fMRI, the cerebro-cerebellar networks to verbal WM (n-back task) in prepubertal 8-12-years old, right-handed and medication naïve children with ADHD combined type (n=18) in comparison with a control group (n=17). Because ADHD is associated to high rates of comorbidity, we decided to only include ADHD participants without comorbidity, to avoid their own impact on different brain regions and functions. In conclusion, functional data indicate significant different activation patterns in WM task between healthy controls and patients with ADHD suggesting less activity in ADHD in left occipital region (area 17/18), and in crus1 region in right cerebellum. These results will be discussed in light of recent literature in this field, and specially the cognitive contribution of the cerebellum in working memory

N2 - Community-based occupational therapy (OT) services are intended to promote social integration and minimize disability. The objective of this study was to describe community-based OT services for children in the province of Quebec, Canada. Specific aims included (a) to determine the proportion of Centres Locaux de Services Communautaires (CLSCs) that provide OT services to children, (b) to describe the nature of the services offered, and (c) to identify factors that are associated with the availability of these services. Surveys were sent to all CLSCs where at least one OT was employed. The response rate was 80. Only 12 of CLSCs offered OT services to children on a regular basis (≤ 1 day/week). Home adaptations were the most frequent service offered, whereas health promotion was rarely addressed. Perceived obstacles to servicing children included prioritization of services to the elderly, limited funding, and shortage of OTs. CLSCs in rural areas and those with a psychologist had significantly more dedicated OT time spent for services to children. The findings suggest that community-based OT services for children in Quebec are poorly developed, which may negatively impact upon timely access to specialized rehabilitation services and may increase activity limitations and family burden. © 2009 by Informa Healthcare USA, Inc. N2 - Research has found that obese and overweight boys and girls are prone to less physical activity. In this study, we reinvestigate the relationship between physical activity and obesity among children. We examined the differences in physical activity between overweight and normal weight children. One-hundred and twenty six Hawaii school-system children participated in this study. The children were measured for height and weight, and answered questions about their activity level. Activity level was assessed by participation in physical education, active play during recess and lunch, and other activities during the past week. Children were divided into obese, overweight and normal weight based on their age and body mass index (BMI). Age-adapted BMI was used as overweight and obesity indicator. The hypothesis for this project is that physical activity will be greater with normal weight boys and overweight girls than it is with overweight boys and normal weight girls

N2 - Two-hundreds and twenty-eight children (127 males and 101 females), mean age 8 years, were enrolled from 2 primary schools, which were located in different sites, for studying pollution related respiratory symptoms and/or diseases in different places of Milan with a different traffic related exposure. The former (School 1) was located near a large park, the latter was located downtown, close to main crossroads (School 2). Daily levels of PM10 and PM 2,5 (diameter < 10 μm and 2,5 μm , respectively) were measured using a mobile detection unit, which was placed either outside the schools (in the school garden) and within common places (corridors), for 7 consecutive days during 2 different campaigns (winter and spring-summer). Children underwent skin prick testing for inhaled allergens, analysis of exhaled nitric oxide and spirometry. The mean values of respiratory function measured by spirometry was within the normal limits in both schools. The mean value of Tiffeneau index (SD) was significantly lower in downtown school: 93.2 (5.5) vs 96.5 (4.1) ($p=0.02$). Mean (SD) concentration of FeNO (ppb) was higher in downtown school: 13.6 (14.6) vs 12.5 (14.9), and the distribution of FeNo concentration significantly differs between the two schools ($p=0.02$). 193 subjects (73 in downtown school and 120 in park school) agreed to undergo to skin prick tests. Prevalence of sensitization to inhaled allergens did not differ significantly between the two schools (downtown school, 32.8% vs park school, 27.5%; $p=n.s.$). Based on ISAAC questionnaire the percentage of asthma exacerbations in the previous 12 months was higher in children from school downtown ($p=0.05$); the prevalence of persistent allergic rhinitis in children allergic to grass pollen was higher in park school ($p=0.03$) with more activity limitation due to rhinitis and associated conjunctivitis ($p=0.03$). Present findings show that different degrees of respiratory function and bronchial inflammation were found in the 2 groups of children. Even if great caution is required when relating data from air quality monitoring to clinical outcomes in humans, it can be inferred that: 1) the different air quality in the 2 schools could have a role in determining observed differences; 2) traffic could be, at

least in part, responsible for the different air quality; 3) reduction of traffic related pollution should be a logical and suitable objective of policy makers

N2 - Exercise-induced asthma (EIA) is one of the major factors that affect optimal performance in sport. The prevalence of EIA is reported to be on the increase among school children worldwide. The aim of this study was to indicate EIA prevalence among primary-school children in South Africa. A field study determined the prevalence of EIA. A convenience sample of 127 children aged 8 to 16 years was selected. A health- screening questionnaire was used. The criteria for selection were that the subjects should be non- asthmatics and should not have any other illness during the screening that could interfere with the results. Peak expiratory flow rate (PEFR) was measured pre- and post-exercise using an ASSESS peak flow meter. The subjects did a six-minute run on a school playground. The post-exercise PEFR was measured within 10 minutes of exercise. The determinant of EIA was > 10% decrease in PEFR after exercise. A total of 112 (88%) subjects participated in the study. Fifteen subjects were excluded (eight had asthma, five had respiratory tract infection and two had other illnesses). The average exercise heart rate was + 80% of predicted maximal heart rate. The prevalence of EIA was 23% (n = 26). The incidence of a history of allergic rhinitis was statistically significantly increased among those with positive tests (p = 0.027). This study highlights the need to screen all children so that EIA can be determined and addressed appropriately. SAAFP

N2 - Exposure of human population in developed countries to chlorination products has considerably increased during the 20th century especially after the 1960s with the development of public swimming pools. Swimmers, however, are mainly exposed when they actively inhale aerolised chlorination products in the air just above pool surface. Studies on elite swimmers has shown that the chlorine-laden atmosphere of indoor pools could be detrimental to the lungs, by increasing the risk of asthma, bronchial hyperreactivity and airways inflammation. Recent studies have suggested these adverse effects of pool chlorine on the airways and increased

risk of asthma even in children with recreational swimming, especially with atopy who regularly attend indoor pools before the age of 5 years. Prospective follow-up studies are needed whether or not a cause-effect relationship really exists between recreational swimming and asthma development. Trichloramine, the gas that builds up in the air of indoor pools, giving them their distinctive chlorine smell, has been identified as a cause of asthma and respiratory problems in pool workers. Even frequent attendance of outdoor chlorinated swimming pool is associated with higher risks of asthma and airways inflammation

N2 - This paper reports a small-scale study to determine whether there is a difference in problem-solving abilities, from a play perspective, between individuals who are diagnosed as ADHD and are on medication and those not on medication. Ten children, five of whom were on medication and five not, diagnosed as ADHD predominantly inattentive type, were observed in school playgrounds in Malta during recess to verify any

differences in the ways real-life problem-solving situations are tackled. Results indicated that children on medication tend to avoid group situations and discussion more often than their non-medicated peers. Additionally, non-medicated individuals tend to jump more quickly from one emotional state to the other and resort to physical aggression more often compared with medicated individuals. Such findings suggest that medication has a negative effect on social interaction processes, while it helps to maintain self-control, at least from a physical stand point. 2009 SEBDA

N2 - Early intervention through the use of a powered wheelchair can meliorate the developmental experience of children with mobility impairment. It is therefore important to design an effective training and assessment strategy to facilitate the potentials of each child in readiness to drive the device. The use of virtual reality (VR) technology for wheelchair training purposes is therefore considered. The skills acquired during training in a virtual reality system should be observable in the functional activities of the learner. It is necessary to evaluate

the degree and the permanence of the skills learnt from the virtual environment to other activities outside the training environment. The mode of evaluation applied during conventional wheelchair training could provide the basis upon which permanence of skills is determined after training in virtual reality. Thus, an induction factor is proposed as a measure of the transfer of powered wheelchair control skills from virtual reality to the functional activities of daily living by the learner. The outcomes show that virtual reality technology could offer an appropriate means of providing powered wheelchair training that can be tailored to the needs of the learner.

N2 - Recently Sinusitis is declining in severity, while allergic rhinitis is increasing in prevalence. Although improved nutrition and the spread of hygiene information have caused a decline of sinusitis, air pollution has caused an increase in rhinitis. Behind these changes, the first factor to consider is air pollution. While areas with no air pollution have more schoolchildren with infectious rhinitis, sinusitis and allergic rhinitis are both notably more prevalent among schoolchildren in air-polluted areas. In a nationwide survey, the prevalence of cedar and cypress pollen allergies was the highest at 26.9% in Yamanashi Prefecture, followed by Nagano, Kochi, and Shizuoka Prefectures. Although it is said that pollen allergies have come to affect children at younger ages, teenagers and younger children are also more likely to have perennial allergic rhinitis. Analysis of the association between allergic rhinitis and sports showed that the prevalence rate was higher among children playing indoor sports and lower among children playing outdoor sports or no sports. The prevalence rate was lower among children who received treatment, health management guidance, and hygiene management guidance. With respect to the association between allergic rhinitis and learning, healthy children had better academic performance records, while placebo-treated children performed worse, and those who received

medication showed varying results, with some children performing well depending on what drugs were administered

N2 - Purpose. The role of levetiracetam in different epileptic, nonepileptic, neurologic, and psychiatric disorders is discussed. Summary. Levetiracetam, an antiepileptic drug (AED), was first approved as an adjunctive therapy for the treatment of partial epilepsy in adults. It is currently being used in the treatment of multiple seizure disorders, including generalized tonic-clonic; absence; myoclonic, especially juvenile myoclonic; Lennox-Gastaut syndrome; and refractory epilepsy in children and adults. Data are emerging on possible uses of levetiracetam outside the realm of epilepsy because of its unique mechanisms of action. There is preliminary evidence about the efficacy of levetiracetam in the treatment of different psychiatric disorders, including anxiety, panic, stress, mood and bipolar, autism, and Tourette's syndrome. The most serious adverse effects associated with levetiracetam use are behavioral in nature and might be more common in patients with a history of psychiatric and neurobehavioral problems. Conclusion. Levetiracetam is an effective AED with potential benefits in other neurologic and psychiatric disorders. The benefit-risk ratio in an individual patient with a specific condition should be used to determine its optimal use. Levetiracetam's use in nonepileptic conditions is not recommended until more data become available from larger trials. Copyright 2009, American Society of Health-System Pharmacists, Inc. N2 - **PURPOSE OF THE STUDY:** To provide a detailed description of the Ponseti method and report the first results of its use, including factors that played a role. **MATERIAL AND METHODS:** In the 2005-2007 period, 91 patients with idiopathic rigid clubfoot (133 feet) were treated by the Ponseti method. The group comprised 62 boys and 29 girls. In most patients the Ponseti method was used as primary treatment, or by 3 months of age when previous treatment failed. In five children this treatment was started between the 3rd and 8th months of age. The result were evaluated by the criteria described by Richards et al., who distinguished four groups. The result was regarded as good when a permanent plantigrade foot was achieved (group 1). Plantigrade feet likely to require posterior release later were considered indeterminate results (group 2). Feet that needed posterior release, anterior tibial muscle transfer or lateral column shortening fell in the fair result group (3). Feet requiring complete subtalar release were classified as poor results (group 4). The results achieved in each year were statistically evaluated using Fisher's test ($p < 0.05$). **RESULTS:** The overall evaluation for 3 years showed good results in 70 %, indeterminate in 7.5 %, fair in 6.76 % and poor in 15.8 % of the treated feet. A detailed analysis for each year revealed that, in 2005, good results (50 %) were recorded in a significantly lower number of feet than in 2006 (72.2 %; $p = 0.032$) and 2007 (93 %; $p < 0.001$). On comparison of the years 2006 and 2007, good results in 2007 were found in a significantly higher number of feet than in 2006 ($p = 0.019$). The poor results

were due to 1) very rigid feet (6 %); 2) initial problems with availability of Denis-Brown splints (19 feet; 14.5 %); 3) problems with shoes not made to custom and not fitting patient's little feet (20 feet; 15 %) 4) faulty techniques of correcting the deformity (4 feet); 5) poor family cooperation in compliance with the bracing protocol (15 feet; 11.2 %). Some of the factors were combined. A delayed beginning of the treatment had no significant effect on the results. **DISCUSSION:** Our 3-year results of clubfoot treatment, by which plantigrade foot position was achieved on average in 77.5 % of the patients, are in agreement with those achieved outside Ponseti centres. However, there were clear differences, with the worst results in 2005. The results comparable with those of Ponseti and his co-workers were achieved by us only in 2007. In accordance with the findings of Richards et al. we suggest that the percentage of short-term good results can change insignificantly within 4 years because of increased recurrence of deformities. **CONCLUSIONS:** Although our initial results were worse than reported in the literature, it can be concluded that the Ponseti method of treating idiopathic clubfoot is more efficient than the methods used previously and can be recommended as an efficient, safe and economical technique. Good compliance with the protocol improves the therapeutic results

N2 - Background: Drowning is a preventable cause of morbidity and mortality. We studied drowning deaths in Isfahan province, focusing on the activity victims were involved in and the setting of the incident. Methods: Retrospective analysis was done on all drowning deaths referred to Legal Medicine Organization of Isfahan province over a period of 5 years from 1 January 2002 to 31 December 2006. Results: During these 5 years, 355 persons suffered fatal drowning in Isfahan province. The annual incidence rate was 1.6 per 100000 population (2.6 & 0.4 for males and females, respectively). Mean age was 21.99 + 14.86 and M/F ratio was 6.5:1. Most victims were 15-24 and 5-14 years of age (172 and 62 decedents, 3.0 and 1.8 per 100000 population/year, respectively). Most incidents occurred in natural settings, of which rivers, canals, lakes and ponds were the most common sites, respectively. The most frequently connected activity was swimming and wading, followed by accidental fall into water. The manner of death was found as following: 85.1% accidental, 1.7% suicidal, 0.3% homicidal and 12.9% undetermined. Conclusions: Although the drowning related mortality in Isfahan province is comparable to developed countries, effective prevention of drowning with better programming and policies might reduce its rate

N2 - Background: Sevoflurane is often presented as a near-perfect anaesthetic. After 10 years in the operating room, new uses are emerging outside. Objective: To remind readers of the principal characteristics of sevoflurane, to affirm its usefulness for day-case anaesthesia and to consider the recent new uses. Methods: The discussion of the physical properties, pharmacokinetics, metabolism, mechanisms of action and clinical effects is based on classic, essential papers. Recent literature concerning emerging utilizations of sevoflurane was analysed. Results: Sevoflurane presents many benefits with minimum inconvenience. It allows rapid inhalation induction, maintenance and rapid recovery. It has little toxicity and its haemodynamic and respiratory depressive effects are moderate and well tolerated. It is already widely use for sedation for magnetic resonance imaging in children. Its use in paediatric or adult intensive care could improve the management of pain and sedation. 2009 Informa UK Ltd. N2 - Background. Enterovirus infections are very common and typically cause mild illness, although neonates are at higher risk for severe illness. In 2007, the Centers for Disease Control and Prevention (CDC) received multiple reports of severe neonatal illness and death associated with coxsackievirus B1 (CVB1), a less common enterovirus serotype not previously associated with death in surveillance reports to the CDC. Methods. This report includes clinical, epidemiologic, and virologic data from cases of severe neonatal illness associated with CVB1 reported during the period from 2007 through 2008 to the National Enterovirus Surveillance System (NESS), a voluntary, passive surveillance system. Also included are data on additional cases reported to the CDC outside of the NESS. Virus isolates or original specimens obtained from patients from 25 states were referred to the CDC Picornavirus laboratory for molecular typing or characterization. Results. During 2007-2008, the NESS received 1079 reports of enterovirus infection. CVB1 accounted for 176 (23%) of 775 reported cases with known serotype, making it the most commonly reported serotype for the first time ever in the NESS. Six neonatal deaths due to CVB1 infection were also reported to the CDC during that time. Phylogenetic analysis of the 2007 and 2008 CVB1 strains indicated that the increase in cases resulted from widespread circulation of a single genetic lineage that had been present in the United States since at least 2001. Conclusions.

Healthcare providers and public health departments should be vigilant to the possibility of continuing CVB1-associated neonatal illness, and testing and continued reporting of enterovirus infections should be encouraged. 2009 by the Infectious Diseases Society of America. All rights reserved

N2 - Objective:- To determine the frequency & pattern of injuries in children less than 15 years of age. Material & Methods:- 500 cases are studied in children less than 15 years of age at Emergency Department, DHQ Hospital Rawalpindi. Place of Study: Emergency Department DHQ Hospital Rawalpindi. Duration of Study: Retrospective study to determine the relative frequency and pattern of injuries in children less than 15 yrs of age. Results:- A total number of 500 children were seen in ED and ages ranged from 1 month to 15 years. There were 321 males & 179 Females representing about 61.2% & 35.8% female respectively with ratio of about 2: 1.

