N2 - Presented here are an hypothesis of language development and a description of a method for studying language, both based on Kantor's psychological linguistics. According to our hypothesis, language develops in four stages. In the first, which spans the first 9 to 15 months, random movements evolve into body management, manual, and locomotor skills that enable an infant to engage in play activities, among other things, with the mother and others. Simple gestural communication soon follows. Random babbling progresses beyond the sounds that are more universal in the language to the family's particular pattern of intonations and inflections, and receptive speech begins, that is, the infant learns to react to simple verbal-vocal requests. During the second stage, which coincides with the child's second year, vocalizations evolve into "idiosyncratic expressions" and rough approximations of heard sound patterns. Language is now holophrastic--one-word utterances--mostly of the mediative variety. During the third stage, which extends to about 30 months of age, language skills are described as first-approximation referential interactions: they are longer and more detailed, include some narrative interchanges, and refer to past and future events. Typically the child now talks to him or herself, or engages in expressive referential interactions. In the fourth stage, when the child reaches the age of 52 months or so, second-approximation speech begins. By now the vocal apparatus is sufficiently developed to enable a child to make most of the vowel sounds, and the enhanced language skills set the occasion for more frequent linguistic interchanges. He or she also begins to respond to symbols and other representations of objects and events. In other words, he or she begins to engage in symbolizing behavior. Language obviously continues to develop beyond the fourth stage. Social conditions outside of the family further affect language style and generate specialized forms of speech, notably the jargon of a particular occupation or hobby. The method for studying language interactions involves, through the use of TV tapes, a description of the behavior of a speaker and the listener, the referent, and the setting conditions. The behavior of a speaker is analyzed in terms of the frequency with which he or she begins a language interchange, the average length of the initiation, the modality (verbal-vocal, gestural, or both) and the accompanying behavior. It is also analyzed for content, including time frame, actuality, and persons, animals, objects, activities, and others. Noted, too, are the feeling reactions regarding the referents.(ABSTRACT TRUNCATED AT 400 WORDS)

N2 - Between October 1986 and September 1987, 7,967 children presented to the emergency department of the Princess Margaret Hospital for Children for the first time with injuries. Head injuries had been sustained by 3,187 (40%). The data was collected by use of a special form distributed by the nursing staff and completed by parents and medical staff. Information was obtained about the age and sex of the patients, the nature of the injury, the site of occurrence, the activity at that time, and the context in which it took place. The use, or otherwise, of safety devices was also recorded. Injury severity was classified as follows: minor treated in casualty department (80.7%); moderate, admitted to general ward (17.1%); severe, admitted to intensive care (2.2%). Examination of the data showed certain recurring problems, ie, surfaces onto which children fell, bicycles, playgrounds, sporting injuries, vehicle accidents, inadequate supervision. Implications for prevention are (1) improved home design, particularly flooring and furniture; (2) better planning of home surroundings, play areas, and equipment; (3) determination of age at which children are capable of riding bicycles and coping with traffic; (4) extension and enforcement of restraint regulations to protect children in vehicles; (5) better supervision of children engaged in sports and recreational activities, and use of safety devices; (6) increased community awareness of the frequency of head injuries, and knowledge of how the numbers can be reduced and the severity diminished; and (7) improved knowledge of child growth and development, and better supervision by all care-givers

 CY - UNITED STATES
 N2 - Using the National Electronic Injury Surveillance System of the United States Consumer Product Safety Commission, I computed the average annual rates per 1,000 population of consumer product-related injuries in residents of Athens County, Ohio, and seem at one hospital. These rates do not include intentional injuries or injuries to occupants of motor vehicles, to pedestrians hit by motor vehicles, or those occurring on the job or in house fires. Average annual rates for all injuries combined ranged from 102 per 1,000 boys 10-14 years of age to 11.7 per 1,000 men 65-74 years of age. For all males, the annual rate was 53 per 1,000 and for all females, 32 per 1,000. The most common parts of the body injured were the fingers (accounting for 15% of visits), face (12%), ankle (8.5%), hands (8%), and head (7.9%). The most common injury types were lacerations (33%), contusions and abrasions (22%), sprains (16%), and fractures (13%). Hospital admission rates varied by age, sex, type of injury, and part of body injured. Comparison of a sample of NEISS records to emergency room records showed that data were abstracted by clerical personnel with a high degree of accuracy. Review of fractures of the lower leg identified a cluster of injuries in young girls from playground merry-go-rounds. Review of burn injuries identified problems with scald injuries in young adult women and with eye injuries from welding in young men. The system can be used to evaluate injury control measures taken on a local level

N2 - This article is based on a year-long study of 207 low-income black youths. The major purpose of the research was twofold: (1) to study black teens' perceptions of family relationships in an effort to identify family member(s) who had the most potential for encouraging greater contraceptive responsibility and influencing teens' decisions about being or becoming sexually active, and (2) to study dating and sexual behavior, attitudes toward contraception, and sources of information, in an effort to identify more specific sex education needs of black teens and provide a basis for delineating pertinent characteristics of an effective sex education curriculum

N2 - The aim of the study was to determine factors associated with running time in children aged 12 years, according to sex and sexual maturation of girls. The physical ability was measured, using a 1000 meter run in a group of 942 boys and girls aged 12. In addition, data was collected on family sports activities and the children's sports activities, using questionnaires for parents and children. Before the 1000 meter run, physical examination was carried out. Nutrition habits of the family in the home and outside were self-reported in a questionnaire. The mean time for run in boys was shorter by 40 seconds than that for girls. Premenarche girls ran significantly faster than postmenarche girls (p less than 0.05). The best predictors for short running time were triceps skinfold thickness and sport motivation of the children. Weaker correlation was observed between food variables, family characteristics and running time. The highest prediction of running time by the measured variables was found for postmenarche girls, explained by the high correlation of running time with the behavioral variables. In boys and premenarche girls, the best predictors for running time were the physical and physiological characteristics of the children

N2 - This report presents key outcomes of joint growth and development studies conducted in children permanently living in areas adversely affected by pollutants in air. Further attention is focussed on the evaluation of effects of some of the so-called compensatory measures applied in Czechoslovakia, namely a 3-week outdoor schooling organized for these children in the relatively clean recreational areas. The beneficial health effects of year's season and specifically of the spontaneous, active and sufficiently long outdoor exercise are documented in graphs. As it is pointed out in this context, children in the place of their permanent residence

tend to have relative little exercise outdoor, may run an increased risk of exposure to indoor pollutants, and may suffer from passive smoking effects if their parents cannot refrain from smoking habits at home

N2 - Investigations into the impact of schistosomiasis on the physical and psychological development of children have yielded contradictory findings. This may be due to a failure to take account of transmission

factors. In areas where *Schistosoma haematobium* is endemic, children who bathe regularly in contaminated water are more likely to contract the disease. The harmful effects of the disease may be masked in these more active and gregarious children, particularly when infections are mild and other parasitic infections and nutritional deficiencies are common. The social interaction of schoolchildren in an endemic area was monitored over a period of four months, and the principal finding was that infected children were more sociable than uninfected children in terms of their membership of the main playground groups. This paper discusses the evidence for selective exposure and the implications of the hypothesis for future research

N2 - The behavioral patterns associated with peer ratings of aggression and withdrawal were explored. First, a discriminant function analysis (N = 74) using seven observational variables was found to significantly identify groups of Aggressive, Withdrawn, and Contrast fourth- and fifth-grade girls and boys. Aggressive/Withdrawn children were not distinguishable from Contrasts. In subsequent analyses comparing the behaviors of children in the four groups at two schools (total N = 117), children in the Aggressive and Withdrawn groups each showed distinctive patterns of social behavior, which were consistent across the two schools. The behavior of the Aggressive/Withdrawn children was not significantly different from that of Contrast children. However, results from one school suggested that Aggressive/Withdrawn children may receive a disproportionate amount of aggression from peers. Finally, the behavior patterns displayed by the deviant groups were similar for girls and boys, allowing for sex differences in base rates of playground behavior. These results confirm the observability

of peer-identified patterns of aggression and withdrawal, and provide a detailed description of the behavior of such children in a free-play situation

N2 - Cell-mediated immune (CMI) response and the concurrent clinical events were studied longitudinally before, during and after treatment in 24 kala-azar (KA) and ten post-kala-azar dermal leishmaniasis (PKADL) patients for a period of six months. The status of specific CMI response was estimated by in vitro tests, viz. lymphocyte transformation and leucocyte migration inhibition in response to *L. donovani* antigen. The generalized CMI response was assessed by lymphocyte transformation in the presence of mitogen (phytohaemagglutinin) and quantitation of the circulatory T-lymphocyte population. To measure the drug response, the extent of clinical improvement following treatment was used as a yardstick. The results showed that suppression of the CMI response was both specific and generalized in nature during the active stage of KA; but in PKADL, unlike in KA, suppression of the CMI response was found to be associated only at the specific level. With administration of the drug (sodium antimony gluconate), the immunosuppression was gradually eliminated with concomitant clinical improvement in both KA and PKADL patients, although the latter took a longer period of time and a larger amount of drugs compared to the former

N2 - Twenty-seven patients with severe anaphylactic reactions were treated by two anesthesiologist-staffed ambulance helicopters during a 5-year period. All patients had signs of respiratory and/or circulatory failure. Cutaneous symptoms were described in 70% of the patients, gastrointestinal symptoms in 30% and central nervous symptoms in 85%. Wasp sting and drugs were the most common causes. Other etiologies were bee sting, snakebite, nuts and exercise. All patients were provided with advanced pre-hospital medical care. Epinephrine was employed in 78% of the patients. I.v. fluid therapy was started in 77%. Three patients (11%) needed endotracheal intubation. The time-span from onset of symptoms to medical attendance exceeded 45 min in two patients; both died. Of the surviving patients, 23 were hospitalized. The majority had no signs of respiratory or circulatory failure on arrival in the emergency room and needed only observation in the hospital

N2 - To help guide policy decisions about removing lead-contaminated soils, the authors estimated a regression model for predicting a child's blood lead level on the basis of his or her household-specific soil lead level. The data analyzed were blood lead levels (1-45 micrograms/dl) and household-specific soil lead levels (53-20,700 ppm) of 596 children aged 1-5 years who lived in the Helena Valley of Montana and the Silver Valley of Idaho during August 1983. A non-threshold, multiple linear regression model indicated that the estimated mean natural log transformed blood lead level increased by 0.231 micrograms/dl for each unit increase in natural log transformed soil lead level (ppm), after adjusting for the average number of daily outdoor play hours and whether someone in the household smoked. The model predicted that, at a soil lead level of 1,000 ppm, a child who does not play outside and who does not live in a household where someone smokes would be at low risk of lead toxicity (blood lead level between 4 and 24 micrograms/dl)

N2 - Injuries are an important health issue for children. Previous research, however, has presented confusing and conflicting results on the determinants of childhood injuries, particularly psychosocial predictors, largely due to methodologic problems. The purpose of this analysis, based on a prospective follow-up study of 532 children, was to identify factors related to injuries encountered in a prepaid group practice during a 12-month

period. Using logistic regression, we found four factors independently associated with the risk of at least one treated injury: high activity level, high rate of pediatric utilization for non-injury-related visits during the follow-up period, occurrence of a treated injury during the year preceding the follow-up period, and negative attitude toward medical care providers by the child's mother. In addition, four factors were found to be independent predictors of injuries judged severe enough to always warrant medical care: occurrence of a treated injury in the preceding year, high rate of pediatric utilization for non-injury-related visits during the follow-up period, working more than 15 hours a week outside the home by the child's mother, and more life events reported by the mother for the year preceding the follow-up period. Since family stressors are related specifically to the risk of more severe injuries, which are unlikely to escape medical attention, we conclude that these factors probably are related to the occurrence of common injuries of early childhood and not exclusively to utilization behavior. We therefore suggest that children from families with these characteristics be targeted for injury prevention strategies

N2 - Playground lead-in-dust concentrations have been measured immediately after the external redecoration of 216 schools in 1983/4 and of 63 schools in 1984/5. Schools were divided into four age categories: A, pre-1914; B, 1914-1939; C, 1945-1965; and D, post-1965. The results show that concentrations can vary widely from school to school within a given age category. For each school, dust samples were collected from an area adjacent to the facade which had been redecorated, referred to here as the 'corridor' area, and from the 'remaining' playground area. The highest mean corridor concentrations were found in playgrounds of schools of age categories A and B, the highest mean value being 74,400 micrograms g-1. The highest value for age category D schools was 2600 micrograms g-1. The mean concentration for all schools in age categories A to D, was respectively 4720, 2820, 820 and 630 micrograms g-1 for the corridor area and 1180, 730, 400 and 440 micrograms g-1 for the remaining area. The highest lead-in-dust concentrations tended to occur within 2.5 m of the building facade. A limited number of measurements showed that concentrations in the corridor area tended to reduce with time, falling to half their initial value (after correcting for the local background level) in about

90-170 days. A model is suggested linking lead-in-dust concentrations in the corridor and remaining areas to lead-in-paint debris dust concentrations

N2 - Few investigations have examined directly the psychosocial functioning of depressed children. In the present study, 20 depressed and 20 nondepressed fourth- and fifth-grade children were observed in free play during their recess period at school, and their self-perceptions were assessed in subsequent individual sessions. The 10 boys and 10 girls in each group were selected according to their scores on both the Child Depression Inventory and the Peer Nomination Inventory of Depression. Analyses conducted on the eight categories of behavioral observations revealed significant differences between the social behavior of the depressed and the nondepressed children. Although the depressed children made more overtures for social contact than did the nondepressed children and were approached by other children more frequently, they spent more time alone and engaged in a higher frequency of negative interactions with their peers. Consistent with these results, the depressed children's responses to the Self-Perception Profile for Children indicated that they experienced themselves as less socially competent in general, as well as less competent across several specific domains of functioning. These findings are discussed as they relate to developmental processes, theories of adult depression, and recent studies on socially isolated children, and directions for future research in this area are offered

N2 - Baseline data obtained from a study of 228 low-income Black and Hispanic mothers of children with asthma were analyzed to test the hypothesis that the presence of adults in the household, and paternal involvement in asthma care would be associated with less disruption of mothers' daily activities due to the child's asthma. The data were analyzed using multiple regression techniques. We controlled for other variables that might affect the amount of disruption that mothers reported, including the child's age and severity of asthma. The mere presence of other adults in the household, including the father, was not significantly associated with disruption. The frequency of the father's involvement in the care of the child's asthma was inversely associated with disruption regardless of his presence in the household. Hispanic ethnicity and severity of the child's asthma were directly associated with disruption while the age of the child was inversely associated with disruption. We conclude that it is a specific type of assistance (sharing asthma tasks) rendered by fathers living within or outside of the household that reduces disruption reported by mothers. The study suggests that health care providers can improve education and counseling for families who have a child with asthma by emphasizing to fathers their importance in the care of asthma, and by helping them identify specific actions they can take to manage the child's disease

N2 - From May to August 1987, ¹³⁷Cs activity was measured in a total-body counter (4 pi counter) in 33 premature and mature newborns (group I), 40 infants and young children up to 2 4/12 years of age (group II), and 15 children between 3 and 6 8/12 years (group III), all from Bonn or its environs. The mean of measurements in group II, at 3.7 Bq/kg body-weight, was lower than that of group I (5.8 Bq) and III (9.4 Bq). Mean radiation exposure, calculated from these data, was 1.7 mrem/a for group I, 1.1 mrem/a for group II, and 2.8 mrem/a for group III. A comparison with present Cs values in adults and measurements made at the end of the 1950's and beginning of 60's showed good agreement. There were no significant differences, as regards Cs

activity, between newborns or infants who had been formula-fed or breast-fed. The measured radiation exposure of the three groups is about 1% of natural radiation exposure. Thus, present-day results indicate that there will be no damage to health outside the natural scatter

N2 - The efficacy of the Haemophilus influenzae type b (Hib) polyribose phosphate vaccine was evaluated in a population of 120,000 children from 23 through 71 months of age in the Kaiser Permanente Medical Care Program (KPMCP) in Northern California over the 2-year period from June 1, 1985, through May 31, 1987.

Approximately 37% of the population were vaccinated by the end of the first year and 60% were vaccinated by the end of the second year. There were 35 cases of Hib disease, 4 of whom were vaccine failures. Cases of Hib disease were identified by multiple modality case ascertainment, consisting of: (1) active surveillance in KPMCP microbiology laboratories; (2) active surveillance on KPMCP pediatric wards by a study physician; (3) retrospective review of computer-stored hospital discharge diagnoses; and (4) a review of all hospitalizations outside the health plan. The medical records of cases, matched controls and a random sample of the population were reviewed to obtain information on vaccination and related variables. Efficacy was evaluated using two

complementary methods. In a retrospective surveillance approach, efficacy was estimated to be 68% (95% confidence limits of 4, 89%). In a matched case-control analysis, efficacy was estimated to be 69% (95% confidence limits of -13, 91%). Adjustment for day care attendance and parental occupation slightly reduced the efficacy estimate. Other possible confounders including race, parental education and number of siblings were considered. Four cases of Hib disease were observed within 1 week following receipt of vaccine and before the time when immunity could have developed. There are several plausible explanations for the occurrence of these early cases including the possibility of chance alone.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - Recently, a new anthropometric method of accurate lower leg length measurement (knemometry) was introduced. The present study was performed to investigate rigorously its strengths and weaknesses for auxological purposes, and to promote a standardized method of use. The data are based on 6 x 2200 single estimations of the lower leg length in 90 children of both sexes with normal, tall or short stature aged between 2.4 and 17.1 years. The overall technical error of this measurement was found to be 0.16 mm, which is reduced to 0.13 mm if the first estimation within each series of six is ignored. The following sources of systematic error could be detected: intra-daily variation, dependency on physical pressure put on or removed from the leg, vigorous physical activity prior to the measuring procedure, and a slow but significant correlation between day-to-day variation of lower leg length and body weight ($r = 0.299$, $b = 0.372$ mm/kg). There was no covariation with atmospheric parameters such as outside temperature, barometric pressure and others. After elimination of a linear trend from the individual growth curves, there was a remaining day-to-day variation of $SD = 0.697$ mm. This represents real changes of lower leg length and cannot be explained by the technical error of measurement

which contributes to less than 10% of the total variation. Some of this day-to-day variation may be explained by non-linearity of growth. Knemometry appears to be a robust and precise new tool for the investigation of short term kinetics of longitudinal growth. Proposals for a standardized use of this technique are given

N2 - The effects of oral verapamil on resting left ventricular (LV) diastolic filling were examined in 10 children and adolescents with hypertrophic cardiomyopathy. Measurements of diastolic filling were made from gated technetium-99m radionuclide angiograms with postbeat rejection of data outside a 5% RR-interval window. LV time-activity curves were generated and the rapid-filling phase fit with a 3 degrees polynomial to calculate the peak filling rate and the time from end-systole to the point of peak filling. All patients had a radionuclide angiogram performed before and after 0.25 to 3 years of oral verapamil therapy. Verapamil did not change the LV ejection fraction but increased the peak filling rate (3.24 +/- 0.15 to 4.62 +/- 1.05 end-diastolic volume/s,p

less than 0.01) and reduced the time to peak filling (217 +/- 57 to 168 +/- 63 ms, p less than 0.01). An increase in exercise endurance as measured by exercise treadmill test and subjective symptomatic improvement were also seen after verapamil therapy. Thus, in children with hypertrophic cardiomyopathy, symptomatic improvement and LV diastolic filling parameters improved with long-term oral verapamil

N2 - In February and in July 1986 the personal exposures to NO₂ of 60 children and their mothers were measured and NO₂-concentrations in their homes were measured. In the summer also the NO₂-concentration in the kitchen was determined during the time that the mother was in the kitchen. The mothers were asked to keep a diary of the activities of her and her child during that day and of the time that the heating appliances, cooking range, etc. were used. In the winter indoor NO₂-concentrations and personal exposures of mother and child were much higher than in the summer. In the winter in many cases the Japanese Ambient Air Quality Standard is exceeded. The elevated levels in the winter can be related to the use of NO₂-producing heating appliances especially the gas- or oilstove without a flue. Appliance of a flue still causes the indoor NO₂-concentrations to be elevated. The division of a study population into two exposure categories on the basis of presence of a non-vented gasstove is therefore inappropriate. An instantaneous gas fired water heater may also contribute to elevated indoor NO₂-concentrations and personal exposures, although the present survey could not provide

detailed information about the use of a flue and the location of the geyser. The time that a gasrange is being used may influence the indoor NO₂-concentrations, but the results from this survey were not clear. Ventilation in the kitchen reduces the indoor NO₂-concentrations, although this seems especially true in case the gas range is being used for a long time. In houses with smokers higher NO₂-concentrations were found than in houses with non smokers. In the winter the non-vented gas stove is the most important indoor NO₂-source. The present study was not able to demonstrate the effect of outdoor NO₂-concentrations on the indoor air concentrations. A longer time span would be necessary. The housestructure, i.e. the construction of the house and the number of rooms influence the indoor NO₂-concentrations and personal exposure. In the winter all indoor NO₂-concentrations are highly intercorrelated and also highly correlated with the personal exposures of mother and child. Multiple regression models based on either measured or time-weighted NO₂-concentrations explain about 85 percent of the variance in the personal exposures of child and mother in the winter. The exposures calculated from the time-weighted NO₂-concentrations correlate very well with the measured personal exposures. This was not the case in the summer.(ABSTRACT TRUNCATED AT 400 WORDS)

N2 - One hundred fifty-nine children (14.5% of the student body) were sampled after a fatal sniper attack on their elementary school playground. Systematic self-reports of posttraumatic stress disorder (PTSD) symptoms were obtained by use of a child PTSD Reaction Index. Analysis of variance revealed significant differences by exposure but not by sex, ethnicity, or age. Additional analyses were conducted of individual item response, overall severity of PTSD reaction, symptom grouping, and previous life events. The results provide strong evidence that acute PTSD symptoms occur in school-age children with a notable correlation between proximity to the violence and type and number of PTSD symptoms. Sampling at approximately one month after the trauma provided adequate delineation among exposure groups. The symptom profile of highly exposed children lends validity to the diagnosis of acute PTSD in childhood

N2 - The authors assessed the convergent validity and the sources of error in an electronic single-plane accelerometer (i.e., Caltrac Personal Activity Computer (Hemokinetics, Inc., Vienna, VA). The device was validated against observed all-day physical activity levels of children in their natural environment. Thirty pre-school children were observed in non-structured activity for periods of approximately 9 h while wearing the accelerometer. The results revealed moderately high but variable Spearman rank-order correlations between hourly readings of the accelerometer and the observational system (range of correlations = 0.62 to 0.95). An all-day accelerometer reading significantly correlated with the observational instrument ($\rho = 0.54$). A step-wise regression analysis revealed that the best behavioral predictor of the all-day accelerometer reading was the

observed behavior of walking, explaining 32% of the total variance. Older vs younger children (i.e., greater than 32.5 months), females vs males, and overweight (i.e., 75 percentile or greater) vs normal weight children tended to show higher correlations between direct observation and accelerometer readings. Implications of these findings and the utilization of the accelerometer in epidemiologic research are discussed

N2 - When the research on the ecology of monkeypox virus entered the latest stage in 1984, three groups of animals were considered priority candidates for maintenance of virus circulations in nature because of their relatively higher population density: terrestrial rodents, squirrels, and gregarious bats. Following the isolation of the virus from a wild squirrel in 1985 another survey was carried out in Bumba zone of Zaire in January-February 1986, which included collection of animal samples, later on tested by WHO collaborating laboratories. No antibodies were found in 233 rodents tested. A high prevalence of monkeypox-specific antibodies (24.7%) found in 320 squirrels of *Funisciurus anerythrus* species suggested that these animals sustain virus transmission in the areas surrounding human settlements. A consistently high level of antibody prevalence found among squirrels *Heliosciurus rufobrachium* suggested that this species is also steadily involved in the transmission. The squirrels, the only mammals frequently infected by monkeypox in the areas of human activities, which are frequently trapped by the population, are obviously a major source of infection for human beings. Out of 39 primates collected during the survey from the primary forest, three were found seropositive for monkeypox. At the moment, however, it is difficult to say whether the primates play an important role in sustaining virus transmission in nature, or (like human beings) that they are an occasional host of the virus. Possibilities are discussed of monkeypox virus transmission being sustained by squirrels outside the areas of major human activities

N2 - A long-term physical exercise program was established for a large number of children with bronchial asthma. Asthmatic children were first taught to swim on their backs to prevent breathing problems customary for beginners using other strokes. They concurrently participated in gymnasium exercises, and the program was later completed with outdoor running. Program effectiveness was evaluated by monitoring asthmatic symptoms, changes in medication, and changes in the activity and physical fitness of the children. Data collected from 121 children showed that during the first year in the program the number of days with asthmatic symptoms decreased in a large majority of the patients while medication was decreased. School absenteeism and hospitalization dropped markedly. Parental evaluation of the children indicated much improvement in 51.2%, improvement in 40.5%, unchanged condition in 7.4%, and deterioration of general health was only reported in one child (0.8%). The same extent of improvement continued during the second year. The Cooper test was applied for the first time to such an exercise program and indicated that the participating asthmatic children performed as well as a control group of nonasthmatic children, and the cardiovascular efficiency of the asthmatics was actually better

N2 - Ethylene oxide (ETO), an alkylating compound of high chemical reactivity, is widely used for gas sterilization, but recently serious ETO side reactions have been recognized. With chronic ETO exposure, increased spontaneous abortion, sister chromatid exchange, and leukemia are observed. After medical use of ETO outside nephrology, contact dermatitis, cardiopulmonary shock (during cardiopulmonary surgery), allergic local reactions to ETO sterilized lenses, and anaphylactoid reactions to ETO sterilized catheters have been described. In numerous dialysis patients widespread hypersensitivity to ETO has been documented by skin prick test and ETO radioallergosorbent test (RAST). Furthermore an anaphylactoid "first-use reaction" was described in dialyzed patients, most of whom were using hollow-fiber dialyzers. After long discussions whether complement activation versus hypersensitivity is the cause of such acute anaphylactoid reactions, more recent studies using either ETO RAST or basophil degranulation tests implicate ETO hypersensitivity as their major cause. The high prevalence of sensitization to ETO and the frequency, unpredictability, and potential danger of anaphylactoid reactions to ETO lead to the conclusion that ETO sterilization of dialyzers should be discontinued, since alternative modalities of sterilization are currently available. N2 - We examined the effects of a peer initiation intervention with high- and low-status nonhandicapped students on the behavior of untrained peers toward handicapped students. In the context of a counterbalanced withdrawal design, high- and low-status nonhandicapped students were taught to direct social initiations to eight severely handicapped students during recess activities. The interactions of the high-status students resulted in higher levels of initiations by untrained peers toward the handicapped students than did the interactions of the low-status students. Social response levels were also differentially affected by the status of the peer initiator

N2 - During the seven-year period from 1976 through 1982, 2133 cervical spine radiographs were obtained for children less than 18 years of age at two hospitals in Tucson. Twenty-five children (1.2%) had x-ray evidence of a cervical spine injury, with a male to female ratio of 4:1. Vehicular accidents accounted for 36% of cervical spine radiographic abnormalities, and sports or playground accidents accounted for an additional 36%. In an attempt to find clinical predictors that might identify x-ray abnormalities, we reviewed the medical records of these 25 children with abnormalities and 713 randomly selected children without x-ray evidence of cervical spine injuries for the following: method of injury, presenting complaints, physical examination findings, therapy, and complications. No single clinical predictor had a sensitivity of 100% when considered in isolation, but clinical assessment consisting of EITHER a complaint of neck pain OR involvement in a vehicular accident with head trauma would have correctly identified all 25 cases of cervical spine injury. If this information had been used prospectively, the number of cervical spine radiographs ordered would have been reduced by 32%. We conclude that the use of this clinical "marker" would have positively identified all children with cervical spine injuries and would have reduced by one third the cost and radiation exposure associated with cervical spine radiographs. Because of the serious consequences of missing a cervical spine injury, we suggest that other studies confirm these results before this information is accepted as a recommendation

N2 - Thirty-two patients, including 29 children, presenting with acute unexplained encephalopathies were studied prospectively for evidence of virus infection, immunodeficiency, and immunologic involvement in the pathogenesis of their illnesses. Twenty-five of these patients had a clinical diagnosis of encephalitis. Twenty-two of these 25 had laboratory evidence of active virus infection, the majority with viruses usually associated with self-limiting illness outside the central nervous system. In patients with encephalitis, immune competence, as reflected by T-cell numbers and subsets in peripheral blood, in vitro interferon production, natural killer activity, and specific antiviral antibody production, was normal. Transudation of albumin into the cerebrospinal fluid (CSF), a measure of blood-brain barrier breakdown, was seen in 40% of patients. Intrathecal antibody

synthesis was suggested by an elevated IgG index in 9/20 CSF/serum pairs but was confirmed by an elevated specific IgG ratio in only 3. The serum IgG1 and IgG3 subclass levels were significantly elevated at the time of the illness and remained elevated 8 months later; IgG2 and IgG4 levels were normal. IgE levels were elevated in 50% of patients. Serum levels of IgM antibodies against *Escherichia coli* measured 8 months after the neurological illness were also significantly higher in encephalitis patients than in age-matched healthy controls. Human myelin basic protein did not induce proliferation in peripheral blood lymphocytes in any patient. We conclude that most encephalopathies associated with viral infections are not due to an underlying generalized immunodeficiency, and probably result from an inappropriately vigorous immune response

N2 - School injuries occurring in a municipal school system during a 2-year period were reviewed to identify epidemiologic features of school injuries, to determine data requirements for ongoing injury surveillance, and to identify potential preventive strategies. Overall, 3,009 injuries were reported (2.82/100 students per year). Elementary school students had only a slightly higher rate (2.85) than secondary school students (2.78).

However, the cause, nature, school location of injury, and body area injured formed distinct patterns in these two groups. Playgrounds were responsible for the highest overall and elementary school rates, whereas sports areas and classrooms had the highest rates among secondary school students. Falls were the most frequent cause of injury in elementary schools whereas, as expected, sports injuries were the most frequent cause among secondary school students. Contusions and abrasions of the head were the most frequent type of injury for both groups, although more common among elementary school students, whereas fractures, sprains, strains, and

dislocations were more frequent among secondary school students. Although the proportion of severe injuries to secondary school students was slightly higher (39 v 35%), the rate of referral of students to a hospital or physicians among secondary school students (1.21 per 100 student-hours) was almost twice the rate of elementary school students (0.65 per 100 student-hours). Problems with definition of injury severity and the need to explore the social aspects of schools as a factor in injuries emerged as important considerations for future research

N2 - Therapeutic and corrective work with stammering preschool children conducted at a day-time semi-hospital institution presents a complex of measures aimed at improving the speech and the entire psychic activity of the child. A semi-hospital form of the organization makes it possible, along with therapeutic and corrective measures, to constantly train the speech in the most diverse situations of the microsocial environment outside the hospital and thus contributes to the development of social and adaptive behaviour which the child needs for further studying in the general education school

N2 - Three 7-year-old boys with histories of negative interactions were appointed to monitor individual classmates during daily noon recess. As monitors, the boys awarded points to their classmates for playing appropriately and, on rare occasions, withdrew a point for negative interactions. The three boys immediately decreased their own rates of negative interactions during the sessions in which they were appointed as monitors. Two of the boys concomitantly increased their rates of positive interactions. Their reductions in negative interactions were not maintained during reversals and did not clearly generalize to the morning or afternoon recess periods. Subsequent appointment of the boys as peer monitors during the morning recess produced similar improvements in their behavior. Results suggest that appointment to the role of peer monitor may itself function as an intervention

N2 - Sensitization to pollen from wind-pollinated trees causes significant allergy problems during springtime. The magnitude of prevalence is comparable with and, in some areas, even higher than grass pollen allergy. The symptom periods are often prolonged by cross-reactivity among species and sometimes families as well as by simultaneous sensitivity to several trees, pollinating at different times. There is a need for standardized extracts to improve diagnostic precision and treatment efficacy. A substantial amount of immunochemical data on the allergens from Betulaceae species, particularly *Betula* (birches), are available. Relevant methods to quantitatively and qualitatively measure the allergens of birch pollen extracts are clearly reproducible in laboratories around the world. By international collaboration, such work has generated an IS that has been accepted by the IUIS Subcommittee on Allergen Standardization. The IS is a yardstick for authorities, manufacturers, and researchers that is carefully specified in terms of 1 major and a few intermediate allergens, and also of total biologic activity by RAST inhibition. A meaningful declaration of biologic activity in vivo is awaited. As yet, only a few clinical trials have been undertaken with standardized tree pollen extracts. These are, however, highly interesting, particularly those that now have started with an oral route of administration.

N2 - The risk of cancer to humans exposed to soil treated with wastewater/sewage treatment plant sludge, known to be contaminated with small amounts of polychlorinated dibenzodioxins and dibenzofurans (PCDDs and PCDFs), was evaluated. The particulate-bound PCDDs and PCDFs are found in trace amounts in the effluent from ground water pumping (dewatering) at an abandoned wood preservation facility. The water, which was sent to a water recovery plant, underwent primary and secondary treatment prior to discharge. The residual sludge was added to agricultural soil as a conditioner. The present analysis treats the extreme case of sludge applied near the home of a target individual, a lifetime resident, who is also a farm worker in the area of the application. The successive stages of infancy, childhood and adulthood are treated separately to assess the contributions of typical age-specific indoor and outdoor activities on exposure rates. Five toxicity rating schemes using so-called TCDD equivalents, and two unit risk slopes are applied to the chemical profile in sludge to determine the cancer potency of the soil contaminants. These risk estimates range from 1×10^{-8} to 3×10^{-7}

N2 - We assessed the efficacy of time delay and peer modeling procedures in increasing autistic children's spontaneous verbalizations of affection. Four autistic children were taught to spontaneously say "I like (love) you" in response to a hug from a familiar person and their mother. Generalization from a free play training setting to free play outdoors and at home was assessed. Ancillary social and affection behaviors were also observed. Results indicated that the time delay was a quick and effective procedure for all the children. Peer modeling was unsuccessful in teaching the target behavior

N2 - A review of the workload of two newly appointed clinical haematologists in a health district with a population of 307,000 showed that the clinical case load increased rapidly in the first two years. The management of patients with blood disorders, which had previously been dispersed among many departments both within and outside the district, was now concentrated within a single unit with occasional referral as

appropriate to regional centres. The development of a clinical haematology service in district general hospitals cannot occur without funding and facilities, including suitably located beds for haematology patients and specifically appointed junior medical staff. Highly trained and experienced nursing staff are essential for the management of patients with bone marrow failure; day care facilities and community nursing are also valuable. Changes and developments in the laboratory as a result of these additional clinical activities are also necessary

N2 - The incidence of injuries among youth soccer players (under age 16) participating in indoor soccer was 4.5 times that of youth players in outdoor soccer when calculated per 100 hours of team play, and 6.1 times greater when calculated per 100 hours of player game participation. Injuries were few among players under age 10 in either game, and the number of injuries increased with age in the older players. Medical assistance was required for 6.5% of the injuries among outdoor players and for 24.3% among indoor players. Overall, 66.6% of the injuries were the result of physical contact between players. No relationship was observed between the risk of injury and playing position, conduct of warm-up exercises, or the team having a licensed coach

N2 - We compared recipients of eight lots of factors VIII and IX voluntarily withdrawn from distribution because one donor was known to have subsequently developed the acquired immunodeficiency syndrome with a nonexposed cohort matched by age, sex, and factor use. The factor VIII recipient cohorts did not differ in prevalence of antibody to human immunodeficiency virus (HIV) (exposed, 75%; nonexposed, 86%), T-cell subset numbers (median: exposed, 619 T-helper cells per cubic millimeter; nonexposed, 659 T-helper cells per cubic millimeter), T-helper to T-suppressor ratios, or immunoglobulin levels. Exposed individuals had higher levels of immune complexes by C1q binding and staphylococcal binding assays and lower responses to phytohemagglutinin and concanavalin A. However, only the staphylococcal binding assay values were outside the normal range for our laboratory. Factor IX recipient cohorts did not differ in HIV antibody prevalence (exposed, 30%; nonexposed, 40%) or any immune tests. Although exposed and nonexposed individuals did not differ from each other in a clinically meaningful fashion at initial testing, both the exposed and nonexposed cohorts had high rates of HIV seroprevalence. Market withdrawals were clearly insufficient means of limiting the spread of HIV in hemophilic patients; however, the currently available methods of donor screening and viral inactivation of blood products will prevent continued exposure within this population

N2 - The maladaptive behavior of 474 persons from a residential facility for mentally retarded individuals was investigated. Eleven independent variables pertaining to demographic and environmental characteristics were initially related to the frequency and topography of residents' maladaptive behavior. Multiple regression analysis revealed that maladaptive behaviors were related to sex, social age, chronological age, resident's time spent on outside activities, number of residents per direct-care staff member, presence of sensory handicaps, and ambulation. Results were related to existing literature and discussed in terms of their use for intervention efforts and differential assignment of resources

N2 - This study evaluated methods for empirically identifying environmental determinants of aggressive and disruptive behavior in three developmentally delayed children. A variety of sessions conducted on an inpatient treatment unit were designed to stimulate contingencies maintaining aggression and disruption in the subjects' natural environments. The basic analog conditions included: instructional demands, contingent social disapproval, and structured play. In addition, variations of the three basic conditions were developed based on informal observation and parental reports of naturally occurring contingencies. Results showed considerable variability both between and within subjects. However, for each subject a specific analog condition was shown to produce relatively higher rates of aberrant behavior. Subsequently, behavioral treatments based on assessment results were successfully implemented with two of the subjects. Results are discussed in terms of the importance and practical limitations of conducting systematic assessment of aberrant repertoires in developmentally delayed clients

N2 - The present study concerns ethnic, age, and gender playmate preferences of deaf and hearing preschoolers who were observed during outdoor free play at their respective schools over a 7-month period. Hispanic, black, and white children were included. It was hypothesized that peer preferences would be less apparent among deaf children than among hearing children if these preferences were based on (a) language differences between ethnic groups (e.g., Spanish-English differences), age groups (e.g., verbal fluency differences), or gender groups; or (b) cultural values communicated by speech. Both deaf and hearing children preferred to play with children of the same ethnicity, gender, and age as themselves. In addition, play among children of the same ethnicity, gender, and age was qualitatively different from play among children of different ethnicity, gender, and age. The only effect of deafness was to decrease the amount of gender segregation that occurred. The results suggest that the development of ethnic, gender, and age playmate preferences is not dependent on intergroup language differences or spoken cultural messages. Several nonlinguistic factors that might contribute to early peer preferences are discussed

N2 - The purpose of this study was to investigate the use of a self-monitoring activity in the clinical and natural environment as a method of promoting rapid generalization of a target speech sound to beyond-treatment conditions. The subjects were 13 children who lateralized /s/ and /z/, substituted /theta/ for /s/ and /delta/ for /z/, and/or substituted /w/ for /r/. The children attended public school speech therapy, individually or in small groups, twice weekly for 15- to 20-min sessions throughout the entire study. The investigation was conducted in the context of a multiple baseline research design replicated across subjects and behaviors (for 1 subject). The results demonstrated that when the self-monitoring activity was implemented, the children began to generalize the use of the correct speech sound to their spontaneous speech outside of the treatment setting. The results are discussed in terms of their theoretical implications for generalization issues and in relation to their applied value for clinicians with large case loads or otherwise limited amounts of time to spend with individual clients

NO₂ - This study was performed by a comparison between summer and winter for the purpose of demonstration the actual conditions of health effects of indoor air pollution with special reference to NO₂ and smoking, on the subjects composed of 820 school children and their 546 mothers in the two areas with different ambient NO₂ concentrations. In either case, examination was carried out with standardized questionnaire test for respiratory symptoms, personal NO₂ exposure measurement using the filter badge by Yanagisawa, and analysis of urinary hydroxyproline and creatinine in two areas with different ambient NO₂ levels. Personal NO₂ exposure level in winter season was 2-3 times higher than that in summer, particularly NO₂ level among residents living in homes with non-vented stove for space heating was substantially higher from those of residents with vented stove. Wives with vented stove had a moderate exposure level in winter season by the contribution of NO₂ originated from the kitchen and poor ventilation rate. Since the hydroxyproline to creatinine ratio (HOP-ratio) of children increased more, their household location were nearer to any heavy traffic roads in summer, health effects from automobile exhaust were suggested only in summer season. In summer season, personal NO₂ exposure level were almost the same with the ambient NO₂ concentrations over both areas. These results suggest that indoor air pollution in winter season may be separated from outdoor air pollution. It was a matter of course that hydroxyproline to creatinine ratio in winter season was higher than that in summer, in any group and in any area, but the range of variation of hydroxyproline to creatinine ratio was smaller by far than that of personal NO₂ exposure level. Judging from urinary hydroxyproline to creatinine ratio, health effects of active smoking and passive smoking increased with increasing the number of smoked, dose-dependently in any season. According to stepwise multiple regression analysis, hydroxyproline to creatinine ratio had significant relation to either NO₂ and active or passive smoking, but personal NO₂ exposure level had no relation to cigarette smoking. NO₂ and cigarette smoke were seemed to make hydroxyproline to creatinine ratio increase, independently each other

N2 - It has recently been suggested that in cystic fibrosis (CF), there is no rheological abnormality of airway secretions other than that associated with purulence, and that the apparent inhibition in the mucociliary transport rate might be partly due to a ciliary inhibitor present in these secretions. In order to ascertain this assumption, expectorated airway secretions were collected without salivary contamination in twenty-four CF patients and the rheological properties were measured. Using a photometric method, the effects of CF sputum samples were analysed on the ciliary beat frequency (Fm) of the frog palate, and we measured their mucociliary transport rate (TR). In all but one CF sputum, TR and Fm were lower than that of the control frog mucus (median TR: 18.7 and 11.6 mm min⁻¹; median Fm: 12.3 and 11.3 Hz, respectively). In the eighteen patients in whom the rheological properties were outside the range for optimal mucociliary transport, the clinical Shwachman score was significantly (P less than 0.05) lower (median score: 66.2 points) than in the six patients with optimal rheologic properties (median score: 73 points). In the eleven CF patients with superinfection, the apparent viscosity (η_o) was significantly higher (P less than 0.01; median η_o : 24.4 Pa. s) and TR, expressed as a percentage of the reference value, was significantly lower (P less than 0.05; median Tr: 54.5%) in comparison with the values obtained for the thirteen non-superinfected CF patients (median η_o : 15 Pa. s and median TR: 66% respectively). The CF patients with markedly hyperviscous sputum (η_o higher than 30 Pa. s) exhibited a low Shwachman score

N2 - Talocalcaneal articulations are relatively complex and functionally very important because they play a major role in the movements of inversion and eversion of the foot. Few reports on arthrography of the subtalar joints are available in the literature, and, similarly, little attention has been paid by arthroscopists to these joints. This preliminary study briefly defines the normal anatomy of the subtalar joints and describes a new technique of arthroscopic examination of the posterior subtalar joint. The distal lower extremities of six fresh cadavers were used in these experiments. All the subtalar joints were supple. A 2.7-mm arthroscope was used to carry out arthroscopic and anatomic examinations. A technique of examination with one anterior portal and one posterior portal is described in detail. When the anterior portal was used, the egress needle was placed posteriorly; when the posterior portal was used, the converse was true. By using the two portals, the following intraarticular structures could be visualized: a major part of the convex posterior calcaneal facet of the talus and the posterior talar facet of the calcaneus; the synovial lining laterally and posteriorly; the posterior aspect of the interosseous talocalcaneal ligament; and the posterior recess of the joint. The results of this experimental study indicate that arthroscopy of the posterior subtalar joint is technically feasible. Clinically, the possible indications for arthroscopy would include state of the articular cartilage in suspected cases of degenerative arthritis, rheumatoid arthritis, and infection; visualization of the joint after intraarticular fracture to evaluate chronic pain syndrome in the hindfoot; biopsy; management of sinus tarsi syndrome; loose body removal

N2 - From 1973 to 1983, 49 Florida residents were reported with confirmed Rocky Mountain spotted fever (RMSF), 25 of whom were considered to have had Florida-acquired disease. Although there was no history of tick exposure for six of these 25 persons, all had contact with dogs or outdoor activities during the incubation period. The tick vectors of RMSF are widely distributed throughout Florida. We conclude that RMSF, although rare in Florida, can be acquired in the state

N2 - This manuscript reports the results of a problem-solving exercise presented to participants at a Workshop on Neurotoxicology Testing in Human Populations held in Rougemont, North Carolina in October, 1983. Response recommendations are the consensus of workshop participants. These are not comprehensive or definitive solutions and should be interpreted with caution. Each exposure scenario represents a "real world" situation previously encountered by neurologists and epidemiologists. Ideally, a toxin affects a single, easily tested modality early in the illness before producing a complex neurological syndrome. Unfortunately this rarely happens; difficult choices and compromises about testing are usually necessary. At the end of each scenario likely areas of early subtle dysfunction were discussed and possible testing methods were outlined. Working participants were instructed to comment on the approach to the scenarios and to add to or dispute the proposed tests. It is clear that there are no right or wrong answers; however, the participants were urged to try to reach

some sort of consensus. In each instance participants assumed that they were being notified by the company and not by a state or federal agency, and were to determine what would be the most reasonable and effective way to offer help or obtain outside assistance in these situations

N2 - The epidemiology of malaria was studied in a West African mining town (Yekepa) and three surrounding zones defined as Close, Middle and Far areas. Malariometric parameters were investigated in children two to nine years of age at the end of the rainy season. In Yekepa, vector control measures and intense suppression of malaria with drugs had created an almost hypoendemic situation with a spleen rate of 11%. In Close area, vector control was applied to some extent and malaria drugs were frequently used for treatment; the spleen rate was 40%. In Middle area, a mobile clinic provided sporadic malaria treatment to small children, but the clinic did not reach out to Far area. The spleen rates were 95 and 99%, respectively. Three species of Plasmodium were found in all areas. The prevalences in Far area were P. falciparum 82%, P. malariae 39% and P. ovale 9%. The crude parasite rates increased from 13% in Yekepa to 92% in Far area, whereas haematocrit levels decreased from 37.6 to 35.2, respectively. Plasmodium falciparum seropositivity, as measured by indirect immunofluorescence, was 74% in Yekepa and 99% in Middle and Far areas. Total IgG concentrations ranged

from 18 g1(-1) in Yekepa to 33 g1(-1) in Far area. Three main anopheline species were found in the zones outside Yekepa. Their relative frequencies in Far area were Anopheles funestus 45%, A. hancocki 37%, and A. gambiae 18%. The local inoculation rates gradually increased outwards from Yekepa from less than 0.01 to 0.17 inoculations per man and night at the beginning of the dry season.(ABSTRACT TRUNCATED AT 250

N2 - Measurements of the quantity of lead on the hands of schoolchildren and of the concentration of lead in dust from school playgrounds have been carried out; the hand-lead was collected by wiping with a moist tissue. When hand-lead and dust-lead values were averaged for each school, a statistically significant relationship between the two sets of means was obtained. Some limited measurements of size distribution of the dust particles on the children's wipes were also made; these indicated that most of the particles were less than 10 micron in diameter

N2 - The negative interactions of a mildly retarded child, Dennis, were reduced in three daily recess periods, with the use of a point system. Adult monitors initiated the intervention in the morning recess; reductions achieved during adult monitoring were maintained in that recess during two subsequent conditions: peer monitoring and self-monitoring. Dennis' negative interactions were reduced next in the afternoon recess by peer monitors. Again, reductions were maintained during a subsequent self-monitoring condition. Finally, during the noon recess, Dennis was trained to serve as a peer monitor for Ed, a moderately retarded classmate. Dennis' rate of negative interactions quickly decreased following his appointment as a peer monitor. The results show that a point system, originally designed for adult monitoring, can be adapted without loss of program effectiveness for peer monitoring or self-monitoring. The results also suggest that classmates who serve as peer monitors may benefit significantly from their role. The conditions under which these therapeutic effects occur and the role that treatment order effects may play in this process require further investigation

N2 - Details of all deaths in children (less than 16 years) resident in Oxfordshire and West Berkshire from 1970-9 were ascertained; 259 non-natural deaths were identified. Half were due to road traffic accidents, and another quarter occurred during play outside the home. There were differences in sex, age, and social class between the types of accident. A clustering of fatal accidents, particularly to pedestrians, was observed at around the time of the child's birthday. It is suggested that the excitement engendered overrides the child's normal caution. Local action to reduce accidents from specific hazards might complement national education campaigns

N2 - IgG, IgA and IgM antibody activities in human serum to six dietary and eight gut-related microbial antigens were measured by an enzyme-linked immunosorbent assay (ELISA). IgG activities to five of the dietary antigens decreased with age; IgM activities to four of them were weaker in old people than in children. Old people showed weaker IgM but stronger IgG activities to some of the microbial antigens than children did. A decline in IgG and IgM antibody titres to most dietary antigens with increasing age is consistent with the development of systemic hyporesponsiveness due to continuous antigenic stimulation of the intestinal immune system. Persistence of microbial antigens in the gut, moreover, may lead to systemic hyporesponsiveness of IgM-producing cells. Concurrently raised IgG titres to three of the bacteria might be explained by antigenic stimulation outside the intestinal immune system

N2 - The association of cardiopulmonary variables with outcome was investigated in 42 pediatric patients (18 survivors) with septic shock. All cardiopulmonary variables were obtained during active BP support. The variable distributions were separated into ranges by two empiric cutoff methods: normal ranges and the survivor median values. The proportion of survivors with normal values of wedge pressure and cardiac index was significantly (p less than .05) higher than the proportion of survivors outside the normal range. The percentage of survival also significantly (p less than .05) increased with above-normal values of oxygen consumption, arteriovenous O₂ content difference, O₂ extraction, pH, and core temperature. There were significantly (p less than .05) more nonsurvivors with wedge pressure, pulmonary shunt, and pH values below the survivor medians. Therapeutic goals based on the distributions of these eight variables isolated patient groups with survival rates of 59% to 75%, compared to the overall survival rate of 43%

N2 - The family as culture transmitter plays a role in the development of health maintenance practices. A review of the epidemiological variables associated with obesity suggests that familial factors--genetic and environmental--have a significant effect on the onset, causes, and prognosis of treatment. Chances of success in losing weight may depend upon the extent of family functioning or upon finding a support system within and/or outside the family. The weight control program described is family oriented. Life-style changes learned in the group meetings reach home and affect family members. Four-pronged in its approach (nutrition, behavior change, exercise, and a positive support system), the program uses "skill builders," which are special situational modules that deal with specific family situations. A skill builder offers a step-by-step guided approach to identifying and changing problem behavior in the area of diet and exercise, e.g., eating in social situations, new food shopping patterns, and the role of significant others in the weight loss process. N2 - Pressure activity in the stomach and upper intestine was studied in 104 patients referred to the Mayo Clinic for evaluation of functional symptoms (nausea, vomiting, upper abdominal pain, or other dyspeptic symptoms in the absence of structural gut abnormalities). Manometric abnormalities were found in 75 patients. Forty-three of these had gastric abnormalities and 32 patients had both gastric and intestinal abnormalities. In the stomach, decreased antral phasic pressure activity after a solid meal was the most common abnormality. In the upper intestine, unpropagated bursts of phasic and tonic contractile activity were a relatively frequent abnormality but a number of other altered manometric patterns also were observed. Digestive tract symptoms were not good predictors of the presence or site of the gastrointestinal manometric abnormalities. Patients with associated neurologic, urologic, or metabolic (diabetes) disease were more likely to exhibit manometric abnormalities than were those without evidence of disease outside the gut. Almost two-thirds of the patients with symptoms and normal manometry presented features suggestive of psychiatric disease. We conclude that in patients with severe functional-type symptoms gastrointestinal manometry is a useful technique to evidence the underlying gut motor disturbance that is present in a relatively high proportion of these patients

N2 - Retrocalcaneal bursitis is a distinct condition causing posterior heel pain in active, healthy children. It appears to result from post-traumatic inflammation of the soft tissues of the posterior heel, and is unrelated to avascular necrosis of the calcaneal apophysis. The diagnosis may be confirmed radiographically by the loss of the lucent retrocalcaneal recess, with a normal Achilles tendon and superficial soft tissue contour, and intact cortex of the underlying os calcis

N2 - Visceral larva migrans, VLM, is a disease of young children. Due to lack of awareness of the disease as well as its non-specific symptomology, a survey of the potential risk of acquiring the disease was conducted in the Baton Rouge, Louisiana area. The greatest number of dogs showing positive results to tests for the presence of the eggs of *Toxocara canis* were those less than one year of age. Very few of the soil samples collected from twenty different parks/playgrounds were found to contain eggs of *T. canis*. A higher percentage of soil samples from individual yards proved to be contaminated with the eggs of the parasite. Even though the incidence of VLM in Baton Rouge is reported to be quite low, the potential for the infection certainly is present.

Veterinarians must be prepared to take a leading role in the education of their clients as to the potential of the disease for the children associated with new puppies, and the measures parents can take to reduce the exposure potential

N2 - A total of 239 children, including 22 high-risk children and 55 non-high risk diseased children have been immunized with a live varicella vaccine (Oka strain) since June, 1978. No clinical reaction attributable to the vaccine has been observed. Of these children, 87 received emergency vaccination. Of 47 children receiving emergency vaccination because they had been in contact with varicella patients either in hospital, school or a playground, only 5 developed varicella and their symptoms were mild. Of 40 children receiving emergency vaccination because of exposure to varicella in their home, 10 developed mild varicella and 30 were protected. Clinical symptoms of varicella when seen seemed to be due to incomplete protection because the vaccine was given too late rather than to clinical reactions to the vaccine. During follow-up period of 6 to 66 months after vaccination, 8 children showed very mild rashes without fever as the result of exogenous varicella infection

N2 - Most evaluations of programme effectiveness are based on process data (the data generated by the programme) and used for internal monitoring and service development. Context (the ecology of therapeutic systems), input (the identification of what is in fact different between two therapeutic systems) and product (the consequence of different inputs, taking account of context) evaluations are rarely, if ever, produced. In this paper (using input and product evaluations) the progress of twelve Down's syndrome and twelve multiply-handicapped children attending, over a period of 18 months, two different therapeutic systems operated by the New Zealand Society for the Intellectually Handicapped (Auckland Branch/outside Auckland Branches) is assessed. The progress of the Auckland children is significantly better in a number of areas than for those outside Auckland. This improvement in progress can be attributed to input differences that reflect the Auckland Branch's policy of service development. The most important determinants of a successful programme are not staff/student ratios, time in class or specialist assistance, all of which favour the outside Auckland groups, but the degree of structure, detail of programmes and assessments, and quality of parent contact in which Auckland seems superior. The results for the Down's syndrome group compare favourably with those from other Down's syndrome programmes

N2 - During an investigation of 31 sandpits in children's playgrounds in and around Frankfurt/M Toxocara eggs were detected in 27. The prevalence in areas with few or no parks (averaged 14.8 eggs 100 g-1 sand) was much higher than in districts where there was more room for the dogs to run about (5.3 eggs 100 g-1 sand). Larval development was complete in 40% of isolated Toxocara eggs after four weeks. The importance of these findings in connection with the risk, to children playing, of a possible infection (larva migrans visceralis) and preventive measures are discussed

N2 - A profoundly retarded male with severe congenital impairment of vision and hearing was treated for self-inflicted eye gouging. Prior to intervention, continuous mechanical restraint was required to prevent the response, precluding participation in educational and play activities. The response topography, the nature of the client's deficits, and a preliminary behavioral and medical assessment suggested that the response functioned as a source of sensory self-stimulation. Presentation of toys plus differential reinforcement of other behavior (DRO) as alternate sources of stimulation during baseline had no impact on eye gouging. The introduction of a contingent response interruption procedure reduced eye gouging and decreased the amount of time spent in restraints. Treatment effects were replicated in a group setting, and in the natural environment. Parents and school personnel were trained to use the treatment, and eye gouging remained infrequent at a 9-month follow-up

N2 - A small, personal monitoring study was performed in a subpopulation (14 families) of a case-control study on the relationship between indoor nitrogen-dioxide exposure and respiratory diseases of schoolchildren. Mothers, schoolchildren and pre-schoolchildren were asked to carry duplicate Palmes diffusion tubes during one week. Simultaneously nitrogen-dioxide concentrations were measured in the kitchen, living room, bedroom, outdoors and--for a few participants--at school and at work. Information on time activity patterns was gathered by means of a self administered diary. Several models for estimating exposure were constructed and tested against measured exposure. The personal exposure of the participants could well be explained by models containing indoor concentrations. Models with time-weighted average concentrations did not explain personal exposure better than models containing indoor concentrations. A calculated time-weighted average exposure was found to underestimate measured personal exposure by an average 20%, probably because the average concentration in a location does not necessarily reflect the actual exposure in that location. Personal exposure of mothers and children was very similar and highly correlated, indicating that the personal exposure of the mother might be a reasonable estimate for the exposure of the child

N2 - From 1978 to 1982, 117 cases of Lyme disease were reported in New Jersey. The number of cases increased each year from four in 1978 and 1979 to 56 in 1982. Forty-eight percent of cases occurred in a four-township area in central Monmouth County. The proportion of cases with arthritis decreased in 1982 because of early antibiotic treatment and better reporting of milder cases. The proportion of cases with positive serology increased with severity of the clinical syndrome. About 25 percent of patients had exposure to ticks because of occupations that required outdoor activities. Lyme disease is a growing public health problem in New Jersey

N2 - Four questions are asked about the use of social skills training procedures with mentally handicapped people. The first is, 'What are social skills in the context of mental handicap?', and it is suggested that they involve a complex array of perceptual, cognitive, motor and motivational processes, all of which can be disrupted due to various problems common among mentally handicapped people. The second question, 'What changes do social skills training programmes aim to achieve?', leads to the conclusion that most programmes have concentrated on motor, and to some extent on motivational processes, at the expense of perceptuo-cognitive ones. In asking, 'Have the programmes been successful in achieving these changes?', the answer is a guarded 'yes', given the limited aims of most investigators. Generalization to the natural environment has only occasionally been established, though it is often not measured. The fourth question is, 'What is the clinical significance of the changes obtained by such programmes and how can future ones be made more clinically relevant?'. The answer to the first part of the question is that, in general, their clinical utility has not been established. Future programmes could be made more clinically relevant if they were integrated with strategies for producing more benign and stimulating environments for mentally handicapped people. N2 - A questionnaire was applied to 159 consecutive patients with smear-positive and 187 with smear-negative pulmonary tuberculosis attending the 8 full-time Government chest clinics in Hong Kong for the first time for their current illness, who had already attended a private practitioner at a private general practice, a private clinic, or an independent hospital, outside the Government or Government-subsidised Service. The aim was to obtain details of management by private practitioners, and in particular of the antituberculosis chemotherapy prescribed. The great majority (86%) of the patients had originally attended a private practitioner because of symptoms. Only 18% had had their sputum examined, although 76% had had a chest radiograph; 65% of the smear-positive and 71% of the smear-negative patients had been told that they had, or might have, tuberculosis. For 40% there was an interval of more than a month between their first attendance at a private practitioner and at a Government chest clinic. Only 11% of the patients were referred without delay to a Government chest clinic, and another 21% once tuberculosis had been diagnosed or suspected. The patients were asked to name the drugs they had been prescribed, to produce samples, or to identify them from a perspex board containing samples of all 49 antituberculosis tablets and capsules known to be available in Hong Kong at the time. In the event, only 11% of the patients could name some or all of their medicaments and only 7% could produce samples, although a further 76% were able to describe them with or without the aid of the perspex board. In all, 19% of the patients were definitely or probably prescribed an antituberculosis regimen, although this was not always an adequate regimen. The findings suggest that there is considerable scope for active case-finding aimed at encouraging patients who are likely to have tuberculosis to attend a Government chest clinic

N2 - Injuries represent the single greatest threat to the health and well-being of US children. A large number of childhood injuries are sustained in schools, yet little is currently known of the epidemiologic features of school-related injuries. A surveillance of injuries occurring in a large, urban school district during a 2-year period was conducted. Nurses in each of the district's 96 schools completed reporting forms on all injuries meeting standardized criteria, and both principals and nurses completed questionnaires on school characteristics that were judged potentially important to the injury rate in individual schools. A total of 5,379 injuries were reported, among the district's 55,000 students, for an overall injury rate of 49 injuries/1,000 student-years. Injury rates were higher for boys than girls at all age levels. Self-caused and sports-related injuries comprised nearly half of all those reported, and 14% were related to use of playground or sports equipment. Eighteen percent of injuries were severe, and playground- and equipment-related injuries were significantly more likely to be severe (P less than .001). Rates of injury among individual schools varied markedly, with schools at the two extremes separated by a 25-fold difference in rates. Higher overall injury rates were found in schools with longer hours, alternative educational programs, less experienced school nurses, and lower student-to-staff ratios (P less than .0001)

N2 - Among 49 000 cases of infantile emergencies which were received in the BUCI (Bloc d'urgence chirurgicale infantile: surgical infantile emergency unit), 5 546 were sport traumas. At an early age, they were caused by outdoor plays; during adolescence, the main cases were caused by team sports. Males are

predominant. The number of cases has been regularly progressing, particularly since 1976. The fashion in sports is influenced by medias (i.e. skate board), and can be opposed to the continuous practice of popular sports (swimming, ball games, bicycle. There are winter, summer, school timed sports (the latter being influenced by the sportive scholar associations). The most frequent sports are cycling, football playing, swimming and horse riding, athleticism skating, Other are occasionnal. Changes in sport fashions, female increasing participation, such as horse riding and skating, democratisation (skiing, riding), the worsening of traumas; the pathology concerning bystanders, are described. Cranial and peripheric pathology are dominant. Trunk traumas are scarce but severe. Each sport has an elective pathologic localisation. Injury mechanisms are found, such as stirrup, saddle, ski baton pathology. There is traumatologic similarities; skate board and roller skating; judo and atheleticism; cycling and horse riding. Sport in children is not a replica of the one among adults. Riding a bike is not cycling. Some sports are dangerous: cycling, horse riding, rugby. A traumatological outline is revealed. Preventive measures should be taken. The socio-economical cost is heavy

N2 - We studied the epidemiologic features of playground equipment-related injuries occurring in a large, urban school district over a two-year period. Nurses in each of the district's 68 elementary schools completed self-coded reporting forms on all injuries meeting standardized criteria. A total of 511 equipment-related injuries were reported, an incidence of 8.9 injuries per 1,000 student-years. One-fourth of the injuries were severe, and climbing equipment was disproportionately represented among playground equipment associated with injuries. Extreme variability was found among school-specific rates of equipment injury, with schools at the two extremes separated by as much as a 40-fold difference in incidence. Two school characteristics--smaller

student enrollments and the presence of alternative educational programs--were significantly associated with higher equipment-related injury rates

N2 - Biological monitoring of lead effects in specific population groups living in the vicinity of a lead smelter has been followed up after effective emission control, in order to estimate the length of time necessary before the characteristic indicators of increased lead absorption normalize. The period established could be a realistic basis for predicting the time necessary to elapse before a lead contaminated area can be proclaimed as safe for normal living. Three groups of subjects were examined: preschool children, school children and mothers. The biological monitoring included the measurement of delta-aminolevulinic acid dehydratase activity (ALAD) and the concentration of zinc-protoporphyrin (ZPP), blood lead (Pb-B) and hemoglobin (Hb). The results obtained demonstrated a gradual normalization of the characteristic indicators of lead absorption, although they were still outside corresponding values in the control group even four years after the installation of effective emission control. These findings emphasize the advantages of biological monitoring over environmental for objective assessment of internal and external lead exposure following effective engineering control of the emission source

N2 - As part of a longitudinal study of the respiratory health effects of indoor and outdoor air pollutants, pulmonary function, respiratory illness history, and symptom history were recorded at 2 successive annual examinations of 10,106 white children living in 6 cities in the United States. Parental education, illness history, and smoking habits also were recorded, along with the fuel used for cooking in the child's home. Maternal cigarette smoking was associated with increases of 20 to 35% in the rates of 8 respiratory illnesses and symptoms investigated, and paternal smoking was associated with smaller but still substantial increases. Illness and symptom rates were linearly related to the number of cigarettes smoked by the child's mother. Illness rates were higher for children of current smokers than for children of ex-smokers. The associations between maternal smoking status and childhood respiratory illnesses and symptoms were reduced but not eliminated by adjustment for parental illness history. Levels of forced expiratory volume in one second (FEV1) were significantly lower for children of current smokers than for children of nonsmokers at both examinations and highest for children of ex-smokers. Levels of forced vital capacity (FVC) were lower for children of nonsmokers than for children of current smokers at both examinations, but the difference was statistically significant only at the first examination. Both the increase in mean FVC and the decrease in mean FEV1 among children of current smokers were linearly related to daily cigarette consumption. None of the respiratory illnesses and symptoms studied was significantly associated with exposure to gas cooking in the child's home.(ABSTRACT TRUNCATED AT 250 WORDS)

N2 - The relative effectiveness of a structured physical fitness program was compared with that of the customary organized activities for fifth grade students. The level of fitness was compared at the beginning and end of the nine-month academic year as well as after the three-month summer recess during which time no structured program was offered. The experimental group showed significant improvement over the control group in flexibility, strength and endurance during the school year; part of that improvement was maintained over the summer months; the physical fitness program had a positive influence on the general activity level of the students and was adopted by nine of the other 10 classrooms in the experimental school

N2 - An endemic version of the Good Behavior Game was applied in a rural Sudanese second-grade classroom. Official letters of commendation, extra time for recess, victory tags, and a winner's chart were used as backup reinforcers. The class was divided into two teams, and the teacher indicated she would place a check on the board after every rule violation. The students were also told that the team with the fewest marks would win the game and receive the aforementioned prizes. After an initial adaptation period, the rate of disruption was charted across four treatment phases: viz., baseline I, introduction of the game, baseline II, and reintroduction of the game. It was observed that the game phases were associated with marked decreases in the rate of seat leaving, talking without permission, and aggression. The teacher, principal, parents, and students were consequently individually interviewed, and their comments spoke strongly for the social validity of the game

N2 - Child dental services in Denmark were legally defined in 1971 and have functioned under this law for about a decade. Although no operational goals were defined, it is fair to say that the activities and results of the service have lived up to the expectations held at the inception of the law. The evaluation and planning system has made it possible to monitor developments in health as well as the use of resources. There have been consistent trends towards improved dental health in children and at the same time no increases in the use of personnel. There is general agreement in society that child services should remain a public activity. Pressures upon the services in the years to come must be expected to mount due to increased competition for scarce resources, simultaneous improvement in dental health and a reduction in the number of children. These

pressures will stimulate a re-examination of goals within the service so that appropriate short and long term local action can be taken before outside influences force changes with deleterious effects on the structure and function of the service. The success of the service and its ultimate achievements, therefore, will have to be measured against its abilities to adapt to changes in health as well as to an economic situation which will be more demanding than hitherto

N2 - This paper presents some of the underlying patterns of parenting that have emerged from six years of ethnographic field research into the role of the family in children's acquisition and use of reading and writing skills. The research has provided some insights into the many complex and interrelated ways that children's literate activities are mediated and affected by multigenerational family patterns and by their personal experience of everyday life both within and outside the family. Two central themes are discussed: the spirit of change, which breaks the patterns of the past and brings new interpretations into the present, and the spirit of conservation, which maintains the continuation of family patterns from one generation to the next. Also described are the important parental attitudes of social flexibility and resiliency that are frequently evident in these processes of conservation and change of multigenerational patterns. One specific family story provides the background for the theoretical issues that are explored

N2 - The finding of peanut agglutinin (PNA) binding capacity, supposed to be a marker of immature lymphocytes, within the T-cell population of the human thymus (58%) and tonsil (10%) prompted the comparison of maturation stages of PNA binding (PNA+) and nonbinding (PNA-) T cells in both organs. The proliferative response after mitogenic stimulation of purified PNA+ fractions was significantly less than that of purified PNA- fractions. The results of mitogen dose-response experiments, of variation in time of culture harvest, and of addition of irradiated allogeneic peripheral blood non-T cells indicated the intrinsic mitogen unresponsiveness of cells in the PNA+ fractions. The mitogen response of tonsil fractions was higher than that of thymocyte fractions. Cells with an immature immunologic phenotype were enriched in the thymocyte PNA+ fraction, and almost absent in the tonsil fractions. Both tonsil fractions contained cells with the immunologic phenotype of mature T cells, and showed a purine interconversion enzyme makeup comparable to mature T lymphocytes. It is concluded that the tonsil PNA+ T cell is a functionally immature lymphocyte which is in a further maturation stage than PNA+ or PNA- thymocytes. The presence of PNA+ T cells outside the thymus is of relevance for the clinical evaluation of PNA binding assays and suggests the occurrence of T-cell maturation within the tonsil environment

N2 - Consanguinity has been considered to be the major factor responsible for the high incidence of goiter in the area of Las Hurdes in Spain. However, iodine deficiency was later found to be severe enough to account for endemic goiter, and the presence of cretins in this area. Children from very similar family and socioeconomic backgrounds were found to be on three different nutritional programs, depending on the schools they were attending, and it appeared of interest to determine the effect of nutrition on the goiter incidence in children from the same population. Total iodine, nitrogen and creatinine concentrations were measured in casual urine samples. All three were found to change in parallel in the different subpopulations. They were low in schoolchildren receiving most of their meals at home. Such meals were composed of locally grown food. They were normal in children living in a boarding school, where all of the food is provided from outside the area. They were intermediate in children from a day care center, who received only some meals from an outside source. In the boarding school, goiter incidence was 21%, as opposed to 87% for schoolchildren fed at home. Such results indicate that in this area consanguinity plays a minor role, if any, in the high incidence of goiter

N2 - 2 experiments were carried out to investigate 18- to 30-month-old children's memory for the location of a hidden object. In the first experiment, young children were observed in 2 different memory-for-location tasks, both conducted in their own homes. In 1, a toy was hidden in a natural location, and in the other it was hidden in one of a set of boxes with picture cues on top of them. Memory performance was significantly better when the toy was hidden within the natural environment. The effect of different types of hiding locations was examined further in the second experiment. No age differences were found when an object was hidden either in the natural environment or in 1 of a set of unmarked boxes (although performance was better in the former condition).