A total no of 210 children were injured by fall. In 0-5 year age group fall is either from stair furniture, beds or walker. In 5-15 years age group the playground injuries like fall from owings, slide & sea saws. The injuries were mostly on head and upper limbs

N2 - Introduction: Unsuitable dietary habits and sedentary life are perhaps the main causes of the alarming increase in childhood obesity, and they are closely linked to eating disorders. The school is an ideal place to foster healthier lifestyles. Materials and methods: This is a community-based, interventional, longitudinal, prospective study for the purpose of measuring the improvement in eating habits and physical activity after a year of health education in two schools during the school year 2003-2004. Five hundred one school children ranging in age from 3 to 16 years took part in the project. Surveys were designed and were completed before and after the program. The intervention was designed for children, parents and teachers. Results: We must highlight the low intake of legumes, fruits, vegetables and fish. Of the children who took part in the project, 5.1 % attended class without having had breakfast. The improvements achieved after the program were: at breakfast, a decrease in the intake of industrial bakery and pastry products ($p < 0.000$); at lunch time, a decrease in the consumption of snacks ($p < 0.000$) and, in mid-afternoon, the intake of industrial baked goods, soft drinks (juices not included) and snacks also decreased. In all, 40% of the children involved do not practice any physical activity outside of school and a large number of them watch TV for more than two hours. Despite this fact, we have observed a decrease in the time spent watching TV ($p < 0.005$). Conclusions: After a year of health education in the school, we find little improvement regarding eating habits. It is necessary to promote physical

activity at an early age and reduce the time spent in front of the TV, video games and computers. The school is the best place to develop these programs, but getting parents involved in this task is difficult

N2 - Background: Patients with end-stage renal disease (ESRD) cannot sustain life in the absence of renal replacement therapy (RRT). However, a 4-year dialysis freedom with improved well-being has been reported in ESRD using a new therapeutic approach combining conservative measures and acacia gum (AG)

supplementation. The aim of this paper is to report the achievement of 6-year dialysis freedom. Patients and

methods: During December 2001, six patients with ESRD and significant uremia that required at least one

dialysis session to maintain life were enrolled in a clinical trial investigating the use of a new therapeutic

approach combining conservative measures and AG supplementation aiming at improving well-being and

providing patients with ESRD dialysis freedom. Three patients were treated with this approach. One patient

complied with protocol for only 10 days and died after 6 months peritoneal dialysis. Two patients completed 1

year on this therapeutic regimen. Both patients reported improved well-being. Neither became acidotic nor

uremic, and neither required dialysis during the 1 year of the study period. Both patients maintained serum

creatinine and urea levels not previously achieved without dialysis. The other three patients were managed with

intermittent peritoneal dialysis (IPD). All died within less than 6 months. Of the two surviving patients on AG

supplementation, one patient stopped AG supplementation after 1 year and died within 1 month despite IPD.

The other patient continued to be treated with this novel approach and continued to experience improved well-

being and dialysis freedom. The aim of this paper is to report the achievement of 6-year dialysis freedom in this

patient. Results: During 6 years of therapy the girl continued in experiencing improved well-being and good participation in outdoor activities. Mild uremic symptoms occurred only during periods of noncompliance. Periods of decreased compliance with pharmacologic therapies were associated with anemia and renal osteodystrophy and some degree genu valgum has resulted. Conclusion: It was possible to address ESRD in this particular patient as a disease process that can be treated by totally different medical treatment approaches without the use of either chronic dialysis or transplant. 2009 Japanese Society of Nephrology

N2 - Objective: Foreign body inhalation is a potentially life-threatening emergency and is the commonest cause of accidental death in children under one year old. There is varying opinion regarding the urgency for removal of inhaled foreign bodies; most centres in the United Kingdom will take the patient to theatre as soon as can be arranged, regardless of the time of day. At Great Ormond Street Hospital for children it has been standard practice to perform rigid bronchoscopy and removal of an inhaled foreign body on the next available daytime operating list, providing the patient is clinically stable, even if this incurs a delay until the following day. We aimed to identify if any additional morbidity resulted from delaying removal of the foreign body. Methods: Retrospective case note review of all cases of foreign body inhalation seen at our institution over an 11-year period between July 1996 and July 2007. Results: 165 patients were referred to our institution with a suspected inhaled foreign body in the study period. 14 patients were managed conservatively due to low clinical suspicion and 57 patients underwent a negative bronchoscopy: these groups were excluded from our analysis. Of the remaining 94 patients, only 7 were taken to theatre outside a scheduled daytime operating list. All of these patients had signs of severe respiratory distress and were operated upon within 4 h of their arrival. Of the remaining patients, 41 were taken to theatre on the day of presentation and 46 on the day after presentation; all within normal daytime working hours. No additional post-operative morbidity was identified as a result of our policy to delay bronchoscopy until the next available daytime operating list. Conclusions: It is our perception that delaying removal of suspected inhaled foreign bodies to allow optimal circumstances for manipulation of the paediatric airway is a safe practice at our institution. We have not identified any adverse outcomes related to delaying bronchoscopy to the next available daytime operating list in the clinically stable patient. This remains our preferred method of practice. 2009 Elsevier Ireland Ltd. All rights reserved

N2 - We examined the effects of a teacher implemented playground intervention consisting of activity schedules and task correspondence training on the challenging behaviors and play of three school age children with moderate to severe autism. A multiple baseline design across participants was used to evaluate the intervention effects. Results indicated that each of the participants learned to use an activity schedule to follow a schedule of play activities and demonstrated improved play. Moreover, challenging behavior decreased for two participants during the intervention and remained at low levels for the third participant. The findings from this study provide support for the use of activity schedules and task correspondence training to reinforce appropriate play and decrease challenging behaviors during recess. 2008 Elsevier Ltd. N2 - Changes over recent decades in outdoor concentrations of air pollutants are well documented. However, the impacts of air pollution on an individual's health actually relate not to these outdoor concentrations but to their personal exposure in the different locations in which they spend time. Assessing how personal exposures differ from outdoor concentrations, and how they have changed over recent decades, is challenging. This review focuses on the exposure of children, since they are a particularly sensitive group. Much of children's time is spent indoors, and childhood exposure is closely related to concentrations in the home, at school, and in transport. For this reason, children's personal exposures to air pollutants differ significantly from both those of adults and from outdoor concentrations. They depend on a range of factors, including urbanisation, energy use, building design, travel patterns, and activity profiles; analysis of these factors can identify a wider range of policy measures to reduce children's exposure than direct emission control. There is a very large variation in personal exposure between individual children, caused by differences in building design, indoor and outdoor sources, and activity patterns. Identifying groups of children with high personal exposure, and their underlying causes, is particularly important in regions of the world where emissions are increasing, but there are limited resources for environmental and health protection. Although the science of personal exposure assessment, with the associated measurement and modelling techniques, has developed to maturity in North America and western Europe over the last 50 years, there is an urgent need to apply this science in other parts of the world where the effects of air pollution are now much more serious. 2008 Elsevier Ltd. N2 - Introduction and Objectives: Children and their carers may experience difficulties in obtaining continuing prescribed medicines whilst in primary care. Issues include who will prescribe continuing medication (general practitioner (GP) or consultant) and problems in obtaining appropriate medication from community pharmacies. These issues may be enhanced where the required medicines are unlicensed or used 'off-label', which is frequent in paediatrics.^[1] This study describes the role senior hospital nurses undertake in response to medication issues for patients residing in primary care. Methods An electronic survey tool was developed and created using LimeSurvey version 1.71+(5498). The development included discussion with clinical nurse specialist/advanced nurse practitioners (CNS/ANPs) and was piloted before use. The survey was tokenised to ensure that one invite elicited one response only. The invitation to participate was sent via e-mail with a link to the study to the CNS and ANP of Birmingham Children's Hospital commencing September 2008. Two reminders were sent if necessary at weekly intervals. Responses were entered into MS Excel 2003 for analysis. Results and Discussion A 78% response rate was obtained from study cohort of 100 nurses. Nurses from 23 specialties completed the questionnaire with 49 nurses (63%) working more than 30.1 h per week (0.8 whole time equivalent), nine as prescribers. A majority (n = 57, 73%) reported that in the 3 months preceding the study, they were called upon to organise repeat prescriptions at least once, with 28 (36%) doing so on 6 or more

occasions, and 55 (70%) of respondents organised repeat prescriptions for at least 514 patients over the 3-month period. Fifty nurses (64%) described the risk to patients if they did not assist patients in accessing medicines as significant or highly significant, Only 10 nurses (12.8%) considered that this activity was included in their job descriptions. The respondents indicated that the most common reason for such problems was prescriber issue(s). The respondents gave a range of responses when asked in what ways services can be better organised including require GPs to prescribe all continuing medicines (59% frequency) and require hospitals to prescribe and dispense unlicensed/uncommon medicines (46% frequency). Conclusions Hospital CNS and ANP report frequent interventions to assist patients outside hospital in obtaining the medicines they need. Prescriber-related issues were the most common reason cited for these problems. Further work will be required to identify the rational for this opinion. Hospital CNS and ANP provide an important service to patients in primary care although this may not be reflected in their job description. Pharmacists in all healthcare sectors will benefit from being aware of this activity. The findings of this study suggest that responsibility for prescribing between hospitals and GPs described in 1991^[2] may benefit from review

N2 - In vitro toxicity of complex chloroform-extractable endo- and exo-metabolites of 10 indoor, and related outdoor, *A. versicolor* isolates from a heavily mouldy kids' fashion store in Slovakia with complaints of occupants on irritation of their airways - has been evaluated by a bioassay with 1-day-old chicks' tracheal organ cultures (20 µg of toxicants per mL of cultivation medium). Searching for their possible source, molecular epidemiological study of the isolates was performed using RAMP PCR. Strains colonizing indoor walls of the shop were the highest correlated to the outdoor airborne ones (Pearson correlation 97%). While indoor airborne isolates correlated to the strains growing on retailed clothes at the levels of 90% or 86% according to Pearson. All micromycetes produced secondary metabolites that ceased ciliary beating in tracheal epithelium in the organ cultures already in 24 h of the activity, i.e. in the sense of the method used, they belong to strong toxicants. Two of the isolates tested so far produced also extrolites without toxic effects detectable by the method. It has been proven that toxin production in fungi depends not only onto the species but may vary between every single isolates as well. The most important outcome of the study is that microscopic filamentous fungi present in the dwelling indoor environment under Slovak (Central European) building/housing conditions might produce compounds even with a strong potential to damage upper airways of occupants, while children remain the most vulnerable population

N2 - Background: Because most individuals spend about 85% of their time indoors, we investigated the health effects of indoor air PM₁₀. Methods: PM₁₀ was collected in five schools in Munich during teaching hours. Toxicity was assayed in human primary keratinocytes, human lung epithelial A549 cells and Chinese hamster V79 lung fibroblasts at concentrations from 3 ng/ml to 10 µg/ml. Toxicity after metabolic activation was assayed in cells expressing human cytochrome P450 1A1, 1A2, 1B1, 2A6, 2B6, 2C9, 2D6, 2E1, 3A4, or 3A5. Additional toxic effects were analyzed with affimetrix genome wide gene expression analysis in BEAS-2B bronchial epithelial cells at 10 µg/ml PM₁₀. Results: In A549 and V79 cells no toxicity was observed. In human primary keratinocytes PM₁₀ evoked a slight, but significant decrease in vitality. PM₁₀ was also toxic after metabolic activation by CYP1A1 or CYP2C9.

PM₁₀ induced in BEAS-2B cells the expression of xenobiotic metabolizing genes (CYP1A1, CYP1B1) and inflammatory cytokines (IL-1A, IL-1B, IL-6, IL-8). Indoor PM₁₀ induced xenobiotic metabolizing genes less but inflammatory cytokines up to 6-fold more than outdoor

PM₁₀. Conclusion: Direct cytotoxicity and toxicity after metabolic activation by cytochrome P450 1A1 and 2C9 were significant at a PM₁₀ concentration of 10 µg/ml (about 100l indoor air/ml), which is more than 10,000 times higher than exposure encountered in classrooms. We therefore expect no toxic effects of these particles in school children. The induction of inflammatory cytokines in indoor PM₁₀ treated cells suggests that classroom particles have a higher inflammatory potential than outdoor air particles

N2 - Despite the increasing public recognition of the problem of obesity in many countries, the planning for effective treatment services, especially for children, has lagged behind. Following are some personal reflections on the elements found useful on developing a bariatric medicine service within a large pediatric hospital. Effective staffing is vital. Staff members should be flexible and willing to move outside traditional professional "silos" of knowledge; they should have good teamwork skills, cultural competence and a respectful attitude towards obese people. A multidisciplinary clinical team is required, and ideally should include senior nurse (often the "conductor of the orchestra"), pediatric physician, dietitian, clinical psychologist, social worker, and exercise professional (ideally a dual-trained exercise scientist/ physiotherapist). The clinic facility should have disabled access and wide corridors and doorways, with chairs that are sturdy and can seat large people, weight scales that allow sensitive measurement of very large people (e.g., 250⁺ kg) and large blood pressure cuffs. The service should be supported by a database that can also allow audit and research studies to be undertaken. In establishing such a service, it is important to make the issue of obesity the problem of the institution, and not just of a few enthusiastic clinicians, and hence senior management and clinicians need to be engaged with the issue early. Ongoing health professional training of many levels of staff is required, from undergraduate level through to continuing postgraduate professional education, and for many types of clinician. Coordination with services that manage co-morbidities (e.g., Sleep Unit, Hepatology, Endocrinology, Dermatology, Psychiatry, General Medicine, Gynaecology, Orthopaedics, and Adolescent Medicine) is vital - shared protocols for assessment and management may need to be developed and key staff in the other services may require additional training regarding obesity. Families and young people with severe obesity may have significant family dysfunction, psychiatric co-morbidities and/ or parenting concerns; hence the importance of effective links with Psychiatry, Social Work and even Child Protection Services, and the need for obesity clinical staff to have a good understanding of the psychosocial aspects of pediatric medicine. Finally, a tertiary pediatric bariatric medicine service should only be one part of a much larger coordinated system of delivering health care within a region or country to obese children and adolescents. The Kaiser Permanente Chronic Disease Management model recognises that three different levels of chronic disease care should be offered: Level 1 care, suitable for the vast majority of those affected, emphasises patients' (or patients' families') central role in managing their health, supported by family doctors and community and other health system resources. Level 2 is care of highrisk patients by multidisciplinary disease management protocols and Level 3 is active case management of highly complex patients

IS - var.pagings

N2 - During the end of the last century, obesity was identified as a worldwide health care problem that is affecting the well-being of the population, previously known in the adult population, but in reality, studies are reporting an increasing problem in children too (1). The Gulf region is not exempt. Many surveys have reported the prevalence of overweight and obesity in Saudi children. All areas and provinces of the country have been affected through all ages (2,3). Governmental and local authorities have implemented education programs to help weight reduction or prevention. The abnormal weight in children is still considered by experts as an imbalance between diet and habit, although hormonal etiology in children is a diagnosis that should be ruled out first. In order to add valid information about the status of weight imbalance and child weight status in our region, this study has been conducted in the Eastern Province of Saudi Arabia with the following objectives: 1. To determine the prevalence of overweight and obesity in children from the Eastern Province of Saudi Arabia and study its basic demographic distribution, and to compare it with the Gulf Countries and other areas of the

world. 2. To compare the prevalence with Non-Saudi children living in Saudi Arabia. 3. To propose a prevention and treatment plan for overweight and obesity. This study collected first 10 509 files, including 9 249 consultations done in OPD in Saad Specialist Hospital, from January to June 2006. After excluding follow-up consultations, repetitions and non-completed file data, a total of 7 497 files were enrolled in the study. According to our study findings, 42% of Saudi children in the present Eastern Province sample have a BMI greater than the 85th percentile. It was evident that Saudi children start developing overweight when they are 5-9 years of age, and continue to increase up to their precious adolescent years. Twenty-one percent of children at 5-9 years are overweight and 21% are obese. This could be attributed to the fact that children start going to school at that age, and hence, there is poor control of eating habits and nutrition at this stage. Moreover, children have been less active; few, or none, of them walk to school, spending more time in sedentary entertainment activities, including television viewing, and playing computer and video games. On average, a child spends 6 hours per day in front of screens (4). Our results agree with a previously published study in the country that obesity in both genders is lowest in pre-school children (31%), and highest among adolescents (50-76%) (2,5,6). In our sample, the peak of obesity starts at 10-13 years of age (28%) and keeps the same high prevalence at age 14-18 years. Studies have shown that 80% of obese adolescents become obese adults (7). Adolescence has been addressed as the "critical period for the development for adult obesity" (8). Hence, if intervention before this stage is unsuccessful, intervention at this age becomes vital for both future health and ability to sustain long term weight control. We developed, in our institution, a plan of action for obesity prevention and detection (7). It is oriented towards the community in general and towards children particularly. In our opinion, prevention should start at birth by putting more emphasis on exclusively breast feeding for the first 6 months of age, and continue throughout school age with a special interest starting at the age of 10 years. Regarding screening for early detection and management of these cases, we propose a plan that is based on regular follow-up and supervision. Fifty percent of Saudi children from the Eastern Province in our sample have a body mass index (BMI) greater than the 85th percentile, being overweight or obese. Our study showed that obesity starts early in life (10-14 years), and continues all through the ages of adolescence. Prevalence of obesity is higher among males compared with females, who show a higher prevalence of overweight rather than obesity. Environmental factors seem to play more of an influence on the prevalence of obesity than do genetic factors, because there was no difference in obesity among Saudi and Non-Saudi children, as well as similar weight distribution between males and females in children below one year of age. It is difficult to reduce excessive weight once it becomes established. Children, therefore, should start prevention of obesity from birth by putting more emphasis on exclusively breast feeding for the first 6 months of life. It is becoming a priority to establish natural settings for pre-school, school and adolescent health programs with the emphasis on increasing physical educational hours, and incorporating health messages into school curricula. Integrated preventative measures, screening for early detection/management and educational programs towards a healthier lifestyle are required at the national level