However, in the third condition the older subjects (24-30 months) effectively used a landmark cue (a nearby piece of furniture) to help them remember in which plain box a toy had been hidden, but the young subjects (18-22 months) did not profit from such potential cues. The results, as well as some previous research with delayed-response tasks, were interpreted as reflecting developmental changes in very young children's ability to exploit available cues. The pattern of results suggested the possibility that 2-year-old children are capable of a simple form of mnemonic strategy, actively associating an available cue with the information to be remembered

N2 - A study was carried out to identify some of the cultural factors in the epidemiology of filariasis in an endemic community in Malaysia. The viewpoint of the community, data an responses on knowledge of illness and filariasis, host related factors, health examination, vector study were analysed and discussed. The observations noted on cultural factors were: Occupational pattern: Different agricultural occupations seemed to related to transmission in terms of body exposure. Activities not related to production of crops: Play groups in late afternoon, bathing of household members near and after sunset, congregations at prayer houses very much exposed the population to mosquito bites in different degree in terms of length of time spent outside the house. Knowledge of filariasis: Filariasis was understood in terms of elephantiasis, the chronic stage of the disease. Other signs of disease-adenolymphangitis, red lines running down one or both legs and abscess were generally recognized but not often annonated with specific disease. Attitude toward disease: Filariasis was not seen as a health problem and the idea of filarial worms was still hard to believe. Knowledge on disease causation: Biological causes were generally recognized, though the idea of bacteria was not widespread

 N2 - Three hundred and seventy-four cases of nasopharyngeal carcinoma (NPC) recorded in the Sudan Cancer Registry (SCR) and 512 cases seen at the Radiation and Isotope Centre, Khartoum (RICK) were analysed. NPC formed 5.8% of all cancer cases in the SCR and 7.2% at the RICK; this is the highest frequency so far reported outside the Chinese. The male/female ratio was 3:1; NPC was the commonest tumour in males at the RICK (12.1%) and second commonest in the SCR (9.2%). It tended to occur in younger patients (youngest, 3 yr), with 14 and 12.1% of cases in children 14 yr or under in the SCR and RICK respectively; it is the commonest childhood malignancy in the Sudan. The ethnic and geographical distribution of the cases showed that racial susceptibility played a significant role in the aetiology of NPC in the Sudan whereas environmental factors could be excluded; however, Epstein-Barr virus might be an exciting factor

N2 - To examine the role of early excision and grafting in the preservation of maximal function of hands with deep dermal burns, we prospectively evaluated 164 burned hands in consecutively admitted patients (mean age, 29 years; mean burn size, 37% of body surface). All hands with burn depths of second degree, deep second degree, or third degree above the level of the tendons and joint capsules were assessed preoperatively, intraoperatively, and at discharge from the hospital. Patients were treated by excision and grafting in the first or second postburn week, by delayed grafting alone, or by allowing primary healing. Total active range of motion measurements were made on the day of discharge (mean, 64th postoperative day). Mean operative blood loss per hand was 1,270 ml. When all (alive and dead) patients undergoing early excision and grafting were examined by a binomial probability model, early surgery was shown to produce no adverse affect on survival. Excision and grafting of hands with deep dermal burns, whether early or late, offered no advantage over physical therapy and primary healing in maintaining hand function. Likewise, hands with more superficial burns responded equally to operative and nonoperative treatment. While early excision and grafting of hands with third-degree burns tended to produce poorer results than did initial nonoperative care and late grafting, the differences are just outside the range of significance. Early excision and grafting of selected third-degree injuries of the hands may be indicated in patients with small total body surface burns in order to shorten hospital stay. However, early surgical intervention in patients with massive burns should be directed toward area coverage, not toward hand excision

N2 - Small silicone rubber tubes containing a standard size viscose cellulose sponge (Cellstic) were implanted in wounds of 23 children at the end of routine surgery. The Cellstics were drawn out of the wounds 1-4 days after implantation. Single cells and cell aggregates, called cell aggregation centers (CAC), were washed out of the Cellstic sponges by the retrograde injection technique, centrifuged, studied histologically and histochemically for cytochrome oxidase activity. Small leukocytic CACs and solitary cells, also including some macrophages and a few endothelial cells, were observed on the first postoperative day. On the second postoperative day and thereafter 2-4 endothelial cells were attached to each other surrounding a lumen. These capillary segment-looking formations (CSF) resembled capillary segments and they were seen both inside and outside the (now larger) CACs. Outside the CACs solitary endothelial cells occasionally exhibited ring-like formations. High cytochrome oxidase activity was observed especially in many CSFs but the solitary and the ring-shaped endothelial cells, in- and outside the CACs, also showed intense oxidative metabolism

N2 - Child rearing practices and attitudes were investigated using a questionnaire, among 75 families with 31--60-month-old children in poor suburban Kingston. A pattern emerged of many social contacts, outdoor activities and authoritarian discipline. While teaching and preparation for school were highly regarded, there was little conscious effort to foster cognitive and language development through play. Child rearing appears to reflect the influences of an African heritage, Western urbanization and poverty. Items from the questionnaire were used to devise an index of stimulation. Developmental assessments (DQs) were performed on a subgroup of 45 children. The results correlated positively with the index of stimulation

N2 - This research focuses on the inappropriate, largely aggressive, behaviors of 344 K-2 children assigned to a playground prior to the beginning of the school day. Initially, a system for observing large numbers of children

freely roaming over a large, open area was developed. This observational method was then used to determine the effectiveness of providing organized games for reducing potentially dangerous playground behaviors. Using a reversal (ABAB) design, it was found that the games, rope jumping, and foot racing, along with an infrequently used time-out procedure, significantly reduced the frequency of inappropriate incidents. It is suggested that when dealing with large groups, antecedent environmental manipulations may be more practical than providing consequences for the behaviors exhibited by identified individuals

N2 - Three members of the same family were found to have a clotting defect consistent with the diagnosis of heterozygous factor X Friuli disorder. The main features of the defect were a mild prolongation of prothrombin time and partial thromboplastin time, but a normal Stypven-Cephalin clotting time. Factor X activity was 40-50% of normal using tissue thromboplastin, but was perfectly normal using Russell's viper venom and cephalin. Using chromogenic substrate S-2222 the level was 30% of normal. Immunologically, factor X was normal. Bleeding manifestations were mild if any. The hereditary pattern was autosomal. The family comes from an area far away from Friuli and represents the first example of factor X Friuli discovered outside the Friuli

N2 - Standardized questions were put to the parents of 530 children, referred consecutively for evaluation of asthma, to determine which features in the history were associated with house-dust mite allergy. Bronchial challenge tests performed on 19 of the children confirmed that there is a highly significant association between a positive skin prick test and a positive bronchial challenge test to *Dermatophagoides farinae* mite antigen. One hundred and eighteen (23%) of the children had positive prick tests to the mite. There is a highly significant association between a positive prick test to mite and a history that the subject's respiratory symptoms become worse when there is exposure to domestic activity that stirs up house dust (vacuuming, dusting, sweeping, making the bed, or shaking out blankets) or that the symptoms improve when out of doors. Seasonal variation and other features in the history are of little value in distinguishing mite-sensitive from mite-insensitive asthmatics. Although the 4% whose only positive prick test reaction was to mite had significant worsening of asthma during the colder months compared with the remainder, most mite-positive subjects had multiple allergies and had no characteristic seasonal pattern. The presence of a positive prick test to mite was not associated with aggravation of asthma either at night in bed or in the morning on awakening. A history similar to that of mite-sensitive subjects was elicited in those with a positive prick test to house dust. A positive history of house dust or house-dust mite allergy in asthmatics is one in which respiratory symptoms become worse during domestic activity that stirs up house dust or improve when outdoors

N2 - In angulated long bone malunions in children, bone architectural changes arise which act consistently in kind, location, and direction, while the associated bone strain-stress patterns become definable as qualitative differences from the norm. Comparison of such information reveals that bone architectural adaptations correlate one-to-one with dynamic flexural strain orientation and magnitude but not with any single principal stress. The above plus other facts suggest six axioms which can explain many of the observed architectural adaptations of lamellar bone in response to specific mechanical bone-loading phenomena in normal as well as pathologic states. In essence those axioms state: In growing mammals and under repetitive, uniformly oriented, nontrivial, dynamic flexural strains, all lamellar bone surfaces drift in the concave-tending direction. As a result of these strains, a bone would adopt a size and configuration that minimize its flexural deformation during normal activities. The axioms provide reasonable explanations for inwaisting of vertebral bodies and long bone metaphyses, correction of malunions, increasing outside diameter and cortical thickness during growth, circular, elliptical, and triangular cross-sections, natural curvatures of whole bones, many architectural changes due to neuromotor abnormalities arising in early life, and the more rapid modeling seen in very young children or after recent fractures. N2 - A major problem encountered with autistic children is their characteristic self-stimulatory behavior, which frequently interferes with on-task responding and other appropriate behaviors. However, the experimental literature suggests that with many populations, increased physical activity might positively influence subsequent responding. Therefore, the purpose of this study was to investigate the use of increased physical activity (in this experiment, jogging) as a possible method of decreasing subsequent self-stimulatory behaviors as well as increasing subsequent appropriate responding. Seven autistic children with exceptionally high levels of self-stimulatory behavior participated in the investigation. Self-stimulatory and appropriate behaviors were measured both before and after jogging in a repeated-reversal design. The results demonstrated the following: (1) Brief jogging sessions produced decreases in subsequent levels of self-stimulatory behaviors and also produced increases in appropriate play and academic responding; (2) These changes after jogging were evident in three different experimental settings: during academic responding on preschool level tasks' in a clinic; during ball-playing in an outside play area; and in a quiet room, while no other activity was occurring; (3) Supplementary measures obtained in an applied classroom setting showed a similar relationship with both increases in on-task activity and general interest ratings for school tasks following the jogging sessions

 N2 - In view of evaluating the global efficiency of the epidemiologic investigation in relation to its area an analysis was carried out of 127 investigations involving 1 252 tb contacts. The contacts were classified in three groups: intrafamilial and intradomiciliary, intrafamilial but outside the home, and extrafamilial and outside the home; the results of the examinations were compared between them on the one hand and with the proportion of allergic children (51.6%) and the instantaneous prevalence of bacilli eliminating cases (0.31%) on the other hand. These were obtained in an area with a high endemic ratio of tuberculosis, following integral biological and radiophotographic case-finding. Children who were tb contacts, belonging to the first group also included the highest proportion of allergies (48.3%) while in the other two groups the number of allergic children was similar to that of allergic children in the locality with a high endemic ratio of tuberculosis. The radiophotographic examination of adults who were contacts of tuberculous patients showed that the lowest proportion of tuberculous patients with active tuberculosis (0.4%), which was found in the third group, was still above the instantaneous prevalence of bacilliferic patients from the area with high ratio of endemic tuberculosis. In conclusion, the present technical structure of epidemiological investigations corresponds to the actual level of the endemy and no group of contacts can be excluded from the investigation

N2 - Cardiopulmonary resuscitation (CPR) was attempted in 222 cases of sudden death at the City Hospital, Reykjavik, during 1976-79. Of the 68 patients (31%) successfully resuscitated, 47 died in the hospital and 21 (9%) were discharged, 17 in good mental and physical condition. The mean combined response and transport time was 12.1 min and the ambulance mean time of response 7.3 min. The first ECG revealed considerable prognostic indications. Of the 90 patients who had ventricular fibrillation on admission, 42 (47%) were successfully resuscitated and 18 (20%) were subsequently discharged. Among 114 patients with asystole, resuscitation was successful in 23 (20%) and two (2%) were discharged. Immediate first aid in situ had a definite prognostic influence. These results compare favourably with those obtained elsewhere where the organization of first aid and emergency transport is similar. They do not, however, match the results achieved by fully specialized resuscitation teams trained to operate outside the hospital. Results of CPR of patients with cardiac arrest out of hospital in Reykjavik show increasing improvement over the years. This may be partly explained by a considerable public debate on this issue in 1978 and subsequent streamlining of activities

N2 - About 34 p.c. of the patients coming from Mannheim or outskirts treated in the child and adolescent psychiatric clinic situated in the centre of Mannheim attended a kindergarten, a public school or being at work outside the clinic while in part-time in-patient treatment or before release. These patients scored somewhat but not significantly higher on intelligence tests, had better school attainment and consisted of a relatively higher proportion of females compared with patients who were not involved in activities outside the clinic. Diagnostically a somewhat greater number of psychosis, neurotic/emotional disorders were found among the part-time group and they showed also more associations with abnormal familial background, a higher proportion of part-time patients were not discharged to their families and have been treated for a longer time respectively. Not related to the length of treatment a significantly more positive successful treatment could be demonstrated among the part-time group. Particular aspects of a more realistic approach of treatment are discussed

N2 - A prospective epidemiological investigation of excessive daytime sleepiness (EDS) was carried out in an unselected inpatient population admitted to a general hospital during a 1-year period. The study comprised 2518 patients, 1347 female and 1171 male, aged 6-92 years (mean, 55.2). On the basis of histories and clinical and polysomnographic data, EDS was found in 28 cases (1.11%). Of these, 25 (0.99%; 18 female and 7 male; mean age, 61.3) had sleep apnea syndromes (SAS) with predominantly obstructive apnea. Two patients (0.07%; one female and one male; mean age, 65.5) had idiopathic CNS hypersomnia, and one male patient (0.03%) aged 48 years had a combination of narcolepsy and SAS. Differences and agreements of our findings with previous literature data are discussed. The present study shows that in an unselected inpatient population, EDS is a relatively common sleep disorder, usually found in mild to moderate forms. Because it is not severe, it disturbs only relatively domestic activities of elderly retired patients or others who do not work outside the home, and is often masked by other troubles. For these reasons, EDS in the aging population may pass unnoticed in epidemiological studies based only on data from sleep disorder centers

N2 - Classroom peer perceptions of 18 teacher-nominated hyperactive and 18 teacher-nominated active but normal elementary school-age boys, as revealed in two sociometric measures (Bower's Class Play, like-dislike nomination), were compared. Results indicated that hyperactives were significantly different from actives on all sociometric measures in that they were perceived more negatively. Peer communication patterns also were assessed. The communicative content, communicative quality, and attention to task instructions of hyperactive boys were compared to those of comparison boys. Limited support was found for the earlier finding that hyperactive boys were less likely than comparison boys to modulate behavior in response to changing external cues and to respond to subtle social learning opportunities. The communication task was found to be highly engaging for both groups of boys, and results suggest that hyperactive children may not lack the interpersonal skills necessary for referential communication, although they may be unable to use them consistently in all settings. The need to continue the study of peer relations of hyperactive children in naturalistic settings is stressed

N2 - The tendency of the index, amplitude and its dispersion during the year is opposite to the age-dependent tendency of changes in these indices and points to a chronic component of mental fatigue. It is very important that in the second half of the school year the dispersion of the EEG amplitude increases in all sections of the brain and in all frequency ranges: an increase in EEG amplitude dispersion in parallel with an increase in the amplitude itself indicates that the process of synchronization and the ultraliminal inhibition connected with it in different sections of the brain and in various frequency ranges of the EEG is not stagnant or inert but mobile and

instable and can therefore be relatively easily removed by special hygienic measures. As an example of the latter we can mention the use of a special regime of exercise (Yu. M. Pratushevich et al., 1975), addition of supplementary factors of nutrition to the diet of the time the children spend in the fresh air engaging in outdoor games (Yu. M. Pratushevich, 1964)

N2 - This study addressed the problem of the intraindividual consistency of a class of coercive child behaviors across two school settings. Observational data collected on eight coercive behaviors of 53 boys in classrooms and on the playground. Previous Guttman scale analyses had shown that these eight coercive behaviors constituted a response class. The rates of the eight coercive responses in the response class were rank-ordered separately for each of the 53 subjects in each of the two settings. The intraindividual rank-order correlations were all positive, and 37 were statistically reliable. This number of significant correlations was further shown to be significantly greater than chance. It was concluded that there is a substantial amount of cross-situational consistency if intraresponse class analyses are done for individuals

N2 - A method of combined dynamic and static bone-imaging using technetium 99-labeled phosphonate is described. During the dynamic part of the study, immediately after intravenous injection of the radionuclide, counts per second were recorded over a period of time for analogous regions of normal and diseased bones. The counts per second then were plotted against time to give time-activity curves for each of these regions. The time-activity curves were divided into arterial, venous, and blood-pool phases. Each phase was integrated and then divided by the time-span of the phase to give average total counts per unit of time. The values of these normalized integrals were directly proportional to the blood flow to the regions of bone from which they were calculated. Ratios of normalized integrals from the analogous regions of the diseased bone to the normal bone were calculated to determine whether the blood flow to the diseased bone was decreased or increased. Static images of the bone structures analyzed during the dynamic portion of the study were obtained two hours after the initial injection of the radionuclide and the total number of counts for analogous regions on the static images of the normal and diseased bones were recorded. The total number of counts for each region was divided by the area of that region to give average total counts. Ratios of the normalized counts were calculated for analogous regions of the diseased to the normal bone to determine whether there was an increase or decrease in concentration of the radionuclide. The method first was used to evaluate hip pain in children and adults. In order to recognize an abnormal result, mean values and two standard deviations were calculated for the dynamic and static ratios in a group of fifty patients who had no clinical complaints about the hips or lower extremities. Any ratios outside of the range of two standard deviations were considered abnormal. The method later was used to evaluate other bones, such as the tibia and humerus. Any value for the ratios beyond 1 ± 0.20 was considered abnormal for these studies

N2 - 45 males and 45 females between 7 and 8 years of age were acquired to catch rubber playground balls which varied in both size and color. Prior to the administration of the criterion catch test, subjects indicated their choice for a preferred color ball. Analysis indicated that the 6-in. balls (diameter) were caught significantly better than were 10-in. balls. Although the main effect of ball color was nonsignificant, the children caught balls of preferred color significantly better than those of non-preferred colors. Males scored significantly higher than the females on the catching task

N2 - Social workers have played an integral role in the treatment of psychiatric patients in hospitals since the earliest days of the 20th century. At first totally dependent on the support and approval of the medical profession, psychiatric social work later became professionalized and began to take responsibility for a wide variety of duties in the institution. Through a study of private and voluntary hospitals, the authors found that despite decades of acceptance by medical staff, the social worker today functions in an environment where final administrative authority on hiring staff and deciding the need for social work services often falls outside the social work department. The survey also identifies the relative importance of various professional duties and the impact of social work on institution decision-making. Involvement by social workers in patient discharge planning could well ensure the future of social work in hospitals in a time of tight budgets, they conclude

N2 - In assessing some of the existing patterns and future possibilities in child health care it was found that the continuing large social class differences in morbidity and mortality may be attributed to continued poverty, both of income and therefore of diet, and also to environmental deprivation. The absence of safe places for children to play, for example, is related to the high accident rates experienced by children. Doctors admit to awareness of these social and environmental causes of unnecessary morbidity and mortality among children but have failed to address the causes directly. While the causes are outside the immediate professional provenance of doctors, it is argued that, aware as they are of this aetiology, they have a moral and professional responsibility to act collectively as a pressure group urging improvements on the relevant authorities (as they have done in the case of smoking and clean air, for example)

N2 - A review of 233 cases of childhood strangulation was made to determine injury epidemiology. Consistent patterns of injury were observed. Crib and playground equipment strangulations are already the subject of Consumer Product Safety Commission (CPSC) preventative regulations. High chair-, playpen mesh-, pacifier cord-, and clothing-related injuries would be amenable to prevention by improved product safety regulation. The CPSC has been petitioned to remedy the first two of these hazards. Many crib and rope strangulations can only be prevented by direct patient counseling. Although Congress empowered and required the CPSC to recognize and correct unsafe products, its surveillance systems may obscure the very design defects that cause injury. Likewise, political considerations may slow enactment of new design regulations. Physicians who treat childhood accident victims are in a position to recognize hazardous products and lobby for their improvement. Of the 233 cases 38 were further evaluated to delineate the clinical course of childhood strangulation. Victims who fail to resume normal cardiopulmonary function by the time of hospitalization have a poor prognosis for neurologic recovery with current modes of therapy. Improved treatment of hypoxic and ischemic cerebral injury might prevent some of the deaths and handicaps resulting from strangulation

N2 - Matched pairs of hyperactive and normally active children were observed in six natural classroom settings and a number of specific behaviors continuously recorded. Both groups of children showed differences in behavior as a function of settings (selected to vary in amount of external stimulation and structure), but only certain settings differentiated hyperactive from control children. Hyperactive children displayed significantly more noise-vocalization and more disruptive and off-task behavior in the most frequently observed (low stimulation) classroom settings (e.g., seat work). Type of off-task behavior (out-of-seat or visually off-task) depended upon amount of classroom structure (i.e., teacher- vs. self-directed). Results were discussed in terms of their implications for identification and treatment of hyperactive children through the modification of the antecedent conditions of stimulation and structure

N2 - Caloric intake and expenditure of children in four families were assessed by nonparticipant observations of family dinners and school lunches. In each family there were one obese boy and one nonobese brother whose ages were within two years of each other. For family dinners the nonobese brother served as a control; for school lunches, a nonobese peer served as a control. The obese boys consumed more calories (766 +/- 290) than did their nonobese brothers at dinner (504 +/- 183) and far more (907 +/- 217) than their nonobese peers at lunch (500 +/- 386). The obese boys also ate faster (65.7 +/- 37.0 kcal/minute) than their brothers at dinner (31.7 +/- 13.8 kcal/minute) and far faster (103.5 +/- 40.9 kcal/minute) than their nonobese peers at lunch (46.2 +/- 22.5 kcal/minute). Time-sampled activity assessments showed the obese boys far less active than their controls inside the home, slightly less active outside the home, and equally active at school. When these activity values were converted into energy expenditure by measurement of oxygen consumption, obese boys expended more calories in moving than did their controls; as a result, there was no difference in energy expenditure between obese and nonobese boys at home and greater energy expenditure outside the home and at school. Increased intake, thus, and not decreased caloric output maintained the obesity of these four boys. In this respect, obesity in childhood may differ from obesity in adult life

N2 - Behavioral toxicology in the natural environment can be considered a special branch of epidemiology. Behavioral epidemiology, because it typically relies on complex functional criteria, faces all of the problems of behavior measurement posed by uncontrollable variation, and amplified even further by chemical exposure. Many such issues arose in a study of behavioral responses to artificial food colors in children. Difficulties in employing Applied Behavioral Analysis in such a context run the gamut from selection of retrospective criteria to appropriate statistical models

N2 - The Leishmanin skin test was performed on 1353 people in a kala-azar endemic region of south-west Ethiopia. Physical examinations were also carried out on 2723. Two of these individuals, both males, had active visceral leishmaniasis with *Leishmania* organisms demonstrated by spleen puncture. Two other males, including one member of the research team, had parasitologically proven cutaneous leishmaniasis. Because there was negligible migration and little movement of individuals outside of their tribal territories, the geographical distribution of skin test positivity and clinical findings could be determined and correlated with environmental parameters. The level of positive skin tests for the groups tested ranged from over 64% for the three tribes collectively inhabiting the lower regions of the Omo Valley (altitude approx. 500 m) to 6.4% for the Suri tribe, which lives at 1400 m. Skin test positivity was highest in areas of deeply fissuring montmorillonite soils and where *Phlebotomus langeroni orientalis* have been collected. Termite mounds of the pipe-organ type seemed to occur independently of the proportion of positive skin tests, possibly because alternative resting and breeding sites for sandflies were available in the cotton clay soil or because of the cultural patterns of the people. Almost always, males had a markedly higher prevalence of positive skin tests than did females. The degree of positivity was strongly correlated with increasing age, most positive conversions occurring in the ten to 20 year olds, the age at which males join cattle camps as part of their herding activities. Splenomegaly reached a prevalence of nearly 50% among the Hamar speaking people to the east of the Omo River, where the pattern of disease suggests malaria as the principal cause. Hepatomegaly, however, was highest in the lower Omo Basin among the Nyangatom, Dassanetch and Kerre, where hydatid disease was a major cause of liver enlargement, but seemed unrelated to the proportion of positive Leishmanin skin tests

N2 - Death certificates for 1977 filed with the New York State Department of Health were studied to determine where people died. Data were examined by the location and cause of death and by the age, sex, race, and marital status of the decedent. Comparisons were made with a similar study in which U.S. data were used for 1958 events. Approximately 60 percent of all the 1977 deaths in upstate New York occurred in hospitals; only 27 percent occurred outside an institution. The location of death varied by all the factors studied. Within all age categories, males had a higher percentage of hospital deaths. In those age categories in which nursing home deaths comprised a significant proportion of total deaths, females had a higher percentage of such deaths than males. Differences in the location of death according to its cause reflect the nature of the cause of death, for example, whether it was of sudden onset or the result of chronic disease. Most people do not consider in advance where they might die. The idea that age, sex, and marital status, as well as the more obvious cause, all play a part in the location may seem surprising. Yet all these factors were found to be associated with the location of deaths in upstate New York, and there is no reason to believe that this association does not hold true for the entire nation. More research, however, needs to be done based on more years and other geographic marital status may be instructive as to the present state of health resources

N2 - The symptom pattern previously delineated as the stress response syndrome in a mental health setting was hypothesized to be useful in conceptualizing reactions to a traumatic event in a nonpsychiatric patient population. The experience of loss resulting from nonelective hysterectomy for benign disease in women of childbearing age was selected as a relevant field study model. Twenty-eight women were studied one year after hysterectomy, using extensive psychological interviewing by women clinicians and experiential rating scales. Twelve subjects had a mild stress response syndrome, and five subjects had a serious level of intrusive and avoidant symptoms. Increasing severity of response was associated with persisting child-wish, deterioration in sexual functioning, and change in self-concept. Women who did well postoperatively generally had no future wish for children and were actively committed to achievement outside of the home

N2 - Our objective has been to trace Joseph's disease to its geographic origins and to determine the spectrum of clinical manifestations. This goal we have achieved by documenting type I and II disease within the Joseph and Sousa families. The major neuropathologic findings are a progressive neuronal loss involving the striatum, nigra, dentate nucleus of the cerebellum, and lower motor neurons in the brainstem and spinal cord. The homozygote form of the disease produces type I disease with onset in early childhood of progressive dystonia, athetosis, and spasticity. Type I disease tends to have its onset by age 25 years in heterozygotes and lasts about 15 years on the average. Type II disease, which we consider the result of a single dose of the mutant gene, usually begins somewhat later and runs its course over a 20-year period. Type III disease documented in the Thomas family is the most benign. Its onset is often in the fifth decade, and it progresses slowly into the eighth decade. Patients may benefit from antiparkinson medication including dihydroxyphenylalanine and anticholinergic agents (e.g., amantadine). A molecular marker for the disease is being sought actively, and several interesting patterns have already been documented by means of patient fibroblast cultures and two-dimensional acrylamide gel protein separations. The mutant gene is clearly outside the HLA complex but may be linked to it. The only biochemical change noted thus far is a reduced CSF level of HVA that probably reflects the loss of dopamine-synthesizing neurons in the substantia nigra and is thus a secondary effect of disease. Although the disease is a very old one which we can trace back to the early 19th century on the island of Flores, it may be recurring de novo by new gene mutations at an unstable gene locus in a genetically vulnerable population. Now that the spectrum of clinical expression has been identified and the mode of inheritance established as an autosomal dominant wherever the disease has been found, it is believed that its true incidence will become more evident by virtue of better detection and that the true incidence will actually increase because of increased assimilation of affected persons into other ethnic groups

N2 - The activities of five mitochondrial enzymes tested in liver from patients with Reye's syndrome were measured. Citrate synthase, glutamic dehydrogenase, succinic dehydrogenase, pyruvate carboxylase, and pyruvate dehydrogenase were all outside of the range shown by control samples and well below them in activity. The activity of two extramitochondrial enzymes, glucose-6-phosphatase, which is a microsomal enzyme, and fructose-1,6-diphosphatase, which is a soluble enzyme, were in the normal range in samples from Reye's syndrome patients. In both muscle and brain the activities of the mitochondrial enzyme, citrate synthase, glutamic dehydrogenase, and succinic dehydrogenase were all within the control range. Pyruvate dehydrogenase was found to be normal in muscle from these patients

N2 - The activity of adenosine deaminase (EC 3.5.4.4.) was significantly lower in lymphocytes from patients with lung cancer than in those from healthy subjects, whereas the activity of purine nucleoside phosphorylase (EC 2.4.2.1.) was significantly higher in lymphocytes from the patients than in those from normal controls. When the one activity was plotted against the other, the plots for patients with lung cancer were all outside the frame formed by the lower and higher limits of the standard deviation of the mean of normal activities of the two enzymes. The ratio of adenosine deaminase activity to purine nucleoside phosphorylase activity was lower in patients with lung cancer than in controls. The possible effect of this ratio on the function of lymphocytes was briefly discussed. These enzyme activities were suggested to be useful measures of the immune responsiveness of patients with lung cancer

N2 - A group of sixteen children suffering from osteoarticular tuberculosis were seen over the past five years in the Belgrade Paediatric Surgery Clinic. This disease is now extremely rare and affects chiefly children born outside maternity departments and not receiving BCG vaccination at birth for different reasons. The osteoarticular tuberculosis rate in the Socialist Republic of Serbia over this period was thus one in 500,000 children. The disease is three times as common in male children, most often affecting the hip and presenting above all at about the age of nine. At the time of admission, eight children had tuberculosis lesions affecting the lungs, visible and active or latent, partially or completely. In five children, one of the parents was receiving treatment for active pulmonary tuberculosis at the time of onset of the disease. Conservative treatment (immobilisation, tuberculous bacteriostatic therapy and general measures) was used in fifteen children and only one underwent surgery, in addition to the standard treatment described. In only one child, there was ankylosis of the hip and the end of treatment, the others having less sequelae of returning completely to normal. In one girl, osteoarticular tuberculosis was complicated by exsudative tuberculosis pericarditis

N2 - Among 225 skateboard accidents treated at the Children's Hospital, Sheffield, in 8 months from August 1977, there were 92 fractures (40.9 per cent), of which 19 required manipulation under general anesthetic. Most involved the upper limb. Next most frequent were lacerations, bruises, abrasions, and injuries of joints and soft tissues. Four children had concussions (one with a fractured skull), 8 others had minor head injury, and 23 had soft tissue injuries of the head and neck. As for the reasons for the accidents, 20 per cent were due to hitting a stone, 10 per cent to a hole or bump in the pavement, 8 per cent to collisions, and three accidents to faults in the skateboards. Sixteen of the children were injured on the first day of their skateboarding. The role of protective clothing was uncertain. The city has no skateboard parks. Injuries due to skateboards were compared to injuries due to playground equipment

N2 - The development of the angle of the anterior chamber of the eye in chick embryos (avian eye), in new born rats (rodents), in calf fetuses (ungulates) and in humans (primates) has been studied. The main determinant in the configuration of the angle is the two-layered structure of the mesoderm of the ciliary body: the external muscular layer inserted into the spur and growing with same growth rate as that of the corneoscleral mesoderm and internal fibrovascular layer giving rise to the ciliary processes and growing with same growth rate as that of the neural ciliary and iris epithelium. First the neural epithelium grows faster than the corneoscleral mesoderm and the ciliary processes appear anteriorly positioned and later the corneoscleral mesoderm grows faster than the neuroepithelium and the ciliary processes appear posteriorly positioned. The eyes of premature and low birth weight babies present the different stages of normal embryological development of the angle. The angle in eyes of various embryopathies and developmental diseases presents aspects similar to those of the premature and low birth weight babies. The etiopathogenic mechanism in cause is the same in both groups: arrest of development. During the first post-natal years, the corneoscleral mesoderm grows at a greater rate than the inner neuro-epithelium and the region of the most active growth is located at the ora serrata. That is why, during this period, the ora serrata recedes, giving rise to the formation of retinal teeth, the angle deepens and makes a recess and the Lange fold disappears

N2 - Two experiments investigated the effects of a treatment package on the self-injurious behavior of three profoundly retarded persons who appeared to enjoy the physical restraints used to prevent their self-injury. The treatment package included physically restraining subjects contingent on increasing periods of time during which no self-injury occurred, and providing them with toys and attention during intervals between restraints. A reversal and multiple-baseline analysis documented that the rapid and complete reduction in self-injury by all subjects was due to this treatment package. Because these results suggested that physical restraint might function as a positive reinforcer, in a third experiment physical restraint was applied contingent on a marble placement response with one subject. A reversal design demonstrated that toy play systematically increased when each response resulted in restraint. The experiments have implications for the nonaversive remediation of self-injury in individuals who are restrained, as well as for the development and maintenance of self-injury in natural settings

N2 - 1. The daily intake of selenium by three subjects was supplemented with 100 microgram Se as selenomethionine (Semet-Se) or sodium selenite (selenite-Se)/d for 10-11 weeks, or with 65 microgram Se as in mackerel (*Scomber japonicus*) (fish-Se)/d for 4 weeks. 2. Urinary and faecal excretion of Se was measured and also Se concentration in whole blood, plasma and erythrocytes. Measurements on blood were made at intervals after supplementation had ceased. 3. Selenite-Se was not as well absorbed (0.46 of the intake) during the first 4 weeks as Semet-Se (0.75 of the intake) and fish Se (0.66 of the intake). 4. Blood Se increased steadily with Semet-Se, from 0.08 to 0.18 microgram Se/ml, but more slowly with selenite-Se, reaching a plateau in 7-8 weeks at 0.11 microgram Se/ml. Plasma Se increased more rapidly with Semet-Se than with selenite-Se, so that initially with Semet-Se plasma Se was greater than erythrocyte Se. 5. Daily urinary excretion increased with all forms of supplement, with initially a greater proportion of absorbed selenite-Se being excreted than Semet-Se or fish-Se. A close relationship was found between plasma Se and 24 h urinary excretion. The findings suggested that there was a rapid initial excretion of presumably unbound Se then a slower excretion of residual unbound, loosely bound or bound Se. 6. Total retentions of 3.5 mg selenite-Se and 4.5 mg Semet-Se were large when compared with an estimate of body content of 6 mg Se, derived in another paper (Stewart, Griffiths, Thomson & Robinson, 1978). Retention of Semet-Se and fish-Se appeared to be reflected in blood Se, whereas for selenite-Se, blood Se reflected retention for only a short period after which Se appeared to be retained without altering the blood Se. This suggested that Semet-Se and selenite-Se were metabolized differently. 7. A double blind-dosing trail with 100 microgram Semet-Se was carried out for 12 weeks on twenty-four patients with muscular complaints in Tapanui, a low-Se-soil area. Blood Se increased in the experimental group (from 0.067 to 0.143 microgram Se/ml); clinical findings were not conclusive and will be presented elsewhere. 8. Blood Se was measured in New Zealand residents before travelling to Europe or to North America. On return their blood Se was increased, and depending upon the period of time spent outside New Zealand some values reached concentrations found in visitors and new settlers to New Zealand. 9. The results from these studies and the earlier studies of single and multiple dosing have been used to look at the various criteria in use for assessing Se status of subjects. It is suggested that plasma Se be used in preference to 24 h urinary excretion, and in addition to whole blood Se and glutathione peroxidase (EC 1.11.1.9) activity

N2 - Materials of epidemiological analysis of familial infectious hepatitis nidality in 104 families are presented. The data obtained pointed to the preponderant affection of children constituting 97.1% of primary and 87.7% of subsequent cases in familial foci. Infection was brought to the families by schoolchildren in 57.7% of the cases, and by organized preschoolchildren--in 31.7% of the cases. The greatest affection of schoolchildren aged from 7 to 14 years in the foci with subsequent occurrence of the disease (77.7%) was explained by their marked age activity. This led to the conclusion that mass prophylaxis with alpha-globulin of these particular groups of children was of primary importance. The differences of the specific ratio of adults who contracted the disease in familial foci and in the region as a whole pointed to the possibility of infection of adults outside the family and on the prevalence in them of serum hepatitis

N2 - The outbreak of meningitis during the period from the end of August to the beginning of October 1974 in Kiel affected 45 children, particularly those in the age group between 4 and 9 years. An potential causative agents ECHO viri were identified in 15/45 cases and Coxsackie B viri in 2/45 cases. The patients presented the typical meningitic symptoms (fever, headache, stiffness of the neck). In all cases the disease ran a benign course. - Epidemiologically, it was possible to trace 32/45 cases back to three locally demarcated groups with demonstrable possibilities of contact for the diseased children (family, playground, kindergarden and school). The remaining 13/45 cases occurred isolated over the urban area without any visible connection. - This outbreak of meningitis must be regarded as an accumulation of illnesses resulting from contact infections by enteroviri and lacking or deficient disinfection. Besides the rather limited measures adopted to prevent the spread of such an infection, the correct psychological management of the population especially by the health authorities is of great importance in such epidemics

N2 - Generalization of the Monterey Behavioral Sciences Institute operant language program was assessed. Six male and three female children (4 years, 4 months to 6 years, 3 months) receiving language remediation were randomly assigned to (I) the Monterey program for the syntactic structure "is interrogative" (including the home carryover phase) plus an extended transfer program devised by the investigators (II) the Monterey "is interrogative" program alone (including the home carryover), or (III) a control activity (articulation training). Language samples evoked by a variety of language tasks were collected outside the treatment setting preceding and following treatment. Standard within-clinic measures indicated that groups I and II improved a significant, equal amount. However, the extraclinic language measures showed that group I demonstrated significantly greater improvement than group II; neither group II nor group III showed significant extraclinic improvement. Extraclinic generalization occurred, therefore, only for the group receiving the special extended transfer training

N2 - Traumatic spinal cord lesions in children are infrequent (2 to 5 per cent of all cases admitted to specialised paraplegic centres depending on whether the upper age limit is set at 10 or 15 years). Traffic accidents are

responsible for at least 50 per cent of the lesions; playground accidents and various sports add another 35 per cent. A large proportion of the accidents have been found to be related to the child's normal desire for adventure and exploration. The segment most frequently involved in our own series of 18 cases was the cervical and upper thoracic spine. Histopathological studies have shown that splitting of the cartilaginous end-plate in the growth zone of the vertebrae is a common finding. Radiological signs of spinal trauma are less evident than in adults; they may be totally missing. Precise neurological assessment must rely on repeated examination and close clinical observation, especially in the comatous child with a head injury. Spinal cord involvement must be suspected and the child treated as a paraplegic until definite proof of a normal neurological status is available. Due to a highly labile water electrolyte balance in the early post-traumatic stage and considerable fluctuations in plasma volume and temperature regulation, permanent monitoring of the cardiovascular function, body temperature and diuresis is mandatory. In children below the age of 10, deep vein thrombosis and embolism are exceptional (sepsis creates a high-risk situation requiring anticoagulation). In the initial treatment of spinal injury only conservative measures should be considered; there are no indications for laminectomy, nor for spinal fusion. In the tetraplegic child below the age of 6, skull-traction should be avoided and immobilisation of the cervical segment achieved by bilateral padded head-rests

N2 - By sequential random numbering 10 schools in greater Winnipeg were selected for a nutrition survey. Interviews were conducted with 201 grade 3 children and 182 grade 6 children for whom parental consent was obtained. Of these, 48 in grade 3 and 51 in grade 6 were studied in further detail. There were no differences in descriptive data between the general and detailed groups or among the 10 schools. Most fathers were skilled or

unskilled labourers and about 50% of the mothers were homemakers without outside employment; parental occupation did not influence eating patterns. Breakfast was the meal most often missed; 8% of the 383 children had come to school without breakfast. Since many children in grade 3 had prepared their own breakfast and since there was a relative lack of physical activity, school health programs should incorporate more than nutritional supplements and nutrition education. On the basis of body weight and height the nutritional status of the 99 children studied in detail was judged to be generally satisfactory; according to the Boston standards the boys were heavy and tall, and the girls were normal in weight but short

N2 - For a "social environmental protection" as one of the most urgent problems in infantile psychohygiene, the following conclusions should be taken into consideration: 1. In particular during the first years of life the development of the child is, within certain limits, sensitive to influences from the environment and therefore it can be fostered or disturbed from the outside. Congenital, prenatal, perinatal and postnatal injuries to the brain and sensory organs must be given great attention psychohygienically. 2. The social influences exercised on the child by persons of his environment, their availability, their emotional relationships and the development of a durable link predominate psychohygienically. In addition, the material security of young families and their type of accommodation (e.g. granting of loans to help set up a home) must be considered. 3. The possibilities of exercising a positive educational influence on a mentally and psychically sound development of the child as a person and member of society are greatest at the beginning of life and diminish during childhood. The effectiveness of negative educational and social interference factors is also subject to this rule from which again the necessity of adopting psychohygienic measures for the young child is derived. 4. The phenomenon of increasingly imbalanced behaviour of older children and juveniles which cause concern today, are as a rule

symptoms of a chiefly environmentally determined disturbance upsetting the personality, which often originates in early childhood. Psychohygienic measures must be concentrated on this. 5. The inadequate care of young children accounting for one third of the population, a phenomenon which can be read in the statistical records and which has risen sharply during the last few years, makes it possible to forecast a further increase in developmental and behavioral disturbances of both an intellectual and psychological nature as well as in infantile and juvenile criminality in the coming years to an at present unimaginable extent. 6. In contrast to general opinion, the situation calls for an urgent fundamental reevaluation of the importance of intrafamilial social conditions of development and of the parental educational work on the small child, which to date, have been underestimated and neglected. At the same time many of the presently overrated extrafamilial institutions of education and training for the older child need to be relativised. 7. The advances in developmental biology which allow us to realize the basic dependence of the future social fate of the individual - and thus the extent of disturbed social relationships in society - on the intrafamily conditions must become a political issue, if psychohygiene as a means to prevent avoidable disturbances is to be taken seriously. Thus the securing of adequate intrafamily conditions with respect to development and upbringing, in particular of the young child, must head the list of social political priorities, also in times when money is in short supply. 8..

N2 - In order to investigate the difference in the behavioral problems presented by cognitively impulsive and reflective emotionally disturbed boys, the parents of 17 impulsive and 13 reflective boys in residential treatment

were asked to rate their sons' behavior. Results indicated that in contrast to reflective emotionally disturbed boys, impulsives were more likely to talk of others blaming them unfairly, threaten to harm themselves, hit and bully other children, and be excessively rough in play. On the other hand, reflectives were more unwilling to talk with adults outside the family. Results were discussed in terms of supporting both previous research and Kagan and Kogan's (6) "fear of failure" hypothesis

N2 - Tests of immune capacity were performed on blood from 49 children with newly diagnosed, untreated acute lymphocytic leukemia, and relation to prognosis was determined. Patients were treated with multiple-drug therapy and prophylactic cranial irradiation. Median follow-up time was 16 mo (range 10--37 mo). Principal unfavorable findings at diagnosis were absolute numbers of T lymphoid cells outside the range 850--2500/mul blood, absence of whole blood responses to phytohemagglutinin in vitro, a low titer of complexed antibody, and the presence in serum of free leukemic blast cell membrane antigen. Fourteen patients showed two or more unfavorable findings at diagnosis. Eleven of these have died. Four of the remaining 35 patients have died. A shorter duration of first remission was found among patients with abnormal numbers of T cells at diagnosis. The findings suggest that the immunologic capacity of the patient at diagnosis is an important determinant in responses to therapy

N2 - The responses to cold hand test (blood pressure increase and tachycardia) and to a cold face test (blood pressure increase and bradycardia) were used to study the role of the autonomic nervous system in cold

adaptation in humans. The Eskimos (men, women, children) were shown to have a very weak sympathetic response to cold but the vagal response (bradycardia) was identical to that of white people. A group of mailmen from Quebec city living outdoors approximately 30 h/wk throughout the year was also studied. A significant decline in the cold pressor response and an enhanced bradycardia (cold face test) were observed at the end of the winter. Similarly the fall in skin temperature of the cheek was not as pronounced when the measurements were made in May compared to those made in October. A group of soldiers was also studied before and after an Arctic expedition. It was found that the bradycardia of the cold face test was also more pronounced after sojourning in the cold. These results indicate that repeated exposures to severe cold in men activate some adaptive mechanisms characterized by a diminution of the sympathetic response and a concomitant enhancement of the vagal activation normally observed when the extremities and the face are exposed to cold

N2 - 1. Spontaneous flexion-extension tremor of the elbow was recorded in normal human subjects while they exerted a flexing force against different loads.2. Increases in the flexing force up to (1/2) or (3/4) of the subject's maximum were accompanied by increases in the amplitude of the tremor. A further increase to very large forces was associated with a decrease in tremor.3. When the subject flexed against a spring, the frequency of the tremor was related to the properties of the spring; with increasingly stiff springs the tremor frequency increased up to about 12 Hz. With the stiffest springs, however, the tremor became irregular and very small in amplitude.4. Weights added to the limb at the wrist reduced the frequency of tremor.5. By using appropriate combinations of spring and mass, the principal tremor frequency could be adjusted between 2 and 12 Hz, higher

in some subjects. Within this range the frequency(2) was approximately proportional to the spring stiffness/mass, just as it is in a spring-mass system, though the forearm provided some of this mass, and some of the spring-like resistance was in the flexor muscles.6. When by suitable loading the tremor frequency was brought between 8 and 12 Hz, and the subject forcibly flexed his elbow, the tremor became regular and large in amplitude. This was a form of limited instability in the stretch reflex which arose because a powerful reflex response to extension of the elbow acted back on the flexor muscles after a delay.7. When the limb was so loaded that its natural frequency was outside this 8-12 Hz range, it behaved as a filter, and in response to any disturbing noise it oscillated mainly at frequencies close to the natural frequencies of either the mechanical system or the stretch reflex.8. This filtering function of the limb with its stretch reflex probably plays an important part in the control of normal movement and tremor.9. The large flexing forces that were here associated with vigorous tremor normally occur when a limb supports a large mass. Such a mass would give the mechanical system within the limb a low natural frequency; inconveniently large oscillations in the 8-12 Hz range would therefore seldom occur

N2 - It has been known for many years that the eating of leaded paint is the prime cause of lead poisoning and elevated blood leads of children living in deteriorated housing. Recently, there has been speculation that children may eat dirt and dust contaminated with lead exhausted from cars and that this amount of ingested lead is sufficient to contribute significantly to the childhood lead problem. This paper reports on a twopart study conducted to evaluate the validity of the dirt-and-dust hypotheses. The first part of the study was made to

determine the source of lead in dirt to which children are normally exposed. Dirt samples were taken in old urban areas around 18 painted frame houses and 18 houses of brick construction. Samples also were taken around seven old frame farmhouses remote from traffic. Based on the fact that lead concentrations in the dirt were similar in city and rural yards at corresponding distances from the houses, it is clear that nearly all of the lead in dirt around these houses is due to paint from the houses. Lead antiknock additives are therefore not a significant contributor to the lead content of dirt around houses where children usually play. The second part of the study used a naturally occurring radioactive tracer (^{210}Pb) to determine the relative amounts of dust and other lead-containing materials (e.g., paint) eaten by young children. This tracer is present in very low concentrations in paint and in significantly higher concentrations in fallout dust. Stable lead and (^{210}Pb) were analyzed in fecal material from eight children suspected of having elevated body burdens of lead and ten children living in good housing where lead poisoning is not a problem. The normal children averaged 4 μg Pb/g dry feces, with a range of 2 to 7. Of the eight children suspected of having elevated lead body burdens, two had fecal lead values within the normal range. However, the remaining six were 4 to 400 times as high. Despite these differences in fecal lead between the two groups, the groups were essentially identified in the (^{210}Pb) content of their feces. The "elevated" children averaged 0.040 pCi of (^{210}Pb) dry feces, while the normal group averaged 0.044 pCi/g. The results provide sound evidence that these children suspected of elevated lead body burden were not ingesting dust or air-suspended particulate

N2 - Experience with 36 cases of North American blastomycosis in Central Canada is reported. Symptoms referable to the respiratory tract predominated, but no uniform clinical pattern for the disease process was evident. Cutaneous and genitourinary tract involvement was present in only a small proportion of patients. The majority of the patients resided in rural areas or were associated with some form of outdoor occupation or activity. No characteristic radiologic appearance could be identified in this series. Amphotericin B administered intravenously is the treatment of choice for this condition. North American blastomycosis is more widespread on this continent than has been previously demonstrated

N2 - One hundred and one patients with through-knee amputations attending the Manchester limb-fitting centre are reviewed. Most amputations were performed for trauma or vascular disease. The interval from amputation to measurement for the first prosthesis averaged 12 weeks in cases of primary healing, and 21 weeks when healing was delayed. Artificial limbs were successfully fitted to 83%, and only 10% failed to use either a limb or a pylon. Three-quarters of those with outdoor mobility returned to work. Disarticulation through the knee has several advantages over above-knee amputation: in particular, the long end-bearing stump facilitates balance and control of the prosthesis. Disadvantages are a tendency to slow healing of the wound, lack of an internal knee mechanism in the artificial limb, and the bulky appearance of the limb. The results of rehabilitation could be improved by careful selection of patients and attention to operative detail; stump bandaging and exercises; earlier attendance at the limb-fitting centre to be measured for pylon or artificial limb; and improvements in design and production of prostheses

N2 - The frequency of man-biting by mosquitos depends upon the amount of contact between man and mosquito, which in turn depends upon the behaviour patterns of both. In order to examine these relationships in an area with a high incidence of malaria, a study was made in 1965 of the nocturnal movements and of mosquito biting habits in five localities in the malarious area of Colombia that were in the thirteenth or fourteenth cycle of biennial DDT spraying. The populations were classed into five age- and sex-groups, i.e., men and women over the age of 15 years, boys and girls from 5 to 15 years, and children under 5. A number of differences in the habits of these groups were discovered in relation to time spent indoors or outside, but close to, the house. The habits of the four main anopheline vector species were studied in relation to human activities. For three of the species (*A. albimanus*, *A. darlingi*, *A. nuneztovari*) it is suggested that a low relative importance of outdoor biting is caused not by a density-dependent factor but by an anopheline gonotrophic cycle or by relative humidity or both. The fourth species (*A. punctimacula*), common only at one locality, displayed a complex pattern of biting behaviour with, however, a much greater frequency of outdoor biting than in the other species. It is considered that in these localities malaria is probably transmitted mainly inside sprayed houses by vectors that are susceptible to the insecticides in use but which are not sufficiently reduced in numbers or in life-expectancy to interrupt the transmission of the parasite

N2 - The environmental values (EV) of children are, across disciplines and theories, regarded as essential preconditions of environmental behavior (EB). This study identifies and explains variation in EV and what they tell us about the EB of children. The study makes an important contribution to the design and evaluation of environmental education initiatives. The 2006 PISA data were used in the study (398,750 15-year-olds from 56 countries) as well as about 3000 children ages 10-16 from Flanders, Vietnam and Guatemala. Data treatment methods were quantitative and include multilevel regression models to discern different levels of variation in the data (individuals within schools within cultures) and multi-group confirmatory factor analyses to assess issues of measurement invariance in EV. The key findings include; (1) children's EV are not just individual traits, they

are also accounted for the social and natural context within which individuals operate; (2) gender differences in EV might reflect methodological artifacts rather than genuine differences; (3) schools matter, environmental knowledge can be encouraged through hands-on teaching, EV through school participation in environmental learning activities outside the classroom; (4) schools have a greater impact on their students' environmental knowledge than on their EV; (5) eco-schools matter, they have an effect on their students' EV but might be applying an approach that, in the long run, has little chance of achieving behavior change and (6) EV affect EB and do so in a culturally specific manner; educational efforts should account for this cultural specificity.

N2 - Considering the context of large city schools, this study explores what variables in a kindergarten classroom may impact the process of children's engagement with nature. In particular I examine the central role of children and teacher in co-constructing their own unique understanding, knowledge, and attitude towards the natural world. In this study, I examine nature-child's connection considering the complexity of nature beyond a pre-packaged concept (Louv, 2007) and avoiding a linear identification of a cause and effect relationship between children's learning experiences and nature, (Kellert, 2005). This qualitative case study is based on extensive classroom observations, in which 20 kindergarten children and their teacher participate. The children's direct, indirect, and vicarious experiences with nature are documented using digital photography, video-audio recording, and collection of artifacts. I interview the classroom teacher two times and invite the parents to fill up a questionnaire about their children's experiences with nature outside the school time. I use the techniques and procedure of the grounded theory to analyze the data. A comparative analysis of the five learning episodes demonstrates four major factors that when all woven together encourage and sustain the children's engagement with nature. These factors are: investigating children's meaningful and autotelic questions, encountering and experiencing nature in familiar contexts, developing emotional bonding, and having sufficient time. The findings show the crucial role of the classroom teacher in creating five main conditions to engage the children in the process of each inquiry. She offers the children many opportunities to use their prior skills and knowledge, take responsibility of their own learning, and experiment with learning as a process. She often responds positively to the children's learning endeavours and communicates her high confidence and expectations for them. This study makes an important contribution to the field of early childhood education and environmental education by demonstrating the possibilities and challenges in actively and holistically engaging children with nature in school settings. The findings shed light on our understanding of children and teacher's sense of

ownership and motivation as two driving forces of learning. (PsycINFO Database Record (c) 2014 APA, all rights reserved)

N2 - The steady decline of populations taking up recreational hunting is cause for concern among state and federal wildlife agencies. Young hunters are the future of hunting. As the average age of hunters continues to increase, young people participating in hunting activities provide an opportunity for insight to change the current declining trend. Flow theory and hunter satisfaction have both received extensive attention in research literature, however they have been utilized in separate and disconnected settings. An attempt to combine both constructs, as a way to measure intrinsic and extrinsic motivational, mood, and flow indicators of youth hunters has not been attempted to date. Measuring and understanding antecedents of "flow" in youth is an important consideration when determining why youth enjoy hunting as an outdoor recreational experience. This exploratory study utilizes flow theory and the four-channel model of flow to examine relationships among youth hunters' (12 to 16 years of age) experiences and satisfaction during Michigan's Special Youth Firearm White-tailed Deer Hunt (n=43). This research provided a snapshot in time of young hunters, their experiences and the satisfaction of those experiences during the youth hunt. Of the youth participants in this study, 69% indicated that they intend to go back out in the field for Michigan's opening day of firearm deer season (November 15, 2012). Additionally, 97.6% of youth respondents intend to hunt in future years, providing support for implementation of special hunting opportunities where youth and mentors can enjoy the experience of hunting together. This exploratory research suggests that there is a significant and direct relationship between "flow" experiences and young hunters that hear deer and other animals, and see white-tailed deer. Knowledge of congruence between "flow" experiences and hearing deer and other animals, and seeing white-tailed deer offers the opportunity for further research on a much broader scale of licensed young hunters in Michigan. This research also has the potential to inform recruitment and retention personnel of state wildlife agencies about ways to support programs that promote hunting activities within younger populations in the future. N2 - Besides the biological evolutionary process, studies have shown that environmental and social factors can influence the motor development. The aim of this study was to evaluate the motor skills of students participating in social educational projects, sports projects and those not engaged in structured extracurricular activities in Florianopolis-SC-Brazil. Were evaluated 136 children 8-9 years old, both sexes, from 40 public schools. For data collection was used the Motor Development Scale and a structured interview regarding the activities undertaken by the child during the period that they are not in school. Descriptive statistics, ANOVA and the Post-hoc test of Tukey were used to data analysis, with significance level $p < .05$. The results showed higher patterns of motor development in children that participating in social projects with sport character and expressive low coordination patterns in children who do not participate in structured activities or projects outside of school. N2 - Introduction: The metacognitive ability to accurately estimate one's performance in a test, is assumed to be of central importance for initializing task-oriented effort. In addition activating adequate problem-solving strategies, and engaging in efficient error detection and correction. Although school children's ability to estimate their own performance has been widely investigated, this was mostly done under highly-controlled, experimental set-ups including only one single test occasion. Method: The aim of this study was to investigate this metacognitive ability in the context of real achievement tests in mathematics. Developed and applied by a teacher of a 5th grade class over the course of a school year these tests allowed the exploration of the variability of performance estimation accuracy as a function of test difficulty. Results: Mean performance estimations were generally close to actual performance with somewhat less variability compared to test performance. When grouping the children into three achievement levels, results revealed higher accuracy of performance estimations in the high achievers compared to the low and average achievers. In order to explore the generalization of these findings, analyses were also conducted for the same children's tests in their science classes revealing a very similar pattern of results compared to the domain of mathematics. Discussion and Conclusion: By and large, the present study, in a natural environment, confirmed previous laboratory findings but also offered additional insights into the generalisation and the test dependency of students' performance estimations. N2 - The author examined the effects of small-group social skills instruction on the playground behaviors of three second-grade students with emerging emotional and behavior problems. Over the course of six weeks, students were taught three social skills lessons that corresponded to problematic behaviors observed on the playground. A multiple baseline design was used to determine the effect of social skills instruction on social behaviors observed on the playground. Teachers also completed a rating scale before and after the intervention to measure any changes in social skills in the classroom. Over the course of the intervention, students moderately increased their percentage of time spent socializing appropriately during recess, but results varied across participants. Mixed results were also found on the social skills rating scale across students. (PsycINFO Database Record (c) 2014 APA, all rights reserved)

N2 - The evidence concerning the relative importance of physical activity, restorative experiences, and social interaction as mediators between exposure to nature and well-being has been inconsistent. We investigated whether there is a relationship between the average time used for nature-based recreation and emotional well-being and whether it is mediated through restorative experiences, social company and the perceived duration of the most recent nature-based recreation visit. A sample of 3060 Finnish people (38.3% response rate) aged 15-74 years participated in a survey using an internet and a mail questionnaire. Multiple mediation analysis using bootstrapping revealed an association between the self-reported participation in nature-based recreation and emotional well-being through restorative experiences when adjusting for age, gender, household income, the level of leisure time physical activity, and the frequency of active transportation. The amount of social company or the duration of the most recent nature-based recreation visit did not mediate the association between the average time spent on nature-based recreation and emotional well-being. The result accords with the evidence of the restorative and well-being effects of nature exposure but more evidence of causality and studies comparing different mediators in different population groups are needed. N2 - Expertise in processing faces is a cornerstone of human social interaction. However, the developmental course of many key brain regions supporting face preferential processing in the human brain remains undefined. Here, we present findings from an fMRI study using a simple viewing paradigm of faces and objects in a continuous age sample covering the age range from 6 years through adulthood. These findings are the first to use such a sample paired with whole-brain fMRI analyses to investigate development within the core and extended face networks across the developmental spectrum from middle childhood to adulthood. We found evidence, albeit modest, for a developmental trend in the volume of the right fusiform face area (rFFA) but no developmental change in the intensity of activation. From a spatial perspective, the middle portion of the right fusiform gyrus most commonly found in adult studies of face processing was increasingly likely to be included in the FFA as age increased to adulthood. Outside of the FFA, the most striking finding was that children hyperactivated nearly every aspect of the extended face system relative to adults, including the amygdala, anterior temporal pole, insula, inferior frontal gyrus, anterior cingulate gyrus, and parietal cortex. Overall, the findings suggest that development is best characterized by increasing modulation of face-sensitive regions throughout the brain to engage only those systems necessary for task requirements. N2 - The present research sought to determine whether young female chess players would demonstrate stereotype threat susceptibility in a naturalistic environment. Data from 12 scholastic chess tournaments indicated that females performed worse than expected when playing against a male opponent, achieving 83% of the expected success based on their own and their opponent's pre-rating. These effects were strongest for the youngest players in lower elementary school but also present for those in upper elementary. Stereotype threat susceptibility was most pronounced in contexts that could be considered challenging: when playing a strong or

moderate opponent and when playing someone in a higher or the same grade. As evidence of disengagement, those most vulnerable to stereotype threat were less likely to continue playing in future chess tournaments. These results were not found in a matched comparison male group suggesting the outcomes were unique to stereotype threat and not universal to young chess players. N2 - Research Findings: The present study investigated whether active play during recess was associated with self-regulation and academic achievement in a prekindergarten sample. A total of 51 children in classes containing approximately half Head Start children were assessed on self-regulation, active play, and early academic achievement. Path analyses indicated that higher active play was associated with better self-regulation, which in turn was associated with higher scores on early reading and math assessments. Practice or Policy: Results point to the benefits of active play for promoting self-regulation and offer insight into possible interventions designed to promote self-regulation and academic achievement. N2 - Objective: To assess the association between the built environment and physical fitness and physical activity in adolescents. Methods: The study included 3528 adolescents, aged 12.5-17.5 years, who participated in the Healthy Lifestyle in Europe by Nutrition in Adolescence (HELENA) study. The health-related physical fitness components were assessed using the physical fitness tests. Participants wore a uniaxial accelerometer (ActiGraph) for 7 days to measure physical activity. A specific questionnaire addressing the built environment was used. Potential confounding factors including age, gender, body mass index, body composition, pubertal status, smoking, educational level of parents, and socioeconomic status were analyzed using backward stepwise linear regression analysis. Results: Heavy traffic in the neighborhood was the strongest factor negatively associated with both physical fitness and physical activity (both $P < 0.05$). Conversely, a secure bicycling or walking route from home to school was positively associated with various components of physical fitness and physical activity ($P < 0.01$). Outdoor fields and gymnasiums near home were also associated with better physical fitness ($P < 0.01$), but not with physical activity. Conclusions: A favorable built environment may contribute to health-related physical fitness and physical activity of adolescents and should be considered in future interventions and health promotion strategies. N2 - A family survey, ethnographic study, and quasi-experimental study investigated Shalom Sesame's potential to enhance understanding of Jewish culture and identity among preschool families. Preschoolers demonstrated significant learning, recognizing that people who looked different could be Jewish, and in knowledge about Hebrew words, Jewish holidays, and things they would see in Israel. Learning also extended beyond the screen, via spontaneous family discussions/activities, and an increased desire to celebrate holidays or visit Israel. The videos held particular value for interfaith families and those outside established Jewish communities. Parents valued Shalom Sesame for helping children connect to the broader Jewish community, deepening their own connection, and educating non-Jewish relatives and friends. N2 - The study examined the effects of rapport building (emotional, NICHD) and prompt type (what-next, cued-action, cued-emotion, what-think) on 142 4- to 9-year-old maltreated children's spontaneous and prompted emotional language. Children in the emotional rapport building condition narrated the last time they felt good and the last time they felt bad on the playground. Children in the NICHD rapport building condition narrated their last birthday party and what happened yesterday. Following rapport building, all children were presented a series of story stems about positive and negative situations. Emotional rapport building demonstrated some positive albeit temporary effects on children's use of emotional language. Cued-emotion prompts appeared to be the most productive in eliciting emotional language. Overall, there were few effects due to age. Children often produced less emotional language when describing negative events, particularly with respect to their spontaneous utterances, suggesting reluctance. These differences largely disappeared when children were asked additional questions, particularly cued-emotion questions. The results support the utility of emotional rapport building and cued-emotion prompts as a means of increasing children's use of emotional language. N2 - Drawing on data from one-on-one and focus group interviews with high school students from schools in agricultural California, this research examines how American families negotiate what we call net time. The article explores intra-familial bargaining over time spent on the internet. Analysis pays special attention to families that prioritize capital-enhancing activities such as schoolwork and college applications. In these families, access to resources is guided by implicit social contracts between parents and children, as well as between siblings. The findings illuminate how these social contracts imply particular rights and responsibilities depending on the families' level of wiredness: highly wired, partially wired, and unwired families. Comparing the experiences of students from these three groups reveals that members of each kind of family experience a different form of net time. While youths from highly wired families enjoy individualized net time, members of partially wired families divvy up household net time. The most disadvantaged youth come from unwired families in which family members must make sacrifices for youth to obtain net time outside of the household. The examination illuminates the logics that underpin the familial negotiations over each kind of net time. Ultimately, familial social contracts over net time have the power to encourage or hinder use of net time for capital-enhancing activities. N2 - This case study reports the use of eye movement desensitization and reprocessing (EMDR) and family therapy for a 10-year-old boy with severe separation anxiety disorder (SAD). It illustrates how the use of the standard EMDR protocol for the boy and his mother combined with family therapy, led to symptom alleviation and restored appropriate developmental functioning as evidenced by behavioral outcomes. The participant initially presented with severe anxiety about separating from his mother, several years after his parents went through a painful divorce. Treatment focused on processing the boy's disturbing memories of past nontraumatic events in 14 EMDR sessions; his mother received 4 EMDR sessions to address her perceived marital failure and guilt about the effects of her ensuing depression on him. Eight family therapy sessions were used to help the family spend positive time together. Prior to treatment, the child had been unable to play outside, checked on his mother frequently, and could not attend activities without her. At the end of treatment, he was able to play with friends outside, ride his bike around town, engage in after school activities, and sleep over at his friends' houses. Gains were maintained at 6-month follow-up. Treatment did not include instruction in parenting skills or psychoeducation for the mother, or any exposure therapy for the child. N2 - This multi-methods qualitative study aimed to identify environmental factors that influence physical activity participation among young people in Edinburgh, Scotland. School pupils (aged 11-13 years) took part using photography, computer blogs, maps and focus group discussions (FGDs). Eleven computer sessions (n = 131) and 14 FGDs (n = 63) took place. Factors influencing physical activity behaviour included proximity and access to local facilities, family and peers and the school physical activity environment. A variety of facilitators and barriers to participation were also reported. Most notable was the importance of cost and value for money when choosing physical activities which, although more evident among pupils attending schools in areas of low socio-economic status (SES), was relevant across all SES groups. Reporting easy access to sports facilities was more common among pupils attending schools from high/medium SES. Use of green-space for physical activity was reported among pupils from all schools, but was more common among those from low SES schools. Pupils were, in general, satisfied with the facilities available at school, but felt time for physical education could be increased. Findings may help inform interventions, aimed at promoting physical activity at local level.

N2 - The purposes of this naturalistic, descriptive study were to examine the stories that children in one first grade classroom told in a storytelling circle, how the children's knowledge, in-school experiences, and out-of-school experiences were reflected in their stories, and how the children used their knowledge and experiences as tools to make sense of the world through their stories. The study was designed as a naturalistic, descriptive study employing an interpretive approach to examining the children's oral stories. Nine first grade children in one classroom were grouped heterogeneously into three storytelling groups. Data collected from the three groups included a total of 80 story rounds, each of which included an oral story along with preceding and succeeding dialogue from other children and the researcher. The researcher employed participant observation and a discourse analytic method of inquiry to analyze the stories told by children in a storytelling circle. The children proved themselves to be active constructors and co-constructors of meaning who skillfully told their stories for the very authentic purposes of making sense for themselves and for others. The stories were structurally complex and interesting to tellers and listeners. The children flexibly coconstructed stories that included a wide variety of settings, episodes, and codas as well as complex plots that situated people, characters, objects, and actions across time and space in ways that suited the purposes of and were meaningful to the tellers and the listeners. The children also drew upon a wide range of everyday knowledge and experiences, especially from out of school, which they called upon as resources for the co-construction of the stories. They used language in flexible ways that appropriated combinations of genres which they were able to utilize effectively in ways that helped them to organize and relate their experiences through the stories. Listening to the children's stories proved to be an effective way to learn about the children's knowledge, rooted in their experiences both inside and outside of school. This approach broadens current conceptions of children as learners by focusing on their strengths and resources as starting points for teaching and learning. Nine story maps are attached in Appendices E, F, G, H, I, J, K, L, and M. (PsycINFO Database Record (c) 2014 APA, all rights reserved)

N2 - Background. Schools provide an important opportunity for children to meet physical activity guidelines. However, physical activity during school is low, and more evidence is needed to support schools to adopt best practices related to physical activity. Objective. The purpose of the present study was to investigate the relation of elementary school physical activity practices related to Physical Education (PE), recess, classroom time, and after-school time to school SES and children's objectively measured physical activity. Methods. Participants were 172 children from 97 elementary schools in the San Diego, CA and Seattle, WA regions. Children wore accelerometers to estimate physical activity for 3.7+1.7 school days. A survey was completed by school informants (PE teachers and principals) to assess physical activity-related school practices (63% response rate). Accelerometer data were scored based on individual school start and end times to derive in-school and after-school minutes/day of MVPA. ANOVAs with LSD post-hoc tests were used to investigate disparities in physical activity-related practices for low-, moderate-, and high-SES schools. Three-level linear mixed effects regression models were used to investigate the association between school practices and children's MVPA. The 5 most important practices, based on their relationship with in-school MVPA, were combined into a summary score. Results. The 5-item school physical activity practice summary score was significantly associated with in-school MVPA, where children had 2.4 more minutes/day of in-school MVPA for every additional practice reflected in the summary score ($p = .037$). Having a PE teacher was the strongest practice correlated with in-school MVPA, where children at schools with a PE teacher had 6 more minutes/day of in-school MVPA ($p = .114$). Having someone other than a classroom teacher supervise recess was non-significantly related to 3 more minutes/day of in-school MVPA ($p = .363$). Conclusions. The present study provides evidence for adopting a package of school physical activity practices to improve children's physical activity during school. Particularly, not having a PE teacher appears to be a leading contributor to low rates of physical activity. Attention should be paid to economically disadvantaged schools, because schools could be contributing to disparities in childhood obesity and inactivity. N2 - This study examines the psychometric properties and component structure of a newly developed observational system, the Aftercare and School Observation System (ASOS). Participants included 468 children drawn from a larger longitudinal intervention study. The system was utilized to assess participant children in school lunchrooms and recess and various afterschool environments. Exploratory factor analyses examined whether a core set of component constructs assessing qualities of children's relationships, caregiver involvement and monitoring, and experiences in school and aftercare contexts that have been linked to children's behavior problems would emerge. Construct validity was assessed by examining associations between ASOS constructs and questionnaire measures assessing children's behavior problems and relationship qualities in school and aftercare settings. Across both settings, two factors showed very similar empirical structures and item loadings, reflecting the constructs of a negative/aggressive context and caregiver positive involvement, with one additional unique factor from the school setting reflecting the extent to which caregiver methods used resulted in less negative behavior and two additional unique factors from the aftercare setting reflecting positivity in the child's interactions and general environment and negativity in the child's interactions and setting. Modest correlations between ASOS factors and aftercare provider and teacher ratings of behavior problems, adult-child relationships, and a rating of school climate contributed to our interpretation that the ASOS scores capture meaningful features of children's experiences in these settings. This study represents the first step of establishing that the ASOS reliably and validly captures risk and protective relationships and experiences in extrafamilial settings. N2 - This study examines schizophrenic children who received shock therapy and were given a battery of psychological tests both before and after the treatment. The battery consisted of an intelligence test, either the Stanford-Binet or the Bellevue-Wechsler Intelligence test, depending upon the age of the child and his previous psychometric history; educational tests; the drawing of a man; and the Rorschach. In many cases the Thematic Apperception test, the Vigotsky, a word association test, and play techniques were also used. It was felt that this battery covered those aspects of personality functioning which clinically appeared most affected by the disease process. The age range among the hundred or more children examined, was roughly from four to eleven years. On the basis of the test findings it appears that the schizophrenic child shows many of the personality attributes

found in other clinical groups as well as in normal children. However, the development of these attributes and the uses to which they are put are colored by his specific needs and problems. His behavior is an effort at finding equilibrium, at achieving some unity within himself, and between himself and the outside world. This whole question of anxiety, what is gained by keeping it mobilized or by relieving it, is a point which must be answered at this time with due consideration for the techniques available for treating childhood schizophrenia. N2 - This article presents a methodological approach to the evaluation of treatment in young nonverbal children. The evaluation of treatment is only part of a large project which aims to study the play patterns and ego functions of nonverbal schizophrenic and retarded children between the ages of four and six years. At the beginning of the project one of the main problems encountered was intake. During the terminal conferences, various post project dispositions of children were devised. They tended to fall into two main categories: those children who, in the opinion of the staff, would continue to benefit from living at home with the support of psychotherapy and those who should be hospitalized outside the home. The focus in this communication has been on rather gross time measures. In contrast, one might evaluate sequential changes at three-month intervals from our present data and, to take one additional step, monthly, even weekly observations, might be subjected to scrutiny. However, the yearly index changes provide an opportunity to map out directions of movement in areas or combinations of areas which have led, so one notes retrospectively, to a favorable or unfavorable course of treatment. The next goal in evaluating treatment would be to describe more continuously the behaviors of a child in a specific area or combination of areas in which change has occurred, to analyze again the procured data in terms of change patterns, to note focal points where the child appears to be in transition from one phase to another in the treatment process, and finally to describe the events preceding and following these nodal points. N2 - Background: Little research has examined the locations in which youth are victimized, particularly outside the school context. Further, it is not clear if the locations in which youth are victimized vary as a function of grade level or gender. Objective: The goals of the current study were to: (1) Determine the locations inside and outside of the school context in which elementary school students are most likely to report being victimized, and (2) Examine whether the locations in which victimization takes place varies by grade level and gender.

Methods: Associations were examined in a sample of 186 2nd thru 5th grade students (52 % male) who reported experiencing victimization. Results: The playground was the most common place in which victimization was reported, followed by home and the neighborhood. Boys were more likely than girls to report being victimized on the bus or during a sporting activity, while girls were more likely than boys to report being victimized at home. No grade level effects were found, suggesting that specific locations of victimization did not become more or less evident at older grade levels. Conclusions: Findings indicate that there are many locations inside and outside the school context that need to be further monitored for the prevention of victimization and that gender differences may need to be considered. N2 - This article presents a study in the form of an experiment in group psychotherapy with children. In these times when the large group is becoming more of a social necessity with the increased demand for day camps, nursery schools, and after-school playground supervision, the fate of these socially maladjusted children takes on emphatic significance. In an effort to find a solution for the problem this study was undertaken. An attempt was made to analyze the personal needs of a few of these group misfits and lead them into group living through the medium of a small controlled unit built up unobtrusively within the large group. While the present study was carried out under somewhat different conditions than have heretofore been reported, the principles upon which the group was formed and by which it was handled were similar to those laid down by these previous studies. Selection of members for group psychotherapy was made after the camp season had been under way for a week. Through observations made in the small group, the personal needs of each child became apparent and the interactions of the children studied. The group was under the quiet permissive control of an adult who accepted, with friendly emotional response, each child and his attitudes, and whom each child appeared to trust.