N2 - The outdoor activity weekend is a popular method for supporting children with Phenylketonuria (PKU) but equivalent opportunities for adults do not exist in the United Kingdom. Given its success with children, we felt a similar activity for adults would prove valuable in their dietetic management. The weekend away was planned as an exciting opportunity to promote and support the continuation of the diet and was designed to give opportunities for patients to meet other people with the same condition, talk about their experiences in managing their diet, and to share ideas and support. The activity weekend was held over 3 days at an outdoor centre in the Lake District, England. Eleven adults with PKU and one adult with Homocystinuria from Glasgow, Newcastle, and West Yorkshire participated. They were aged between 17 and 37 years with an even mix of males and females. The weekend was split into discussion groups, cookery and leisure activities. For the discussion groups, we facilitated sharing of ideas and experiences on protein substitutes, their importance and the varieties available. They were informed of new low protein foods and how they could be incorporated into their diets. For the cooking activity, the patients were divided into teams for a low-protein cookery competition (there was a wide range of cooking skills in each team, some people's skills were very limited but all could obtain advice from ourselves and the chefs from the centre). The leisure activities such as the high ropes challenges and gorge sliding were designed to build teamwork, self-esteem, and confidence. At the end of the weekend the patients were asked to complete evaluation forms. The results of the evaluation and our own experiences during the weekend demonstrated that it was a success. The patients reported learning the importance of continuing on their diet. Many had the opportunity to try new foods, learn new cookery skills, and exchange practical tips and ideas about their diets with their peers. The cookery teams worked well together and produced some delicious food which inspired confidence amongst the patients. The discussion groups provided an ideal forum for participants to share ideas and discuss the practical aspects of dietary treatment. The leisure activities promoted friendship and sharing across the group. We intend to follow-up the patients in due course to see if they have made any changes in their diet. If the weekend did indeed lead to long-term changes in the patients' dietary choices then it demonstrates that such an event could prove to be a valuable treatment method for metabolic patients and for educating, engaging, and maintaining links with them. We thank the staff of the Derwent Hill Outdoor Education and Training Centre for their support through the weekend. Financial support was provided by the patients, Yorkhill Metabolic Fund, Vitaflo, and SHS International

N2 - Natural selection is a major force behind the shaping of patterns of human genome variability. Inferences concerning the action of selection in the human genome provide a powerful tool for predicting regions of the genome of major functional importance. Genetic variants influencing human susceptibility to disease are likely to affect the fitness of the organism, unless the disease concerned begins late in the life. There is therefore an intimate relationship between disease and selection that can be exploited for the identification of candidate disease loci. To date, some of the strongest evidence for selection in the human genome has been obtained for genes involved in the immune response or host-pathogen interactions. Indeed, before the advent of antibiotics and vaccines, infectious diseases have been paramount among the threats to health and survival for most of human evolutionary history. I will review our most recent studies searching for the footprints of natural selection in the human genome. These studies, which go from global genomewide scans to more fine-tuned analyses in specific genes, highlight how the identification of selected loci or variants may provide insight into host genes or pathways playing an important role in pathogen resistance. For example, we have shown that

natural selection has significantly driven the processes of population differentiation in modern human populations. Specifically, we have identified a number of genes under strong geographically restricted positive selection, some of them involved in host-pathogen interactions. In addition, I will present our most recent data on the Toll-like receptor (TLR) signalling pathway. Our evolutionary data indicate that the different members of TLR family differ in their ecological relevance and increase our understanding of how variation in these genes results in different contributions to the outcome of infectious diseases. More generally, I will show how the identification of the extent and type of selection acting upon human genes involved in host-pathogen interactions make it possible to define the redundant and nonredundant functions of individual immunity-related genes in the natural setting

N2 - Insomnia has long provided a series of challenges to the various classes of physicians responsible for care of those with this complaint. I shall concentrate on the assessment and treatment of insomnia by psychiatrists. One of the challenges is whether the insomnia is a primary symptom in itself, secondary to medical or psychiatric disorders, or a comorbid disorder, existing in conjunction with the primary psychiatric problem. The assessment of this factor is important as it has a major influence on the conceptual approach, management and type of therapy. Primary, secondary and comorbid insomnia: Primary insomnia is a specific disorder defined in the DSM-IV as a condition of at least one month's duration, not caused by a medical or psychiatric disorder. The insomnia can be a disturbed sleep initiation, problem maintaining sleep or early morning awakening; one or more of these must be associated with complaints of daytime dysfunction. Many psychiatric patients have chronic insomnia but in the general population primary insomnia occurs in about 10% of the population. Secondary insomnia is found in a whole series of conditions. The most common is in association with physical disorders such as pain and breathing difficulties. An important recent State-of-the-Science conference focused on the role that comorbid conditions can have in association with insomnia. It was noted that insomnia usually appears in the presence of at least one other disorder. Particularly common psychiatric comorbidities are major depression, generalised anxiety, substance abuse, attention deficit hyperactivity in children, and dementia. This concept of comorbid as opposed to secondary insomnia is becoming accepted as a valid model for understanding the relationships between insomnia and other concomitant disorders. If the insomnia is "secondary" to a psychiatric condition, treatment of the primary disorder would be expected to help the insomnia. However, if the disorder is comorbid, for example, with depression, successful treatment of the depression with antidepressants will not necessarily alleviate the insomnia complaint. Also, people with severe sleep complaints that occurs comorbidly, are less likely to respond than those with milder complaints and may need quite intensive therapy. The most important of these disorders is depression. Sleep difficulties are common symptoms in depressed patients. Insomnia is often the reason that causes depressed patients to seek help. Severe insomnia may lead to exhaustion, poor functioning during the day and accidents. About three quarters of

depressed patients complain of difficulties with sleep, in particular fragmented sleep with disturbing dreams. They wake feeling unrefreshed in the morning and feel tired during the day. Paradoxically, total sleep deprivation can help as a temporary expedient in depression but this lies outside my remit. In many cases the insomnia and depression can be conceptualised as comorbidities. One clue can be adduced from the fact that in depressive disorder a proportion of patients show comorbid hypersomnia not insomnia. The relationship between sleep and mood are closely related. Insomnia can significantly worsen the disorder of depression and can increase the likelihood of a suicide attempt. Insomnia is often a prodromal warning sign of depression that will manifest itself in the next two years. After a depressive episode it is a predictive sign of an incipient relapse and can warn the prescriber not to withdraw the antidepressants while insomnia persists. Early intervention to improve sleep may help abort a possible relapse. Antidepressant treatment can help sleep in depressed patients. Many of the treatments used in depression are sedative. The classic examples are the tricyclic antidepressants, such as trimipramine, with antihistaminic actions. More recently, compounds such as trazodone and mirtazapine have been used to treat depression associated with insomnia. The use of such medication may result in an early amelioration of sleep problems and this can improve the morale of the insomniac depressive and also help improve compliance. An interesting compound is the antidepressant agomelatine but the relationship between its melatonergic properties, antidepressant efficacy and effects on sleep are still being worked out. Other conditions in which the insomnia appears comorbid include bipolar disorder where the manic phase is usually preceded by a shortened duration of sleep. This pattern can often be quite stereotyped. Generalised anxiety is also accompanied by sleep onset insomnia and increased night time awakenings. The sufferers may describe a sense of insufficient and unsatisfying sleep. Other anxiety disorders include post traumatic stress disorders in which there is not only insomnia but parasomnias. Panic disorder may be associated with night time panic attacks that awaken the patient. Patients with schizophrenia can suffer from insomnia at the time of acute symptoms. A circadian rhythm disorder with gradual delay of the sleep period relative to the day may ensue. Carers of schizophrenic patients may recognise this as the onset of a relapse. Dementia is also associated with comorbid insomnia with often fragmentation of the 24-hour sleep wake pattern or even reversal with more sleeping during the day and less at night. Such behaviour may be very difficult to manage and actually be a factor leading the carers to insist that the patient be admitted to full time care. Substance abuse includes alcohol problems, opiate detoxification and the use of sedative hypnotic drugs themselves. Various patterns are seen. One particular source of severe insomnia is withdrawal from psychotropic drugs, in particular sedatives/hypnotics and some antidepressants. Assessment and management: The complaint of insomnia needs assessment and treatment in its own right as the therapeutic approach will vary according to the comorbid psychiatric disorder, its severity and pattern, and the characteristics of the insomnia itself. The treatment of insomnia can be roughly divided into 2 major divisions - the use of medication and behavioural techniques. The latter are becoming more available with evidence that they can be effective when judiciously chosen and applied. The usual hypnotics used are essentially general depressants and have no specific effects on sleep itself. They lie along the sedative/hypnotic/deep sedation/anaesthetic continuum. More recently a series of new approaches have been applied. One of these is a variant of the depressant approach and is eszopiclone. This active enantiomer appears to have long-term efficacy without problems during withdrawal. 5-HT blockers have also been studied for some time and such blockade is part of the profile of action of drugs such as trazodone and mirtazapine. However, newer compounds are being studied. Melatonin agonists have been developed and one, ramelteon, is licensed in some countries. Melatonin itself is too shortacting for much efficacy but long-acting formulations (such as Circadin) have recently been licensed. Another set of compounds involved in sleep regulation are the orexins, and their antagonists are in development. In conclusion, a whole range of compounds are available to treat insomnia. These treatments can be applied symptomatically to primary, secondary and comorbid insomnia. As research progresses into both basic mechanisms and clinical features, distinctions between these aetiologies will become more apparent, and will lead to more focused therapies

N2 - Background: Vascular access for long term extracorporeal photopheresis (ECP) therapy in post allograft or cutaneous T-cell lymphoma patients is a critical problem. Most patients, who have had solid organ transplants, have had their peripheral veins lost during the peri-operative period and thus require some form of central vein catheter. While the primary risk, namely sepsis, associated with percutaneous central line catheters (PCC) has improved over the decade, there are alternatives: either arteriovenous fistulas or subcutaneous infusion ports (SIP). In these alternatives there is no constant residual percutaneous entry way for bacteria, since each access occurs utilizing a needle that is removed at the procedure's conclusion. The use of a specific Vortex SIP has been previously described for long term use in children undergoing erythrocyte exchange. Methods: The records of patients requiring ECP during the past two years were reviewed to compare those requiring a PCC versus SIP. Specific procedures were followed for access and discontinuation with attention given to the volume and concentration of heparin dwelling in the catheter during non-use periods. We recorded the number of catheter associated infections, the number of occasions access occurred through the central line by individuals outside the treatment facility and the frequency with which blood flow problems occurred requiring the use of tissue plasminogen activator (TPA). Patients were also asked quality of life questions relevant to the central line device and their ability to enjoy certain activities. Results: Ten patients had a tangent conical SIP implanted with

244 (range 4-38) procedures performed and 10 patients had standard PCC lines with 246 (range 3-42) procedures performed. The current longest period for evaluation is 24 months for either access. During this time 3 SIP patients had admissions to other facilities, which used the SIP for fluid administration, and did not adhere to the procedures for post SIP use heparin dwell. These 3 patients had 8/11 (73%) of the TPA treatments for SIP blood flow problems occurring after such an admission. No SIP patient had a bacterial line infection. In contrast, there were 20 episodes of blood flow difficulty requiring TPA in 6 of the PCC patients. Two PCC patients had 3 separate line sepsis episodes requiring an exchange of the line each time for control of the sepsis. All SIP patients were able to shower/bathe as they desired, while PCC patients followed a restricted bath procedure. Conclusion: The use of an implanted subcutaneous port with a tangential design appears functional for vascular access, appears to have a reduced incidence in bacterial sepsis related to the time in place, has a reduced frequency for TPA antithrombotic treatment when specific procedures are routinely followed and permits an improved mobility and quality of life for patients

N2 - Background/Purpose: To examine the influence of indoor and outdoors air pollution on asthma in schoolchildren in Urmia, Iran. Although Urmia is not an industrialized city but similar to other Iranian cities popular use of worn out cars with high tailed-pipe emission leads to air pollution in this city. Methods: Parents of 3000 schoolchildren aged 6-7 and 3000 schoolchildren aged 13-14 years themselves filled of International Study of Asthma and Allergies in Childhood (ISAAC) questionnaires. The influence of trucks passage, exposure to passive smoking, electricity/gas/wood cooking and electricity/ wood/central heating at home on wheezing ever, current wheezing, number of attacks, disturbed sleep, limited speech, exercise induced wheeze, dry cough at night and asthma ever was determined. Odds ratios in logistic regression for statistic analysis of the data were used. Results: Among 13-14-year-old group, always or frequent trucks passage through the residential street, compared to seldom one, significantly increased the risk of wheezing ever OR 1.19 (95%CI 1.08-1.31); current wheezing OR 1.32 (1.18-1.47); speech limiting wheezing: OR 1.46 (1.26-1.70); wheezing during exercise OR 1.42 (1.30-1.55) and dry night cough OR 1.21 (1.10-1.34). In 6-7 years old group only exercise induced wheezing was significantly associated with busy roads OR 1.27 (95%CI 1.02-1.59). In both age group parent smoking was strongly associated with asthma symptoms. A significant influence of other investigated air pollutants on other asthma symptoms was not found. Conclusions: Our results suggest that outdoors air pollution significantly associated with asthma symptoms in older children but not younger group. This might be explained by progressive effect of long term exposure to air pollution

IS - var.pagings
N2 - PULMONARY TUBERCULOSIS Pulmonary TB caused by Mycobacterium tuberculosis has traditionally been classified into primary (non-immune) and secondary (delayed hypersensitivity) reactivation. Delayed

hypersensitivity manifests 4-10 weeks after initial infection. Caseation necrosis consequent to development of delayed hypersensitivity is pathologic hallmark of pulmonary TB. Radiologic manifestations of pulmonary tuberculosis (TB) can vary according to several host factors, including prior exposure to TB and underlying immune status. M.TB has capacity to survive and replicate in human macrophages, by down-regulation of the host's antigen processing (latent infection). Continuous lifelong interaction between the individuals and the mycobacteria results in considerable variety of morphologic features. It is a matter of chance when the radiologist first sees the patient. Recently multi-drug resistance TB and increase in immune-compromised patients, including HIV epidemics, make the control of the pulmonary TB more difficult. Atypical manifestation of clinical and radiographic features is common in patients with decreased host immunity, and CT can play a role in this situation.

PRIMARY PULMONARY TB No prior contact with bacilli in this form. Most infections are air-borne, so it manifests as a parenchymal consolidation in any pulmonary lobe or segment. The bacteria spread via lymphatics from parenchymal lesion to ipsilateral hilar and/or mediastinal lymph nodes. Combination of lobar pneumonia with lymphadenopathy is called the primary complex.

REACTIVATION PULMONARY TB Reactivation in majority is reactivation of the dormant lesion at the apical portion of bilateral upper and lower lobes. Caseation necrosis is the pathologic hallmark in this type. It manifests as a heterogeneous, often cavitory nodules or consolidation. Then the bacteria spread via airway to the other healthy lungs. It typically manifests as tree-in-bud appearance, corresponding to the caseous material involving small bronchi and bronchioles. Radiographic stability for 6 months and negative sputum cultures is the best indicator of inactive disease. Activity may not be determined by plain radiography and CT may be more accurate when it can detect cavitation and tree-in-bud appearance, and differentiation of cavity from cystic bronchiectasis or paracatricial emphysema.

COMMON TO THE PRIMARY AND REACTIVATION PULMONARY TB TUBERCULOMA It most often originates from healed primary TB. Pathologically, its centre contains caseous necrosis and viable AFB in most healed lesion, so it has potential to reactivate sometime. The Inner wall consists of epithelioid and Langerhan's giant cells and the Outer consists of lymphocytes and fibroblasts.

Stable tuberculoma The majority remains stable. Its typical findings are the size usually <2 cm in size, smooth or fine speculated outer margin or calcification. When it shows central, laminated, homogeneous Calcification, then the diagnosis is almost certain. CT is helpful in detection of calcification. The contrast enhance of tuberculoma is <20 HU in CT.

Reactivated tuberculoma Any tuberculoma has potential to reactivate. When it reactivates, the nodule Enlarges and calcification disappears. Low attenuation area, thin enhanced capsule and cavitation, Bronchogenic dissemination to the lung adjacent to nodule, so called satellite nodules, can be and in CT. Cavitation means Seminal event in the life cycle of M.TB; aerobic Bacillary proliferation outside the macrophage's cytoplasm. Cavitation implies a high bacillary burden, high infectivity, and is associated with numerous complications including endobronchial spread.

ENDOBRONCHIAL TUBERCULOSIS TB granulomatous change in the bronchial wall is defined as endobronchial TB. The Pathogenesis is usually Erosion from lymphadenitis in primary TB, but usually Lymphogenous spread through submucosal lymphatics or Implantation from infected sputum in reactivation TB. Plain film sometimes detects Narrowing or irregularity of the major airway and more frequently detects the secondary signs, such as Collapse of a lobe or segment or Blocked or tension cavity. CT on hyperplastic stage show Uniform thickening of bronchial wall, Concentric and long bronchostenosis and Lymphadenitis (56%). While CT in fibrostenotic phase, concentric and long bronchostenosis is main finding, and thinner bronchial wall.

PLEURAL INVOLVEMENT A TB infection of the pleura is more common in teenagers and adults than in children. The pathogenesis of the effusion is the result of hypersensitivity to tuberculin in the majority. It usually resolves spontaneously, but it needs treatment to prevent pulmonary TB and fibrothorax. Rarely the effusion is empyema, with complication such as bronchopleural fistua or empyema necessitates.

MILIARY TUBERCULOSIS This disease is more common in small children <2 years old, the elderly, and immunocompromised. Miliary spread may evolve from lung or mediastinal infection eroding into a blood vessel. Typical finding are diffuse, random, subpleural small nodules, but in the early stage it may be subclinical, and seen as a diffuse GGO.