N2 - Networked learning is currently gaining more attention in the study of digital learning. Little attention has been paid to informal networks outside educational institutes. The current study contributes to this knowledge gap by researching the personal online networks of both immigrant and native youth in the Netherlands while focusing on how youth experience these networks in terms of learning. We mapped the online, personal networks of youth from various ethnic backgrounds and education levels living in the Netherlands. We investigated how these networks mediate learning according to participants' perspectives and whether all youth populations make equal use of their networks' learning potential. We applied an ego-network approach and collected information from 1227 participants (aged 12-18) regarding their online network contacts (e.g., age, gender, location) (in total 6135 contacts) and their interactions. Multilevel regression analyses were conducted respectively to measure the impact of individual and network-characteristics on network activities and to see whether network activities predicted perceived learning potential. The results support the relevance of a network perspective for the study of online learning. The divide between the variances of our two dependent variables - network activities and perceived learning potential- underpin that if we want to understand how young people

learn in digital environments, merely looking at the individual level is not enough. Furthermore, the study showed that dense networks, with similar others and strong bonds with online contacts were fostering the perceived learning in networks, although certain patterns also significantly differed per group. N2 - The main purpose of this research is to investigate the relationships between adolescents' Internet addiction, their perceived social support and the activities carried out with the mother, father and family. The study designed with the survey model involved 166 adolescents who applied to Merkez Efendi Public Hospital Moris Sinasi Children's Clinic, Child Development Polyclinic between February 2012 and June 2012 for problems specific to the period of adolescence. The age range of the participants was between 12 and 18 with the average age of 15.5. The findings of the study revealed a medium level of negative relationship ($r = -.37$) between perceived social support and Internet addiction. The adolescents spending time with their mothers had a higher level of perceived social support and a lower level of Internet addiction. Also, t-test was applied to see whether the adolescents' perceived social support and Internet addiction differed with respect to the activities they carried out with the mother, father and family. It was found out that a number of activities (watching TV, eating meals, chatting, shopping and spending time outside) the adolescents carried out with their mother increased their level of perceived social support although the levels of Internet addiction did not differ with respect to the types of activities carried out only with the mother, only with the father and with the family. N2 - Exercising in natural, green environments creates greater improvements in adult's self-esteem than exercise undertaken in urban or indoor settings. No comparable data are available for children. The aim of this study was to determine whether so called 'green exercise' affected changes in self-esteem; enjoyment and perceived exertion in children differently to urban exercise. We assessed cardiorespiratory fitness (20 m shuttle-run) and self-reported physical activity (PAQ-A) in 11 and 12 year olds (n = 75). Each pupil completed two 1.5 mile timed runs, one in an urban and another in a rural environment. Trials were completed one week apart during scheduled physical education lessons allocated using a repeated measures design. Self-esteem was measured before and after each trial, ratings of perceived exertion (RPE) and enjoyment were assessed after completing each trial. We found a significant main effect ($F(1,74) = 12.2, p < 0.001$), for the increase in self-esteem following exercise but there was no condition by exercise interaction ($F(1,74) = 0.13, p = 0.72$). There were no significant differences in perceived exertion or enjoyment between conditions. There was a negative correlation ($r = -0.26, p = 0.04$) between habitual physical activity and RPE during the control condition, which was not evident in the green exercise condition ($r = -0.07, p = 0.55$). Contrary to previous studies in adults, green exercise did not produce significantly greater increases in self-esteem than the urban exercise condition. Green exercise was enjoyed more equally by children with differing levels of habitual physical activity and has the potential to engage less active children in exercise. N2 - This small scale research project examines opportunities for creative thinking and imagination through den making in a rural private day nursery with its own woodland area on the borders of England and Wales in the UK. The research is underpinned by sociocultural theory and is an ethnographic study of non-participant observations of children aged between three and four years old and early years practitioners involved in supporting their play. The focus is on children's creative play in peer social groups and examines the way in which children explore their environment and utilise their play space and resources to sustain imagination and creativity. The research considers how the environment and den-making context provides opportunities for possibility thinking [Craft, A. (2001). Little c creativity. In A. Craft, B. Jeffrey, & M. Liebling (Eds.), *Creativity in education* (pp. 45-61). London: Continuum], where children are encouraged to explore 'what if?' questions. The research explores the way in which an outdoor environment can support flexible opportunities and resources where children are able to engage in imaginative and creative play, develop their communication skills and build relationships with other children and adults. The research considers children's fascination with the story 'bears in the wood' and how early years practitioners facilitated their creative thinking and imagination. N2 - Background: Developmental disorders of language and communication present considerable diagnostic challenges due to overlapping of symptomatology and uncertain aetiology. We aimed to further elucidate the behavioural and linguistic profile associated with impairments of social communication occurring outside of an autism diagnosis. Methods: Six to eleven year olds diagnosed with pragmatic language impairment (PLI), high functioning autism (HFA) or specific language impairment (SLI) were compared on measures of social interaction with peers (PI), restricted and repetitive behaviours/interests (RRBIs) and language ability. Odds ratios (OR) from a multinomial logistic regression were used to determine the importance of each measure to diagnostic grouping. MANOVA was used to investigate differences in subscale scores for the PI measure. Results: Greater degrees of PI difficulties (OR = 1.22, 95% CI = 1.05-1.41), RRBI (OR = 1.23, 95% CI = 1.06-1.42) and expressive language ability (OR = 1.16, 95% CI = 1.03-1.30) discriminated HFA from PLI. PLI was differentiated from SLI by elevated PI difficulties (OR = 0.82, 95% CI = 0.70-0.96) and higher expressive language ability (OR = 0.88, 95% CI = 0.77-0.98), but indistinguishable from SLI using RRBI (OR = 1.01, 95%

CI=0.94-1.09). A significant effect of group on PI subscales was observed ($\eta^2 = 1.38$, $F(4, 56) = 19.26$, $p < .01$) and PLI and HFA groups shared a similar PI subscale profile. Conclusions: Results provide empirical support for a conceptualisation of PLI as a developmental impairment distinguishable from HFA by absence of RRBIs and by the presence of expressive language difficulties. PI difficulties appear elevated in PLI compared with SLI, but may be less pervasive than in HFA. Findings are discussed with reference to the proposed new category of 'social communication disorder' in DSM-5. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) Each man learns early in life that some day he must die. What role does this information play in his development? How does it affect his aims, his wishes, his behavior? At the present time our best sources of information on these questions are outside the field of psychology-in literature, philosophy, religion, and medicine. While such sources have yielded rich insights about the meaning that death has for human beings, there has been little attempt to apply scientific procedures to select among these ideas. Perhaps it is time for this further step to be taken. It is the purpose of this chapter to describe some primitive attempts, utilizing the more traditional techniques and methods of our science, to study some aspects of man's reaction to death. First let us glance briefly at the state of our knowledge about death as it exists in the psychological literature. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - The exit plans of 1,632 students from 15 states attending 92 approved, out-of-district special education programs in the private sector were studied, via a survey instrument, including programs for medical disorders, pervasive developmental and/or communication disorders, and emotional and behavioral disorders. Results indicate that students from programs for medical and pervasive developmental/communication disorders were likely to plan transfers to self-contained programs within their districts, whereas students from emotional/behavioral disorders programs tended to plan transfers to other approved, private programs outside their districts. Among the graduates/aged-out students, those leaving medical and emotional/behavioral disorders programs were likely to plan pursuit of mainstream postschool activities, whereas those from pervasive developmental/communication disorders programs tended to make postschool plans to enter vocational rehabilitation programs. Follow-up studies are needed to determine the degree to which these plans were actually carried out over time. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

N2 - Objective: The primary objective of this study was to evaluate the feasibility and preliminary efficacy of a school-based physical fitness intervention (Fit4Fun) on the physical fitness and physical activity (PA) levels of primary school children. Methods: A group-randomized controlled trial with a 3-month wait-list control group was conducted in two primary schools in the Hunter Region, NSW, Australia. Participants (n = 48 students; mean age = 10.9 years + 0.7) were randomized by the schools into the Fit4Fun intervention (n = 32 students) or the control (n = 17) conditions. Fit4Fun was an 8-week programme that included: 8 x 60 min health and physical education (HPE) lessons, a break-time activity programme (recess and lunch) and a home fitness programme. The control group participated in their usual weekly 60 min HPE lessons. Assessments were taken at baseline and post-intervention (8-week) to determine changes in health-related fitness (HRF) levels, PA and attitudes towards HRF testing. Objectively measured PA (mean steps/day) was assessed using 7 days of

pedometry and HRF was assessed using a battery of tests including: seven-stage sit-up test, push-up test, basketball throw, wall squat, sit and reach, shoulder stretch, 20 m shuttle test, and height and weight measurements. A questionnaire was also administered to assess perceptions of physical fitness and physical fitness testing and changes in attitudes to fitness testing. Intervention effects were assessed using analysis of covariance and Cohen's *d* effect sizes are reported. Results: Children in the intervention group improved in all HRF measures with significant group \times time effects ($p < 0.05$) observed in the seven-stage sit-up test ($d = 0.9$), the sit and reach tests (right leg $d = 1.0$, left leg $d = 0.9$, both legs $d = 1.1$) and the wall squat tests (right leg $d = 0.9$, left leg $d = 0.6$). No significant group \times time effect was found in the beep test, basketball throw, PA measure or psychological measures. The control group did not display significant within-group effects for any measure. Conclusions: Results indicate that a multi-component HRF intervention for primary school children that targeted the three areas of a health-promoting school and incorporated social support for participation in physical fitness activities was feasible and efficacious in improving muscular fitness and flexibility levels of children. N2 - This study examined play and learning in the natural environment and on the playgrounds of Slovene preschools. It included 140 preschool teachers and 264 parents of children who attended preschools in 21 Slovene towns. Data were collected through questionnaires with questions referring to time spent outdoors, children's outdoor activities, barriers to outdoor play and learning, opinions regarding safety as well as parents' perspectives of outdoor play and learning. The results show that, on average, Slovene children spend 23% of their time at preschool outdoors during the warm months and 13% during the cold months, of which they generally spend three hours per week in the natural environment during the warm months and 1.5 hours during the cold. Answers to the question about children's activities in nature and on the playground indicate that the potentials offered by the outdoor environment are not effectively used. Parents' opinions show a positive attitude towards outdoor play and learning. The majority of both parents and preschool teachers thus share the opinion that Slovene preschools should dedicate more attention and time to play and learning in the natural environment. N2 - This study examines media narratives of high-level amateur and professional hockey in Canada during the late nineteenth and early twentieth centuries. In particular, this project analyzes English Canadian newspaper coverage of Stanley Cup "challenge" games and championship series between 1894 and 1907. It assesses local and national newspaper reporting on hockey, as well as the telegraph reconstructions that enabled fans to share a simultaneous experience of distant games. Early Stanley Cup matches are valuable case studies for examining the cultural meanings of hockey in Canada. Media reports and experiences of hockey brought Canadians into local and national communities of interest, while constructing narratives of regional identity, civic boosterism, and community rivalry. Press coverage and telegraph re-enactments of Stanley Cup challenges contributed significantly to the growth of a mediated Canadian "hockey world"-and a broader "world of sport"-during this time period. By 1903, Stanley Cup hockey games had become "national" Canadian events, followed by audiences across the country. Hockey also played an important role in the construction of gender and class identities, and in debates about amateurism, professionalism, and community representation in sport. By examining media descriptions of "brutal" and "strenuous" play, this study explores the connections between violence and manhood in Canadian hockey. Narratives of robust and hard-hitting hockey expressed both ideals of respectable, middle-class masculinity and characteristics of rough, working-class masculinity. In addition, this project analyzes how notions of civic identity changed as hockey clubs evolved from amateur teams represented by players who were "members" of their home community to professional aggregations that included paid imports from outside the town. A growing emphasis on securing the professional athletes that could ensure victory led to praise for a team's efforts to please its supporters, or "customers." By investigating key issues related to media, gender, and community identities in early hockey, this research addresses important gaps in the study of sport history and the analysis of sport and Canadian popular culture. More specifically, this thesis answers the need for careful, scholarly examinations of the cultural narratives attached to Canadian hockey-and the development of the Canadian sports media-in a historical context. N2 - This study examined an effort to improve peer engagement at elementary school for children with an autism spectrum disorder (ASD). Using a wait-list-controlled design, a manualized psychosocial intervention called Engage was delivered to children with ASD during lunchtime and recess. The initial treatment (IT) group consisted of seven (one female) elementary school students with autism and the wait-list (WL) group contained three (one female) children with ASD. The naturalistic intervention aimed to 1) reduce alone time and increase engagement with peers, 2) increase initiations and responses to peers, 3) activate school staff to facilitate peer engagement for children, and 4) demonstrate that children receiving the Engage intervention perceive more peer engagement and rate their overall lunchtime and recess experience higher than the children in the WL condition. Analyses revealed that the proportion of alone or unengaged time was significantly reduced for the IT group. While time spent engaged was not significantly increased for the IT group at exit, there was a significant treatment effect at midpoint. Child initiations and responses to peers were also significantly increased at midpoint but not at exit. School staff at the site where the initial treatment was delivered showed increased responsive and strategic behaviors around participants at lunch and recess compared to staff at the WL school. Lastly, children receiving the intervention reported playing with more peers and having an overall better lunch and recess experience than those in the wait-list group. N2 - Background: An estimated 4.4 million children in the United States suffer from Attention Deficit/Hyperactivity Disorder (ADHD), and most would benefit from a low-cost, side-effect-free way of managing their symptoms. Previous research suggests that after isolated exposures to greenspace, children's ADHD symptoms are reduced. This study examined whether routine exposures to greenspace, experienced through children's everyday play settings, might yield ongoing reductions in ADHD symptoms. Methods: Data on 421 children's ADHD symptoms and usual play settings were collected using a national Internet-based survey of parents. Results: Findings suggest that everyday play settings make a difference in overall symptom severity in children with ADHD. Specifically, children with ADHD who play regularly in green play settings have milder symptoms than children who play in built outdoor and indoor settings. This is true for all income groups and for both boys and girls. Interestingly, for hyperactive children, the apparent advantage of green spaces is true only for relatively open green settings. Conclusions: These and previous findings collectively suggest that it is time for randomized clinical trials testing the impacts of regular exposure to greenspace as a treatment for ADHD. N2 - Increasingly more gay men are becoming parents or desire to become parents. Families headed by openly gay fathers live in environments that are still largely homophobic and heterosexist. This study describes the challenges, opportunities, and rewards gay adoptive fathers experience at home and in their communities. In-depth phenomenological interviews were conducted with gay adoptive fathers from 20 families (18 gay couples and 2 single gay men). Fathers adopted children through both domestic and international routes. The children of the fathers ranged in age from 9 months to 22 years. Using a social constructionist lens and descriptive phenomenological analysis, themes within each interview and across interviews were identified. The men in this study became parents in a society dominated by the beliefs that all children need a female mother, gay men cannot and should not be parents, and homosexuality is morally wrong. Their parenting stories illuminate social landscapes dotted with evolving attitudes towards gay parenting, structural inequities against LGBT communities, and entrenched beliefs about gender, sexuality and family. While some fathers worked with adoption professionals who challenged these attitudes and advocated for same sex parenting, many fathers regularly encountered heteronormative biases in the adoption system. When asked what it was like to parent as gay men, fathers explained that in many respects their day to day experiences were very similar to those of heterosexual parents, and particularly to other adoptive parents. At the same time, they often faced reminders at home and in public spaces that they were not part of a heterosexual order. From sidewalk to airport, hospital to playground, classroom to cafe, gay fathers and their families drew attention. Fathers regularly encountered questions and comments about the nature of their family. They had to decide if and how to explain themselves or correct others' assumptions, while modeling honesty and pride about their families to their children. Research on families headed by same sex parents has largely focused on the "impacts" gay and lesbian parents have on children's social, emotional and psychological adjustment and the degree to which their families are similar to

families with heterosexual parents. The stories shared in this study move beyond such questions and dive into the heart of being with difference and the meanings difference has for gay fathers, their children and those around them. The fathers provide a vivid picture of their emotional bonds with their children and the strengths and resiliencies they and their children develop living in environments that are largely homophobic and heterosexist. With the information provided by this dissertation, practitioners can challenge heteronormative biases in social work practice, education, and public policy. By revealing the insidious ways heteronormativity "shows up", the results prompt social workers to investigate their beliefs about gay male sexuality and intimacy, the primacy of the heterosexual nuclear family, and conventional notions that a child needs both a female mother and a male father. The father's experiences raise provocative practice questions about nurturing and child rearing. The stories urge practitioners to investigate complex and taken for granted notions about gender and parenthood, and help them engage more sensitively with families headed by same sex parents. N2 - This paper takes its departure in a nation-wide program for redesigning school-yards and public spaces to stimulate self-organized physical activity among children and teenagers in Sweden. The purpose of the study was to explore if and how a redesigned schoolyard can promote physical activity among the pupils at the school during the school day. Findings are based on data from 29 interviews, 948 questionnaires and 9 observations at a secondary school in a city in the north of Sweden before and after the renovation of the schoolyard. Results show how the facilities attract first and most already physically active pupils with the less active as spectators. Norms and unspoken rules for usage are established to the benefit of the already physically active, boys and older pupils. This phenomenon is further strengthened by the actual design of the facilities which favors previous experience in sport at the expense of the less experienced. The overall conclusion is that the chances of reaching inactive children and teenagers with this kind of intervention are small. N2 - Obesity is a worldwide problem occurring at earlier and earlier ages. Although obesity is a complex problem with multiple contributing factors, one potential component that may be relatively easy for educators to impact is the amount of physical activity children engage in during the school day. Currently, studies show that many preschool-aged children with and without disabilities are not reaching the recommended daily guidelines for physical activity. This study investigated two ways to increase physical activity during recess for 15 preschoolers - 8 with disabilities, 7 without - using an alternating treatment design. Effects of teacher directed activities and increased presence of playground materials on physical activity levels were evaluated using an Actigraph accelerometer and observational data was recorded using a modified version of the Observational System for Recording Activity in Children - Preschool Version (OSRAC-P). Results showed that both interventions were effective in increasing moderate to vigorous (MVPA) physical and decreasing sedentary activity for most participants. Individual results as well as group comparisons are discussed. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - More adolescents are surviving cancer and being treated outside the hospital-setting, allowing them to return to typical activities of development like attending school. Effective preparation for school re-entry is an important aspect of easing the transition back-to-school following a cancer diagnosis. Previous research has used the terms school re-entry, school re-entry preparation, and school reintegration interchangeably. For the purposes of the current study, school re-entry refers to going back-to-school. School re-entry preparation or

interventions refers to the preparatory process implemented for the initial return to school following a cancer diagnosis. Conversely, school reintegration refers to the ongoing or long-term adjustment of the child or adolescent with cancer to the school environment. Research in school re-entry preparation began in the late 1970s, but much is still not well understood about appropriate school re-entry preparation in terms of application, outcome, or the adolescent's needs. The adolescent with cancer's perspective has been grossly neglected in research. Furthermore, current research lacks an operational definition of "successful school re-entry" and knowledge of specific factors associated with positive school re-entry outcomes. Identifying variables that positively impact the school re-entry process is critical to improving and individualizing school re-entry interventions. The current study used an adaption of the Disability-Stress Coping Model (DSC; Wallander & Varni, 1998) to both define school re-entry success and identify potential predictors that may impact school re-entry success. In addition, to obtain a more comprehensive picture of re-entry success, adolescents with cancer rated the success of their back-to-school experiences. The current study asked 85 adolescents with cancer (ages 11 - 19 years) to complete a web-based survey asking about their re-entry experiences and daily functioning. Results provided tentative support for a discrepancy between professional and adolescent re-entry needs/goals. Findings suggest that a subset of adolescents with cancer may be at risk for poor school re-entry/reintegration outcomes, including females, being of lower SES, having certain types of cancer (brain tumors, leukemia), undergoing specific treatments (radiation, chemotherapy), being out of school for longer periods of time, having pre-morbid academic difficulties, and/or having poor social support. Adolescents who demonstrate these risk factors may warrant increased, specialized attention when preparing to return to school. In addition to systemic and within-person factors from the adapted DSC model, findings suggest that developmental characteristics of adolescence must be considered in planning re-entry intervention. Appropriate modifications to school re-entry preparation for adolescents may include utilizing electronic and social media, implementing peer mentors, focusing on reinforcing appropriate social circles, and emphasizing autonomy. More research is needed to understand how to best assist the adolescent with cancer in returning to school. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - The authors describe an observational and analytic methodology for recording and interpreting dynamic microprocesses that occur during social interaction, making use of space-time data collection techniques,

spatial-statistical analysis, and visualization. The scheme has three investigative foci: Structure, Activity Composition, and Clustering. In each case, these are associated with either acquiring resources or using socioenvironmental features to influence social intercourse. For each point of focus, the authors provide an analytic strategy and demonstration of its usefulness, using data generated from a 2.5-year observational study of young children's play behavior. Each tool, and its associated concepts, is used to illustrate how early socializing behavior is embedded in time and space. The results show that geography is a significant catalyst for social dynamics in young children: It provides the opportunity for novel interpretations of sociality along with a better understanding of the influence that geographical factors (location, space, place, spatial structure, spatial composition, landmarks, site) have on the evolving reciprocal interplay between individuals and groups. N2 - School bullying is a source of growing concern. A number of intervention programs emphasize the importance of a positive school climate in preventing bullying behavior. The aim of the presented pilot study was to examine whether calming background music, through its effect on arousal and mood, could create a pleasant atmosphere and reduce bullying occurrence. On the first week, 56 sixth-grade students from two classes completed a bullying and arousal questionnaire after the big recess on three consecutive days, as a baseline measurement. On the second week, calming background music was played during the big recess on three consecutive days and children completed the same questionnaires. On the final week, music was removed and participants completed the questionnaires again on three consecutive days. Results showed significantly reduced bullying occurrence, lower arousal levels, and higher enjoyment of recess when music was played. Bullying occurrence increased on the third week, though it remained lower than on the first week. Arousal levels returned to baseline level once music was removed. Results suggest calming background music may be used in combination with other intervention actions to create a positive school atmosphere and reduce aggressive behavior. N2 - The purpose of the present study was to investigate how early childhood teachers working in Head Start programs made meaning of preschool-age children's physical activity play by exploring their personal childhood and professional experiences with physical activity play. The study was conducted to contribute research-based recommendations for promoting evidence-based practices in young children's physical activity play at inclusive preschools serving diverse children and families. Thirteen early childhood educators from Head Start centers serving children who are ability, culturally, linguistically, and socioeconomically diverse in the greater Washington D.C. area participated in the phenomenological investigation. Data was collected via an in-depth phenomenological interview and two questionnaires. Findings provide research-based evidence that teachers' beliefs about physical activity play influence their practices and may be an important factor impacting the implementation of evidence-based practices in young children's physical activity play at preschool. Teachers' beliefs about the following factors influenced their professional practices related to physical activity play: disability, parents'/caregivers' responsibilities, the teacher's role during outdoor recess, interactions with siblings and peers, administrative policies, practices, and expectations, SES, gender, and the changing culture of childhood. Findings inform the design and delivery of effective professional development initiatives, as well as evidence-based recommendations for professional organizations for evidence-based practices for promoting preschoolers' physical activity play. N2 - Few studies have documented the literacy activities in an after-school setting of affluent early adolescents assigned to remedial reading. This may be because these students are not considered to be at risk of academic failure. The out-of-school literacy activities of 3 sixth-grade students were examined in this qualitative research. Multiple data sources included observations, interviews, detailed field notes, audio and video tapes, and literacy

samples. They were analyzed using grounded theory methods for coding data as well as a priori coding. From the data analysis 4 hypotheses were generated: (a) in addition to staying connected to their peers, participants were using social networking to support their academic work; (b) the participants demonstrated more skills and competencies in their out-of-school literacy practices than standardized tests measure; (c) the participants engaged in personally relevant literacy activities outside of school in which they have a high level of self-efficacy; and (d) participants were creating as well as seeking distractions at different times during the study. The participants each presented a unique literacy profile. John demonstrated an ability to locate different forms of media and combining them (Video and Music). However, his visually sophisticated presentations camouflaged his lack of understanding. He has a high level of self-efficacy as a video game player but those skills are not valued in the school setting. John needs support to further develop his skills and competencies particularly for academic contexts. Sally demonstrated a thorough understanding of concepts. She utilized different sources of information for her project. She persevered when encountering difficulties in school related tasks. The study revealed a discrepancy between her test scores and her skills and competencies. Amanda demonstrated an ability to create multimedia presentations. She has a negative perception of herself as a learner. However, she appears to have a high level of self-efficacy related to technology and computers. She is aware of her challenges and seeks assistance. An awareness of the participants' unique literacy profiles outside of school will work towards expanding our understanding them as learners. N2 - Depressive symptoms are considered to have evolutionary social functions to reduce social risks with peers and family members. However, social processes and their relationship to depressive symptoms have been understudied in adolescent boys. Low engagement in social contexts may predict depressive symptoms in adolescent boys, as it may signify efforts to reduce social risks. To address these issues, this study focused on 160 boys at risk for affective problems based on low socioeconomic status. We evaluated how behavioral and physiological engagement in peer and family contexts, respectively, in late childhood predicted depressive symptoms at age 12 and age 15. Social withdrawal was measured across late childhood (ages 9-12) in a camp setting using a latent variable of teacher ratings of withdrawn behavior, peer nominations of withdrawn behavior, and camp counselor ratings of withdrawn behavior. Physiological reactivity was measured during a provocative parent-child conversation using respiratory sinus arrhythmia (RSA) at age 12. Social withdrawal in

late childhood predicted depressive symptoms at age 12. The combination of high levels of social withdrawal with peers from ages 9-12 and low RSA reactivity with a parent at age 12 predicted higher depressive symptoms at age 15. Withdrawal in multiple social contexts may place boys at risk for depressive symptoms during the vulnerable period of adolescence. N2 - The current study investigated the effectiveness of an evidenced-based social skills program, the Superheroes Social Skills program to determine its effectiveness with children who have autism spectrum disorders (ASD) and have been identified by teachers or parents as being highly bullied at school. Three participants with ASD, between the ages of 6 and 10, received social skills instruction using the Superheroes Social Skills program. Along with the social skills lessons, Superheroes Social Skills includes lessons that specifically address bullying. All participants received instruction three times a week for 12 weeks. There were also eight normally developing students who attended the lessons and served as peer models. Generalization probes of social interaction during free play periods, in both a research and naturalistic setting, were conducted for each participant in order to determine treatment efficacy. After the implementation of the program, effect sizes (ES), Percentage of All Non-Overlapping Data (PAND), and Percentage of Non-Overlapping Data (PND) were calculated to examine differences in the amount of social interaction during the free play periods. The average total social engagement score for the participants showed a moderate ES using PAND (ES=0.34) and the No Assumptions method (ES=0.42). In the naturalistic setting, which was the playground at recess, large ES were found using PAND (ES=0.92) and the No Assumptions method (ES=0.85). In order to assess the program's impact on the victim's response to bullying, the participants with ASD engaged in bullying role-play scenarios during the intervention. The victim's behavioral responses were coded to determine if any changes were made. Increases in appropriate responding to bullying and the use of appropriate body language were observed across participants. Along with the observational data, the participants' responses on pre- and postmeasures of social responsiveness and victimization were compared. The results of the study suggest increases in social skills and decreases in reports of being a victim of bullying. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - There were two purposes of this descriptive research design. The first purpose of the study was to investigate family literacy activities with preschool-aged children and parental expectations of their children's development and future school success as reported by Asian immigrant families. The second purpose was to observe the interactive reading behaviors of parents and their preschool-aged children. The online Family Literacy Activities Survey (Payne, Whitehurst, & Angell, 1994) and the Adult-Child Interactive Reading Inventory (DeBruin-Parecki, 2007) were employed for data collection. The survey data was coded and analyzed by using the SPSS 19.0 for Windows. Correlations were calculated to determine the relationships between parental reading behavior categories and child behavior categories. In all, 265 respondents took the Family Literacy Online survey and 25 parent-child dyads voluntarily participated in the video recorded observation of interactive reading sessions. The findings revealed that more than half of the parents were not having any reading difficulty when they were in school. Parents reported that they spent time outside home an average of 3-5 hours a day, and they hardly ever went to the library with their preschool aged child. Parents themselves spent from one to three hours watching television per day, and they allowed their preschool aged children to watch television one to three hours daily. Regarding family reading activities, almost fifty percent of the parents reported that they owned approximately 11-20 picture books. The parents reported that they or another family member began to read to the preschooler at 7-12 months on average. One hundred thirty-seven (52.1%) of the respondents reported that their children requested a parent to read with them "once or twice a month," While one hundred thirty-seven of the parents reported that their children looked at books by themselves once or twice a month. When the preschool aged child was read, more than half of parents responded that their children genuinely liked it. Concerning parental expectations for their children's development, and future school successes, the findings reveal that teacher, school, parent, and child equally share responsibility for the preschooler's development in different aspects including health, school success, social skills, and acquiring reading ability. However, in all of these aspects of development, teachers have a slightly larger share of the overall responsibility except in the area of increasing vocabulary. Parent and child behaviors evident in video recordings of shared reading sessions provided findings that revealed for both adults and children, as measured by the Adult-Child Interactive Reading Inventory (ACIRI), the highest means scores were in the category "Enhancing Attention to Text", while the lowest mean scores were in the category "Using Literacy Strategies". In terms of the relationships between parental reading behavior categories and child behavior categories, the findings demonstrated that the relationships between parental reading behavior categories and child behavior categories were found to be significantly correlated in a positive manner. The results of the study will potentially benefit parents, children, and families by providing child development specialists and early childhood educators with information about the home literacy environments and literacy support activities of Asian immigrant families. N2 - This study examined the relationship between fifth-grade students' out-of-school reading habits and measures of their reading comprehension and writing abilities. The sample was composed of forty-two students attending an urban school in Northeastern Massachusetts. Each morning, for fifteen consecutive weeks, students recorded an approximation of the number of minutes they spent on designated out-of-school activities for the previous evening. The total amount of minutes they spent reading was recorded on an evening activity-log and the mean amount of nightly reading volume, per student, was calculated. Student reading comprehension ability was measured by percentile scores on two standardized reading assessments. Students produced written responses in a weekly journal, and these were analyzed by way of two qualitative writing rubrics. A Least Squares Regression model was adopted for the analysis of outcome variables. The regression mode is explicitly sought to investigate Stanovich's Matthew effects theory (2000), where student reading volume operated as the predictor variable. Results confirmed the study's research hypothesis. Student reading volume provided a correlation coefficient of $r=.37$ for reading comprehension and $r=.61$ for writing achievement. Moreover, all regression model results proved to be significant at a $p=.05$ level. Student reading volume proved to be a significant predictor for both reading and writing outcomes. The findings of this study support the overarching argument of the Matthew effects theory. Students who read a great deal outperformed their peers on measures of both reading comprehension and writing ability. This is because the increased amount of print exposure they experienced resulted in an expansion of their cognitive and linguistic knowledge base. In turn, this increased knowledge base reciprocally affected literacy outcomes. The educational implications of the study are that classroom practices which encourage student reading habits, both inside and outside of the classroom, are critical for all aspects of student literacy development. N2 - Introduction: Learning difficulties at school are characterized by complex causes and serious consequences both socially and psychologically. Various studies have established the link between learning difficulties and low self-esteem [3-7] as well as their fundamental role in determining the pupil's future and their daily experiences. However, some research has also shown that children with learning difficulties often have other emotional problems, notably higher anxiety and depression scores [9-13], which raises the question of the specific role of self-esteem. The objective of this article is to examine the potentially independent role of these psychological variables (self-esteem, anxiety and depression) and their distinct impact on the daily life of pupils with learning difficulties. Method: Participants: two groups of sixth grade pupils were selected based on their results in national tests in French and Math according to their rate of correct responses in the two subjects (TRC2 M): one group of students "highest school performance" (TRC2M > 80%) and the other "poorest school performance" (TRC2M < 50%). These pupils were chosen from ten randomly selected middle schools in the Gironde: "normal" middle schools (n = 5) or middle schools in educational priority zones ("ZEP"; n = 5). In total, 128 adolescents in sixth grade (55% girls) took part and the average age was 11.44 (SD = .62). Sixty-six of these pupils were doing well and 62 were struggling. Procedure: using the Experience Sampling Method (ESM), the participants were equipped with a PSION REVO palmtop computer for a period of 7 consecutive days.

Every time the integrated computer alarm emitted a beep, pupils were invited to respond to a series of questions on the screen. These alarms sounded outside school hours and the pupils were questioned about their physical and social environments, their activities and their moods in their daily lives. Alongside this method, pupils had to respond to clinical questionnaires measuring anxiety, depression, self-esteem, and also provide sociodemographic information. The data was analyzed with the help of multilevel models to examine the role of individual differences concerning self-esteem, anxiety and depression on intra-individual variables, such as emotional states, perceived impact of events and emotional reactivity to stress. Results: Children with learning difficulties had lower self-esteem and greater anxiety or depressive symptomatology than students who were doing well. However, with the ESM method, the results showed that self-esteem was not significantly associated with anxious or depressive moods, or with the perceived impact of negative events. In contrast, the level of anxiety and clinical depression was associated with higher daily levels of anxious or depressive affect, even with a higher perceived impact of daily events. Discussion: Thanks to the ESM method, the independent relationships linking self-esteem, anxiety and depression in the pupil's daily life were analyzed. Contrary to what was observed with the anxiety trait and depression, self-esteem was not significantly associated with negative affect in daily life, with perceived impact of events or with emotional reactivity. These results are useful in the prevention or appropriate treatment as they suggest that distinctive strategies are necessary to improve low self-esteem in relation to other emotional problems in this population. To identify possible therapeutic targets, future studies could examine the links between self-esteem and other aspects of daily life, such as positive emotions, social interactions, or other variables not examined in the current study. N2 - Aims: The purpose of this study is to assess the relationships between trips in nature, gathering of wild plants, fishing and hunting and weight status. Methods: Data from a cross-sectional questionnaire survey of 996 parents of sixth- and seventh-graders from 38 randomly chosen schools in two Norwegian counties. All data are self-reported: Weight and height (participants were considered as overweight if BMI were 25 or higher), family trips in nature (dichotomized into >once a week vs. less than once a week), gathering of wild plants/mushrooms, fishing and hunting (all dichotomized into >sometimes vs. never), sex, family education level and general physical activity level. Multivariate logistic regression analyses were performed with overweight as the dependent variable Results: Adjusting for all outdoor activities; those engaging in nature trips (OR = 0.52; 95% CI = 0.37-0.75) and those engaging in gathering (OR = 0.73; 95% CI = 0.55-0.98) were less frequently overweight, while those fishing (OR = 1.83; 95% CI = 1.35-2.47) were more frequently overweight. After also adjusting for sex, family education level and general physical activity level, nature trips (OR = 0.52; 95% CI = 0.36-0.75) and fishing (OR = 1.53; 95% CI = 1.12-2.10) were still significant, gathering was not. No association between hunting and weight status was observed. Conclusion: Frequent family trips in nature might be an important behaviour in order to reverse the obesity epidemic. N2 - The present study examined effectiveness of a training program for the transition from kindergarten to elementary school by children with developmental disabilities. The purpose of the training program was to teach the children skills needed in order to participate in classes in elementary school. Participants were 5 senior kindergarten students with developmental disabilities. The 4-session training program was conducted in the elementary school that the participants would be entering. In the first session, the children introduced themselves and did exercises, such as with a trampoline and balance beam. The second session consisted of activities such as how to use the nurse's office and the lunch room. The third session consisted of arts and crafts, and the fourth, of language training and stacking blocks. In addition, all sessions included practice on greetings for the start of the class, recess, and free time, including greetings when entering the classroom, greetings at the start of class, raising one's hand for permission to ask a question, watching the presenter, and standing in line. Children who performed a target behavior correctly were praised; if they did not practice the target behavior, the trainer prompted them to do so. The children's target behaviors were evaluated through video recordings of the children and from questionnaires completed by the trainers. In addition, after the children had entered elementary school, their behavior was assessed there. The assessments indicated that after the training, all the children had acquired most of the target behaviors, and did them even after the end of the training program. The present results suggest that the training program was effective in assisting these children in the transition from kindergarten to elementary school. N2 - Following a bioecological framework, this dissertation closely examines the prevalence, predictors, and associated outcomes of self care (unsupervised time outside of school). The dissertation utilizes the nationally representative Panel Study of Income Dynamics Child Development Supplement (N=2,570, ages 5-18) and the longitudinal NICHD Study of Early Child Care (N = 959, ages 8-10), two large-scale national datasets that offer

detailed time-diary information as to child and adolescent activities and supervision. Both variable- and pattern-based approaches were used to create self-care types based on three contextual features (i.e., supervision, location, and the presence of peers during self care) in order to elucidate: (A) factors that predict the use of child and adolescent self care, and (B) the circumstances under which child and adolescent self care are associated with study outcomes. Overall results suggest that self care is (1) a common context for children and adolescents, (2) that the type of self care utilized differs according to several characteristics (e.g., amount of time in self care, child age, family income-to-needs, and neighborhood poverty), and (3) that associated outcomes of self care differ by self care contextual features. More specifically, the location of and peer association during self care are associated with several study outcomes, including higher externalizing behavior (adolescents but not for younger groups), lower well-being, and higher body mass index. Relations between self care and academic outcomes were not statistically significant. (PsycINFO Database Record (c) 2013 APA, all rights reserved) SN - 0419-4217

N2 - This paper presents the psychometric properties of the MoMo-AFB (Bos, Worth, Opper, Oberger & Woll, 2009), a questionnaire designed to measure the physical activity of children and adolescents. The MoMo-AFB consists of 28 items, covering the fields of everyday physical activity, sports within and outside of organised clubs, physical education as well as compliance with physical activity guidelines. A study was conducted with 109 boys and 87 girls aged between 9 and 17 years. The MoMo-AFB was given on two separate occasions to evaluate reliability and was compared with accelerometry data of ActiGraph GT1X to evaluate validity. The overall kappa/weighted kappa coefficient for the one-week test-retest reliability was .66 (SD = .19) and the overall intraclass correlation (ICC) .68. Self-reported and accelerometer-measured average weekly time spent performing moderate to vigorous physical activity were significantly correlated (Spearman $r = .29$). Regarding reliability and validity, the MoMo-AFB is comparable with other international published physical activity questionnaires for adolescents. N2 - The purpose of this case study was to examine the interactions between parents and children as they participated in weekly tutoring sessions to develop phonemic awareness (PA) with the use of kinesthetic motions for the phoneme (KMP). The study examined how the parents extended the learning and explored the changes in their literacy understandings. In addition, it documented the children's growth in PA. The four major sources of data of the study were: field notes constructed from recordings of the tutoring sessions and dyads reading a poem at the beginning and end of the study; parental logs; interviews; and literacy measures of the children. The study chronicled the change in the parents as they developed the ability to teach PA. The parent-child interactions demonstrated the parents acted as effective tutors. They scaffolded attending to sound with KMPs and developed the following understandings through the use of poetry: to direct their children to attend to print non-verbally by pointing and verbally with the use of specific language for directionality, letters and punctuation. The children developed PA, as evidenced in their use of KMPs outside of the sessions, in their identification of letter sounds and ability to encode phonemes. The parents' guidance of the children to text resulted in growth in concepts about print. The implications of the study include the need to incorporate concrete markers, such as the KMP, with preschoolers in PA activities, the need to teach parents to scaffold interaction with text through pointing, and the need to seriously consider engaging parents in academic tutoring. N2 - Introduction: This study examined the differences between boys and girls in relation to activity levels during play and sensory preferences for activity level, body position and movement. A review of the literature revealed no evidence to explain if boys and girls prefer different body positions while playing or if body position might be used to measure their activity levels. Method: This retrospective study used data from demographic forms, children's Sensory Profiles and observations of children's play in classroom settings. The sample consisted of 53 typically developing children between ages 3-5 years from a suburban preschool in Kansas in the United States. Results: Analysis of data from play observations revealed no significant differences between boys and girls in relation to body position mean ($p = 0.33$), body position standard deviation ($p = 0.19$) and total number of change position times ($p = 0.28$). Analysis of data from children's Sensory Profiles showed no significant differences ($p = 0.97$) between boys' and girls' seeking preferences reflected by activity level, body position and movement items in the Sensory Profile. Conclusion: Future research should investigate children's play in outdoor playgrounds and implement more rigorous methods in rating activity levels. N2 - Play constitutes a significant portion of childhood and is a natural setting in which children display their understanding of the world and practice social skills. The current study measured the effects of a play intervention on the development of play and social skills among three four-year-old preschoolers who displayed low-level skills in both domains. The intervention involved 12 30-minute sessions following a plan-play-review structure, adult facilitation of social and pretend play, and inclusion of a peer model to reinforce newly learned skills. All three children improved their play skills according to observational data from the PIECES. Two children increased their time spent in pretend play versus exploratory play, and one child increased time spent involved in play versus nonplay. None of the children increased the frequency of their social interactions with playmates as a result of the intervention, indicating these children may benefit from more direct social skills instruction. N2 - Social skills are important for success in school as well as in life. Social skills training (SST) has been effective in teaching students required skills within the context of the training site, but often these have not generalized to additional settings (DuPaul & Eckert, 1994). This study researches the effect of adding self-management to an existing training program to determine if it will increase generalization of learned behaviors. Elementary students in a mid-west school were taught social skills in a pull-out program, but those skills did not generalize for many of those students into the classroom or other settings. Five students were then selected for additional intervention by teacher and counselor nominations. Each student had a target social skill that was identified for improvement. The target skill was assessed using multiple measures such as records of student discipline, teacher ratings, student ratings, grades, teacher survey, parent survey, and student survey. Adding a self-management system for four weeks increased generalization of learned social skills to other settings such as classroom, playground, cafeteria, art, and music classes. Implications for practice and future research are discussed. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - Handheld technology devices allow users to be mobile and access the Internet, personal data, and third-party content applications in many different environments at the users' convenience. The explosion of these mobile learning devices around the globe has led adults to value them for communication, productivity, and learning. Outside of the school setting, many adolescents and children have access to, or own mobile learning devices. The use of these devices by children on a daily basis in schools is a relatively new phenomenon, with just four percent of elementary students doing so in classrooms in 2010 (Gray, Thomas & Lewis, 2010). This mixed methods study researched a one-to-one implementation of 287 mobile technology devices, the iPod touch, in fourth- and fifth-grade elementary classrooms over eight months. The focus was to explore the mobile learning device's relationship to English language learners' reading achievement levels, to English language learners' self-efficacy in reading English, and to explore the benefits and limitations of the device's daily use as perceived by the students. The hypothesis was that the practice of reading and related literacy activities with the iPod touch would augment English learners' vicarious learning experiences, and thereby effect student cognitive engagement, reading self-efficacy, and reading academic achievement. The study used validated surveys and assessments to measure students' beliefs about reading and their knowledge of reading. Additionally, English language learner interview data were collected and analyzed to uncover perceived benefits and limitations of utilizing 1:1 mobile learning devices for daily literacy activities. Analysis of the data revealed significantly elevated levels of self-efficacy in reading for the experimental group with 1:1 handheld technology, while academic gains in reading for the experimental and control groups were statistically similar. Students in the experimental group described a virtually-enhanced socio-cultural context for communicating and learning with the handheld technology. Implications for practice, policy, leadership, and future research are discussed.

N2 - The study examines how perceptions of crime affect outdoor recreation and physical activity among Mexican-American youth of different ages and how Mexican-American youth negotiate constraints related to fear of crime. Theories of environmental stress and human territorial functioning theory are used to frame the findings of the study. In-depth interviews were conducted with 25 Mexican-American adolescents ages 11-18 residing in Chicago, Illinois. The findings show that crime prevents youth from visiting parks or places that require crossing gang boundaries, and that fear restricts participation in outdoor recreation. Activities that take place in the vicinity of homes and on school property during school hours, as well as activities that are organized and supervised by adults, are considered safer than unorganized and unsupervised activities.

Adolescents use negotiation strategies to foster their participation in outdoor recreation and physical activity.

N2 - The current study evaluated the effectiveness of the Superhero Social Skills program in increasing the social engagement skills and decreasing the aggressive behavior of students with externalizing behavior problems as implemented by a resource teacher. There have been no empirical evaluations of the Superhero Social Skills program as implemented by educators other than graduate students in school psychology familiar with the program. The Superhero Social Skills program was administered to 5 elementary age participants with training occurring for 30 minutes twice per week in a public elementary school. The participating resource teacher taught 11 lessons from the program across 11 weeks. Effects were primarily assessed through a momentary time sampling procedure during both analog (structured free play) and recess (unstructured play) situations, for intervention and follow-up phases. The momentary time sampling recorded each participant's percentage of time spent socially engaged (initiating and responding) and/or engaged in aggression (verbal and physical). Both effect sizes and the percentage of all nonoverlapping data points (PAND) were calculated. Pre- and posttreatment effects were also evaluated for the Social Skills Improvement System (SSIS) and the Behavior Assessment System for Children, 2nd Edition (BASC-2). Consumer satisfaction, social validity, and treatment integrity factors were also examined. Results indicated that the Superhero Social Skills program had a small effect in enhancing participants' social engagement with peers and had a medium effect in reducing aggressive behavior of student participants. Positive social engagement was observed to generalize from the instructional setting to the natural setting of recess. The current study also found that the Superhero Social Skills program was implemented with a high rate of fidelity (85%) by a resource teacher unfamiliar with the program as measured by treatment integrity probes across each lesson. Additionally, the participating resource teacher rated the program as easy to implement and the Superhero Social Skills program was rated as being socially valid, acceptable, and effective by the student participants, parents, and teachers. N2 - Presents a case report of a 9-year-old boy had an established diagnosis of autistic disorder, made at 3 years of age because of delayed language (he did not speak until he was almost 4 years of age), idiosyncratic language, stereotyped movements and play, sensory intolerances, unresponsiveness to instruction, poor social skills, poor eye contact, emotional distance, disregard of people, heedlessness of real danger (darting, running into street), and irrational fear of harmless situations/objects. After some instruction in behavior modification, his parents trained him to use words and observe some social amenities. Once he attained language, it became obvious that he was high-functioning, with clinical intelligence quotient (IQ) estimate above average. His parents had heard of the nicotinic receptor deficiency hypothesis for autism described previously, and requested a trial of varenicline, knowing the risks. A cautious trial was initiated, with availability of phone consultation; the parents were given a copy of the Ohio Autism Clinical Impressions Scale to plot his progress. At that point (age 9) he weighed ~40 kg. He started with half of a 0.5 mg tablet per day for a week and then was given 0.5 mg/day. Within a month, observers outside the family were spontaneously commenting about the improvement in conversational ability, social interaction, and reasoning/coherence. He was continuing his 10 mg atomoxetine. To our knowledge, this is the first report of an individual with autism treated with varenicline, an 4b2 nicotinic receptor partial agonist. The unintended ABAB treatment experience made an experiment of nature with rather encouraging results. The parents were so impressed with the results that for several months they continued to buy varenicline for him at considerable expense (because the off-label use is not covered by their insurance). They share the prescriber's concerns about long-term safety and volunteered to have this case study published to promote research in a more controlled fashion. N2 - In recent years young children have concurrently experienced startling rises in their rates of obesity and stark reductions in their opportunities for physical activity. These trends have potentially serious implications for young children's school performance. However, much of the current physical activity research is concerned with health-related outcomes and the prediction of physical activity. Less work has examined the influence of activity on other domains of child development, such as academic and social skills. The current dissertation is comprised of two studies examining opportunities for and levels of physical activity in two distinct developmental periods (preschool and elementary school) and elucidating associations of physical activity with children's self-regulation and achievement. Examining two independent samples facilitated comparisons of physical activity characteristics and associations across age groups, school settings and demographic contexts. The first study consisted of a within-group analysis of a primarily low-income minority subsample of 4 and 5 year-old preschoolers (N = 104) drawn from the Pitt School Readiness Study, a study of preschoolers from the metropolitan Pittsburgh area. Results from this examination suggest that, although children's moderate to vigorous activity was not related to self-regulation or achievement, opportunities for physical activity seemed important. Specifically, more time in free play predicted worse attention, and more time in recess predicted more externalizing behavior, less self-control, and worse math achievement. In contrast, more physical education time predicted better reading and math skills. The second study consisted of analyses on a large, economically and ethnically diverse sample of third and fifth graders (N = 993) and a low income subsample (n = 297). Across these samples, more physical education emerged as a positive predictor of self-control but more recess time was negatively associated with math achievement. Accelerometry measured physical activity was not predictive across outcomes. Finally, post-hoc examinations revealed that attention, self-control, and externalizing behaviors acted as possible agents of indirect associations between opportunities for physical activity and achievement. Overall, findings across both studies suggest that children benefit most from physical activity that is structured and regularly scheduled within school settings. Furthermore, large quantities of unstructured activity seemed detrimental for self-regulation and achievement. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - (from the chapter) Rapid developments in mobile devices and pervasive wireless networks continuously redefine the ways in which we live, work, play, and learn. In fact, wireless mobile devices enable anytime and anywhere access to digital tools and resources in popular and easy-to-use formats and allow instant communication across time and place. As such, they place an ever-increasing amount of control in our hands and enable us to have rich user experiences as we access, aggregate, create, customize, and share digital information in a variety of formats. These unique characteristics and capabilities of wireless mobile devices provide exciting opportunities for teaching and learning that can change what is "pedagogically possible". Specifically, their mobility and connectivity allow students to access information at their fingertips and connect their learning to the outside world across a variety of real and digital contexts. The unique affordances of mobile technologies and their implications for teaching and learning are the focus of this chapter. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - As mathematics identity affects students' learning and doing of mathematics, it is critical to understand the mathematics identities of African American and Hispanic students as the mathematical performance and pursuits of far too many continue to lag behind. Further, as community schools have been shown to positively impact students in urban communities, it is also critical to understand how mathematics identities are developed within community schools. This study explores the culture, structures, and processes of an urban elementary community school including its afterschool archery program relative to fifth grade students' mathematics identities. It also explores students' math positioning, enactment, and perspectives in the classroom and archery. The theoretical framework encompasses multiple theories and perspectives: identity theory, cultural-historical activity theory, ecological systems theory, and culturally responsive pedagogy. Ethnography of one urban elementary community school was conducted over one school year plus summer camp using mixed methods. In total, 33 fifth graders and 13 adults participated in the study. In addition to school and community agency artifacts collected, observations inside and outside of the classrooms were conducted along with student brainstorming exercises and student and adult interviews. State math assessment scores were collected for 2009 and 2010 and pre- and post-surveys on students' mathematics beliefs and attitudes were conducted. While 7 out of 10 fifth graders favored mathematics and considered themselves as mathematicians, as defined in a broader sense that reflects habits of mind as opposed to simply skills, less than four out of 10 saw themselves in careers considered math- or science-related. Interestingly, students who had heard the word "mathematician" scored significantly higher on state math assessments than their peers who had not. In the classroom, students positioned themselves in different ways relative to their mathematics identity such as leader, helper,

independent, math smart, social learner, and agent of their own learning. Outside of the classroom, the afterschool archery program bore positive relevance in students' mathematics identities, including a student with Attention Deficit/Hyperactivity Disorder, through culturally responsive instruction, a culture of respect, and goal-setting. Study results can inform community school processes, cultures, and structures as well as children's media. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - The purpose of this study was to test the Overseas Middle Years Student Bullying and Victimization Questionnaire for validity and reliability, then identify statistically significant differences between gender, grade, and national status with four constructs; traditional bullying, traditional victimization, cyber bullying, and cyber victimization. A cross-sectional, self-report, nonexperimental, quantitative research design was employed. Out of a population of 496, the sample included 189 (38.10%) sixth, seventh, and eighth-grade students in two overseas schools in Europe. The results of two reviews by a panel of experts found the instrument was valid. The reliability was tested using Cronbach's for overall correlation (.917), each of the constructs; traditional victimization (.864), cyber victimization (.898), traditional bully (.813), and cyber bully (.916). Furthermore, each construct was tested by removing one item. In 18 of 19 items, the correlation decreased while the nominal increase in the other item was insignificant. The study found that bullying most often occurs in hallways and lockers (60.3%), on the playground (44.4%), in the cafeteria (27.0%), and in classrooms (27.0%). Young men were found to be significantly more likely than young women to be physical victims and verbal bullies. Sixth-grade students were significantly more likely to be verbal victims, eighth-grade students were significantly more likely to be physical bullies, and sixth and seventh-grade students were significantly more likely to be relational bullies. Finally, traditional bullies were 3.27 times more likely than cyber bullies while traditional victims were 2.44 more likely than cyber victims. Limitations included the small sample size and the number of I do not know responses in each of the construct items. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - The impact of additional structured outdoor playtime on preschoolers' physical activity (PA) level is unclear. The purpose of this pilot study was to explore the effects of increasing structured outdoor playtime on preschoolers' PA levels. Eight full-day classrooms (n = 134 children) from two preschool programmes were randomised into a treatment (STRUCT, n = 4) or control (CON, n = 4) condition. Both groups received an additional 30 minutes of outdoor playtime three days per week for four weeks. The STRUCT intervention consisted of previously tested structured outdoor playtime activities/games. The CON intervention consisted of free outdoor playtime. Children were individually recruited (n = 75) for the objective assessment of PA levels. The PA levels of 67 children (age, 4.190.8 years; STRUCT, n = 38; CON, n = 29) were assessed at baseline and during week four for seven consecutive days using Actigraph accelerometers. Data were analysed using mixed-model analysis of variance. Time spent in vigorous PA significantly increased during the 30-minute intervention time for the STRUCT group compared with the CON group (group x time interaction: $F(1, 36) = 4.91, p = 0.04$). Compared with baseline, a significant increase was observed in the STRUCT group's time spent engaged in moderate-to-vigorous PA (MVPA) during the intervention time, but this increase was not significant compared with the CON group (baseline: STRUCT, 1.7 + 2.0 min; CON, 1.9 + 2.4 min; week four: STRUCT, 4.9 + 3.1 min; CON, 3.3 + 2.5 min). Compared with the CON group, the STRUCT group spent a significantly greater percentage of time engaged in MVPA and a significantly lower percentage of time engaged in sedentary activity during the preschool day. In conclusion, this study provides preliminary evidence that increasing preschoolers' exposure to structured activities during outdoor playtime could lead to improvements in their PA levels. The present intervention could be used to help preschoolers meet the recommended levels of PA. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

N2 - The purpose of this study was to explore the concept of play through the eyes of talented and gifted (TAG) fifth- and sixth-grade students. Three focus groups consisting of fifth- and sixth-grade TAG students were conducted in one urban, one suburban, and one rural school district in the Midwest. Students were asked to describe the value of play in the cognitive, physical, and social domains. Additional open-ended questions were asked about the importance of play and its relevance to their lives. From these results, an online survey was created. Data from an additional 162 fifth- and sixth-grade TAG respondents substantiated that play is a significant activity for learning and socializing in the general classroom, gifted programs, and outside their classrooms. Despite its importance, students experienced structural barriers for time to play. Putting the Research to Use: Results of this study hold implications for teachers to acknowledge the value of play as a tool for learning. Children see play as a renewal activity. They see play as motivating and as a way to increase attention, retention, and focus in learning. Children emphasized that play develops teamwork and problem-solving skills. Play enhances meaningful activities in the talented and gifted program as well as the general classroom. Results of this study suggest that parents should acknowledge their children's need for play in all three domains (cognitive, physical, and social) and allow time for self-directed play after school with limits on scheduled activities. N2 - (from the chapter) The procedures most common to psychological assessment in school settings are relevant to the populations and problems served in schools. Therefore, school-based psychologists emphasize assessment of academic achievement and student learning, use interventions that emphasize educational or

learning approaches, and use consultation to implement interventions. Because children experience problems in classrooms, playgrounds, homes, and other settings that support education, interventions to address problems are generally implemented in the setting where the problem occurs. School-based psychologists generally do not provide direct services (e.g., play therapy) outside of educational settings. Consequently, psychologists in school settings consult with teachers, parents, and other educators to implement interventions. Psychological assessment procedures that address student learning, psychoeducational interventions, and intervention implementation mediated via consultation are emphasized to a greater degree in schools than in other settings. The remainder of this chapter addresses aspects of psychological assessment that distinguish practices in school-based settings from practices in other settings. The chapter is organized into three major sections: assessment purposes, current practices, and future trends of psychological assessment in schools. N2 - (from the chapter) Since the first edition of this book in 2006, the concept of using cognitive-behavioral therapy (CBT) techniques with children and adolescents with autism spectrum disorders (ASDs) has gained popularity in terms of available techniques and research. Children and adolescents with ASD, by definition, exhibit social impairments, which occur concurrently with deficits in expressive and/or receptive verbal and nonverbal language and the presentation of perseverative behaviors and a restrictive pattern of interests. These behaviors all present a need for intervention, and may be targeted by speech/language therapy, occupational therapy, classroom management systems, and social-skills training, to name a few. For ASD, each "symptom" is typically treated by differing types of intervention, which requires comprehensive evaluations of the problem behaviors and careful treatment planning. Of the symptoms present, cognitive-behavioral therapy has been used to help in the areas of improving social skills, enhancing perspective-taking, increasing self-monitoring behaviors, and reducing comorbid symptoms of internalizing disorders, specifically anxiety. This chapter aims to highlight some promising treatment options for children and adolescents with ASD, and to help practitioners select and monitor interventions to help establish evidence of effectiveness. It is the hope that this chapter is able to highlight the importance and need for more research in this area. (PsycINFO Database Record (c) 2014 APA, all rights reserved)

N2 - (from the chapter) School-based programs to prevent eating disorders and improve body image have evolved since the heavy focus on psychoeducation in the late 1980s. Psychoeducational programs were traditionally based on the adaption of clinical psychological counseling techniques to be implemented in school settings, and they also relied heavily on the didactic presentation of knowledge and information. Most school-based programs now include a range of strategies and preventive approaches combined with traditional psychoeducational strategies, including media literacy, cognitive dissonance, small-group work activities, role play, peer-led teaching, and the use of computer and Internet technology. Several challenges for school-based prevention impede progress, including disputes over program delivery and content, the personal attitudes and professional training of teachers, and issues of measurement among "normal" populations in natural environments. More evidence is required in order to produce effective programs that can be implemented in a cost-effective manner, throughout the world, among males and females of all ages. This chapter aims to provide an overview of the research in school-based body image programs and to identify the current trends and future directions in this area. N2 - Referrals of elementary students who had engaged in aggressive behavior on the playground prompted the implementation of a nonclassroom treatment package as an extension of a schoolwide positive behavior support

program. The package consisted of (1) teaching students new playground rules during physical education class and posting the rules in the gym and on the playground, (2) providing reminders of the rules, (3) modifying the playground to facilitate appropriate play, (4) encouraging playground monitors to take a more active supervisory role, and (5) conducting a self-management program for the students who consistently engaged in aggressive behavior. The effects of the program were evaluated by recording three students' levels of physical and verbal aggression and appropriate play and by asking the playground supervisors to rate the recess behavior of all students during baseline and treatment. N2 - In the past different researchers have come to diverging cognitive ability estimates for people in Africa and of African descent. The paper tries to check the validity of past results by comparing them with outcomes of two new psychometric test studies from East and South Africa; with results from student assessment studies; with predictions based on those variables which, outside Africa, correlate most strongly with intelligence; and by comparing them with further indicators of cognitive ability (descriptions of everyday life and human accomplishment). Integrating these cognitive ability measures with the application of several corrections (due to the higher age of students in Africa, lower African school enrollment, selectivity of samples and higher African secular IQ rise), the best guess for an African average is IQ 75. Finally, possible environmental and genetic (evolutionary, therefore past environmental) causes are discussed and suggestions are given how to enhance cognitive development in African countries. VL - 6:

IS - 1

N2 - Current imagery literature suggests that imagery perspectives may be subject to a default position (Morris & Spittle, 2001), with experience influencing how successfully individuals can utilize internal and external visual imagery. According to this proposition, the default imagery perspective is an internal 1st person perspective. However, few imagery inventories have been designed to differentiate and accurately measure these imagery perspectives (see Morris, Spittle, & Watt, 2005). Fewer still have considered athletic populations, in particular adolescent cohorts. Consequently, the current research examined the use of internal visual imagery (IVI), external visual imagery (EVI), and kinesthetic imagery (KI) amongst adolescent sport performers and whether the amount of hours engaged in practice outside of competition influenced their adoption. Eighty-seven (36 male, 51 female) county level participants from sports academies in the United Kingdom (M age = 14.0, SD = 1.92), from 6 interactive sports, completed the Vividness of Movement Imagery Questionnaire-2 (VMIQ-2; Roberts et al., 2008). Participants were grouped relative to the amount of practice they had engaged in since playing their current sport competitively. A repeated measures ANOVA recorded significant differences amongst participants vividness of imagery, Wilkes' F (2, 85) = 3.166, $p < 0.05$, $\eta^2 = .07$, post hoc pairwise comparisons using a Bonferroni adjustment revealed no significant differences between sub-scales. Results to MANOVA recorded no significant differences between VMIQ-2 sub-scales and three accumulated practice groupings, Wilkes' F (3, 82) = 436.14, $p > 0.32$, $\eta^2 = .04$. The results demonstrate adolescent sport performers possess between clear and reasonably vivid to moderately clear and vivid imagery ability when using IVI, EVI, and KI. Future research should consider the impact of environmental factors that influence the development of these modalities and perspectives. N2 - The transition from kindergarten to Grade 1 is marked by a sudden decrease in children's play time (Brostrom, 2005; Hartmann & Rollett, 1994). This study sought to examine 69 Montreal-area Grade 1 children's beliefs about out of school play, as well as their parents' (N = 56) perceptions of their play. Findings indicate that parents value play for their child's development and education, for building relationships and self-esteem, for processing emotional experiences, for relaxation, and for fun. Many parents expressed a preference for active outdoor play, as well as pretend and creative play, board games, and puzzles, explaining that they discouraged television and video games, aggressive play, and play with sexual themes. Children reported enjoying active outdoor play, toys, construction and art activities, and video game play, with parents, siblings, friends, and pets. Limitations to play included lack of neighbourhood children, parents or siblings who did not play, and restrictions to inviting friends over. N2 - (from the chapter) The events described in this chapter took place in the early 1980s. It was a time when educational drama (Slade 1954) and drama therapy (Jennings 1973), as well as psychodrama, were taking their place amongst other developments in a movement towards the 'education of the whole person', and around which there was great excitement. Our project still seems to us both universal and timeless. We believe it represents an educational approach still being fought for in today's mainstream classroom. Despite its title, The Playground Project happened in a classroom with a group of 23 children, aged 10-11 years old, and their teacher at a primary school on a deprived inner-city estate. Strong feelings, often reflected in the children's behaviour, were getting in the way of useful learning, and the teacher was looking for ways of addressing the problem. At that time a freelance performer working in the school as actor-in-residence suggested that the psychodramatist Olivia Lousada might be able to help. The Playground Project was the result. Like the project itself, the name originated through Olivia Lousada's experiences both as a professional and as a parent. She had been running a course for teachers who ran nurture groups, in which each session focused on a theme such as trust, power, or status. When the teachers tried out the material in the classroom, they were amazed to discover what was really going on in the peer group of the children: who liked whom, who stuck up for whom, how they felt about the bully in the class who felt he had no friends. This they learnt through the sociometry (the mapping of

relationships). Olivia saw that the same insights might help her own six-year-old son, who was himself having a bad time in the playground. She knew that many children find the playground difficult and lonely, with a culture of its own. What if the energy of this peer group culture could be harnessed and used creatively? The original project took the form of six fortnightly sessions of one and a half hours each, but the richness of the process meant that sessions soon had to be doubled in length, something more easily managed in the days before the National Curriculum. We have chosen two of these sessions to describe in detail: the third session, 'Power', in which we ran into difficulties-from which much was learned-and the fifth session, 'the Magic Shop', which illustrates the access to creativity of this work. N2 - This paper reports on a systematic review of 210 pieces of educational research, policy and professional literature relating to creative environments for learning in schools, commissioned by Learning and Teaching Scotland (LTS). Despite the volume of academic literature in this field, the team of six reviewers found comparatively few empirical studies published in the period 2005-2011 providing findings addressing the review objectives. There was, however a reasonable weight of research evidence to support the importance of the following factors in supporting creative skills development in children and young people: flexible use of space and time; availability of appropriate materials; working outside the classroom/school; 'playful' or 'games-bases' approaches with a degree of learner autonomy; respectful relationships between teachers and learners; opportunities for peer collaboration; partnerships with outside agencies; awareness of learners' needs; and non-prescriptive planning. The review also found evidence for impact of creative environments on pupil attainment and the development of teacher professionalism. LTS intend to use the review as a basis for recommendations to Scottish schools in promoting creativity within Curriculum for Excellence. However, the findings of the review and methodological gaps in the reviewed studies have implications for policy, practice and research internationally. N2 - A modified multiple-baseline design across participants was used to evaluate a procedure for teaching the mand "Where?" to 3 children with autism. The participants were 3 and 5 years old and were participating in an intensive applied behavior analysis program. The participants were able to mand for items they wanted when the items were not in sight but were unable to ask where an item was located. The procedure consisted of a preference assessment for play activities, contrived conditioned motivating operations (CMO's), prompting the children to mand "Where," and consequences for correct and incorrect responding. Each contrived CMO consisted of an opportunity for the child to mand "Where" while playing with a selected activity, prompting the child to mand, and reinforcing a correct response by answering the question "Where." Two of the participants learned to mand "Where" after training with 1 CMO and the mand generalized to novel contrived situations, activities, and the natural environment and was maintained over time (up to 4-weeks), whereas one participant required training with a second CMO before generalization occurred. N2 - Self, peer and teacher reports of social relationships were examined for 60 high-functioning children with ASD. Compared to a matched sample of typical children in the same classroom, children with ASD were more often on the periphery of their social networks, reported poorer quality friendships and had fewer reciprocal friendships. On the playground, children with ASD were mostly unengaged but playground engagement was not associated with peer, self, or teacher reports of social behavior. Twenty percent of children with ASD had a reciprocated friendship and also high social network status. Thus, while the majority of high functioning children with ASD struggle with peer relationships in general education classrooms, a small percentage of them appear to have social success. N2 - The primary purpose of the present study was to examine adherence to current active play and electronic media use guidelines in a sample of US preschool-aged children and to examine whether differences occurred across gender and parental education. 164 parents completed an on-line survey to estimate preschool children's active play and sedentary behaviors. For weekdays, 50% of the sample met the active play guideline with this increasing to 65% during the weekend. With respect to electronic media use, 90% of the sample met guidelines during the week, with the percentage meeting guidelines dropping to 78% during the weekend. A greater percentage of preschool children from high parental education families (83.4 + 3.3) met electronic media use guidelines on the weekends, compared to preschool children from low parental education families (59.4 + 8.1) ($p = 0.002$). Our findings indicate that a substantial portion of preschool children are not meeting active play guidelines and that adherence to active play and electronic media use guidelines may be influenced by parental education. N2 - Children who engage in physical risk taking experience more injuries. In the present study children 7-12 years completed laboratory tasks and standardized questionnaires to explore inter-relations between measures of risk taking and to determine if the Balloon Analog Risk Task (BART) is a valid index of physical risk taking. Emotion regulation skills also were assessed to determine if poorer skills are associated with greater risk taking, and what measures of risk taking show these relations. Results revealed that general measures of risk taking propensity predicted both BART performance and physical risk taking. Similarly, poorer emotion regulation skills were associated with greater risk taking scores for both the BART and physical risk taking task. Measures of physical risk taking related to one another, however, none of these scores related to performance on the BART. Implications for measuring physical risk taking and exploring emotional links to risk taking in future research are discussed. N2 - Research has suggested that academic stress may "spillover" into other life domains and have negative psychological or social consequences for children and adolescents outside of school settings, but relatively few investigations have examined mediators and moderators of spillover. The current study explored the mediating role of state affect and the moderating roles of prior academic performance and mood disturbances on spillover in a sample of 131 French adolescents. Participants completed clinical measures of anxiety and depression and participated in a 7-day ambulatory monitoring phase that involved multiple daily assessments of mood, behaviors, and activities. Spillover was observed for family events and subsequent school-related events, as well as between family and leisure events. These associations remained significant when controlling for immediate mood responses, suggesting that state affect does not play a salient mediating role. There was no evidence that spillover was moderated by academic difficulty, anxiety, depression, or gender. Results are discussed in terms of the role that emotional processes may play in spillover phenomena as well as the reciprocal influence that academic and non-academic events may exert each other. N2 - (from the chapter) Research unequivocally demonstrates the negative effects of parental substance abuse or dependency on their children. For example, children of alcoholics demonstrate higher rates of substance abuse, behavioral problems, aggression, internalizing disorders (e.g., anxiety or depression), attention deficit/hyperactivity disorder (ADHD), and psychiatric distress than their nonaffected peers, and they tend to have lower academic achievement and verbal ability. The most serious threat, however, is to younger children whose fathers are drug abusers and live in the household; in contrast, those with fathers who do not abuse substances have the lowest rates of clinical symptoms. A parent who is addicted or who is abusing alcohol or drugs is often impaired and unable to take proper care of a child, which may lead to a student's unkempt appearance, tardiness to school, falling asleep in class, or incomplete or missing homework (the case for Anthony in the vignette). Parents may drive their children while intoxicated or high. An affected child may have an advanced knowledge of alcohol or drugs, or there may be great discomfort when the subject is mentioned. These children may also get uncomfortable when the topic of parents is discussed, given the potential for feelings of guilt or shame. Other indications may be that the parent is never involved in any of the child's

activities or that the student partakes in various after-school activities as an attempt to avoid having to go home. It is clear that the problem of parental substance abuse is widespread and poses serious challenges to children and adolescents, putting them at risk for a host of problems. It is also clear that many of the solutions to these problems lie outside the reach of educators in schools. Nevertheless, there are strategies that any educator can employ to engage these students more successfully, to provide them with the optimum learning environment, and to support their efforts to meet the challenges with which they are faced. With this understanding in mind, educators can be better prepared to help these students, who are always present in their classrooms and whose success depends on an informed and caring dedication on the part of those who teach them. N2 - Background: This study aimed to examine associations between aspects of the neighborhood social environment and body mass index (BMI) in youth both cross-sectionally and prospectively; and whether this association was mediated by physical activity, screen-time and sedentary time. Methods: Data were collected in 2004 and 2006 in high and low socio-economic areas of Melbourne, Australia. In 2004, 185 children aged 8-9 years (47% boys) and 359 children aged 13-15 years (45% boys) participated. Parents reported their perceptions of aspects of the social environment (i.e. social networks and social trust/cohesion), and physical activity (i.e. time spent outdoors by their children; and their younger children's walking and cycling trips) and screen-time (i.e. TV viewing, computer use). The older children self-reported their walking and cycling trips and their screen-time. All children wore an accelerometer to objectively assess outside-school hours moderate-to-vigorous physical activity and sedentary time. BMI was calculated from height and weight measured in 2004 and 2006. Multilevel linear regression analyses were conducted to examine associations between the social environment and BMI. Mediation analyses using the products of coefficient method were conducted to determine whether associations between the social environment and BMI were mediated by the time spent in a range of physical activity and sedentary behaviors. Results: Cross-sectional and prospective regression analyses showed that a more positive social network and higher social trust/cohesion was related to lower BMI among children. There was no evidence that time spent in physical activity or sedentary behaviors mediated this relation, despite significant associations between social networks and screen-time and between screen-time and BMI. Conclusions: The findings suggest that the neighborhood social environment may be important for preventing overweight and obesity in children. Further research investigating the mechanisms through which the neighborhood social environment exerts its effect on BMI is needed. N2 - Educators have observed reluctance in middle school students to vocally engage in small group learning tasks, the result of which could be a decrease in student learning. The same students have been observed collaborating with peers outside of the classroom when using technology. The purpose of this study is to determine if technology provides a means to increase participation in the classroom, which in turn may increase student learning. Social constructivism and developmental theories guided this study. Eighty eighth-grade middle school students participated in a mixed-method, between-subject quasi-experiment to determine whether there was a difference in participation amount and content by students in small-group, learning-centered discussions using online vs. face-to-face environments. Students in groups of four used either an online chat tool or face-to-face discussion during a four-part activity. Data was coded, guided by Cohen's Kappa inter-rater reliability. The data was analyzed using independent sample t-tests, Fisher exact tests, relative percentage comparisons, Gini Coefficient comparisons, and Mann-Whitney-Wilcoxon testing. Significant findings ($p < .05$, $p < .01$) were demonstrated in participation amount, participation content, male participation amount, male participation content, and female participation content. Technology has the ability to enhance educational systems in order to prepare students to effectively and efficiently communicate and collaborate in today's high-tech environment. Accessing Web 2.0 tools in the classroom is a good first step as students can integrate their current out-of-school technological lifestyle and place it into the hands of educators to mold and form into quality 21st century life skills. N2 - (from the chapter) Over \$20 billion game industry and just now educators are seeing the benefit if used for good. Although some innovators have been using educational games for some time, it has only been in recent years. Serious Educational Games (Annetta, 2008) have become a highly sought after initiative by both educators and researchers alike. Gaming has conventionally been viewed as a mindless activity engaged in by young men and women during their free time. As a high school teacher in the mid- 1990s I had tried to assign homework to my students. When no homework came back or homework came back without much evidence of deep thinking, it was apparent students were engaging in something outside of school much more interesting than what I was proposing for them to spend their time doing. It was the mainstreaming of console game systems-such as Nintendo and Sega Genesis. It was then I knew we had to make that bridge. Through several years of research and funding, we have begun to develop a framework for fostering creativity in science learning. We did this by allowing students, and in some respects teachers, the ability to create their own games in a three-dimensional environment. We anticipated that creating games would foster a deeper understanding of content. Our data supported this notion (Annetta, 2010; Annetta & Bronack, 2010; Annetta, Folta, & Klesath, 2010; Annetta & Holmes, 2007; Annetta, Holmes, Cheng, & Folta, 2010; Annetta, Lamb, Bowling, & Cheng, 2011; Annetta, Lamb, & Stone, 2010; Annetta, Mangrum, Holmes, Collazo, & Cheng, 2009; Annetta, Minogue, Holmes, & Cheng, 2009; Cheng, Annetta, & Folta, 2011; Holmes, Thurmond, Annetta, & Sears, 2012). This chapter will focus on the research and development we have been working on and how it is grounded in learning science, psychology, and cognition. N2 - Introduction: Exposures to airborne microbial contaminants in sub-micrometer particles (PM1) have not been well characterized in different environments. Health effects due to these exposures are even more obscure. **Methods:** Concentrations of airborne size specific (<1, 1-1.8, >1.8 m) microbial contaminants (endotoxin, -glucan) were determined using cyclone samplers in two distinctly different environments: farms and homes. Using inhalable samplers and vacuum cleaners airborne inhalable and dust contaminants from these homes were collected. This approach was used to compare PM1 microbial contaminants in a particular home with those in inhalable particles and in dust inside the same home. Samples were analyzed with *Limulus Amebocyte Lysate* assays for endotoxin and -glucan. Walkthrough surveys and questionnaires determined home characteristics and other exposures. Airway inflammation was assessed in school-age children by measuring exhaled nitric oxide (eNO) levels with non-invasive nitric oxide monitoring system (NIOX-Flex). Skin-prick test were also employed to determine atopy. **Results:** Relative proportions of PM1 (<1 m) microbial contaminants from total airborne concentrations were significantly higher in homes despite their significantly higher actual concentrations on farms. In homes, PM1 and inhalable endotoxin concentrations correlated weakly with that in dust and with each other. PM1 endotoxin levels were not significantly associated with eNO levels in asthmatics but had significant inverse association with eNO levels in non-asthmatics. Among non-asthmatics, eNO levels were significantly lower for those children who lived in homes with levels of dog allergens above detection limits and for those with lower parental income. **Discussion:** Moderate disturbance activities in homes preferentially allow PM1 microbial contaminants to predominate among total airborne particles compared to farming environments that have dynamic activity levels that cause re-suspension of large particles. In addition to dust, airborne PM1 or inhalable microbial contaminants may originate from outdoor sources. High PM1 endotoxin was protective only for non-asthmatics. It is well known that T-helper 1 cells predominantly mediate immune responses in non-asthmatics who do not have pre-existing airway inflammation. PM1 endotoxin exposures, therefore, may have a beneficial effect; along with dog allergens, these could possibly drive naive immune systems away from inflammatory responses. For asthmatics, detectable dog allergens in homes may incite inflammatory response, possibly as irritants, in their already primed allergic immune systems. Among non-asthmatics from low-income parents, an adaptive immunity favoring Th1 immune response through higher microbial contaminant exposures may have favored protection against development of atopic response. This is in contrast to non-asthmatics from highest income parents who had significantly less microbial contaminant exposures. Subsequently, this may have led to predominantly Th2 adaptive immune response that is highly associated with atopy. Because atopy is a significant predictor of airway inflammation, it infers that non-asthmatics from lowest income parents had protective effects against airway inflammation compared to those non-asthmatics from highest income parents. **Conclusion:** PM1 endotoxin may be a better predictor of health outcome than inhalable or larger particles. Exposures to PM1 endotoxin may protect against airway inflammation in non-asthmatic school-age children. Whether this protection is sustained, needs to be confirmed through follow-up studies. N2 - The Los Angeles County Department of Public Health estimated that the obesity prevalence among Los Angeles County public school children is estimated to be 26%, with another 19% of children at risk of becoming overweight. Consequently, obesity increases the likelihood of developing many diseases, such as hypertension, chronic kidney disease, heart disease, diabetes mellitus, glaucoma, osteoporosis, neurological diseases, certain cancers, and even Alzheimer's disease. This dissertation systematically examines the Instant Recess exercise break intervention implemented in classroom settings, to see if it allows students to get more physical activity throughout the day. This project has implications for school districts around the country, as the childhood obesity epidemic spurs the passage of school physical activity promotion policies with untested efficacy or effectiveness, particularly in low-income environments. This is a classic intervention study in which mixed methods were used to analyze the data, including: accelerometer and pedometer recordings, teacher pre and post surveys, and weekly teacher logs. In conclusion, quantitative results found that students took 1840-1910 more steps with Instant Recess than those without. Qualitative results found that teachers were more likely to implement Instant Recess in their classrooms if they felt their administration was supportive about using Instant Recess as well. Additionally, issues of teacher IT savvy, technical support, and student enthusiasm were factors in Instant Recess uptake. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - This dissertation focused on the learning and interactional characteristics of LA 4 prekindergarten children who have remained in the first quartile at the end of the school year on the Developmental Skills Checklist. Their data were examined using a qualitative research design. This design used progress reports, artifacts, child observation and teacher semi-structured interview data. The children were observed during their free play time in learning centers. This observation format was chosen because it represents their most natural, authentic play setting, thus allowing an opportunity to see them through the lens of their own choices. The results of these data were examined using the categorization of artifact teacher progress reports, context of observational interaction, and interactional/learning activities, as well as teacher interviews. Observer reactions were presented to more fully interpret findings. Patterns emerged revealing similarities and differences in the various contexts and activities for both the target group of struggling children and the comparison group who demonstrated progress out of quartile one by the end of the school year. Results characterize the target group as less interactive and likely to initiate conversation, preferences for solitary and parallel play, limited literacy knowledge, and readiness for kindergarten, as well as increased inattention to their chosen play activities and inappropriate social skills. This study reveals the importance of analyzing interactional behaviors of children in natural settings. Important implications regarding the value of qualitative research designs to investigate the actual social interaction, language, and literacy characteristics of children who fail to make progress in a high quality