BRONCHIECTASIS, CONSTRICTIVE BRONCHIOLITIS, FIBROSIS Bronchiectasia and post-TB bronchiolitis obliterans are common as sequel of primary or reactivation pulmonary TB, these are secondary to traction by parenchymal fibrosis, distal obstructive pneumonia following endobronchial-TB, or healing of bronchiolitis after bronchogenic dissemination of caseous material.

NONTUBERCULOUS MYCOBACTERIAL (NTM) INFECTION NTM organisms are ubiquitous and infection arises from environmental exposure, not from human to human contact. *M. kansasii*, *M. avium-intracellulare*, *M. xenop* are commonest pathogen. This infection can be classified in to two groups. *M. avium* complex can complex can cause both types, but *M. Kansasii* & *xenopii* usually manifests as TB-like pattern.

"Classic" pattern The one group is affection mainly of males > 50 years old with pre-existing lung disease. The constitutional symptoms and the radiographic findings are very similar to that of pulmonary TB. It is characterized by upper lobe cavitory lesion and bronchogenic dissemination. Cavities tend to be multiple,

smaller and thin-walled. More pleural reaction and less parenchymal infiltration "Non-classical" pattern The other group is affected by mainly elderly women without pre-existing lung disease, and the radiographic findings consist of bronchiectasis, multiple small nodules and branching centrilobular nodules, involving right middle lobe and lingular segment. "Hypersensitivity pneumonia" pattern The radiographic features are similar to the HP of other origin, such as diffuse ground glass attenuation, micro centrilobular nodules, and mosaic attenuation

N2 - Aim: Lymphocyte activation markers CD26 and CD30 are also present as soluble forms in circulating plasma. Serum soluble CD30 (sCD30) has been suggested to be associated with childhood asthma. We examined the association of serum soluble CD26 (sCD26) and sCD30 concentrations with asthma at school age. Methods: Serum sCD26 and sCD30 were measured in 34 children with clinical asthma (positive history and pathological lung function or challenge test finding), in 31 children with possible asthma and in 147 controls. In addition, the association of flow-volume spirometry, methacholine inhalation challenge and free running test results with serum sCD26 or sCD30 were analysed. The tests were taken at a non-acute phase (outside an acute infection). Results: The levels of serum sCD30 were significantly higher in children with asthma (mean 91.5 IU/ml, SD 23,0) than in children with possible asthma (85.0 IU/ml, 28.5) or the control children (78.8 IU/ml, 25.9) (P = 0.042). However, there was a considerable overlap between the groups in serum sCD30 levels. No significant differences were found in serum sCD26 levels between the groups. In flow-volume spirometry, there

was a significant negative correlation of mean mid expiratory flow values with serum sCD26 ($r = -0.22$, $P = 0.0018$) and of borderline significance with serum sCD30 ($r = -0.14$, $P = 0.054$). Neither methacholine inhalation challenge nor free running test results were associated with serum sCD26 or sCD30 levels. Conclusions: Serum sCD30 levels were higher in children with clinical asthma. However, a marked overlap in serum sCD30 levels between asthmatic and healthy children may limit the usefulness of serum sCD30 as a diagnostic marker of asthma. The finding that neither serum sCD26 nor sCD30 was associated with bronchial hyperresponsiveness supports this notion

N2 - The purpose of this study was to describe dietary habits, media use, and physical activity in 2 to 5-year-olds born to overweight (BMI = 25) mothers. Data were collected on 174 preschoolers, of whom 72.8% were white, 23.1% African-American, and 4.1% other races. Mothers reported the time their preschooler spent watching TV and videos and using the computer, the number of servings of certain food groups eaten, and the duration of outdoor play. Preschoolers spent 3.4 ± 1.0 hours watching TV and videos and 1.4 ± 0.7 hours using the computer each day. They spent 4.4 ± 3.1 hours each week playing outdoors. In bivariate analyses, there was a positive relationship between hours of TV watched and servings of soda, sweetened beverages, fruit juice, fast food, and French fries; and a negative relationship between hours of TV and milk servings. Time spent using the computer was positively related to sweetened beverage and fast food intake. Outdoor play was positively related to fruit and sweetened beverage intake, but not to soda, fruit juice, fast food, or French fries. Media use and physical activity were not related to yogurt, dessert, or vegetable consumption. Results of this exploratory

analysis suggest that there is a relationship between increased media use by preschoolers and a higher intake of less healthy foods. Higher levels of physical activity are related to increased sweetened beverage intake

N2 - The purpose of this study was to examine the dietary habits according to TV watching and internet usage and to establish the desirable extracurricular activity and eating habits in elementary school children. A questionnaire was filled out by children in 4th, 5th and 6th grades in 6 elementary schools within Gwangju and Jeonnam region and 712 cases were analyzed by SPSS 12.0. TV watching time was related with dietary habit score in subjects. The children who watch TV "=1 hour/day" in weekday had a better dietary habit score than the children who watch TV "=1 hour (p<0.0001). The children who watch TV "=2 hours/day in weekend had a better dietary habit than the children who watch TV "=2 hours" (p<0.0001). The internet usage was related with dietary habit score in children. The children who use internet "=1 hour/day" in weekdays had a better dietary habit score than the children who use internet "=2 hours/day" (p<0.0001). The children who use internet "=2 hours/day" in weekend had a better dietary habit than the children who use internet "=2 hours/day" (p<0.0001). These results indicate that the children who have more appropriate daily activity pattern showed better dietary habit score and TV watching and internet usage time occupy much of the elementary school children's extracurricular activities. Therefore, it is essential that the program development of both educational and social levels for active and outdoor extracurricular activity of school children

N2 - Rationale: Children with generalized epilepsy may have a non-specific IGE syndrome (IGE NOS). They are intellectually and neurologically normal with generalized tonic-clonic seizures (GTC) and an interictal EEG showing generalized spike-wave without a known cause. The prognosis is not well described. Methods: Children with IGE NOS were selected from the Nova Scotia Childhood Epilepsy Study - a population-based cohort including children with >1 unprovoked seizure with onset between 1977-1985. Follow-up was in 2007-

2008 by personal contact. Results: Of 692 in the cohort, 39(5%) had IGE NOS. 5 had <5 years follow up and were omitted. Age at onset averaged 6.3 + 4 years. Follow-up averaged 22.5 + 7.5 years, at age 29.3 + 8.5 years. There were 18 females. 26 (76%) had a terminal epilepsy remission (seizure-free and off medication) for 16.7 + 8.3 years (range 1-31). Only 3 had an episode of status epilepticus but no one developed intractable epilepsy. Even though 41% had >10 convulsions, there was only one injury-related seizure. All patients had at least 4 years seizure-free during the follow up period (average 17.5 years, range 4-33). During the last year of follow-up, only 3 had any seizures (2 GTC). Of the 8 patients with persistent AED treatment at the end of follow-up, 4 had never received valproic acid, lamotrigine or topiramate suggesting suboptimal treatment. Only one developed Juvenile Myoclonic Epilepsy (JME) while no other patient changed epilepsy syndrome over time. There were no deaths. (For comparison 3.5% of the overall cohort had JME.) At the end of follow-up, of those >18 years of age (N=29), 22 (76%) had significant learning problems as evidenced by >1 school grade repeated (16), resource help (12) or special class (6). Only 17 (59%) completed high school with 4 attending university. 11 (38%) had mental health visits with 21% having depression sufficient for medication treatment. 17(59%) lived with a "life partner" and 7(25%) alone. 9 women had >1 pregnancy and 7 men fathered a child. Only 4 pregnancies were planned and 11 were outside a stable relationship. 35% were unemployed and 14% received government assistance. 60-65% were satisfied with their lives, friendships and social activities. We defined markers of poor social outcome as: a psychiatric diagnosis, no high school graduation, pregnancy outside of a stable relationship, living alone, unemployment. 7(24%) had no poor social outcome markers, 8 had 1, 7 had 2, 5 had 3, 1 had 4 and 1 had all 5. Conclusions: IGE NOS is a recognizable syndrome within the spectrum of IGE. The seizures are nearly exclusively GTC and are transiently problematic for most. Eventually 75% have complete epilepsy remission. 76% have learning difficulties and overall 75% have at least one major indicator of unsatisfactory social outcome

N2 - Objective: To determine the relationship between aspects of participation and health-related quality of life (QOL) among youth with spinal cord injury (SCI). Design: Survey research. Participants/Methods: Youth ages 7-18 years who had been injured at least one year and were receiving care within 3 specialty hospitals completed the Children's Assessment of Participation and Enjoyment, Pediatric Quality of Life Inventory, and Revised Children's Manifest Anxiety Scale. Caregivers completed a demographics questionnaire. Injury-related information was gathered from medical records. Analyses included hierarchical linear regression. Results: 175 youth were enrolled: mean age was 12.77 years (SD=3.12), 54% were male, 63% were Caucasian, 73% had paraplegia, 56% had complete injuries, and mean age at injury was 6.90 years (SD=5.30). Participating in more activities was related to increased school QOL ($p=.028$). As youth participated with others outside of family or participated further from home they experienced higher emotional ($p=.023$, $p=.024$, respectively), social ($p=.046$, $p=.020$, respectively), and overall psychosocial ($p=.045$, $p=.016$, respectively) QOL. After controlling for current age and youth anxiety, participating in more activities significantly predicted higher school QOL ($p=.021$), and participating with a broader group of people significantly predicted higher emotional QOL($p=.011$). Conclusion: There are relationships between diversity of activities and with whom youth participate and aspects of QOL. Results suggest that exposure to more types of activities and increased social networks can increase QOL among youth with SCI

N2 - Hydroa vacciniforme (HV) is a rare pediatric photodermatitis characterized by pruritic blisters which heal with scarring. The purpose of this study was to investigate the effect of HV on quality of life (QoL) and to compare our results with life quality indices reported for other dermatoses. A disease-specific questionnaire was developed, and participants recruited from a web-based, international HV support group. Impact of HV on QoL was measured using the Dermatology Life Quality Index (DLQI) or the Children's DLQI. Fifteen HV patients participated: 9 (60%) males and 6 (40%) females. Median age at onset was 7 years, and 11/15 (73%) were younger than 18 years. Most patients self-identified as Caucasian (93%). The mean CLDLQI and DLQI scores for HV were 12.1 and 8.5, respectively, which suggests equal or greater impact on patient QoL compared to previously reported indices for childhood psoriasis (9.2) and generalized eczema (9.1), and atopic dermatitis in adults (4.5). Children cited QoL as being negatively impacted most by an inability to play outdoors while adults noted QoL influences due to limitations on choice of clothing. Embarrassment associated with their skin condition was also noted by children and adults surveyed, but personal relationships were not reported as being significantly impacted by either group. Patients with HV have significant impairment of QoL. When compared to other common childhood dermatoses, HV appears to have an equal or greater impact on patients' QoL. Dermatologists should be aware of the substantial psychosociologic impact of this disease

N2 - Objective: Amanita phalloides, known as the death cap, is a poisonous fungus and when ingested it can have fatal consequences of poisoning. It has high toxic potential, so that even a small intake can cause serious toxicity. Children are considered more sensitive than adults. Besides early gastrointestinal decontamination, there are only a few effective treatment regimens, and a child should therefore always receive treatment if ingestion is suspected. Case report: A 14-month old female was found by the staff at a nursery playground with a mushroom in the mouth. The location was suburban and distant from a forest. Albeit the unusual place of growth, the preliminary identification by the poison centre arouse suspicion of an Amanita phalloides mushroom. Although there was no observation of the child swallowing the mushroom, which was broken in several pieces, she had been under no observation for minutes and could theoretically have ingested a toxic dose. She was immediately brought to the ER where she was aspirated and treated with activated charcoal. Simultaneously, the mushroom was identified by an expert as Amanita phalloides. Treatment with the antidote silibinin was started within 3 hours of ingestion and the child was moved to an intensive care unit for continued treatment. During the following day the child did not show clinical signs of poisoning including gastrointestinal symptoms and the liver parameters remained normal. Conclusion: The deadly Amanita phalloides may thrive in unexpected surroundings as in the presented case where it grew in the playground in an urban area. It grew together with several similar mushrooms close to a beech hedge. Thus the case represents an unanticipated and in some ways unpreventable risk for serious poisoning in a setting with expected high security standards. The child in our case underwent immediate and relevant treatment in collaboration with the Danish Poison Centre and showed no clinical signs of poisoning or rise in biochemistry. The child was discharged from the hospital on the second day of admission without sequelae

N2 - A 50-year-old woman presented with a 10 year history of progressive back and right hip pain radiating to the ankle. After an MRI of the lumbar spine revealed fatty infiltration of her paraspinal muscles, she was referred to an outside neurologist. She reported spells of weakness, once or twice a year for the past 10 years, where her right leg would give out and she would fall. With further questioning, she admitted to mild leg and arm weakness causing difficulty in exercising at the gym in recent years. Family history was negative for neuromuscular disorders on the mother's side, father's side was unknown. Three half sibs and 2 grown children are healthy. Examination revealed relatively symmetric proximal > distal weakness of the legs > arms. She had an exaggerated lordosis with a waddling gait. There was equivocal calf hypertrophy. She was diffusely areflexic except for preserved triceps jerks. Sensory exam and cranial nerve exam was unremarkable. CK level was 288 IU/L (ULN 235). Nerve conduction study showed mild reduction in amplitude of the right peroneal compound action potential and bilateral absence of H reflexes, otherwise NCS were normal. Needle examination revealed occasional fibs and positive sharp waves and prolonged duration, polyphasic motor units some with satellite potentials in proximal leg and paraspinal muscles. Interference pattern was reduced. Given the neurogenic nature of her EMG and her clinical exam, genetic testing for SMA was done. The diagnosis of SMA was confirmed genetically with zero copies of SMN1 gene and more than four copies of SMN2 gene

N2 - Introduction: Since 2000/2001 clear progress in the treatment of severe sepsis: immediate & aggressive therapy; mortality & morbidity decrease significantly in our unit, but non in our region. Objectives: to improve treatment of paediatric septic shock in children. Methods: Regional paediatric intensive care network (PIN) reference PICU & 25 children's hospitals in Lower Saxony, Saxony-Anhalt & Nordrhein-Westphaly, (2003).: 3.000.000 inhabitants. Standardised treatment/training of septic shock including standard resuscitation courses EPLS with intraosseous access, fluid-/drug-management, recognition of critical ill child, septic shock scenarios & post resuscitation care. Highly advanced Simulation Training since 2008. Implementation of emergency training, diagnosis & treatment of Waterhouse-Friedrichsen syndrome with human protein C concentrate (PC) by symposia, workshops & 6-months training periods for physicians of the network in reference PICU. 24-h-Service for transport & consultation provided by central PICU. Results: Implementation of EPLS in own PICU & network with international cooperation: 24 courses, 2 instructor courses, 450 participants & 30 instructors inside the network. 8 courses outside the network. Treatment of 26 children with septic shock (herein 17 patients with Waterhouse-Friedrichsen syndrome WFS) within the network, 1 patient of non network hospital. Announcement-time: 15 min.-1 h (not network patient: 8 h.). Consultation was requested by hospitals via phone; treatment was induced immediately. Transportation-Team of tertiary centre went to patients by ambulance or helicopter. Continuation of treatment on site & after transfer, in the tertiary centre. All patients showed typical signs of WFS with purpura fulminans & severe multi organ failure. None of the patient died. One patient had necrosis of skin, already present at admission. The others had restitution ad integrum. The patient from outside presented several areas of necrosis, needed ECMO, 1 lower leg was amputated. No adverse effects subministrating PC concentrate. Patients were retransferred to network hospitals as soon as possible. Conclusions: EPLS is a significant factor for pediatric survival leading to active networking with high acceptance. EPLS it is an important tool for standard treatment and training. Survival rate & outcome after implementation of new treatments & trainings were excellent

N2 - Purpose: Mounting evidence supports that Mediterranean diet has favorable effects on the cardiovascular system, while albuminuria is associated with atherosclerosis progression and increased risk. The aim of the study was to investigate the relationship of dietary habits with urinary albumin excretion, expressed as the albumin to creatinine ratio (ACR), in a cohort of adolescents. Methods: A total of 365 adolescents 12-17 years of age [212 males, aged 13.9 years, office blood pressure (BP)=115/67 mmHg] that were included in the Lyceum Leontio Albuminuria (3L) study were considered for analysis. In all participants ACR values were determined in a morning spot urine and for each adolescent a questionnaire was completed in order to retrieve information on dietary habits (through a semi-quantitative Food Frequency Questionnaire), lifestyle and socio-economic characteristics. Moreover, the Mediterranean Diet Quality Index for children and adolescents (KIDMED) was estimated and accordingly subjects were divided into those with optimal (>7), average (4-7) and low (<4) score. Results: Only 6.8% of the participants had optimal KIDMED score, whereas 51.2% had an average and 42% had a low score. Participants with at least average KIDMED score (n=187) compared to those with low KIDMED score (n=153) were more frequently males (64.5 vs 53.4%, p=0.029), had higher body mass index (22.2 vs 21.4 kg/m², p=0.043) and waist circumference (77.6 vs 75.4 cm, p=0.044), spent more frequently time for sports activities outside school (75.2% vs 58%, p=0.001), reported less consumption of foods outside home (3% vs 14%, p<0.001), less hours of watching television (1.75 vs 2.05 hours, p=0.013) and more hours of leisure time (5.4 vs 4.4 hours, p=0.026). Moreover, those with at least average compared to those with low KIDMED score exhibited higher systolic BP (117 vs 114 mmHg, p=0.039) and pulse pressure (49 vs 47 mmHg, p=0.01), whereas had lower heart rate (84 vs 87 bpm, p=0.014) and ACR levels (12.6 vs 20.5 mg/g, p=0.015). In the total population, ACR was associated with age (r=-0.11, p=0.044), male sex (r=0.160, p=0.003), body mass index (r=-0.131, p=0.016), systolic BP (r=-0.144, p=0.008), heart rate (r=0.141, p=0.011) and KIDMED score (r=-0.111, p=0.041). Conclusions: In adolescents there is an inverse relation of KIDMED score with albuminuria and those who adhere to the Mediterranean diet exhibit lower levels of ACR. However, the paradoxical associations of both ACR and KIDMED score with obesity markers and BP levels suggest distinct mechanisms of albuminuria development in adolescents