prekindergarten program are essential to increasing our understanding of their deficits. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - In recent years physical inactivity among students has become a matter of great concern. Nearly 65% of students do not meet the daily recommended level of physical activity, which is 60 minutes or more of moderate to vigorous physical activity each day, with 50% of that time being spent in moderate to vigorous levels of activity (CDC, 2010b). As a result, the 21st century has shown to be a time of many health problems such as, obesity, diabetes, and heart disease. In fact, nearly one third of all children are considered obese or overweight (Slawta & DeNeui, 2009). Researchers suggest that these health problems are directly related to students' sedentary lifestyles (Pate et al., 2006). Schools play a pivotal role in addressing and increasing physical activity during the school day. The purpose of this research study was to measure levels of physical activity in elementary students during school hours. Specifically, the study sought to discover if there were increased levels of physical activity while students were using a cross-curricular adventure playground, as compared to when they were engaged in free play or physical education class. The study also compared the different measurement types (pedometers, accelerometers, and the observational method) used to assess physical activity, to indicate which measurement types were most feasible in the elementary school setting. Schools are ideal locations for assessing levels of physical activity, as 95% of all children are enrolled in these learning institutions (National Center for Educational Statistics, 2005). The data indicate that physical education provided for the highest levels of moderate to vigorous activity, while both free play and cross-curricular activity still rendered adequate levels of physical activity. After studying the different measurement protocols (pedometers, accelerometers, and the observational method) used in this study, results suggested the pedometer to be the most feasible device to use for measuring children in these types of physical activity settings. One implication for practice was implementing cross-curricular physical activity as a supplement to other physical activities or as an addition to physical education classes in an effort to allow more time for academic instruction while having students engaged in physical activity. Another recommendation for practice was to use pedometers as a cost-effective physical activity measurement device for elementary students. N2 - The rise of childhood obesity in the past three decades has established this issue as a national health crisis and an epidemic. Schools are primary sites for both the study and the prevention of childhood obesity, because they are environments where most children can be reached, and where children's health habits are influenced (IOM, 2005). The study was a secondary data analysis using data from the 2000 and 2006 School Health Policies and Programs Surveys (SHPPS). The goal of this study was to examine and compare data pertaining to exercise, nutrition, health screening and education in elementary schools by the economic level of the school and by the year of the survey. Chi-square Tests were used to examine the relationship between the economic level and the variables in the study, and between the year of the survey and the variables in the study. The Mantel-Haenszel Test was employed to examine the relationship of the economic level with the study variables while controlling for the year. By year of survey, the results indicated that in 2006, schools were less likely to screen for Body Mass Index/Height and Weight, less likely to provide nutrition education, and less likely to provide nutrition education than in 2000. In 2006, schools were more likely to provide recess in grade four, offer fruit, and not allow junk food at school parties than in 2000. By economic level, the results indicated that poor schools were less likely to provide soda sports drinks not 100% juice, and were more likely to require physical education than the not poor schools. While controlling for the year of the study, the not poor schools were more likely to offer soda/sports drinks not 100% juice, were less likely to require physical education, and were more likely to offer physical education 3 days or less per week than the poor schools. The results of this study showed that although there have been some small changes in the school health environment related to preventing childhood obesity, these changes have not met the recommendations of expert groups in the field of childhood obesity. N2 - We engaged over 430 Canadian children in a series of activities designed to reveal their evaluations of three ethnic groups (White, East Asian and South Asian), their identification with these groups, and their behavior towards them in a dictator game. Our experiments took place at the children's schools during their normal school day, allowing us to evaluate the salience and effects of ethnic identities on economically relevant behavior in an important natural setting. We find that children from the dominant White category have a clear sense of White ethnic identity, and tend to favor White recipients in the dictator game relative to East Asian or South Asian recipients. Minority East Asian children reveal a more complex ethnic identity; they perceive themselves to be equally similar to White and East Asian children. Unlike Whites, East Asian children do not favor recipients from their own East Asian category, nor do they favor recipients with whom they tend to identify. If anything, East Asian children show out-group favoritism. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Background: To promote regular physical activity (PA) among children and adolescents, authors recommend that physical education (PE) teachers offer their students programmes that would allow them to be physically active outside PE classes. However, such programmes are rarely rigorously assessed and it is recommended that further studies be undertaken to better understand characteristics of interventions that render children and adolescents more physically active. Aims: The purposes of this study were (a) to examine the effectiveness of a PA intervention, the team pentathlon, and (b) to examine whether the impact of team pentathlon was different for boys and girls. Method: Four primary school PE teachers and eight 5th grade elementary classes (two for each PE teacher: one experimental and one control) took part in the study. Overall, 86 students (44 girls; 42 boys) experienced team pentathlon in addition to their regular PE classes whereas 82 students (41 girls; 41 boys) simply attended their regular PE classes. The research design included: (a) a 3-week

baseline measure of the physical activity volume (PAV) for both the experimental group (EG) and the control group (CG); (b) the implementation of a 5-week intervention programme and weekly PAV measures for the EG (weeks 4 to 8) and periodic PAV measures for the CG (weeks 4, 6 and 8); (c) a 2-week recess for both groups (weeks 9 and 10); (d) PAV measures for both groups during weeks 11 and 12. PAV was computed in terms of pentathlon hours (PH), meaning the actual number of activity hours reported by students, corrected according to the intensity (energy cost) of the practiced physical activities. A repeated measures ANOVA was performed to see if there was a difference between the experimental and control groups, between boys and girls and between the four repeated measures. Non-parametric analyses were performed to see if there was any significant difference between reported volumes of physical activity for each PE teacher's classes. Results: Overall the results showed that control students' level of activity remained stable while experimental students were significantly more physically active at the time of the pentathlon implementation as well as three weeks after the end of the intervention programme. In both experimental and control groups, girls accumulated less pentathlon hours each week than boys. Results also showed that the regular practice of PA, outside of PE classes, varied between schools, both in control and experimental conditions. At times, the weekly volume of physical activity also varied greatly among students from the same classes. Conclusion: Team pentathlon brought about a greater volume of physical exercise among ten- and eleven-year-old children. Although girls reported a slightly larger raw volume of physical activity per week than boys, they accumulated lower pentathlon hour values due to their choice of less intense activities. Finally, the results also showed that regular PA, outside PE classes, may vary from one school to another or even among students from the same class. N2 - Background: Sedentary behaviour has been linked with a number of health outcomes. Preschool-aged children spend significant proportions of their day engaged in sedentary behaviours. Research into the correlates of sedentary behaviours in the preschool population is an emerging field, with most research being published since 2002. Reviews on correlates of sedentary behaviours which include preschool children have previously been published; however, none have reported results specific to the preschool population. This paper reviews articles reporting on correlates of sedentary behaviour in preschool children published between 1993 and 2009. Methods: A literature search was undertaken to identify articles which examined correlates of sedentary behaviours in preschool children. Articles were retrieved and evaluated in 2008 and 2009. Results: Twenty-nine studies were identified which met the inclusion criteria. From those studies, 63 potential correlates were identified. Television viewing was the most commonly examined sedentary behaviour. Findings from the review suggest that child's sex was not associated with television viewing and had an indeterminate association with sedentary behaviour as measured by accelerometry. Age, body mass index, parental education and race had an indeterminate association with television viewing, and outdoor playtime had no association with television viewing. The remaining 57 potential correlates had been investigated too infrequently to be able to draw robust

conclusions about associations. Conclusions: The correlates of preschool children's sedentary behaviours are multi-dimensional and not well established. Further research is required to provide a more comprehensive understanding of the influences on preschool children's sedentary behaviours to better inform the development of interventions. N2 - Background: Independent mobility (IM) and perceptions of the built environment may relate differentially to children's participation in various physical activity contexts. This cross-sectional study investigated whether independent mobility and perceptions of the built environment in boys and girls were related to physical activity in three different contexts (outdoor play, structured exercise/sport, active commuting). Methods: Thirteen hundred and seven 10-11 year old boys and girls from 23 schools in a large UK city completed a computerised questionnaire. Independent variables in logistic regression analyses were weekly self-reported frequency of participation in outdoor play, structured exercise/sport and mode of travel home from school. Dependent variables were perceptions of the environment (aesthetics, nuisance, safety, social norm, constraint, play space, accessibility), local and area independent mobility and linear distance from home to school. Analyses were adjusted for body mass index, minutes of daylight after school, level of neighbourhood deprivation and pubertal status. Results: For boys, local independent mobility (Local-IM) was related to an increased likelihood of everyday participation in play (OR 1.58: 95% CI 1.19-2.10), structured exercise/sport (OR 1.42: 1.06-1.89) and active commuting (OR 1.40: 1.07-1.87) but was only related to active commuting for girls (OR 1.49: 1.07-2.07). Boys and girls were more likely to report playing out every day if they had higher scores for Social Norm (Boys: OR 1.63 (1.12-2.37); Girls: OR 1.53 (1.01-2.31)) and, for girls only, more positive perceptions of traffic safety (OR 1.63: 1.14-2.34). Easy access to a range of destinations was the dominant predictor for taking part in structured exercise/sport everyday (Boys: OR 1.62 (1.01-2.66); Girls: OR 1.65 (1.07-2.53)). Shorter distance from home to school (OR 0.99: 0.98-0.99) and, for boys only, greater perceived accessibility (OR 1.87: 1.04-3.36) were significantly related to active commuting to school. Conclusions: Perceptions of the physical environment relate differently to different physical activity contexts and by gender. The only consistent correlate for outdoor play, structured ex/sport and active commuting was higher independent mobility to visit local destinations (Local-IM) for boys. Considering both the physical activity context and its independent correlates should improve the specificity of physical activity interventions in children. N2 - The benefits of recess can be reaped by all students regardless of socioeconomic status, race, or gender and at relatively little cost. The purpose of this study was to examine physical activity (PA) variables related to the recess PA patterns of third and fourth grade children and the social preferences and individuals influencing their PA (friends and parents). Data were collected on students (N = 115) utilizing the System of Observing Children's Activity and Relationships during Play (SOCARP) instrument. In addition, each child was interviewed during the recess period in which SOCARP was completed. Results found that boys spent significantly more time being very active ($t(95.64) = 3.252, d = .62, p < .008$) than girls and preferred sport activities ($t(73.62) = 5.64, d = 1.14, p < .0125$) in large groups ($t(69.34) = 4.036, d = .83, p < .0125$). Meanwhile, girls preferred locomotor activities ($t(113) = 3.19, d = .60, p < .0125$), sedentary activities ($t(113) = 2.829, d = .53, p < .0125$) and smaller groups ($t(112.63) = 4.259, d = .79, p < .0125$). All 115 participants indicated that they wanted to spend time with their friends during recess. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study examined the effectiveness of three conditions in which 48 fourth-grade students were prompted to be physically active out of school. Using an alternating treatments design (Cooper, Heron, & Heward, 2007) the three intervention conditions included: (a) Baseline: No prompting of students, (b) Teacher Prompts: Verbal prompt to "remember to do something active after school today", and (c) Teacher Prompts and group-oriented contingencies: Verbal prompts with an index card where students could record their activity to earn bonus points as part of a team challenge. Graphically plotted pedometer data depicting data paths, variability, and trends within and across three conditions showed that students were more active outside of school only when the contingent reinforcement (c) was in place. This suggests that using prompts and group-oriented contingencies within Sport Education appears to be an effective and authentic context for promoting independent (i.e., free play) out-of-school time physical activity. N2 - This study examined time management in 12 kindergarten classrooms from 9 Chilean schools with diverse sources of funding and socioeconomic status (SES). We conducted 33 observations in the 12 classrooms (average duration 197 minutes), and determined the amount of time devoted to different activities. More than half of the time in these classrooms was spent in non-instructional activities such as recess, snack, and managing the children's behavior. Additionally, the distribution of instructional time is not in accordance with current findings regarding the activities that are more fruitful for children's development. These results are independent of the schools' source of funding and SES. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Purpose: To explore the perceptions of young people with a spinal cord injury or disease (SCI/D) about their leisure participation at school, home and in the community. Methods: The study used narrative enquiry to elicit the unique leisure stories of three participants aged 8-11 years with a SCI/D during two face-to-face, semi-structured interviews. Pictorial data about participants' interpersonal relationships were also gathered using a 'social atom' tool. Results: Thematic analysis of participants' narratives produced three themes. 'Inside school leisure' and 'outside school leisure' detailed participants' lived experiences of leisure. 'A can-do approach to leisure' drew attention to the optimistic attitudes held by the participants and their active engagement in leisure despite their SCI/D. Conclusions: Clinicians, families and educators should explore the leisure preferences of young people with a SCI/D and support their participation in activities, which offer enjoyment, friendship and a sense of achievement. N2 - Background: Speech-language interventions are often complex in nature, involving multiple observations, variable outcomes and individualization in treatment delivery. The accepted procedure associated with randomized controlled trials (RCT) of such complex interventions is to develop and implement a manual of intervention in order that reliable treatment delivery can be achieved. Aims: To present the rationale, structure and content of an intensive manualized intervention as implemented within an RCT for children with complex pragmatic and social communication needs; to investigate factors associated with implementation in a mainstream school environment; and to determine treatment fidelity. Methods & Procedures: The manualized SCIP intervention, including procedures for developing individualized treatment plans, was developed and then implemented within an RCT with 57 school-aged children with complex pragmatic communication needs (CwPLI). The paper describes the delivery protocol, staffing requirements, and content and structure of the intervention. A mapping procedure for individualization of intervention and the implemented components of intervention are presented. The findings from a school-therapy alliance checklist for recording factors affecting implementation in a school context are also reported. Treatment fidelity was carried out using measures of delivered versus planned treatment content and quality of therapy. Outcomes & Results: The manual was effective at detailing intervention procedures and allowing for development of individualized treatment plans whilst maintaining satisfactory treatment fidelity. Treatment planning and delivery required continuous specialist speech and language therapist input with assistants needing substantive training and supervision. Key components of intervention for CwPLI were therapies aimed at improving conversation skills, narrative construction, comprehension monitoring, understanding of social cues and metapragmatic awareness. The school-therapy alliance checklist indicated high rates of therapist-education staff and therapist-parent liaison. Parents were nearly always involved in treatment planning though only half-attended therapy sessions. Learning support provision in schools for participating children was highly variable. Conclusions & Implications: Predetermining theoretical background, structure, and content in a treatment manual contributed towards the quality and reliability of intervention within the context of an RCT. The implementation of SCIP intervention in a broader clinical context is discussed with reference to staff expertise, the therapeutic process and the essential ingredients of social communication intervention. N2 - This paper presents clinical material from the psychoanalytically oriented therapy of an 8-year-old girl, who was born and raised in a cult. The author considers how this child's response to the traumatic events of her cult experience influenced her developing personality. Therapy sessions, beginning about thirty years ago, occurred during two time frames: Play therapy lasted for 2 years. Therapy was resumed for 1 year in adolescence. Play therapy focused on helping this client deal with some of her painful cult experiences and aided in the transition to a new world outside. Later, talk therapy during adolescence enhanced her ability to deal with adolescent difficulties that appeared to be impacted by cult experiences. N2 - This article questions the design of mobile learning activities that lead students to spend time focusing on the mobile devices at the expense of interacting with other students or exploring the environment. This problem is approached from an interaction design perspective, designing and analysing geometry-learning activities. The authors present six guidelines for designing mobile learning activities, where mobile devices support rather than distract students from contents and contexts relevant to the learning goals. The guidelines are developed through video analysis of groups of middle school students doing learning activities outdoors and evaluated using the task model. The guidelines suggest that students (1) assume roles based on a different functionality of each device, (2) use devices as contextual tools, that the activities, (3) include physical interaction with the environment, (4) let teachers assume roles, (5) encourage face-to-face communication, and (6) introduce students to the mobile devices. N2 - Mobile technology opens up opportunities for collaborative learning in otherwise remote contexts outside the classroom. A successful realization of these opportunities relies, however, on mobile learning activities providing adequate collaboration structures. This article presents an empirical study aimed at examining the role played by mobile devices, teachers and task structures as a means for collaborative learning in geometry. The study focused on the analysis of the nature of collaboration that unfolded when students measured areas outdoors in the field. The analysis of the mobile learning activity was conducted from an Activity theory perspective. The findings obtained indicate that the collaboration observed may be impaired if: 1) the functionalities needed for collaborative problem-solving are asymmetrically distributed on a number of mobile devices; 2) task-related information is not accessible to all learners; 3) the task structure is not sufficiently complex; 4) teacher scaffolding is too readily available; and 5) necessary collaborative skills are not developed. N2 - Linguistic support given to migrant students who incorporate late into the school systems is usually situated in two opposite poles. On one end of the pole is the linguistic support offered in mainstream classrooms and, on the other end, learning the school language in special classrooms outside school premises. With the creation of linguistic support classes in schools which receive migrant population, Catalonia has adopted an intermediate position. The research shows the weight which some explanatory variables have in the learning of Catalan. Two different tests were used: one to measure school adaptation and another to measure linguistic knowledge. The participants were 10415 primary school children who attended linguistic support classes. The results reveal that the variable school adaptation is the one which modifies more the probability of students succeeding in the different linguistic tests used. However, the probability is not the same in the tests assessing oral and writing skills. In the writing tests, the students who have a high school adaptation have nearly twice as many probabilities of being successful whereas in the oral tests the variable length of stay in the country plays an important role as well. The students' family language also modifies the students' linguistic results. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Observation competence plays a fundamental role in outdoor scientific investigation. The computerized concept mapping technique as a Mindtool has shown the potential for enhancing meaningful learning in science education. The purposes of the present study are to develop a concept map integrated mobile learning design for ecology observation and to examine the implementation effect for elementary school children. Also, the difference in growth slopes between gifted and average students is investigated. Eighteen gifted students and thirty average students were included in this study. A computerized dynamic assessment system which combines a Computerized Ecology Observation Competence Assessment (CEOCA) and a concept map

integrated ecology observation learning design were implemented. The results of the hierarchical linear model (HLM) analysis reveal that the overall growth slope is significant ($= 0.27, p < .01$). The effect size is 0.53. The growth slope of the gifted students is a little higher than that of the average students. However, the slope difference between ability groups is not significant. The results suggest that a well designed concept map integrated learning system demonstrates very promising potential for enhancing both the gifted and average students' mobile observation competence. The system developed in this study could be a useful resource for elementary school outdoor learning design. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study examined characteristics of child care centers associated with preschoolers' moderate-to-vigorous physical activity and sedentary behavior while in child care (MVPA-C, SB-C), and attributes of outdoor play areas associated with the same behaviors during outdoor time (MVPA-O, SB-O). Participants were 89 children (3-5 years) recruited from 10 child care centers in Brisbane, Australia. Children's activity was measured by accelerometer over a 3-day period. Center characteristics and outdoor play area attributes were identified through survey and observation. We found that children were mostly sedentary while in child care. Lower child-staff ratios and using indoor play areas for motor activity were associated with more MVPA-C and less SB-C. Fixed play equipment in outdoor areas was conducive to more MVPA-O and less SB-O. This study suggests the possibility of enhancing preschoolers' activity levels through changing these attributes. Further research with more centers from diverse settings is needed to test these findings. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - A connection to nature index was developed and tested to measure children's affective attitude toward the natural environment. The index was employed through a survey that investigates students' attitude toward Lagoon Quest, a mandatory environmental education program for all fourth-grade, public school students in Brevard County, Florida. Factor analyses were conducted to explore and confirm different factors in the connection to nature index. A path analysis was conducted to examine the association among variables. The results suggest four dimensions in the children's connection to nature index: (a) enjoyment of nature, (b) empathy for creatures, (c) sense of oneness, and (d) sense of responsibility. Children's connection to nature influences their intention to participate in nature-based activities in the future. Children's connection to nature, their previous experience in nature, their perceived family value toward nature, and their perceived control positively influenced their interest in performing environmentally friendly behaviors. N2 - Young children (5 to 6 years old) from an individualistic (the Netherlands) culture and a collectivistic (South of Spain: Andalusia) culture were videotaped during leisure time on their school playground. Based on the perspective of individualism-collectivism (IND-COL), cultural differences were expected with respect to observed conflict behaviors. Conflict episodes were analyzed with respect to conflict issues, strategies, and outcomes. In Andalusia, an unexpected high number of conflicts were observed, about three times higher than in

the Netherlands. As expected, Andalusian children turned out to be more concerned with control of play and behavior and Dutch children more with control of objects and space. With respect to strategy use, Andalusian children used negotiation more often than Dutch children. The latter included more often nonverbal and directive ingredients in their strategies. Dutch children ended their conflicts by means of social or physical rupture much more often than Andalusian children. The latter preferred to continue the interaction, even if this required submission to others' wishes. Results are discussed from the perspective of IND-COL, with particular emphasis on four characteristics of studies of peer conflicts: definition of conflict, method of data collection, age of participants, and social setting of the participants. N2 - It takes a special person to be an educator at the middle school level. Young adolescents during these years are often dazed and confused as they are undergoing more changes in their lives than any other time, outside of infancy. In recognizing these needs, educators began calling for a reform to create "developmentally responsive" schools since the early 1900's. The idea of "developmentally responsive" becomes even more critical in the middle school years as adolescents need advice, models, guidance and direction. In response to these needs, many national organizations have recommended advisory programs as a component of an effective middle school program. While many have given this idea valiant effort, many schools have failed to implement and sustain an effective advisory program. This mixed methods intervention study examines the ways in which a middle school developed and implemented an advisory program. The goal of this program is to establish positive student-teacher relationships which will in turn impact student achievement. While the entire school district participated in the middle school advisory program, this study uses sixth grade teachers at one school as the participants for the study. Ten teachers participated in the study to assess seventeen student-teacher relationships based on the Student Teacher Relationship Scale (STRS) developed by Dr. Robert Pianta. This instrument analyzes the dimensions of Conflict, Closeness and Dependency to determine the overall quality of the relationship. Pre and post test surveys were administered after one semester of the intervention advisory program. In addition, interviews were conducted with teachers and administrators based on the survey results. The findings from this study show that the development, training, implementation and evaluation of the advisory program in this form had a positive impact on 65% of the student-teacher relationships. The Closeness subscale had the largest impact on the relationship as 71% of the studied relationships improved in this area. Teachers who designed lessons and activities geared towards the needs of the students and equally, participated yielded the greatest results. School division leaders, administrators, teachers and legislators should continue to

strive to develop positive relationships with students. The findings from this study should be examined when considering the development of a middle school advisory program. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the chapter) Longitudinal study of student engagement patterns is relatively rare but sheds useful light on the factors that contribute to different levels of student engagement in school and its role in student achievement. This chapter uses data from a New Zealand study to focus on changes in student engagement patterns between the ages of 10 and 16, to show (a) the range of individual trajectories of student engagement that lie behind overall declines, and (b) how these different trajectories are related to differences in competency levels and to activities and relationships outside school in ways that compound the patterns of engagement in learning in the school environment and vice versa. Looking at student engagement longitudinally raises the question of whether decline in student engagement levels overall is related to transitions between schools or occurs more as part of general human development that may be better supported by different learning opportunities than schools currently provide. The chapter ends with the case for more longitudinal research into the nature and role of student engagement across different schooling contexts. N2 - Activism has the potential for reform (Howard, 1976). Unlike previous studies on high school activism this study places a primary focus on underground newspapers and argues that underground newspapers allowed high school students to function as activists as well as educational reformers. In order to make this argument, this study examined over 150 underground newspapers and other primary source publications. The goals and tactics of high school activists evolved from the 1950s to the 1970s. During this time there were some shifts in ideologies, strategies, and priorities that were influenced by both an ever increasing student frustration with school leaders and by outside historical events. Underground newspapers captured the shift that occurred in the objectives and tactics of student activists. As a result, the contents of underground newspapers were the primary focus of this study. My study reveals that there were three types of student activists: "incidental" activists who simply wanted to change individual school policies, "intentional" activists who wanted high school students to have greater authority and autonomy in schools, and lastly, "radical" activists who desired an end to oppression of people based on race, class, sex, and age. The evidence overwhelmingly indicates that for the most part incidental, intentional, and radical student activists were all working towards improving their high schools. This common goal was pivotal in the development of a Youth Empowerment social movement, which would be born out of the actions of all three types of high school activists. Incidental activists were the focal point of attention for school administrators in the 1950s, however; intentional and radical activists would take center stage by the late 1960s. Throughout the 1970s intentional and radical activists would overshadow incidental activists and dominate the high school activism scene. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Research Findings: This descriptive study examined classroom activity settings in relation to children's observed behavior during classroom interactions, child gender, and basic teacher behavior within the preschool classroom. A total of 145 children were observed for an average of 80 min during 8 occasions across 2 days using the Individualized Classroom Assessment Scoring System, an observational measure that conceptualizes behavior into teacher, peer, task, and conflict interactions. Findings indicated that on average children's interactions with teachers were higher in teacher-structured settings, such as large group. On average, children's interactions with peers and tasks were more positive in child-directed settings, such as free choice. Children experienced more conflict during recess and routines/transitions. Finally, gender differences were observed within small group and meals. Practice or Policy: These findings might encourage teachers to be thoughtful and intentional about what types of support and resources are provided so children can successfully navigate the demands of particular settings. These findings are not meant to discourage certain teacher behaviors or imply the value of certain classroom settings; instead, by providing an evidence-based picture of the conditions under which children display the most positive interactions, they can make teachers more aware of choices within

these settings and assist powerfully in professional development and interventions. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Twenty-eight early adolescent boys and girls suspended from school for bullying provided accounts of the importance of reputation in their daily lives, specifically how they initiated, promoted, and then maintained their reputation through bullying. Overall, bullying was a deliberate choice perpetrated to attain a nonconforming reputation and was initially promoted through visibility of physical bullying. These actions became more covert, particularly among girls, during the promotion phase. Sex differences were most marked in the maintenance phase. Although both boys and girls used cyber bullying to deliberately induce a sense of apprehension and fear, boys also deliberately damaged their victim's houses and gardens outside of school hours to induce a greater sense of fear and hence maintain their nonconforming reputation. N2 - Evidence from studies of language development indicates that abilities in specific cognitive and language domains are likely to show different patterns of strengths and weaknesses across individuals. Therefore, we hypothesized that the relationships between distinct cognitive and language proficiencies and the underlying neural activity for specific language functions also differ across individuals. To date, the understanding of relationships between language proficiency and neural indices mediating language processing has been limited to the use of composite measures of language proficiency in adults. Furthermore, very little evidence exists regarding the interactions between various aspects of cognition and event-related brain potentials (ERPs) indexing language processing in children. The current study addresses the following question: How do proficiencies in specific cognitive and language functions impact neural indices mediating language processing in children? Thirty typically developing seven- and eight-year-olds were divided into high-normal and low-normal proficiency groups based on performance on nonverbal IQ, auditory word recall, and grammatical morphology tasks. ERPs were elicited by semantic anomalies and phrase-structure violations in naturally spoken sentences. Consistent with our hypothesis, the proficiencies for each of the specific cognitive and language tasks uniquely contributed to individual variability in neural indices of semantic (N400) and syntactic (P600) processing. These results suggest that distinct aptitudes within broader domains of cognition and language, even within the normal range, influence the neural signatures of semantic and syntactic processing. Furthermore, the current findings have important implications for the design and interpretation of developmental studies of ERPs indexing language processing, and they highlight the need to take into account cognitive abilities both within and outside the classic language domain. N2 - Social reciprocity deficits are a core feature of the autism spectrum disorders (ASD) and a major source of impairment regardless of cognitive or language ability (Carter, Davis, Klin, & Volkmar, 2005). Since these impairments do not naturally remit with age, it is critical to intervene as early as possible to offset potential risk factors (Tantum, 2003). Group training approaches provide children with teaching opportunities with other children and allow for the direct instruction of skills within a structured environment (Bellini, Peters, Benner, & Hopf, 2007). Research in social skills group research has increased, but several questions remain. This study

evaluated the outcome of a social skills curriculum for 37 children between the ages of 8 to 14 with a diagnosis of ASD within two different treatment contexts, the camp and clinic model. The camp model simulates a natural setting in which children with ASD spend 5 hours each day for 10 days where social skills are taught through engaging activities and interactions with peers both typical and with ASD. The clinic model, on the other hand, is a one hour a week session spread over 10 to 12 weeks where social skills are taught and practiced while parents observe through a one-way mirror and are trained on the intervention methods. Both clinic and camp model treatments are then compared with a third group who experience both treatments within the clinic and camp setting. Results show that the combined context had the highest treatment effects, followed by the camp model and, finally, the clinic model. Analysis of covariance did not indicate the groups differ from each other significantly in terms of treatment gains. The implications of these results are discussed in terms of translation of research into clinical practice, use of appropriate outcome measures, and generalization of skills through parent training and utilization of training programs within the natural context. While the intervention and results are promising, replication with larger samples and use of a control group are needed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - High sensation seekers (HSS) prefer messages that allow them to maintain an optimal level of arousal (i.e., highly arousing messages). Transportation theory suggests that narrative immersion in a story may moderate reader arousal, and thus HSS message selection. To test this idea, a survey was administered to 120 fourth and fifth graders. In addition to measuring sensation seeking and transportation, the survey assessed interest in reading outside of school (i.e., leisure reading). HSS were found to be less likely to engage in leisure reading. Consistent with the activation model of information exposure, a moderated mediation analysis revealed that whether HSS engaged in leisure reading hinged on their level of narrative transportation (moderator) and subsequent reader boredom (mediator). HSS who successfully transported while reading were no different than their low sensation seeking peers. From a genre standpoint, high sensation seeking children with high narrative transportation scores were found to be especially interested in science fiction/fantasy books. Strategies for increasing leisure reading as well as constructing narratives that are engaging to high sensation seeking children are discussed. N2 - Presents a case report of eight-year-old previously healthy boy fell off a swing in a playground and hit his head on the ground. He presented vomiting but no disturbance of consciousness. He was admitted to the emergency unit of the hospital on the same day. Cranial computed tomography (CT) was then performed, which demonstrated an arachnoid cysts (AC) in the right frontal convexity, with compression and distortion of the frontal lobe, and bulging of adjacent bone, thereby causing cranial asymmetry. There were no neurological deficits. The child was discharged from the emergency unit and referred to the outpatient clinic. Magnetic resonance imaging (MRI) obtained 40 days later confirmed the previous CT findings. The possibility of spontaneous disappearance of ACs may corroborate the use of conservative therapy, especially for incidental findings of ACs. Prophylactic surgery on asymptomatic ACs is not justified, because the course with spontaneous regression has been increasingly reported in the literature. Since asymptomatic ACs may not be diagnosed, the actual rate of spontaneous disappearance of ACs may be higher than it is suggested by the literature. IS - 2012

N2 - (from the chapter) In the author's role as a remedial teacher/Educational Psychotherapist at the Tavistock Clinic, (1973-1986), she saw children individually and in peer and family groups, the latter sometimes with colleagues. All the children were referred for either lack of basic skills, suspended learning (suddenly being unable to continue learning), or showing resistance to learning. Unlike the established mode of family therapy, our work focussed on the family dynamic relating to, and often reflecting, the referred child's capacity and attitude to learning skills and tasks. The dynamic of family behaviour sometimes mirrored their referred child's learning problems, particularly in relation to communication. If there were hidden agendas words became, consciously or unconsciously, misinterpreted. Families sometimes revealed certain attributes similar to those of their child, including: an aggressive stance, bored indifference, low self-esteem, poor temporal sense (e.g. about appointment times), defensive behaviour (blaming others) and an unclear sense of themselves as "competent and active members of the outside world" (Heard & Barrett, 1977). A crucial key to understanding any family interaction is our own understanding of what we are experiencing in the transference or countertransference. Observation offers insight into secure or insecure patterns of attachment behaviour seen in the interaction between family members. Encouraging them to express opinions and feelings about each other either enhances or inhibits their willingness to acknowledge the significance of family loss or transitions. The parents' experience of their own education may affect the extent of their co-operation with us by their choosing: limited acceptance of help for their child, to include parental ongoing participation, to be open to links being made between family interactive behaviour and a referred child's capacity to learn. Although some families are resistant to new experiences, the author thinks that any intervention into family dynamics is likely to bring about some change. In families who are secure in their attachments, losses will be managed in a way that enables the family, and the individual members within it, to mourn, express anger, sadness or joy, and to play, explore, learn, and continue their goal-seeking. For those whose experience has led to anxious attachments, a new way of playing and learning may be dismissed or only partially tolerated. While maintaining homeostasis may feel safer for parents, the author has found that many children recognize and readily respond to the idea of this new way of learning that is being proposed. N2 - Context-awareness techniques can support learners in learning without time or location constraints by using mobile devices and associated learning activities in a real learning environment. Enrichment of context-aware technologies has enabled students to learn in an environment that integrates learning resources from both the real world and the digital world. Although learning outside of the traditional classroom is an innovative teaching approach, the two main problems are the lack of proper learning strategies and the capacity to acquire knowledge on subjects effectively. To manage these problems, this study proposes a context-aware ubiquitous learning system (CAULS) based on radio-frequency identification (RFID), wireless network, embedded handheld device, and database technologies to detect and examine real-world learning behaviors of students. A

case study of an aboriginal education course was conducted in classrooms and at the Atayal u-Museum in Taiwan. Participants included elementary school teachers and students. We also designed and used a questionnaire based on the Unified Theory of Acceptance and Use of Technology (UTAUT) theory to measure the willingness for adoption or usage of the proposed system. The experimental results demonstrated that this innovative approach can enhance their learning intention. Furthermore, the results of a posttest survey revealed that most students' testing scores improved significantly, further indicating the effectiveness of the CAULS.