N2 - Purpose: to assess feasibility and effectiveness of extranodular no touch multipolar radiofrequency ablation of hepatocellular carcinoma (HCC). Materials/methods: 26 patients (56-82 years, mean: 68+7 years) with cirrhosis (Child-Pugh A/B: 21/5) and one or two (22/4) HCC (1.5-5.5 cm, mean: 3+0.9 cm) were treated with no touch multipolar radiofrequency ablation consisting of simultaneous activation of two to four bipolar coaxial electrodes inserted just outside the tumors. Safety and effectiveness of the no touch technique were assessed. Treatment response was evaluated with CT scan. Results: to achieve complete ablation of all tumors (100%) one to two sessions (mean: 1+0.3) including one to two applications (mean: 1+0.2) of 16 min to 45 minutes were required. The mean number of electrodes used per tumor ablation was 3.1+0.6. 40 to 220 kJ were delivered per session into the tumors (mean: 119+43 kJ). Two deaths occurred within three months after the procedure: one at 82 days in a patient who experienced uncontrolled pneumonia and the other at 54 days in

patient who had infected ascites. Two other patient experienced minor complications: transient jaundice in one and pleural effusion in other. After a mean follow up of 6.6+5 months, no local tumor progression was detected. Distant multinodular recurrence occurred in one patient 2 months after the treatment. Conclusion: multipolar radiofrequency ablation of HCC using no touch technique seems to be a very effective method in term of tumor control. However, owing to the large volume of non tumorous liver tissue ablated, a careful selection of patients is mandatory

N2 - Introduction: Only 20 to 30% of patients with hepatocellular carcinoma (HCC) are candidates for curative treatments and most of them are suitable only for locoregional therapies or palliative care. Intra-arterial treatment as transarterial chemoembolization (TACE) and transarterial embolization (TAE) are considered as palliative therapy for multifocal HCC in advanced stage. Several alternative minimally invasive treatments have been proposed but recently only TACE has been shown to improve survival compared with best supportive care in meta-analyses of randomized trials. However, it is not clear whether TAE alone gives the same survival advantage nor whether specific patient characteristics affect outcome or any particular technique in performing transarterial therapy is better than any other. Some authors have reported experience in treating liver tumor by mean TAE by using different materials and techniques: not selective, selective and superselective injection of fibrine sponge, glue, particles and so on. The main purpose of this study is to assess feasibility and local response in patients affected by unresectable HCC, treated with TAE using microparticles sized 40 and 100 microns. Rationale for using well calibrated small sized microparticles for treating liver tumors is mainly based on the evidence that all hepatic malignancies are mainly or exclusively fed by arterial blood flow. Vessels within the tumor have been reported to have a size ranged between 20 to 120 microns and it should be, in our opinion, the target for achieving a deep ischemia and necrosis by using TAE. Bigger particles will embolize bigger vessels outside the target nodule: the more bigger the particles used, the more far from the tumor will be the embolization. Methods: Between October 2007 and April 2008, 22 patients underwent TAE. Diagnosis of HCC was based on radiological findings (MDCT scan), alfa-fetoprotein level and biopsy according to the Barcelona criteria. Inclusion criteria were HCC nodules not suitable for surgical resection or percutaneous therapies. Exclusion criteria were patients older than 80 years, advanced liver disease (Child Pugh class-C), active gastrointestinal bleeding, encephalopathy, refractory ascites, portal branch occlusion and documented arterovenous hepatic shunts. All patients underwent upper-abdomen multi-phase MDCT before treatment. MDCT scans were also used for defining vascular anatomy supplying the liver and for assessing tumor feeding vessels. A total of 32 target lesions were embolised using 40 and/or 100 μ micro-spheres (Embozene /Celonova); average treated nodule diameter was 5.7 cm. Angiography of celiac trunk and superior mesenteric artery were always obtained before every treatment, in order to assess arterial anatomy and possible variants and for detecting the feeding vessels to the target lesions. Superselective catheterization of tumor feeding arterial branches was obtained by using micro-catheters (Renegade High Flow/Boston Scientific). When it was not possible to detect the feeding vessels to the lesion, CO₂-microbubbles-enhanced liver ultrasound has been performed; it consists into the intra-arterial injection of CO₂ microbubbles through the micro-catheter, by changing the positions of the tip within different arterial branches feeding the tumour area. Right vessel to be used for TAE was detected when the target lesion enhanced during micro-bubbles injection. Hepatic perfusional scintigraphy with intrarterial injection via the main hepatic artery of macro-aggregates of albumine (TC99-MAA) was performed just before TAE, in order to exclude pulmonary shunting. Just before the embolization, 5 mg of levobupivacaine was injected via the micro-catheter in order to obtain local parenchymal analgesia; then, microspheres were gently injected under fluoroscopy, until blood flow was stopped. Upper abdomen MDCT was performed 24 hours after treatment, for assessing early local result and for detecting any possible complication. MDCT scan was then repeated at 30 days, three and every six months. Local efficacy of the treatment was defined according to RECIST criteria on CT follow-up imaging: complete response was defined as the disappearance of treated target lesion. Moreover, post TAE amount of tumour devascularisation (i.e. necrosis) has been also evaluated: complete response (=devascularisation) was defined as

the absence of any contrast enhancement during arterial phases in MDCT, massive response as the necrosis of the huge portion of the lesion and partial response as the necrosis of a portion of the lesion. We considered a complication due to the treatment if it occurred within 3 weeks from TAE. Results: Patients received a total of 29 sessions of TAE. Technical success was achieved in all TAE procedures. Only one pt within the study had a 6% pulmonary shunting detected at MAA liver scintigraphy. Minor complications were observed in 2 patients: 2 pancreatitis restored in few days. Major complication occurred in one patient who died within 24 hr after TAE. This 74-y.o. patient had a previous history of breast cancer, CRC and heart infarction due to chemotherapy. She had even liver surgery for HCC two years before (S2-S3 resection), with early recurrence within S4, just between the right and the median hepatic vein. Post-mortem examination showed the presence of a large necrotic portion of the lesion and the presence of necrotic emboli in the right pulmonary artery. Microspheres were observed in arterial and portal liver vessels, but also into both lungs. Pathologists supposed that a massive tumor necrosis and wall rupture of the tumor involved hepatic vein occurred few hours after TAE with passage of necrotic tissue and microspheres to the lungs via the median hepatic vein. Complete necrosis (hypodensity) was observed in 30 nodules at 24 h CT, while 2 nodules showed poor response. All patients included have at least one month FU (average: 10 months) and evaluation based on RECIST criteria shown 2 progressive disease (PD), 13 stable disease (SD), 6 partial response (PR= ranging between 33 and 78% of diameter reduction) and 1 complete response (CR). Discussion: There is no standard therapy for patients with HCC unsuitable for surgical treatment. Cirrhotic patients with HCC have a poor prognosis, mainly influenced by hepatic reserve function and tumor staging. In these cases, TAE and TACE are the most used treatments with proven improvement on survival in selected patients with well preserved liver function. Actually, there is no absolute evidence that TACE is better than TAE. Six randomised trials of arterial embolizations, with or without chemotherapy, have shown a strong antitumoral effect, but none detected survival benefits in comparison with conservative management or suboptimum treatments. Some authors describe an important rule represented by survivin, a member of family of inhibitors of apoptosis protein and promoter of mitosis and therefore cancer cell survival and growth. Theoretically, TACE, combining the effect of drug with hypoxia, should be more effective than TAE. Survivin expression, increase under anticancer drug and further increase over, after the administration of a combination of hypoxia and anticancer drug. No survivin protein expression is observed in the hypoxia condition without drug. There is no evidence of an additive or synergistic antitumoral effect of TACE vs TAE alone. Three different randomized trial studies have failed in demonstrating a significant difference in survival between the two different treatments. Probably, ischemia resulting from embolization might be the main factor inducing reduction in tumour size after TACE. Conversely, hypoxia and inflammation, as they are powerful stimulators of angiogenesis, might inadvertently promote tumour growth. Kobayashi et al. showed an increasing of serum concentration of vascular endothelial growth factor in patients who underwent TACE, suggesting a direct link between the degree of embolization, tumour hypoxia, and the stimulation of new blood vessel growth. Moreover, it has been suggested that TACE may facilitate the hematogenous dissemination of malignant cells in the systemic circulation by disrupting cell-cell adhesion, and by damaging the endothelium. In the major part of the studies concerning HCC treatment with TAE, the embolizing agent is gelatine sponge that induces hypoxia only temporarily. In some studies, polyvinyl alcohol (PVA) particles were used to cause a permanent or semi-permanent vessel occlusion. Nowadays, there are few studies on the new embolizing agents, such as resin or gelatine microspheres. There is no consensus about which is the most effective embolizing agent. Theoretically, an embolizing agent that has a standardized particle size and that can be delivered into smaller arteries and cause permanent thrombosis should be more effective than temporary or heterogeneous sized embolizing agents. Moreover, smaller particles will effect within the tumor vessels, avoiding any possible arterial blood relapse as it can occur if more distal vessels are occluded. In this scenario, some other new vessels from outside the nodule will develop and feed the tumor. The new microparticles (Embozenes) we used for TAE have some distinctive features, which may lead some other advantages in obtaining tumor necrosis than other materials. Precise and well calibrated small size and antiinflammatory effect (due to the coating film with Polyzene-F) are the most important characteristics, which may allow for deep ischemia without inflammatory reaction of surrounding tissue. According to the RECIST criteria, we had one patient with complete response (tumor disappearance) at 14 months follow up

N2 - MRSA infections in community accounted for 3-11% of S. aureus infections in resource-limited regions of Asia especially due to availability of over-the-counter antibiotics, their frequent self-administration for inappropriate indications and taken for irregular durations, low cost and substandard quality. We would like to expand those data by a small cohort of 102 HIV-infected children from Cambodia treated with HAART for 4 to 5 years. Of 102 HIV-infected children in the orphanage House of Family run by St. Elizabeth University, 62 were colonized within last 58 months with S. aureus, which caused 149 episodes of infection, 118 MRSA and

31 MSSA. Proportion of MRSA colonization was very high at the baseline (75-100%) without any previous known hospital contact as well as during first 24 months, then dropped to 57,1% and 43% after 27 respectively 30 months but then rose again to the level at baseline of 76% after 51 months. Meta-analysis which analyzed exposure of antibiotics as a risk factor for MRSA infection showed that risk of acquiring MRSA was increased by 1.8-fold in patients who had taken antibiotics. Quinolones increased risk 3-fold, glycopeptides 2.9-fold, cephalosporins 2.2-fold and other beta-lactams 1.9-fold. When looking for previous exposure with antibiotics one month before infection, children infected with MRSA were significantly more frequently receiving oral 2nd and 3rd generation cephalosporins (67% vs. 23%, P<0.01) and macrolides (47% vs. 23%, P<0.05). However aminopenicillins, quinolones and cotrimoxazole were not significantly related with MRSA in HIV-infected children. Quinolones were less associated with MRSA in our group of children because of less frequent use in children. The prevalence of MRSA remained high but did not increase despite frequent antibiotic treatment of *S. aureus* infections during entire 58 months assessed period. Use of cephalosporins and macrolides were significantly related to the increased of MRSA infection but surprisingly despite children were receiving cotrimoxazole during the entire period of 4 to 5 years for prophylaxis as recommended by WHO, use of cotrimoxazole was not related to resistance selection. Emergence of MRSA in a resource-limited countries in Asia fuelled by uncontrolled antibiotic use outside hospital settings may pose a significant threat for risk group of patients such as our group of HIV-infected children from Cambodia

IS - var.pagings

N2 - We experienced a living liver transplantation of an unusual indication of uncorrectable intra- and extrahepatic biloma after transcatheter arterial chemoembolization (TACE) which could be a relative contraindication so that we are reporting it. A 45 year old patient was a carrier of HBsAg for more than 25 years. He was diagnosed to be hepatocellular carcinoma (HCC) in 2004. He then underwent TACE 6 times and had a complication of biliary stricture in Nov. 2007. At that time the problem was solved with an interventional procedure. In Apr. 2008, he underwent another TACE for HCC, and after that a long segment of biliary stricture was developed. With recurrent cholangitis, there developed two huge biloma, one in the liver and one outside the liver. Percutaneous transhepatic biliary drainage for the intrahepatic biloma and percutaneous drainage for the extrahepatic biloma with long standing antibiotics administration were done, but with all effort there was no improvement. The Child-Turcote-Pugh score was 6 and Klebsiella pneumoniae was detected in culture for the drain discharge. The CT shows two large biloma; one in the liver and one outside the liver. There was massive adhesion due to recurrent infection and inflammation in the abdominal cavity. Small amount of pus was inevitably spilled into the abdominal cavity. The extrahepatic biloma was found to be abdominal wall abscess which was covered with thick peritoneum. The total recipient operative time was 12 hours and 25 minutes and required transfusion was 8 units of packed RBC and 4 units of FFP. The biopsy showed HCC of 3.0 x 1.5 x 1.2 cm in the caudate lobe. Hepatolithiasis with chronic and active cholangitis and multiple abscess formation was also seen. He is now visiting the outpatient clinic without a problem. Although usually active and uncontrolled infection outside of the hepatobiliary system is thought to be an absolute contraindication to liver transplantation and chronic and refractory infection is thought to be a relative contraindication. In the present case, however, the localized, controlled infection and biloma did not cause the posttransplant septic complications. Therefore, a liver transplantation could be considered for uncorrectable, infected biloma if other treatment modalities failed

IS - var.pagings

N2 - Introduction: A 2 year old male presented to the ER after refusal to eat for the past 6 hours, gesturing to his mouth and saying "coin." Parents did not witness ingestion of a foreign body (FB) and denied any previous complaints of dysphagia or abdominal pain. ER vital signs were stable and physical exam was unremarkable, revealing a playful, interactive child with no drooling or distress. Review of symptoms did not identify any previous gastrointestinal(GI) complaints in this child. Initial evaluation: Chest X ray (CXR) revealed a 2.0 cm radio-opaque FB in upper esophagus at the T3 level. Subsequent CXR taken 18 hours later showed no change in the FB location. Gastroenterology (GI) team performed an esophagogastroduodenoscopy (EGD) and removed a coin from the upper esophagus by using forceps. Evidence of furrowing was found in the middle and lower thirds of the esophagus, of which biopsies were collected. Results: Pathologic evaluation of the biopsies

revealed more than 70 eosinophils(EOS) per high-power field (HPF) in both the middle and lower thirds of the esophagus. Epithelial reactive changes, spongiosis, and hyperplasia of the squamous epithelium were also appreciated. The patient was referred to GI and Allergy for further evaluation. Allergy evaluation revealed positive skin prick testing (SPT) to multiple indoor, outdoor allergens, and egg. Patch testing revealed numerous positives to multiple foods including: milk, soy, wheat, peanut, rice, beef, potato, turkey, and oat. Clinical Course: The patient was diagnosed with eosinophilic esophagitis (EE) by the GI team. He was started on a daily proton pump inhibitor medication in addition to an elemental diet. Subsequent EGD and biopsy 6 months later showed interval improvement in the mid and distal esophageal biopsies revealing 30 and 9 EOS/HPF, respectively. Conclusion: This case illustrates an unusual presentation for EE in a healthy child with no previous GI complaints. This case also highlights that failure of a FB to pass through the esophagus may reflect underlying pathology. Therefore, endoscopy to remove such a FB should include evaluation of the overall condition of the esophagus

N2 - Objectives: The goal of this work is to evaluate the salient features of headache patients, to whom the Pet Therapy had long-lasting benign effect. Background: Pet Therapy effectiveness studies are rarely found in international publications, although in the common practice, also outside clinical environment, there exist very high statistics of well responding patients. Our group has been using for several years the Pet Therapy as child's headache first choice Therapy. In several works we authored, we noticed a reduction of headache-defining parameters, as well as of associated psychological markers. Methods: All patients which underwent Pet Therapy

in 2006 have been contacted and questioned. Out of the 74 patients, 65 patients have been reached; out of the group of questioned 65, 55 patients declared to not show anymore headache symptoms. Data from 2006 clinical charts of the responding 55 patients have been reanalyzed (35MWoutA, 7 MwA, 13FETTH,)36f, 19m, mean age 10,4+/-3,4 range 6/15). Results: At birth, neuro-behavioral and developmental aspects in the first years of life there is no noticeable difference between the two groups. Regarding headache features outside TTH details and migraine, it has been found a precocious insurgency of migraine 3 years versus 1 year for TTH, as the presence of a traumatic psychological event in the pathology genesis in 75% of the migraine patients, versus 30% TTH. Differences have been spotted in the psychological features of the patients: 95% of migraine patients suffering from anxiety, out of which in 25% of those associated with depression; while in the TTH anxiety was present 69% of the times. Main difference was found in the duration of the Pet Therapy treatment: 22 + 3 sessions for TTH, against 37 + 12 in migraine patients. Conclusions: In the Pet Therapy, we found no specific characteristics in the two diseases, in addition to a significant difference in processing time. This once again suggests that the child's headache could be a continuum from one form to another; so that the Pet Therapy seems to elicit adaptive psychological structures that activate the unrealized potential of neuronal plasticity. This longitudinal study confirms the effectiveness of the stabilization of the results of Pet Therapy, paradoxically, without fail, even if we have not an experimental model explanatory

N2 - Participating in recreation is widely recognized by healthcare professionals as beneficial for all children. Meaningful activity contributes to a child's physical, social, emotional, spiritual and intellectual growth. This is

even more important for children with disabilities because recreation is by its very nature, nurturing and restorative. Many studies, however, show that children with disabilities are often less involved than their peers. They have been found to be less active and more at risk of obesity and impaired health due to lack of activity (Steeles et al., 2000). Bloorview Kids Rehab's Therapeutic Recreation Life Skills program undertook a series of consultations with our families, clients, staff, volunteers and service providers to look at some of the reasons for diminished participation. One of the key findings was the need for engaging, easy-to-access information (e.g., appealing to youth; realistic; easy-to-understand for those whose first language is not English; available for viewing on our website and/or while waiting for appointments at Bloorview) about winter activities, especially for children with higher needs. As a result, we developed a 12-minute, open-captioned video inviting people with disabilities to get outside in the winter. Shot at WindReach, a wheelchair-accessible farm, the film demonstrates a variety of adapted winter equipment, tips and activities to promote healthy, active living in the community

N2 - Background/Objectives: Studies testing methods to promote physical activity require accurate and precise measurements of both physical activity and energy expenditure in children. StepWatch (SW) accelerometer data has been found to accurately count strides across speeds and predict oxygen costs of walking in lean and obese adults. This project aims to test the accuracy and precision of the SW across walking speeds against the gold standard of manual stride counting and to pilot the prediction of oxygen consumption modeled from SW counts in youth developing typically (YDT). Design: Instrument development and validation with a clinical case series. Participants and Setting: A volunteer sample of ten YDT (5 boys, 5 girls), average age of 14.1 (SD 2.2) years, average leg length 86.2 (SD 7.5) cm, weight 50.2 (SD 11.2) kg and BMI 18.3 (SD 2.2) participated with recruitment through (children of) employees of a tertiary care children's hospital. Materials/Methods: Two SW monitors were calibrated to individual walking patterns using SW software and leg length. A self-selected walking (100+ stride) sample with the SW was compared to manual count with accuracy of 99% (SD 0.47). Participants underwent treadmill cardiopulmonary exercise testing (CPET) wearing two SW monitors (outside right, inside left ankles) at 1, 2, 3 and 4 mph for 3 minutes. Absolute disagreement, with a ratio and interclass coefficients (ICC) to manual counts were employed with hierarchical linear regression to develop a prediction equation. Results: Average sign-corrected disagreement for strides counted between the two SW monitors was 0.4 (0.51), 0.2 (0.42), 0.1 (0.32) and 0.1 (0.32) for 1, 2, 3 and 4 mph respectively. SW stride counts to manual counts (accuracy ratio) averaged 100.03 (0.10) with ICC=0.995 (precision) across the four walking speeds. The derived prediction equation for oxygen consumption was: $VO_{2} = -1.2 * \text{gender} + 0.58 * \text{age. (years)} + 0.31 * \text{SW strides} + 8.35$ with $r^2=0.84$. Conclusions/Significance: The SW data demonstrates excellent accuracy and precision for treadmill walking across speeds in YDT. With SW data corrected for gender and age, acceptable prediction of walking oxygen consumption in youth 10-16 years of age appears possible within the context of day to day life versus the current lab based measures. Future work will explore prediction of oxygen consumption with the SW during selfselected walking speeds, with varying terrain and community based activity. Such information will allow testing of interventions to improve walking efficiency, physical activity and/or energy expenditure in children and youth

IS - var.pagings

N2 - Background/Objectives: Current StepWatch (SW) accelerometry data describes walking activity with the numeric variables of strides/day, % time active and peak strides/durations of time. Ambulatory activity curves allow interpretation of these variables in a combined format. The purpose of this study is to characterize community based daily ambulatory activity patterns in cerebral palsy as compared to non-impaired youth.

Design: Cross-sectional comparison cohort. Participants and Setting: Eighty-one children with CP, gross motor function classification system [GMFCS] levels I [n=31], II [n=30] and III [n=20]; seen for care at three regional pediatric specialty care hospitals and 204 youth developing typically (YDT), all ages 10-13 years.

Materials/Methods: Participants wore the SW on their lateral ankle for 7 days during waking hours. Five days of data were plotted for average minutes per day spend at each stride rate from one stride per minute to the highest rate per participant. Time spent at each intensity level (strides/ min) was represented in log-scale with a Lowest curve fit for visualization of the youth with CP by GMFCS level and YDT. Y axis is the natural log and average strides taken with X axis the # of strides/minute. Results: Youth with CP at level I on average were as active, have similar stride/min rates between <20 and >60 strides and are capable of peak stride rates (85 strides/min) similar to YDT. Their primarily limitation appears in stride/min rates between 20 and 60 strides [Fig H1].

Participants at Level II were less active on a daily basis demonstrating rates consistently lower than the YDT peaking at 75 strides/min as documented by a initially steeper curve that remains flat. Youth at level III demonstrate a low level of daily activity with the average stride rates outside the confidence band for YDT between 10 and 50 with a peak stride/min of 70. Conclusions/Significance: Day to day walking activity of youth with CP demonstrates characteristic patterns of lower levels of walking activity, intensity levels across stride rates and peak stride rates than YDT as expected by GMFCS level. Youth with CP are more heterogeneous across stride rates than YDT. Ambulatory activity curves with the StepWatch have the potential to capture levels of daily ambulatory function temporally as well as in terms of intensity. This 'snapshot' analysis of average daily walking activity patterns may have application for clinical practice and/or outcome research (Graph presented)

IS - var.pagings

N2 - Background/Objectives: Balance impairments are common following acquired brain injury (ABI).

Children with ABI often have goals related to participation in sports and recess activities that require high-level balance skills. The community balance and mobility (CB&M) scale (Howe et al, 2006) is used by physiotherapists (PTs) at our pediatric centre to measure balance, and may be better at detecting changes in this area than the Gross Motor Function Measure (GMFM). While the CB&M's psychometric strength has been shown with adults, it has not been tested in pediatrics. The purpose of this study was to determine inter-rater and test-retest reliability of the CB&M in ambulatory youth who have an ABI. Design: Prospective, repeated measures design. Participants and Setting: Twenty-four ambulatory youth (13 females and 11 males) with an ABI, ages 8 to 17 years (mean age=14 year 1 month, SD=2.1) who were in-patients or day-patients at a pediatric rehabilitation centre. Materials/Methods: Six PTs were trained as assessors. Each passed the study's CB&M criterion test. The PTs were assigned in pairs to do the CB&M assessment. At baseline, one PT assessor administered and scored the CB&M, while a second PT observed and independently scored it (inter-rater reliability). Children were reassessed 3-10 days later by the PT assessor who administered the baseline CB&M (test-retest reliability). Each PT had equal opportunity to serve as assessor or observer over the course of the study. Results: The participants' GMFM mean score at baseline was 93.4% (SD=7.8). CB&M baseline mean scores were 63.5% (SD=18.4) and 64.7% (SD=18.5) for PT assessors and observers respectively. The interrater reliability ICC was 0.93 (95% confidence interval [CI]=0.85-0.97), and a Bland-Altman plot revealed an indication of smaller inter-rater differences for lower CB&M scores (i.e., slightly greater agreement on lower scores). The assessor retest mean score was 68.7% (SD=17.0). The test-retest ICC was 0.92 (95% CI=0.84-0.96). No systematic bias was indicated in the test-retest Bland-Altman plot. The minimum detectable change

(MDC90) estimate was 12.6% points. Previous clinical CB&M follow-up at our centre of 17 youth with ABI with similar baseline scores to our reliability sample showed mean change score of 23.6% points [SD=13.5] from baseline to discharge assessment, suggesting that this study's MDC estimate is clinically realistic.

Conclusions/Significance: The CB&M showed excellent inter-rater and test-retest reliability in youth with an ABI with estimates similar to those of the published reliability work by Howe et al (2006) with adults post-ABI. In our sample, there was little room for gain on the GMFM, while the CB&M showed scoring scope to detect improvement. Future work should focus on formal evaluation of the CB&M's responsiveness to change in rehabilitation centre and community intervention contexts

IS - var.pagings

N2 - Background/Objectives: The ASKp is a self-report measure of common physical activity for children 5-15 years of age with limitations due to musculoskeletal disorders. The ASKp measures how often a child performed specific activities over the past week using a five point Likert scale. Since the original psychometric properties were published, the ASKp has appeared in 30 and 38 item versions. The objective of this study was to perform exploratory and confirmatory factor analyses of the 38 item ASKp and determine model and item fit statistics. **Design:** Instrument Development and Validation. **Participants and Setting:** The ASKp38 was administered to 200 children (mean age 12.2 + 2.3 years) with a variety of physical impairments. Administration of the ASKp occurred during IRB approved home or center based research visits. **Materials/Methods:** Confirmatory (CFA) and exploratory (EFA) factor analyses were done in MPlus. Item fit statistics were calculated using the Rasch partial credit model in Winsteps. **Results:** EFA with unweighted least squares and Quartimax rotation was done. Five factors with eigenvalues >1 were identified, but only two factors explained >5% variance. Comparison of one and two factor models indicated better fit for the two factor model based on higher communalities and higher factor loadings. There was good separation between the two factors with three cross-loaded items (Figure 1). CFA fit statistics for a two factor model were acceptable (CFI=0.974, TLI=0.991, RMSEA=0.049). Fit statistics for higher factor models were better but exhibited significant item cross-loading. The first factor consisted of "physical activities of daily living" (ADLs): all Personal Care, Dressing, Eating and Drinking, Miscellaneous, Locomotion, Standing Skills, Stairs, and Transfers items, with the exception of #19 "kept up with friends outside" , and #28 "sat on the floor" . The second factor consisted of the one Play item, the eight sports-focused Additional items, and items 19 and 28. Rasch analysis created a hierarchy based on the frequency of successful performance of items. "ADLs" showed a range from -0.67 (least frequently performed: stood still for 10 minutes) to 0.85 logits (most frequently performed: got around inside my home). For the "sports" activities, the range was from -1.19 (least frequently performed: ran in a race) to 0.63 logits (most frequently performed: sat on the floor). Infit (range 0.42-1.56 logits) and outfit statistics (range 0.13-1.59 logits) were acceptable. **Conclusions/Significance:** Factor analysis reveals a two-factor model underlying the ASKp38 instrument indicating two different constructs. One factor consists of 27 "ADLs" and the other factor consists of 11 sports-related physical activities. Clinicians should consider other factors such as motivation, opportunity, inability, and lack of need when interpreting this performance measure. **Acknowledgement:** Research Supported by NIH Grant 5U01AR052171 (D. Amtmann, PI), NINDS F31-NS048740, Staheli Endowment Fund, Seattle Childrens' Hospital and 2008 AACPD Clinical Research Planning Grant. (Graph presented)

N2 - Background/Objectives: To accurately assess the long term impact of orthopedic interventions, more information is needed about changes in the walking abilities of people with cerebral palsy (CP) that occur from adolescence to young adulthood. Additional information about current levels of activity and participation can document the interrelationships among walking abilities and other aspects of health. The purpose of this study was to document changes in walking abilities from adolescence to young adulthood in people with CP, and current level of activity and participation. Design: Outcomes research. Participants and Setting: Thirty-three (50/191 located, 17 cancelled or refused) people with spastic CP who had a previous motion analysis evaluation (3DGA) at a tertiary care hospital (initial gross motor functional classification system [GMFCS] levels I [n=1], II [n=14], III [n=14], IV[n=4]; ages: 20-36 years; time between evaluations: 5-19 years). Materials/Methods: Follow-up evaluation included GMFCS level, functional abilities (FIM), Gillette Gait Index (GGI), living arrangements, employment, level of education, canadian occupational performance measure (COPM), short form health survey (SF-36), and 5 year goals. Results: Thirty out of 33 maintained or improved GMFCS Level since initial evaluation; 22/26 maintained or improved GGI. Sixteen out of 33 were living with parents, 15/33 apart from parents, and two in skilled care facilities. Twenty-two out of 33 had education or specialized training past high school. Nineteen worked outside the home for pay, eight were students, six were not employed. Family values, medical issues, and lack of personal care attendants were reasons for unemployment. Lack of transportation, employment, socialization, and personal care attendants were the most frequently cited perceived problems. No relationships were found among changes in GMFCS levels or GGI with FIM scores, SF-36 sub-domain scores, COPM barriers, level of education, employment, or living arrangements. The two subjects with the greatest declines in walking abilities were either working full time or married, with children. Subgroup analysis of subjects who did not decline demonstrated an association of orthopedic interventions with maintained or improved walking abilities ($R^2=0.82$, $F=35.0$, $P=0.000$). Conclusions/Significance: The majority of the subjects maintained walking abilities into young adulthood, and the relationship between changes in walking abilities, orthopedic interventions, personal and environmental characteristics, and participation in society requires additional investigation

N2 - Magnetic resonance spectroscopy (MRS) is a technique which can be readily combined with conventional magnetic resonance imaging to measure the levels of various metabolites, lipids and macromolecules in a

specified volume of tissue. The most clinically available form is 1H MRS which provides a broad metabolite profile with approximately 15 metabolites being quantitated in brain tumours. Due to the comparative ease of performing 1H MRS in the brain, brain tumours have been the most widely studied tumour group, however, there have also been many studies of prostate cancer and breast tumours. It is well established that 1H MRS metabolite profiles are a powerful characteristic of brain tumours and the use of 1H MRS as a non-invasive diagnostic tool is well investigated. The most impressive results have been obtained by coupling 1H MRS with pattern recognition techniques and large multicentre prospective studies have shown a high level of diagnostic accuracy for many tumour types but a lower accuracy when trying to distinguish between glioblastoma and metastases. Fewer studies have been published in children but small studies indicate that the accuracy is similar. Total choline and mobile lipids have been noted as indicators of tumour aggressiveness and a decrease in choline has been used as an indicator of tumour response to drugs. Similarly, myoinositol correlates with lower grade in gliomas and is a good prognostic marker in pilocytic astrocytomas in children. Animal and cell line studies show particular promise for mobile lipids as early indicators of cell death, however these findings are yet to be verified clinically. MR spectroscopic imaging allows MRS to be collected from several locations at the same time with a spatial resolution down to 1 cubic cm in the brain using a 1.5T clinical scanner and much higher resolution in the prostate using endorectal coils. Using choline as a marker of active tumour, often as a ratio to another metabolite, has allowed accurate targeting of biopsies and is used commonly in some centres for improving the accuracy of prostate biopsies. MR spectroscopic imaging is also useful for identifying tumour invasion and has detected diffuse tumour outside the regions delineated by conventional MRI. This shows promise in radiotherapy planning. 31P MRS can detect phosphorous containing metabolites and phospho-lipids. It is technically more demanding than 1H MRS but is useful in certain circumstances. Phosphocholine and glycerophosphocholine can be quantitated individually rather than the combined value usually provided by 1H MRS. The ratio of these two metabolites is a powerful discriminant of some tumour types such as medulloblastoma and of response to treatment with the phosphocholine/glycerophosphocholine ratio decreasing in responding tumours. Dynamic Nuclear Polarisation (DNP) is an exciting new technique for the production of tracer metabolites which can be detected by MRS and has the particular advantage that the parent molecule and its metabolites can be detected separately. The first clinical studies of DNP using pyruvate as a marker of apoptosis are about to start

N2 - The objective of this study was to investigate the effect of seasons on sleep in 22 pairs of healthy preschool children and their mothers. They were informed of the study protocol and provided their written consent. The study was performed at the subjects' homes during spring, summer, fall, and winter. Wrist actigraphy and temperature and relative humidity (RH) outside and within the bedroom were measured for 7 consecutive days. Bedroom illumination and subjective sleep evaluation were determined on 2 nights. The bedroom temperature significantly increased in summer and decreased in winter as compared to fall or spring, while no significant difference was observed in the humidity. Bedroom illumination was significantly higher in the morning in summer and spring than in fall or winter. Among the mothers, the sleep efficiency index increased and the wake after sleep onset decreased in spring as compared to the other seasons. The mean activity during sleep increased and the sleep time decreased in summer as compared to the other seasons in the preschool children. Among the mothers, the subjective sleep evaluation was improved in spring as compared to the other seasons. The subjective sleep onset was delayed in summer in preschool children. These results indicate that effect of season on sleep may differ between preschool children and their mothers. Furthermore, care should be taken to prevent disturbed sleep in preschool children in summer

N2 - Outdoor particulate matter (PM10) is associated with a wide range of health effects and a European threshold limit of 50 $\mu\text{g}/\text{m}^3$ was established in 2005. However, most individuals spend at least 85% of their time indoors where particle concentrations are mostly higher than outdoors. Since children represent a vulnerable group, we investigated the health effects of indoor air PM10 collected in classrooms compared to outdoor air PM10. PM10 was collected in five schools in Munich during teaching hours. Cytotoxicity was assayed as a decline of cellular ATP concentration in human primary keratinocytes, human lung epithelial A549 cells and Chinese hamster V79 lung fibroblasts at concentrations up to 10 $\mu\text{g}/\text{ml}$. In addition, toxicity after metabolic activation was assayed in V79 cells expressing human cytochrome P450 1A1, 1A2, 1B1, 2A6, 2B6, 2C9, 2D6, 2E1, 3A4 or 3A5. For a genome wide expression analysis BEAS-2B bronchial epithelial cells were incubated with 10 $\mu\text{g}/\text{ml}$ PM10. RNA was isolated and analyzed on Affymetrix HG U133A 2.0 expression arrays. While in A549 and V79 cells no toxicity was observed, in human primary keratinocytes PM10 at a concentration of 10 $\mu\text{g}/\text{ml}$ caused a slight decrease in vitality. This cytotoxic effect was also found in V79 cells after metabolic activation by CYP1A1 or CYP2C9. Genome wide analysis of PM10 from outdoor and indoor air showed the overexpression of xenobiotic metabolizing genes (CYP1A1, CYP1B1) and of inflammatory cytokines (IL1A, IL1B, IL6, IL8). Indoor PM10 caused a lower induction of xenobiotic metabolizing genes but a up to six fold higher induction of inflammatory cytokines compared to outdoor PM10. Direct cytotoxicity and metabolic activation by cytochrome P450 isoforms 1A1 and 2C9 were statistically significant at a PM10 concentration of 10 $\mu\text{g}/\text{ml}$, which is about 10 000 times higher than exposure encountered in classrooms. We therefore expect no toxic effects of these particles in school children. The reduced induction of xenobiotic metabolizing genes but increased induction of inflammatory cytokines in indoor PM10 treated cells suggests that classroom PM10 is less toxic but has a higher inflammatory potential than outdoor PM10

N2 - Cerebral palsy (CP) describes a group of disorders of posture and movement that occur early in life. Although the disturbance in the developing brain is non-progressive, motor function may change over time. From the outset, parents want to know whether their child will walk. Although walking is valued by individuals of all ages, youth with CP may be more concerned with mobility; getting from place to place in a safe and efficient manner to do things with other people. The objective of this presentation is to provide a lifespan perspective of gross motor function of individuals with CP. The perspective is informed by two longitudinal studies, the Ontario Motor Growth Study and the Adolescence Study of Quality of Life, Mobility and Exercise, completed at the CanChild Centre for Childhood Disability Research. The rate of gross motor development among children with CP is highest at younger ages. Children approach the upper limit of their motor capacity at approximately 3-6 years of age depending on Gross Motor Function Classification System (GMFCS) level. Children and youth in Levels I and II maintain motor capacity; while children in Levels III, IV, and V demonstrate peak motor capacity at 7-9 years of age before declining an average of 5-8 points on the GMFM-66. By 3 years of age, almost all children in Level I walk at home, school, and outdoors. By age nine, the probability of walking is high in all settings for children and youth in Level II. Children and youth in Level III demonstrate variability in usual method of mobility in all settings. For children in Level IV, the probability of using powered mobility increases with age. Only a small percentage of children and youth in Level V mobilize (powered mobility) without physical assistance of a person. Youth spoke of constantly adapting to situations that often reflected a lack of control over the environment and having to plan ahead to go places and do things. The findings provide evidence of prognosis for gross motor function and have implications for decisions on goals, outcomes, services, and supports. Personal and environmental factors are important when making decisions on mobility including attitudes and beliefs regarding walking and wheeled mobility. The preferred method in one setting may not optimize participation in another setting. Task accommodations, environmental modifications, and assistive technology are interventions that have the potential to optimize activity and participation. Implications for adulthood are discussed

N2 - Background: There are various instruments designed to measure activity limitation in children with cerebral palsy (CP) that rely on self-report to measure performance. Performance can be described as what a child 'does do' and differs from capability which describes what a child 'can do'. Performance instruments are often more relevant to the child and family because they assess function in everyday life, however they are used with the assumption that what is reported accurately reflects what is really happening. Objective: The aim of this study was to determine if a self-report instrument, the Functional Mobility Scale (FMS), truly measures performance by correlating it with direct observation of mobility of a group of children with CP. Design: A prospective study of instrument validation. Participants/setting: Included were children with CP aged 4-17 years, classified as GMFCS levels I-IV. They were recruited from a special school and were clients of a tertiary care facility. Materials/Methods: Participants were rated on the FMS by an independent experienced physiotherapist. The same children were observed directly at home and at school by a different physiotherapist and their various mobility methods were recorded. These observations were used to generate an 'observed' FMS score which was correlated with the usual self-report FMS score using unweighted kappa statistics. Results: 18 children (11 males, 7 females) of 27 eligible to enter were included. The age range was 8-17 years (mean 12.7 years). Direct observation showed that many children used more than one method of mobility, particularly those classified as GMFCS III. Seven children used more than one method at home and 13 used more than one method at school. Correlations between 'observed' and self-report FMS ratings were fair to moderate with unweighted kappas of 0.27 for 5 m (home), 0.45 for 50 m (school) and 0.29 for 500 m (community). Conclusions/clinical implications: The fair to moderate correlation of self-report and direct observation using the FMS was lower than expected. This is potentially the result of the multiplicity of mobility methods children with CP are observed to use. Because it is not always practical for clinicians to measure children in their natural environments, self-report measures remain the most convenient method of assessing performance. Further investigation of this clinically

important issue with other self-report measures is required to ensure that it is a valid and clinically relevant method of reporting

N2 - Background: Active and pleasurable involvement of disabled children in activities outside school is a key measure of successful participation. Participation is influenced by many factors including the skills and interests

of the child and social and environmental supports (Hammal et al. Dev Med Child Neurol 2004; 46: 292-298; King et al. Child Health Care 2006; 35(3): 209-234; Forsyth et al. Dev Med Child Neurol 2007; 49(5): 345-349). Policies and social expectations in different countries vary and these may also influence participation. Objective: This study investigated the extent to which selected individual, family and environmental variables were associated with participation of Australian children with cerebral palsy in formal and informal activities outside school. Design: Prospective population-based survey. Participants: All children born in 1994 or 1995 in Victoria and diagnosed with cerebral palsy were eligible for inclusion. Complete data were available for 108 of 114 participating children (49.3% of the known living population) in Gross Motor Function Classification (GMFCS) levels I:23%; II:37%; III:9%; IV:20%. Methods: Participation was measured using the Children's Assessment of Participation and Enjoyment (CAPE) (King et al. Children's Assessment of Participation and Enjoyment and Preferences for Activities of Kids. San Antonio, Texas: PsychCorp 2004). Independent variables included gender, child's activity preference, motor function measured by the GMFCS and the Manual Ability Classification Systems (MACS), child's temperament and communication ability. Family variables included family type (single or two-parent family), background (Australian-born or not) and socio-economic advantage/disadvantage. Environment variables included living and school environments. Linear regression analysis was used to assess associations between these variables and diversity of participation in informal and formal activities. Results: Other than where children lived, all variables had univariate associations with informal participation. The variables with the strongest multivariate associations with informal participation were manual ability (MACS level independently accounted for 22.6% of the variance), a preference for informal activities (accounted for 7% of the variance) and gender (2.6% of variance - girls participated more). Only two variables were important in the multivariate model for participation in formal activities: preference for formal activities (2.9% of the variance) and attendance at mainstream school (7.1% of the variance). Discussion/Conclusion: Child characteristics were more strongly associated with informal participation than environment or family characteristics. The explanatory power of the multiple regression model for formal participation was very limited but attendance at mainstream school was important. It is likely that MACS level is relatively stable, although improved manual ability may influence participation. Preference for activity in childhood may be more amenable to change. Being exposed to a range of activities within supportive environments may provide the opportunity to develop preferences, especially in activities where children with cerebral palsy have reduced participation, such as in physical activities (Maher et al. Dev Med Child Neurol 2007; 49(6): 450-457)

N2 - Excessive sunlight exposure in early childhood is associated with an increased risk of developing cutaneous malignancies (Masso M. Policy and practice in preventing skin cancer in children. Public Health Nurs 2006; 23: 361-5). In 2004, Cancer Research UK's SunSmart campaign produced guidelines on developing sun protection policies for day nurseries and preschools. We devised and distributed a postal questionnaire to 137 local day nurseries to assess awareness of the SunSmart campaign and evaluate its impact on sun protection policy development. Of the 137 surveys sent, 68 were received back (50%). Of all the nurseries that returned their surveys, 53 (78%) were aware of the SunSmart campaign. Fifty-five nurseries (81%) had a sun protection policy in place and only eight of these (14%) stated that their policy was in place before 2004. Comparing policies with the SunSmart guidelines, 93% of nurseries stated that they asked parents to provide sun hats for their children and 38% asked parents to provide long-sleeved tops. Parents were asked to provide suncream for their children by 84% of nurseries and a further 10% of nurseries provided their own suncream. Of these, 55% suggested a minimal SPF of at least 15. No nursery stated that staff were not permitted to apply suncream to children. Usually, written consent was obtained (63%) before staff would undertake this activity. Outside activities during sunny weather were restricted by 82% of nurseries. Almost two-thirds (61%) of these were in line with the SunSmart guidelines of staying in the shade between 11am and 3pm and 48 (71%) had a designated shady area for activities. Of the nurseries surveyed 90% aimed to educate their children about sun protection and 72% of nurseries hoped to inform parents about the importance of sun protection. A nursery without a sun protection policy may be less likely to return their questionnaire, which would obviously introduce bias in our results. From these data however, it is apparent that nurseries who are aware of the SunSmart campaign have often taken steps towards introducing sun protection policies in line with the guidance provided and the campaign therefore has had a positive effect. The number of policies and the timing of their development would suggest that other sources of information must also be involved in influencing childcare providers into introducing sun protection policies. Cancer Research UK continues to redevelop its guidelines for this public sector. More active targeted campaigns may be beneficial in raising awareness and influencing policy in the remaining nurseries

N2 - Many patients with liver transplant in poor countries have difficulties to follow medical prescriptions due to economical and social problems; that may have some influence in rejection rates. Our objective was to evaluate the impact of a new social policy that gives educational and economical support to liver transplanted patients in the Uruguayan Liver Transplant Program. Methods: We conducted a descriptive and retrospective study including 40 liver transplanted patients (24 children and 16 adults. All of them have post-transplant medical assistance in the Uruguayan Liver Transplant Unit. Data on two periods of time were compared: from January to June 2008 (6 months) and to July 2008 to June 2009 (12 months). During the first period, there was not a specific social assistance program for transplanted patients. During the second period, of social and educational support was conducted by the Social Assistant and the Pediatricians of our team. The policy included: regular telephone supervision, educational activities, economical help (for bus tickets and food) and hosting (for patients living outside the city of Montevideo). The total cost of the social program (for the 40 patients) was 100 dollars per month, 36 hosting nights per year and the 400 dollars per month (Social Worker salary). We evaluate the rate of assistance to the scheduled postoperative medical controls, the incidence of rejection and the correct (Graph Presented) immunosuppressant drug administration. Results: In the second period, the patients followed the immunosuppressant treatment much better than in the first period ($p < 0.0001$); they also had a tendency to go to scheduled postoperative medical controls than in the first period. In the first 6 month of the study, 5 patient had rejection (confirmed by biopsy); while in the following 12 months, only 3. Conclusions: social work was an inexpensive and very effective policy to improve immunosuppressant treatment adhesion in liver transplanted patients in Uruguay. This might help to reduce the rate of graft rejection

N2 - Introduction: Although per capita crime has generally fallen over the period which coincides with the obesity epidemic, it has not fallen uniformly across communities. It also has not fallen enough to allay fears on

the part of parents. Over the past 30 years, technological changes have made the indoor alternatives to playing outside, where children are more vulnerable to criminal activity, more enjoyable (cable TV, video games, and the internet) and comfortable (the spread of air conditioning to low income neighborhoods). We determined whether indoor sedentary behavior patterns are associated with community crime statistics. 4th graders in the U.S. are typically 9 or 10 years old. Methods: We used data from the 2004-2005 Texas School Physical Activity and Nutrition (SPAN) survey linked with U.S. Department of Justice, Office of Justice Programs, Bureau of Justice Statistics data for the years 2000 through 2005 and Texas State data on sexual offenders. The probability-based sample included a total of 7,907 children in grade four. Multistage probability sampling weights were used. The dependent variables included were hours of TV watching, video game playing, computer use and total indoor sedentary behavior after school. Incremental Relative Rates were computed for community crime rates including robberies, all violent crimes, murders, assaults, property crimes, rapes, burglaries, larcenies and motor vehicle thefts as well as for sexual offenders living in the neighborhood. The neighborhood refers to the areas where the students at each school live. In the case of sexual offenders, sexual offenders per capita are estimated using the per capita rate in the zip code of the school attended; all other crime statistics are estimated by the crimes per capita in the police department jurisdiction covering the school attended. After controlling for sex, age, and African-American and Hispanic, cross-sectional associations were determined using multivariate Poisson regression. Results: 4th grade boys were more likely to play video games in communities with increased per 100 population rates of larceny and burglary as well as in communities with increased per capita sexual offenders; 4th grade girls were more likely to watch television in communities with increased per capita sexual offenders. While 4th grade girls were more likely to watch TV in communities with increased per capita sex offenders, they were less likely to use computers. Per capita sexual offenders were negatively related to computer use amongst 4th grade girls. Conclusion: By combining community crime and cross-sectional individual level data on indoor sedentary behavior, we found that there is an association between community crimes/sex offender rates and certain types of indoor sedentary behavior. The development of technologies in recent decades which makes supervising children easier indoors, where children are much less vulnerable to crime, may be contributing to the epidemic of childhood obesity. 2008 Brown et al; licensee BioMed Central Ltd

N2 - Background: An appropriate measurement of physical activity (PA) in children is useful, since inactivity is associated to obesity, cardiovascular and metabolic risk. Aim: To assess the reliability of the INTA questionnaire of PA, to compare the derived PA score with accelerometry and to assess its ability to identify excessively inactive children. Material and methods: One hundred eighty children aged 8 to 13 years answered an interviewer-administered questionnaire about their usual PA, consisting in 5 items (recumbent, seated, walking, playing outdoor, sports). The answers were converted to a PA score with a 0-10 points scale. Reliability was tested in 87 children by test/retest conducted 3-5 days apart. The PA score was compared with 3-day accelerometry in 77 of 93 children (35 obese and 42 non obese). Receiver operating characteristic (ROC) curves were used to determine the optimal cutpoint for identify an excessively sedentary child. Results: The test/retest reliability of the questionnaire was 0.69 to 0.93 (Lin coefficient). Accelerometry was significantly associated with PA score (RHO: 0.60, $p=0.008$), outdoor plays (RHO: 0.37, $p=0.0009$) and practicing of sports (RHO: 0.33, $p=0.003$). Obese children were less active than non obese children, according both to PA score and to accelerometry. The optimal cut-point for classifying a child as too sedentary was a score of 5 (sensitivity =0.89). Conclusions: The INTA-test is a valuable instrument for measuring usual PA in clinical practice and is easy to administer

N2 - Introduction. Antiretroviral therapy for treatment of human immunodeficiency virus type 1 (HIV-1) infection has improved steadily since the advent of combination therapy in 1996. Objective. The pharmacological therapies of the infection by HIV/AIDS were documented in order to determine if effective treatment regimes were prescribed. Materials and methods. Pharmacological therapies of the human immunodeficiency virus infection were compared in 997 patients affiliated with the health security system, of both sexes and all ages. All had been in treatment for more than three months (July-September 2006) and were distributed in 15 Colombian cities. The data were retrieved from medication consumption files which were maintained by the institutions that had distributed medications to the selected patients. Results. The average age of patients was 37.7+13.2 and 82.6% were men. All the patients received between three to five antiretrovirals. The medications most commonly prescribed were nucleoside reverse transcriptase inhibitors (96.4%), nonnucleoside reverse transcriptase inhibitors (54.9%), protease inhibitors (39.8%) and others (0.4%). All of the doses were at recommended levels. The most common combinations were lamivudine-zidovudine-efavirenz (35%), lamivudine-zidovudine+lopinavir/ritonavir (8.4%), abacavir+lamivudine-zidovudine (5.5%), lamivudine-zidovudine+nevirapine (5.2%) and others (45.9%), consisting of 65 different combinations. Conclusions. All agents were used at internationally recommended doses and rational prescription patterns prevailed in the initial therapy. However, the use of 69 different associations suggested that after the beginning of treatment, clinicians do not have adequate criteria to prescribe in accordance with international guidelines of antiretroviral therapy; they adopt a variety of options that may be outside of established recommendations

N2 - Experiencing invasive medical procedures can be a devastating experience for some children and their parents. The potential impact on staff who perform the procedure and who may have to restrain the child who is unwilling to have an essential procedure is a neglected area of research. Children's distress and their coping are affected by those around them so it is important to understand how nurses react in these situations. AIM: To explore the experiences of nursing staff involved in facilitating invasive procedures for children who do not want them. METHOD: Participants were selected at random from staff lists of one hospital in the West Midlands. Data collection was undertaken using unstructured qualitative interviews with ten paediatric nurses and in two focus groups. Theories generated from each interview were tested and validated with participants in subsequent interviews and then in the focus groups. FINDINGS: The most common experiences reported by the participants were 'getting upset' and 'getting stressed' by some aspect of the medical procedure, either because the child or parents became upset or the procedure had gone wrong in some way. Procedural protocols that exist to protect children, for example, by limiting the number of unsuccessful attempts to undertake the procedure, also protect staff by providing a framework to manage emotions during the procedure. Being able to explain the process and need for the procedure to the child and parents, obtaining consent where possible for the use of certain techniques, such as restraint, and having the time to adequately prepare a child for a procedure, all helped minimise the likelihood of an unsuccessful procedure, thereby reducing the risk of the nurse being emotionally affected by a distressed child. CONCLUSION: Nurses working with children who are unwilling to undergo invasive procedures experience negative emotions but these are short lived due to a combination of protective factors and coping strategies. Further research is needed to understand the experiences of medical staff and of nurses working outside paediatric environments who may not experience the same support and protection as those in paediatric settings

N2 - Aim: To compare the prevalence and characteristics of bullying between two towns in Bosnia and Herzegovina - Stolac, which was exposed to firearm conflict during the 1992-1995 war in Bosnia and Herzegovina, and Posusje, which was outside of the active combat zone. Methods: In this cross-sectional study, we included 484 primary school pupils attending 4th-8th grade of elementary school, 217 (44.8%) of them from Stolac and 267 (55.2%) from Posusje. The pupils were interviewed using a standardized questionnaire on the experience of bullying. Results: Every sixth pupil (16.4%) experienced at least one form of bullying almost every day, while 34 (7.0%) pupils constantly bullied other children. Sixth-eighth graders were more often bullies than 4th-5th graders ($P = 0.044$). Girls were most often victims of bullying, while boys were most often bullies ($P = 0.036$). The expected difference in bullying between the two towns was not observed, except for older pupils in Posusje, who were more violent than their peers in Stolac ($P = 0.044$). Among the analyzed variables of sex, age, town, and school achievement, only male sex was significant predictor of bullying ($P = 0.010$), increasing the relative risk by 3.005 times. Conclusion: Bullying among primary school pupils did not differ between areas that experienced war activities in 1992-1995. Our results could be useful in the introduction of specific prevention measures against bullying in postwar situation

N2 - Arterial thromboembolism is rare in children. The frequency of arterial thromboembolisms has paralleled the advances in pediatric tertiary care with increasing numbers of children surviving life-threatening primary illnesses and, paradoxically, developing previously rare complications. The pathophysiology of thrombosis in children differs from that of adults, underscoring the need for a unique diagnostic and therapeutic approach in pediatrics. This review is a summary of the available data on the etiology, diagnosis and management of arterial thrombosis, occurring outside of the CNS, in children. 2008 Future Drugs Ltd

N2 - We present the results of an outbreak investigation on a *Cryptosporidium parvum* outbreak among 35 people, (27 students and 8 teachers), who participated in a school excursion to an outdoor adventure farm in South West England, from 22 to 26 May 2006. A cohort study was implemented to investigate possible sources of infection during the farm visit. The most likely transmission route was contact with faecally contaminated surface water following heavy rainfall, or consumption of water from the private well. Disinfection of the water reservoir was by chlorination, to which cryptosporidium is resistant. Supplemental disinfection or filtration methods of private water supplies on livestock farms may be needed. This study highlights the fact that epidemiological investigations of outbreaks as a result of environmental exposures are complex but important to inform the public and health professionals of the risks posed by private water supplies and outdoor activities. This is particularly so after heavy rainfall, as this may result in an increased effluent from faecally contaminated land, causing a wide variety of pathogens to wash into surface water and potentially, private wells. This poses risks for public health. IWA Publishing 2008

N2 - Background: Many health promotion interventions rely on active participation, if uptake is low the impact of the intervention is diminished at population level. This study aimed to identify the main reasons for non-participation in a modelled health promotion programme. Methods: A classification for eligibility and for participation in a modelled health promotion intervention was applied to a database of all 3-5 year olds in 3 PCTs in Manchester, UK. This identified which children would have been participants and which non-participants. Results: Of the 29,220 children in the cohort, 90% would have been eligible to have received the model intervention as they were resident in Manchester before they became 24 months old. Of these, 75% would have participated by having either of the required contacts with health care personnel in the Manchester PCT area. Of these only 43% were attending Manchester LEA schools or pre-schools at the age of 3-5 years when the health benefits would be evaluated. Population churn, uptake of health services outside of the intervention area and non-uptake all accounted for a high level of 'non-participation'. Conclusions: The success of public health interventions are seriously threatened by high levels of non-participation due to population transience in some areas

N2 - Objective: To identify the most common causes of death during sports activity in the population of Hamburg, Germany, and to identify which groups of sportspeople are particularly in danger of dying during sports and in which types of sport most fatalities occur. Design and setting: We performed a 10-year autopsybased retrospective study of all 48 335 fatalities in Hamburg and the surrounding areas that were subjected to police investigations between 1997 and 2006 and screened for sports-related deaths. The main outcome measure was cause of death depending on form of sport, age and risk factors. Results: Most of the fatalities were male. In natural deaths, cardiac causes were the most frequent causes found, with running and football being the most frequent forms of sport in which death had occurred. In some of the cases, sports medical examinations had been performed before death, certifying eligibility for the respective activity. Traumatic deaths were found in all age groups, with younger age groups more likely to have traumatic than natural deaths, and as expected, occurred more commonly in "risky" outdoor activities. Conclusions: Although exercise can have beneficial effects on health, fatalities related to sports activity occur. Cardiac disease is the main cause of sudden death from natural causes. In patients with pre-existing coronary heart disease, left ventricular hypertrophy constitutes a risk factor for exercise-related sudden death. Traumatic deaths often happen on holiday outside the person's country of dwelling, and are most commonly attributable to drowning and blunt trauma. Preparticipation medical screening cannot always prevent fatal incidents during sports activity. Postmortem macroscopic and histological examination can clarify the cause of death and legal issues

N2 - Few dog bite risk factor studies have been conducted. This veterinary clinic-based retrospective cohort study was aimed at identifying human-canine environmental risk factors for non-play bites in Kingston, Jamaica (660) and San Francisco (SF), USA (452). Data were analysed using modified Poisson regression with confounders selected using directed acyclic graphs (DAGs) and the change-in-estimate procedure. Dogs acquired for companionship were more likely (RR = 1.66; 95% CI 1.02-2.70) to bite than those acquired for protection. Routinely allowing a dog into the presence of visitors was also positively associated with it biting. A dog sleeping in a family member's bedroom was a risk factor for biting in Kingston (RR = 2.54; 95% CI 1.43-4.54) but not in SF, while being able to leave the yard unaccompanied was a risk factor for biting in SF (RR = 3.40; 95% CI 1.98-5.85) but not in Kingston. Overall, dogs which were less restricted in their interactions with humans were at elevated risk for biting. An observed association with dog bites in one cultural setting might not exist in another. 2007 Elsevier Ltd. All rights reserved

N2 - Chronic obstructive pulmonary disease (COPD) is an important cause of morbidity and mortality in both high- and low-income countries. While active cigarette smoking is the most important preventable risk factor globally, outdoor and indoor air pollutants can cause or exacerbate COPD. In high-income countries, historic air pollution events provide clear evidence that exposure to high levels of outdoor air pollutants is associated with increased mortality and morbidity due to COPD and related cardiorespiratory diseases. Studies in the last 20 years continue to show increased risk associated mainly with particulate matters, even at much lower levels. Populations in low-income countries are largely exposed to indoor air pollutants from the combustion of solid fuels, which contributes significantly to the burden of COPD-related diseases, particularly in non-smoking women. Effective preventive strategies for COPD may vary between countries, and include continued improvements in air cleaning technology, air quality legislation and dissemination of improved cooking stoves. A joint effort from both society and governments is needed for these endeavors. 2008 The Union

N2 - Asthma is children's foremost chronic disease. If the medicinal progress is unambiguous, therapeutic education as well as rehabilitation efforts are integral parts of asthmatic children's global care. Initiated and proposed by the Association asthme et allergies, a protocol that defines place, dates, purposes and means, received the agreement of the French ministry for Youth and Sports. Thirteen children (eight boys, five girls, with an average age of eleven) who suffer from persistent asthma, from moderate to severe and/or exercise-induced asthma, were selected by two Parisian hospitals. The children spent fourteen days on vacation in Ardeche (altitude, 1400 m) during the month of July and were supervised by a medical and an animation team. Motivating children to engage in sports activities and strengthening therapeutic education trained in asthma's schools (ecoles de l'asthme) were the dual purpose of the stay. An educational diagnosis and an evaluation of the knowledge of each child were realized at the beginning and at the end of the stay. A flexible program was set up and combined outdoor games, role-playing, educational workshops on breathing, techniques of inhalation and measurement of breath... associated with tests and coupled with physical or sportive activities practiced individually or collectively. Climatic conditions did not provoke any asthma attack or intercurrent affection. The questionnaire dispensed at the end of the stay reveals the children's global satisfaction. In terms of health, preliminary results are promising, particularly regarding their aerobic capacity and physical performances. A medium-term evaluation is in progress, but consequences of this experience - shared by children coming from different social milieus and in a less polluted environment - seem to confirm the interest for promoting educational and sportive stays supervised by health professionals specialized in therapeutic education and spent in specific places which correspond to the standards of allergens' eviction. 2008

N2 - Aim: To determine the prevalence of metabolic syndrome in children and adolescents in Crete (Greece) and examine associations with diet quality and physical fitness. Subjects and Methods: A representative sample of 1,209 Cretan children and adolescents aged 3-17 1/2 years participated in this cross-sectional survey. The study took place in kindergartens, primary and secondary schools in the cities of Heraklion and Chania and kindergartens and schools in semi-urban and rural regions outside Heraklion. The metabolic syndrome was defined as the presence of >3 of: impaired fasting blood glucose, hypertension, abdominal obesity, hypertriglyceridaemia, and low HDL-cholesterol. Diet quality was assessed by the Healthy Eating Index score (USDA) and physical fitness by the 20-m shuttle run test. Results: Approximately 4% of Cretan children and adolescents assessed (4.2% of boys, 3.6% of girls) had three or more metabolic syndrome factors. Over 25% of the subjects had a "poor" diet, defined as Healthy Eating Index <51, and higher diet quality scores correlated

with decreased mean body mass index, waist/height ratio, systolic blood pressure, total cholesterol, and number of metabolic syndrome risk factors present. Clustering of metabolic syndrome risk factors was also associated with decreased physical fitness, as well as increased body mass index, waist/height ratio and total cholesterol/HDL-cholesterol ratio. Conclusions: Presence of three or more factors related to the metabolic syndrome was strongly associated with poor diet quality and low physical fitness, as well as overweight, in Cretan children and adolescents. Health promotion strategies in childhood should encourage weight control, the establishment of healthier dietary patterns, and adequate physical activity, as a means of preventing the increase in the prevalence of this public health issue. 2008 Springer-Verlag

N2 - Aim: To assess the current prevalence and influencing factors of rickets in children of Shanghai city.

Methods: In Spring of 2005, the cluster and stratified random sampling study was used to examine 821 children under 6 years of age living in Shanghai to evaluate the living environment, feeding patterns, outdoor activity, nutrition, past history of disease, and pregnancy of mother by questionnaires. Rickets was defined as the guideline of "Prevention and Treatment of Rickets in Nurseling" by the State Ministry of Health in 1996.

Results: Totally 769 cases were included in the analysis, consisting of 396 boys and 373 girls; 456 collective residences and 313 scattered livers. 1 The morbidity rate of rickets aged from 0-6 years in Shanghai was 17.3% (133/769), 17.4% in boys and 17.2% in girls. 2 The morbidity rate of rickets in children was associated with feeding patterns (breast feeding, mix feeding and bottle feeding were 13.0%, 17.5%, 25.2%), supplement of cod liver oil (regular supplement, occasional or no supplement of vitamin D was 13.5% versus 32.5%), living environment (living in urban, suburb was 23.6% versus 10.56%; collective residences, scattered liver were 13.8% versus 22.4%), time of outdoor activity (do out door activity often, occasionally was 12.9% versus 31.8%), repeatedly respiratory tract infection (with or without infection was 26.9% versus 12.9%), and the deficiency of calcium in the duration of mother's pregnancy (the morbidity rate of rickets in their children was 33.2% versus 12.0% who with or without the deficiency of calcium ($P < 0.01$)). Conclusion: The morbidity rate of children rickets in Shanghai increases recently, and is associated with multiple factors, such as pollution of city, reduction of breast feeding and insufficient knowledge of child care by Parents

N2 - Aim. Human activity generates mixtures of pollutants and outdoor air pollution has been known to cause clinically significant adverse effects. Methods. We studied the possibility of associations among long-term exposure to environmental air pollution and respiratory symptoms, and pulmonary function and atopy in a cross-sectional study. The target population was a sample of 744 adolescents living in an industrialised town and a sample of 287 adolescents living in mountain valleys in the Alps. Notes on respiratory symptoms were obtained from a questionnaire; all the subjects performed a lung function test, skin tests and plasma levels IgE determinations (PRIST). Results. Significant lower values of forced vital capacity (FVC) and even lower values of forced expiratory volume in 1 s (FEV₁), of FEV₁/FVC and of maximal expiratory flow at 25% of FVC (MEF 25%) were detected in the metropolitan population. The tests resulted pathological in a significantly higher number of clinical silent subjects of this group. About atopy, high plasma IgE levels were significantly more frequent in the metropolitan group, while PRICK tests more frequent in the mountain group. Conclusion. This study seems to provide evidence that long-term exposure to air pollution in adolescents may be associated with lower lung volumes, and especially expiratory flows. The lack of a concordance between anamnestic respiratory symptoms from questionnaires and pulmonary functions may point out the suitability for periodical controls of them in young subjects of air polluted areas

N2 - Background. Successful malaria vector control depends on understanding behavioural interactions between mosquitoes and humans, which are highly setting-specific and may have characteristic features in urban environments. Here mosquito biting patterns in Dar es Salaam, Tanzania are examined and the protection against exposure to malaria transmission that is afforded to residents by using an insecticide-treated net (ITN) is estimated. Methods. Mosquito biting activity over the course of the night was estimated by human landing catch in 216 houses and 1,064 residents were interviewed to determine usage of protection measures and the proportion of each hour of the night spent sleeping indoors, awake indoors, and outdoors. Results. Hourly variations in biting activity by members of the *Anopheles gambiae* complex were consistent with classical reports but the proportion of these vectors caught outdoors in Dar es Salaam was almost double that of rural Tanzania. Overall, ITNs confer less protection against exophagic vectors in Dar es Salaam than in rural southern Tanzania (59% versus 70%). More alarmingly, a biting activity maximum that precedes 10 pm and much lower levels of ITN protection against exposure (38%) were observed for *Anopheles arabiensis*, a vector of modest importance locally, but which predominates transmission in large parts of Africa. Conclusion. In a situation of changing mosquito and human behaviour, ITNs may confer lower, but still useful, levels of personal protection which can be complemented by communal transmission suppression at high coverage. Mosquito-proofing houses appeared to be the intervention of choice amongst residents and further options for preventing outdoor transmission include larviciding and environmental management. 2007 Geissbuhler et al; licensee BioMed Central Ltd

N2 - The psychological effects of thermal injury and children and their mothers were investigated in a three-part study; Part 1 is concerned with group comparisons regarding the psychological effects of thermal injury on children; Part 2 with aspects of the thermally injured group and Part 3 with psychological effects on their mothers. A total of 44 thermally injured (aged 11-16 years) injured 3-14 years previously, were matched according to age, sex, burn percentage and site of injury. In-depth interviewing and questionnaire responses on measures of psychological disturbance indicated that thermally injured children were differentiated in terms of psychopathology from matched Fracture Controls and Normal Controls. Such differences embraced many

aspects of social and recreational functioning, and group differences emphasised depression, anxiety (particularly situational anxiety) and anti-social disorder as being particularly prominent in the thermally injured group. Therapeutic approaches are briefly discussed. 2007 Informa UK Ltd

N2 - Large meningococcal group A epidemics occur periodically in the Sudan, a country within the "meningitis belt" of Sub-Saharan Africa. Immunization with meningococcal polysaccharide vaccine induces protective serum bactericidal titers but little information is available on the duration of protection. Serum samples were obtained from 20 subjects, aged 11-47 years, who resided in the Sudan, and who had participated in a meningococcal polysaccharide immunogenicity study five years earlier. Persistence of serum group A bactericidal titers (measured with human complement) was compared to that of 12 immunized adults in North America with no known exposure to group A organisms. One month after vaccination, there were no significant differences in the serum bactericidal titers of the two groups. By five years the respective reciprocal geometric mean bactericidal titers had declined in both groups (82 to 34 in Sudanese, and 69-11 in North Americans, $p <$

0.03). However, the proportion of sera with protective bactericidal titers (>1:4) at five years was higher in the Sudanese than North Americans (80% vs. 42%, $p < 0.05$). Recommendations for periodic meningococcal polysaccharide vaccination every 3-5 years to maintain group A immunity may be more appropriate for persons living outside of endemic areas than for persons residing in endemic regions since immunity in endemic areas can be maintained by periodic exposure to group A organisms, even during periods between epidemics. 2007

N2 - OBJECTIVE - To assess participant and parent experiences in the parenteral insulin arm of the Diabetes Prevention Trial for Type 1 Diabetes (DPT-1). RESEARCH DESIGN AND METHODS - Before trial results were publicized, surveys were completed by 82 intervention participants (the intervention group) (who received annual 4-day insulin infusions and daily insulin injections), 81 closely monitored control subjects (the closely monitored group), and 135 parents of children in the trial. RESULTS - Survey results suggest that participant perspective (adult, child, parent, and sex), study procedures, and group assignment have important implications when planning clinical trials. Parents rated the trial more favorably but worried about hypoglycemia and diabetes onset. Children had the least favorable reaction to the study. Parents preferred assignment to the intervention group; child/adult participants preferred assignment to the closely monitored group. The intervention group rated the annual 4-day insulin infusions more negatively than all other study procedures. Intervention group participants/parents reported poorer insulin injection adherence over the course of the study. Intervention group participants, parents, and female subjects expressed an interest in additional psychosocial support during the trial. Random assignment was viewed negatively by both study groups. Close observation for diabetes onset was viewed as the most favorable aspect of the study. Behaviors outside of the study protocol to prevent or delay diabetes onset were common and should be monitored in future prevention studies. CONCLUSIONS - Overall, most participants were positive about the trial, and many expressed optimism about the intervention's potential for success. These results have implications for study design, recruitment, and retention procedures in future prevention trials. 2007 by the American Diabetes Association