N2 - This study reports on the use of Cognitive Behavioral Intervention for Trauma in Schools (CBITS), an evidence-based practice, with 43 students in six schools on three American Indian reservation communities. CBITS was helpful in treating the majority of American Indian children and adolescents who were experiencing symptoms of post-traumatic stress disorder and depression. Using a limited quasi-experimental design, on a measure of traumatic stress, there was symptom reduction with the passage of time; however, symptoms reduced more substantially with treatment. Local cultural experts, that is, Tribal Elders, were invited to provide traditional cultural activities and teachings in the introductory lesson and at graduation. A 3-year follow-up involving school counselors reported on acceptability and additional impacts of the program. They expressed that treating trauma was a priority for their students, CBITS was perceived as an advantageous approach, and counselors said they would use it in the future. Further, counselors observed positive results outside of the treatment setting, and integrating traditional cultural activities was perceived favorably. We discuss some of the issues surrounding attempts to evaluate the nature and contribution of traditional American Indian cultural activities to evidence-based trauma treatment. N2 - Adults associate their childhood with playing outdoors, often in natural settings. This type of free play is valuable to child development. Children tend to use outdoor play areas in physically active ways, and time spent outdoors relates positively to increased physical activity in children. However, children today are spending an increasing amount of time indoors rather than outdoors. Recent research has shown that the amount of time children spend in outdoor play is directly related to parental concerns about their children's exposure to outdoor hazards. The purpose of this project was to investigate the relationship between parental attitude toward nature and the development of fine and gross motor skills in young children. The sample for this study was drawn from parents of children ages 3 to 5 years old enrolled at one of two University Child Development Centers. The assessment tool used was composed of sections that ask parents about their attitudes toward nature, about their young children spending time outdoors, how much time their children actually spend in outdoor and indoor activities, and standard demographic questions. The childcare centers independently assessed children's motor development. Statistical comparisons included correlations and ANOVA. Results from this study indicated that parents had positive views toward nature and towards their child's outdoor recreation. Parents who had more positive views toward nature also tended to have more positive views toward their child's outdoor recreation. Children who participated in certain indoor activities tended to score higher in the area of fine motor skills. However, children who spent more time indoors in free play had lower gross motor skill scores. Parents who scored better on the Parental Attitude toward Their Child's Outdoor Recreation scale reported that their child spent more time in outdoor free play and outdoor organized sports and activities. Parents preferred outdoor play spaces when compared to indoor play spaces and specifically those outdoor spaces that were constructed with more nearby natural components. N2 - Youth gangs are ubiquitous around the world and have been problematic for the social and criminal justice agencies. Despite widespread public concern, there has been relatively scarce empirical scrutiny of youth gangs internationally and little outside of America and Europe. In particular, the activities of youth gangs, the function of gang membership, the criminogenic needs of gang-affiliated youth, and the risk of criminal recidivism for gang-affiliated youth remain unclear. Against this background, this study explored the sociodemographic characteristics, risk and rate of criminal recidivism in a cohort of 165 male youth offenders in Singapore, of which 58 were gang-affiliated. Multivariate analyses revealed that gang-affiliated youth offenders were significantly more likely to have histories of substance use, weapon use and violence than nongang-affiliated youth offenders. Gang-affiliated offenders also scored higher on measures of risk for recidivism (SAVRY and YLS/CMI), and engaged in violent and other criminal behaviors more frequently during follow-up. These differences indicate a significant relationship between gang affiliation and criminal recidivism in youth offenders. Furthermore, these findings have important clinical and policy implications, indicating an increased requirement for additional and more intensive assessment and tailored interventions for gang-affiliated youth offenders. VL - 72:

IS - 11-A

N2 - Oral language is an essential communication skill that is often overlooked when preparing children to read (Miller, 2010). Children in lower-income families typically have fewer conversations with adults and by the time they enter kindergarten they have only heard and are able to understand half of the words that high-income children can (Hart & Risley, 2003, 1995). Boys start school speaking fewer words than girls, which in turn leads to lower average reading scores for boys (Tyre, 2008). This puts boys at risk, as they need critical reading skills to be academically successful (Brozo, 2010). Considering the importance of oral language in the development of

early literacy skills, it is necessary to provide consistent times for conversations to take place in preschool classrooms (Bond & Wasik, 2009). The current quantitative study is guided by the following questions: What is the importance of teacher-student conversations in preschool and if preschool teachers regularly schedule conversations with individual students, will it improve their language and literacy development? Does the preschool teacher's encouraging the children to communicate affect their language and literacy development? Does the amount of years a preschool teacher has been teaching affect the student's language and literacy development? This study examined the developmental growth on five language and literacy Measures from the Desired Results Developmental Profile Revised (DRDP-R) of 54 lower socioeconomic status (SES) state preschool boys in a large urban school district in southern California. The students' 27 state preschool teachers scheduled unscripted conversations with them four times a day for three months-during mealtimes, at recess, at the dramatic play area, and at the library center. Research-based strategies were used to guide the conversations. The teachers' ability to encourage children to communicate and their years of teaching experience was also considered. The results of this study indicated that there was a highly significant difference ($p < .01$) in the developmental growth by the Scheduled Conversations Treatment Group compared to the Infrequent Conversations Control Group based on the t-test on the DRDP-R: Comprehends meaning (oral language), Expresses self through language, and Uses language in conversation and significant difference ($p < .05$) developmental growth on Letter and word knowledge. The Pearson product-moment correlation did not show a significant correlation between the student's developmental growth on the measures and the teacher's ability to encourage children to communicate nor on their years of teaching experience. N2 - A lack of exposure to the natural world has led to a generation of children disconnected from nature. This phenomenon has profound negative implications for the physical and psychological well being of today's youth. Residential environmental education provides one avenue to connect children to nature. One purpose of this study was to investigate the role of Outdoor School, a residential environmental education program, on ecological knowledge, children's connection to nature, school belonging, outdoor play attitude, environmental stewardship attitude, outdoor play behavior, and environmental stewardship behavior, as reported by participants. A quasi-experimental research design was utilized in the study. A total of 228 fifth grade students (156 treatment, 72 control) from central Pennsylvania participated. The results of the program evaluation indicated that Outdoor School was successful in achieving significant, positive gains in the areas of ecological knowledge, connection to nature, outdoor play behavior, and environmental stewardship behavior. No change was found from pretest to post-test in outdoor play attitudes, environmental stewardship attitudes, and school belonging. Additionally, the study addressed gaps in the literature regarding the relationship between connection to nature, environmental stewardship, and outdoor play using two different approaches. An adaptation of the Theory of Planned Behavior (TPB) was used to predict outdoor play behavior in children. In this model, favorable attitudes, subjective norms, and perceived behavioral control lead to intentions to perform a given

behavior. Intention to perform the behavior is the best predictor for behavior performance. For this study, participants' feeling of connection to nature was added as an affective independent variable. This model explained 45% of the variance in outdoor play. The hypothesis that a connection to nature would be a significant predictor of both attitudes toward outdoor play was supported by testing of the model. Finally, nature connection was tested as a full mediator of the relationship between outdoor play and environmental stewardship. There is support for the idea that direct experience in the outdoors facilitates environmental behaviors, but more research is needed to understand this relationship. Testing of the model failed to demonstrate that nature connection fully mediated the relationship between outdoor play and environmental stewardship; however, a feeling of connectedness to nature augmented the influence that outdoor play behavior exerts on environmental stewardship behavior. N2 - Sharing leisure experiences is thought to promote family bonding and communication, and foster children's intellectual, social and psychological development. Such time is 'purposive', and requires planning, organisation and maintenance, usually from the mother. Do parents and children spend more time in shared leisure together in countries where mothers do more childcare and spend longer each day with children? Using time use data we compare shared parent-child shared leisure time in four countries with different maternal work-force participation and attitudes to substitute childcare and child-raising: USA, Australia, Denmark and France. We create harmonised measures of leisure time mothers are with children, and time both parents are with children engaging in leisure in the same location (except in the USA, which has information from only one parent). To isolate shared interactive activities, time is further subdivided into (a) watching TV, DVDs or videos with children, (b) non-TV leisure time with children and (c) leisure time with children outside the family home. We find that overall time with children varies substantially between countries, reflecting mothers' average time in paid work, but time in shared parent-child leisure, particularly outside the family home, does not. N2 - The importance of play for children's development and wellbeing has been well established. However, disabled children and their families frequently find accessing play sites challenging due to a range of physical and social barriers and are therefore unable to experience many of the benefits play in this setting provides. Increasingly, United Kingdom policy has recognised this with the 2008 Play Strategy making an explicit commitment supported by funding to ensure that more inclusive public play facilities are developed. Using a case study example of a newly developed 'inclusive' play facility, this paper examines the views of young disabled people and their families regarding what makes a play facility inclusive. Using a socio-spatial analysis, the paper identifies the importance of not only addressing physical constraints but also creating a space where disability is viewed positively and able-bodied discourses are not privileged at the expense of others. The importance of consulting with families, location of facilities and the role of play workers are all analysed. The paper concludes by critically examining the implications of the findings for the delivery of the Play Strategy particularly within the context of public spending cuts imposed by the new Coalition Government, and considers whether inclusive play spaces can become a standard and embedded part of community facilities. N2 - Joint attention is pivotal to the development of complex social skills and language, and many individuals with Autism Spectrum Disorders display deficits in this domain. Behavioral interventions targeting joint attention are evidenced to be effective in teaching these skills to young children with autism, but these treatments have traditionally been implemented by adults in structured settings. Concerns regarding the generalizability of skills acquired under such conditions have been raised. Four typically developing children were trained to implement a joint attention intervention to their siblings with autism in the home. Joint attention was measured pre-treatment and post-treatment during play sessions and during a structured, adult-mediated assessment to evaluate maintenance and generalization. Gains in responding to joint attention were observed for all four participants; gains in initiations were observed in three participants. Rates of imitation and behavioral requests also increased in structured and naturalistic settings. This study supports the efficacy of siblings as interventionists to target complex social skills in the natural environment. The implications of these findings for treatments targeting joint attention and for siblings as interventionists are discussed. N2 - Investigating children's outdoor play unites scholarship on neighborhoods, parental perceptions of safety, and children's health. Utilizing the Fragile Families and Child Well-being Study (N = 3,448), we examine mothers' fear of their 5-year-old children playing outdoors, testing associations with neighborhood social characteristics, city-level crime rates, maternal mental health, and social support. Living in public housing, perceptions of low neighborhood collective efficacy, and living in a Census tract with a higher proportion of Blacks and households in poverty are associated with higher odds of maternal fear, but crime rates are not a significant predictor of fear. We also demonstrate that not being depressed-but not social support or collective efficacy-buffers the influence of neighborhood poverty on maternal fears of outdoor play. N2 - This article extends our conceptual understanding of social capital and school achievement through a comparative race and ethnic approach. Using the National Educational Longitudinal Study (NELS) 1988-1990 panel, this article develops a more comprehensive understanding of school achievement by exploring circumstances, which the authors call "preconditions," leading to the potential for the realization of social capital. These "preconditions" are used to explain academic engagement disparities between Southeast Asian, Black, Mexican, and White high school youth. Whereas previous research on social capital leaves the mechanism through which social capital influences school outcomes unspecified, this study focuses on a behavior associated with positive educational outcomes-time per week spent on homework outside of school. Although preconditions for parental capital appear to have some influence on students' study behavior, so too do preconditions between and within schools, such as peers and teachers. This research shows that relationships outside the family-that is, within and between school opportunities for social capital-play a significant role in explaining variation between the four ethnic groups. N2 - Background: Environmental factors may play an important role in the determination of physical activity behaviors. Methods: This study used the Child Development Supplement of the Panel Study of Income Dynamics to examine the association between the availability of objectively measured commercial physical activity-related instruction facilities and weekly physical activity participation among high school students outside of school physical education classes. A Negative Binomial count model was used to examine the number of days of vigorous physical activity (at least 30 minutes/day) per week and a Probit model was used to examine the probability of frequent (4 or more days/week) vigorous physical activity participation. Results: The results indicated that an additional instruction school per 10,000 capita per 10 square miles was associated with an 8-percent increase in the weekly number of days of vigorous physical activity participation and a 4 percentage point increase in the likelihood of frequent physical activity participation for female adolescents only. By income, associations were larger for low- versus high-income female youths. Conclusion: Increased availability of local area physical activity-related instruction facilities may help to increase female high school students' physical activity levels, particularly among low-income female students. N2 - This article reports the Finnish component of an international mapping exercise concentrating on students' motivation to study music as compared to other school subjects. The study was based on expectancy-value theoretical framework, and the data was collected using a questionnaire. The questions focused on students' competence beliefs, values and perceptions of task difficulty. A sample of 1654 students (grades 5-12) was taken from the Finnish elementary (lower and higher levels) and upper secondary schools. The questionnaire was sent to all Finnish schools, with the principals acting as gatekeepers. The data was generated at schools from all over Finland, and it may be considered representative. The results show that Finnish children like music education, although they do not consider it among the most valuable school subjects. Those students who learned music also outside school seemed to be more interested in all schools subjects than were other students. N2 - We use data from the Fragile Families and Child Wellbeing Study (N = 3,572) to examine relationships between maternal depression and mothers' time investments with their 5-year-old children in outings, trips to playgrounds or parks, time spent reading with the child, and time spent playing indoors with the child. We also examine whether mothers' self-assessments of neighborhoods are associated with time investments in children. Findings indicate that persistent maternal depression is associated with fewer time investments in all four activities with 5-year-old children. Mothers' fear of children playing outdoors and self-assessments of neighborhood collective efficacy are associated with indoor and outdoor activities with children, but do not mediate the relationships between maternal depression and maternal time investments. In sum, maternal depression and neighborhood context play significant but largely independent roles in regulating mothers' time spent in primary child-care activities. N2 - This project evaluated the feasibility of a child-centred 24-week physical activity intervention. The Play5 strategy encourages children to choose to play vigorously five times a day for about as long as school recess. The seven-year-old children were randomised to control (n = 176) or intervention groups (n = 132). Data were collected at baseline and post-intervention. Programme evaluation included parent questionnaire, teacher records and a seven-day pedometer record with a sub-sample of children. The programme was successful in increasing vigorous activity (p = 0.04), but did not impact on moderate or sedentary activities. Young children were able to choose to be active without parent or teacher direction. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) A considerable body of research addresses the role of physical environment in child development. Children's experience of their environment is connected with their perception of safety and with the feelings of fear. Safety is an essential resource for everyday life that could influence the sense of well-being. The first purpose of this chapter is to analyse the feelings of safety and fear of crime that arise from living as a child in urban environments that differ in structural and social features; afterward to investigate children's self-esteem and well-being and their relationship with sense of security. 518 Italian students (average age 10 years) from primary schools of three different urban neighbourhoods participated in this study. The questionnaire was composed by demographic information, measures of urban sense of safety and self-esteem, and well-being scale that includes measures of outdoor and indoor activities. The children's personal sense of safety does not seem to be related to structural elements of neighbourhood. These data underline that more research is needed to analyse this construct in relation to neighbourhoods that are different in structural features. Furthermore, children who

participate in more outdoor activities report higher levels of well-being and self-esteem. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the chapter) I examine in this chapter how children invoke cultural conceptions of gender by categorizing persons and their actions in certain ways, and how this practice serves to deal with local matters of participation in peer group activities. Drawing on a corpus of video-recorded recess activities of two groups of students attending grades 2 and 4 respectively (roughly corresponding to 8 and 10 years of age) at an English school in Sweden, I present two episodes of interaction in which the participants are pursuing different interactional projects with regard to play participation. In the first episode, two girls are collaboratively building their actions so as to enforce their territorial rights. The second extract shows how a group of girls strive to engage two boys in an upcoming play event. The analysis explores how, in pursuing these interactional projects, the participants invoke and exploit some culturally distributed notions of gendered behaviour. By examining the participants' categorization work, I demonstrate how gender stereotypes are brought about in the interaction to accomplish social action. In other words, the present chapter points at some ways through which gender relations as well as social and moral orders are invoked and locally produced in children's mundane interaction. By fleshing out the methods through which the participants accomplish this, the analysis adds to the existing body of work in ethnomethodology on gender-in-interaction. More generally, by analysing the interactional workings of membership categories, this chapter contributes to our understanding of how young people draw upon and exploit local orders-as well as those of society at large-to organize their ordinary activities. N2 - (from the chapter) For many children, play of varying kinds provides a means for engaging with the world around them. Children can observe and play out patterns of behaviour and other social and cultural phenomena, sometimes as a solitary pursuit, but frequently in the company of others. In this chapter, I examine the ways in which school-aged children construct meaning through the generation and performance of musical play forms, both drawing on and transforming cultural influences. Issues of appropriation, transculturation and identity as manifested in musical play are addressed. The interactive pedagogy of the playground, through which children's agency is fully realized in processes of mutual learning and teaching, is also demonstrated. N2 - This paper examines students' activity during reading hour in a multicultural secondary school in Madrid (Spain). It discusses two dimensions of the event: (1) How elements such as body posture, reading volume, reading speed and clarity were used by students to position themselves in relation to their linguistic competencies, the social order of the classroom and the institutional arrangements they participate in; and (2) how interactions around the text were used by students for peer play by drawing from identities formed outside

the classroom. The data illustrates how reading hour was taken by students, especially by some Latin American students, to temporarily redefine aspects of the institutional order they were placed in. These results also invite complicating the outside/inside distinction by showing the multiple layers of institutional and out-of-school life that are collapsed into these categories. IS - 10-B

N2 - Studying emotion regulation in childhood has particular importance for understanding the developmental trajectory of these abilities, as well as for informing preventative work that could offset later psychopathology. Gross (1998a) has distinguished between antecedent- and response focused emotion regulation strategies, and has shown that emotion regulation strategies that occur earlier in the emotion generative process have more favourable outcomes. The first step in antecedent emotion regulation is situation selection, which involves seeking out or avoiding certain situations or environments in order to regulate emotion. In fact, there is a growing psychological literature on children's environmental choices, or environmental niche picking, and how they may affect self-regulatory processes such as emotion regulation. To date, most research has focused on environmental choices for preferred (favourite) environments, and little attention has been focused on non-preferred environments, namely the school playground - the predominant social environment in which children spend their formative years. One's ability to plan, think about the future, and delay immediate gratification are also thought to be important factors in antecedent focused emotion regulation, as such skills allow an individual to move beyond immediate concerns. Few studies have investigated the relationship between emotion regulation and children's future time perspective and planning ability. The present study sought to add to existing research on emotion regulation by investigating the mechanisms by which children develop healthy emotion regulation skills. It was hypothesized that children who scored higher on future time perspective and planning ability would demonstrate better emotion regulation and be rated by peers as less aggressive. It was also hypothesized that any relationship between emotion regulation and aggression would be mediated by future time perspective and/or planning ability. Participants were 82 elementary school students in grades 3 (13 females, 15 males), 4 (17 females, 13 males), and 5 (17 females, 7 males). Parents and homeroom teachers of children also participated by completing the Lability/Negativity scale of the Emotion Regulation Checklist (Shields and Cicchetti, 1997). Children completed peer nomination measures of social behaviour using the Revised Class Play (Masten, Morrison, and Pellegrini, 1985) and one measure of emotion regulation, the Environmental Choices task (Ledingham, Rafter, & Genot, 1995). Children also completed two measures of means-end thinking: the Children's Time Perspective Inventory (Myers, 2000), and the Woodcock-Johnson III Test of Cognitive Abilities - Planning subtest. Results indicated that children as young as the age of 7 could be classified as having a future time perspective, and that future time perspective significantly predicted peer nominations of children's aggression. In addition, children's planning ability, as measured by the Woodcock-

Johnson, played a significant role not only in predicting children's self-reported emotion regulation reasons for environmental choices, but also in accounting for parent ratings of children's emotion regulation. This study also highlighted the importance of environmental niche picking for emotion regulation, with a majority of children indicating that they actively used different locations on the playground to help them regulate their negative emotional states. Contrary to hypotheses, there was no evidence that future time perspective or planning ability mediated the relationship between emotion regulation and aggression. Limitations and implications of the current findings are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Research on toddlers' mathematical knowledge is sparse. Studies on children's mathematical competencies before school age have mostly focused on older children. Few of the previous studies have included large groups of toddlers, few have been conducted in natural settings, and few have been directed at a broad field of mathematical knowledge. The objective of this study was to investigate which mathematical competencies a large group of toddlers' in Norwegian kindergartens expressed through play and daily life activities. A total of 1,003 children participated. Their competencies were registered when they were between 30 and 33 months. The assessment material consisted of 36 items, divided into three main areas: number and counting, geometry and problem solving. The information was collected through authentic assessment; the staff in the kindergartens observed the toddlers' competencies in play and daily life activities. The competencies were registered as mastered, partly mastered or mastering not yet observed. The toddlers showed mathematical competencies in all areas observed. A wide dispersion was found; both for the total score and the subareas' scores. The largest variance was found in number and counting. Our participants displayed lower levels of competencies in using number words and reciting number sequences than reported from previous studies and higher competencies in puzzle-making and following instructions on spatial words. The results indicate that the assessment material may be a valuable tool for the preschool teachers in identifying the variety of competencies mastered by the children in kindergarten. The need for future research is highlighted and discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) This chapter discusses the space within which therapy in schools occurs. Before looking at the practical aspects of the room-what's involved in booking and preparing it for sessions-it's useful to think about the symbolic significance of the space, both on a conscious and unconscious level. Using the same room each week communicates to the child that the physical boundaries framing the work are reliable and dependable, echoing the consistency and availability of the therapist for the child. Ensuring that the same room is available each week contributes to creating a therapeutic culture both within the room and outside, in the school at large. Staff and pupils come to know what the room is used for and when sessions take place. This should result in fewer disruptions, especially once the school therapist has established the service. As the therapeutic relationship unfolds, the room in which the ongoing narrative takes shape acts as a symbolic container. The room itself holds the client's story as well as the emotional history of past and present relationships, including both the real and the transference relationship between client and therapist. On a deeply unconscious level, the room comes to stand for the outer receptacle holding the contents of the client's mind, a concrete manifestation of the therapist's mind, which contains and processes what is revealed, both verbally and non-verbally, as well as all that is fantasised about in that particular space. Because of the symbolic power of the room, most practitioners choose to arrange it in the same way each week and have a fixed set of art and play resources available. This conveys the message that in the face of powerful primitive feelings, fantasies and mental states, the room-and, by association, the therapist's mind-can function as a robust enough container. It goes without saying, however, that the most important component of this process is the therapist's mind: her capacity to go on thinking and not be overwhelmed by the material presented. So, while a dedicated and secure room is the ideal, many therapists do their work day in and day out in less than perfect circumstances ranging from different rooms every week in the school setting to providing out-of-door sessions in refugee camps.

N2 - To better understand peer exclusion in young children, 42 four- to six-year-olds were observed in an outdoor setting, and their verbalizations were recorded using wireless microphones. The frequency of peer exclusion and social aggression, the various techniques children used to exclude their peers (unmitigated, mitigated, ignoring, and planning exclusion) and the relation of gender and social status (acceptance, rejection, and dominance scores) to children's use of exclusion were examined. Peer exclusion occurred frequently, whereas nonexclusionary forms of social aggression were rare. More dominant boys, less rejected boys, and more rejected girls excluded peers more frequently than did other children. Children who were more socially accepted tended to more frequently ignore their peers to exclude them. All girls and boys who were more socially accepted used higher rates of mitigated, subtle forms of exclusion. In addition, boys who were more dominant used higher rates of unmitigated, direct peer exclusion. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This article draws upon the initial results of a survey of school students from eight European countries regarding their experiences of victimisation and offending while travelling to and from school. This is the first such comparative survey to be undertaken. This article provides evidence from the research that travel between the perceived safety of home and school is a risky activity for a significant proportion of young people across Europe. Utilising the notion of anti-social behaviour as the most useful measure for comparative research of victimisation of young people, this article suggests that almost one-fifth of the young people are regularly subjected to behaviour they consider anti-social. However, the majority of young people show surprisingly high levels of self-confidence and security. The key is the existence of friendship groups, which provide security

from victimisation, and if something negative does occur, the friendship group also provides a place to share concerns. Teachers, police officers, youth workers and even parents are far less important in dealing with incidents of anti-social behaviour. This article concludes by arguing that this points to a move away from increasing 'formal' interventions, such as CCTV, adults travelling on buses with young people, or police officers outside schools, towards supporting the, already existing, informal methods used by young people to limit the possibility of victimisation. N2 - This study investigates the academic literacy experiences of elementary English Language Learners (ELLs) in first grade, fourth grade, and sixth grade. Participants included students as well as their reading/language arts mainstream teachers and their English for Speakers of Other Languages (ESOL) teachers. Informed by both cross-sectional cross-case study and narrative inquiry methodology, this study used positioning theory and identity theory as complementary analytic lenses. Students' positionings, both reflexive self-positioning and interactive positioning by others, were identified and named through analyses of their interactions in academic literacy events during reading/language arts. In order to consider the ways that students' positionings may afford or constrain their access to and engagement with academic literacy events, the researcher created an analytic framework naming student positions. Additionally, positions were considered in light of the ways that they mediated students' levels of engagement as literacy events unfolded. To investigate the construction of students' literate identities, the researcher examined students' patterns of positioning during literacy events and considered interview data from students and teachers as well as field notes that documented conversations with participants. The researcher also gathered two self-portraits from student participants, including one self-portrait showing the student engaged in an academic literacy task at school and one showing the student engaged in a fun activity outside of the school context. The study demonstrated that students' positionings, both positive and constraining, may work to construct and re-construct students' literate identities even as students' literate identities may inform the ways that students take on and negotiate positions in a recursive process. The study also found that students with strong literate identities bridging home and school contexts took on more positive positions thus engaging more deeply with academic literacy tasks than students with striving literate identities. Students with striving literate identities often took on positions of constraint in strategic moves that allowed them to get through literacy tasks without engaging deeply. Finally, this study demonstrated the powerful ways that teachers may support students' deep engagement with literacy tasks through positive positioning and following through on their lesson implementation by offering opportunities for re-positioning and the use of scaffolds. N2 - Introduction: It is estimated that tobacco use kills more than 5 million people annually; it is the leading cause of preventable deaths. Recent public health interventions have likely contributed to a steady decline in rates of smoking over the past decade. Nevertheless, innovative and cost-effective approaches to smoking cessation remain a public health priority. The purpose of this study was to profile physically active smokers. Method: Data from the Canadian Community Health Survey 2007-2008-Ontario Sharing File were used. Responses from 41,800 persons aged 12 years and older were assessed to compare (a) the sociodemographic characteristics of physically active smokers to physically active nonsmokers in Ontario and (b) the types of leisure-time physical activities that are more commonly practiced among active Ontario smokers to active nonsmokers. Results: Pearson 2 and independent samples t tests revealed that active smokers were more likely to be male, younger, single, and less educated and to have lower income than active nonsmokers. Active smokers were also more likely to report inexpensive, low-intensity, and solitary leisure-time physical activities. Conclusion. Our findings have important implications for physical activity promotion among smokers. Physical activity interventions for smokers need to be tailored differently than for nonsmokers. N2 - Joint engagement is the child's ability to share an experience involving an object with social partners. This skill is critical to the social and communication development of young children. Previous semi-structured investigations in clinical settings revealed that children with Autism Spectrum Disorder (ASD) present with deficits in joint engagement. Additionally, findings from retrospective studies of home videotapes of children later diagnosed with ASD indicate that ASD symptoms can be observed within naturally occurring activities prior to a diagnosis. Therefore a systematic method of examining the joint engagement skills of children at risk for ASD within everyday activities is warranted. Children between 17 and 34 months (N=42) were recruited from the FIRST WORDS Project prospective study based on risk for ASD. Participants were videotaped during everyday activities and interactions with maternal caregivers. Consistent with the results of retrospective home video studies of children diagnosed with ASD and previous joint engagement investigations, the participants in the current study spent more time playing with toys than in other everyday activities, such as book reading and playing with people. Results indicated that the participants spent the majority of their time in object engagement without symbols and rarely participated in supported or coordinated joint engagement. Children who spent more time in coordinated joint engagement received lower autism severity ratings in the social affect domain of the Autism Diagnostic Observation Schedule (ADOS; Lord, Rutter, DiLvore, & Risi, 2002). Additionally, object engagement with and without symbols was associated with autism severity. The understanding and use of symbols during various engagement states was associated with fewer autism symptoms and higher verbal ability. Overall, these findings indicated that systematic home observations of children's joint engagement skills could contribute to the early identification of ASD symptoms in infants and toddlers. These observations also provide detailed information on children's use and understanding of symbols within everyday activities. Examining the joint engagement skills of children at risk for ASD in natural environments could validate caregivers' concerns of ASD symptoms and help build consensus with a diagnostic evaluation in a clinical setting. The current findings also have important implications for promoting the education of caregivers and professionals on the importance of this pivotal skill. N2 - School environments provide an ideal setting for children to develop and adopt active living behaviors as a way of life. The primary purpose of this investigation was to describe state, district and school level policy regarding in-school physical activity, the school built environment and in-school physical activity of children ages 6 through 11 years in the Mississippi Delta. A mixed-methods approach was used to garner a rich

understanding of how current policy and the built environment influence in-school physical activity and weight status. Eleven public schools in three districts representing two counties in the Mississippi Delta participated in this investigation. The mean physical education class time was 39.2 minutes +8.13 (range 38.33; 95% CI = 37.66-40.75). The mean percent of physical education class time spent in moderate-to-vigorous physical activity (MVPA) was 36.43% + 1.5% (95% CI = 33.57-39.28), a mean of 13.99 minutes + 5.78 (range 27.0; 95% CI = 12.89-15.08). A significant relationship was found between children's in-school physical activity and their BMI ($r = 0.629$; $p = 0.05$). There were significant inverse relationships between the presence and quality of amenities to the school built environment and the students BMI ($r = -0.619$; $p = 0.04$), waist-to-height ratio ($r = -0.819$; $p = 0.002$) and total body weight ($r = -0.615$; $p = 0.044$). There was also a significant inverse relationship between the presence and quality of built environment features and waist-to-height ratio ($r = -0.713$; $p = 0.014$). There was no significant relationship between children's in-school physical activity and aspects of the school built environment. If students are given the opportunity for unstructured daily physical activity it is likely they will meet current physical activity guidelines. Two of the schools in this investigation provided little opportunity for physical activity through recess and physical education classes and had the highest BMI scores. Not surprising, when students in these schools were given the opportunity to be physically active they were among the most physically active students in this study. Despite Mississippi State law, school districts and schools are failing to adhere to policies that provide students the opportunity to engage in 150-minutes of weekly physical activity and are in violation of current state law. N2 - (from the chapter) Project WetKids provides Pascagoula, Mississippi middle school students and their families with wetland, environmental, estuary, and watershed experiences with local scientists, engineers, and naturalists. Extensive activities provide participants (1) real-world, locally relevant science-based events; (2) meaningful scientific experiences and interactions with field scientists; and (3) exposure to science, technology, engineering, and mathematics career opportunities in the Gulf Coast region. This chapter will detail the bi-monthly out-of-school experiences, weekend family events, and Summer Academy provided by Project WetKids. Participants' science content knowledge, their environmental awareness and actions, and their career aspirations were (and continue to be) monitored during the program. Results of these analyses as well as the activities, events, and inspiration that precipitated their growth are described in the chapter. Environmentally rich activities, students' exposure and interaction with scientists, and family-based events provide the

scaffolding to move the community toward awareness and then action of the importance of wetlands education specifically and eco-education more broadly. In addition to the benefits for individual students, there is great potential for a broader impact for an increased science, technology, engineering, and mathematics (STEM) workforce if students gain that sense of excitement from science. As stated by Saunders (2009), "If America hopes to effectively address the 'STEM pipeline' problem, we must find ways of developing young learners' interest in STEM education and must sustain that interest throughout their remaining school years." In this chapter, we describe how Project WetKids seeks to make such an impact. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - From a Bourdieu-inspired understanding of how personal resources ('capitals') enable certain practices in certain contexts, the links between families' cultural, social and economic capitals, and children's daily physical activity were investigated in 500 suburban Danish schoolchildren using questionnaire data and accelerometer measures. Family socio-economic position (SEP) was found to be positively associated with children's participation in organized sport, which could be explained by differences in family capitals. By contrast, this study found no relationship between families' SEP and the amounts of general physical activity in children. This reflected the tendencies for club-organized sport to contribute a relatively small amount to the overall amount of physical activity in children, and for children of low SEP to be equally active in other settings such as school-breaks, day care and neighbourhood playgrounds. N2 - Field trips are effective because they situate learning and facilitate knowledge transfer, thereby influencing students learning attitudes, interests, and motivation. Variations in field trip configurations and the subsequent affective and cognitive influences provided the motivation for this study of Outside Day-an environmental education field trip for 6th-grade students. The participants were immediately postassessed on their attitudes toward the event and 1 month later assessed on their event activity recall. Results indicate the students held positive attitudes toward the field trip and recalled a hands-on orienteering activity most frequently. The discussion provides explanations and implications of findings. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Preschools offer two main opportunities, recess and physical education (PE), for preschool children to participate in physical activity (PA) and are considered a suitable institution for PA promotion given the large number of children enrolled. Although PE can have a meaningful effect on preschoolers' PA levels, preschool PE characteristics associated with increased PA have, to the best of our knowledge, not been identified. Therefore, the purpose of the present study was to examine preschooler's PA levels and the associations with

lesson context, teacher behavior, and environment during preschool physical education. A random sample of 573 preschoolers (288 boys; Mage = 5.4 years, SD = 0.4) from 35 preschools was examined during one PE class. Findings indicated that preschoolers accumulated 12 min (33%) of moderate-to-vigorous PA (MVPA), 5 min (13%) of light PA, and 20 min (54%) of sedentary behavior during PE. Forty-seven percent of the variance in pupils' MVPA may be attributed to differences between PE classes. Less knowledge content, less promotion, less management, less preschoolers per 100 m², using obstruction material, and not using throwing equipment were significantly associated with higher MVPA levels. These predictors explained 56% of the variance in MVPA at the PE class-level. To conclude, PE in its current format contributes only a small amount to the PA requirements of preschoolers. Preschoolers' MVPA levels were related to modifiable PE characteristics indicating that preschool PE can be restructured to increase MVPA. IS - 8-A

N2 - Previous research suggests that bullying is a serious problem with long-term consequences for both the bullies and the victims. These consequences run the gamut from school maladjustment to criminal behavior to suicidal ideation. This longitudinal study utilized ex post facto data collected by one Burlington County school district. Perceptions and behaviors of students in the district's two middle schools were examined by comparing survey responses collected in October 2007 with survey responses collected in October 2009. In addition, survey responses collected in October 2009 were compared with May/June 2010 responses to see if students' perceptions and behaviors changed over the course of one school year. Finally, survey responses from the district's October 2009 seventh graders were compared with survey responses from the district's May/June 2010 sixth graders. The incoming seventh graders had not participated in any of the district's planned interventions while the outgoing sixth graders had participated in the interventions throughout the 2009-2010 school year. The groups were relatively similar in age and middle school experiences so it was believed that the October 2009 seventh graders could represent the pre-intervention group and the May/June 2010 sixth graders could represent the post-intervention group. Results were compared to examine the effectiveness of the school's ongoing bullying interventions. Grade level and gender comparisons suggested that most students felt less safe during the course of one school year. Sixth graders were most likely to be fearful of bullying and were most likely to perceive bullying as a serious problem. All forms of bullying increased as students moved from sixth to seventh and from seventh to eighth grade. All forms of bullying except verbal bullying increased during one school year. The most problematic areas where bullying was most likely to occur were outdoor recess areas, hallways and hall locker areas. Gender comparisons suggested that boys were more likely to bully physically and verbally and

girls were more likely to bully indirectly or through cyber-bullying. When students' ethnicities were considered one interesting finding was that African American students at the two latter survey dates and Hispanic students at the final survey date were more likely to believe that they were bullied due to their race, whereas all other groups reported that the most likely reason for bullying was appearance or dress. Two-year comparisons of October 2007 and October 2009 responses suggested that students in 2007 felt safer and students in 2009 were more likely to perceive bullying as a serious problem. The 2007 group was more likely to bully physically, verbally or indirectly whereas the 2009 group was more likely to cyber-bully. The only exception to this was cyber-bullying through instant messaging, which was more prevalent in 2007. Pre- and post-intervention comparisons suggested that the district's interventions may have been at least partially successful. While outdoor recess continued to be the most likely place where bullying would occur, the percentage of students who reported this dropped precipitously when these two groups were compared. Verbal bullying also declined suggesting that although the interventions did not specifically target this behavior they may have played a role in the decline. Unfortunately it is impossible to know with any degree of certainty whether these declines were due to the interventions or due to some other unknown influence. Recommendations for the school district and suggestions for future research were also discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Children need to develop active living behaviors that will continue into adolescence and adulthood as well as increase their physical activity to reduce the risk of obesity and related chronic illnesses. Using a multilevel social ecological approach, the overall aim of this study was to identify neighborhood correlates of children's physical activity and active commuting to/from school. Methods: A cross-sectional research design was employed to acquire and link secondary data from several sources at the individual and neighborhood level. The sample included 863 children, ages 5 to 14, and a household member living in 89 neighborhoods/ZIP codes in the Denver metropolitan area. Child data were obtained from the 2005 and 2007 Child Health Survey (CHS), which was directly linked to family members' data from the 2005 and 2007 Behavioral Risk Factor Surveillance System (BRFSS). Neighborhood data were linked to child and household data. Results: The combined partial proportional odds model revealed that mean neighborhood safety (for five or one to four days versus zero days) and percentage of minority residents were significantly related to children's active commuting to/from school. For boys, the individual level hierarchical linear model found that family members' physical activity influenced boys' physical activity, and the separate neighborhood models revealed three neighborhood variables (percentage of individuals with at least a BA degree, reported incidents for rape, and reported incidents for all violent offenses) that directly influenced boys' physical activity. For girls, the individual level multiple linear regression model revealed that family members' physical activity predicted girls' physical activity, and the

separate neighborhood models found four neighborhood variables (population density, reported incidents for murder, reported incidents for robbery, and number of school playgrounds) that directly influenced girls' physical activity. Contrary to the hypothesis, parental perceptions of neighborhood safety did not mediate the effect of total violent crime on boys or girls' physical activity or active commuting to/from school. In addition, children's physical activity was not correlated with their active commuting. Conclusion: Neighborhood safety is an important factor for discretionary active commuters. Future research should explore in greater detail the influence of crime on boys and girls' physical activity. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Traffic-related air pollution can be a major public health concern in any urban area. This problem is compounded in the Paso del Norte region that has experienced rapid economic growth, and a substantial number of people living in close vicinity of major roadways. The desert surroundings, arid weather, frequent temperature inversions, heavy border traffic at the international ports of entry between El Paso and Ciudad Juarez, and poorly maintained vehicle fleet further exacerbates this problem. A growing body of air quality and epidemiologic research has discerned the linkage between traffic emissions and respiratory disorders. Initial health investigations in the Paso del Norte region have found associations between various air pollutant indicators and adverse respiratory outcomes. However, monitoring traffic pollution as an indicator of population health and the subsequent ability to accurately reflect changes in the respiratory health of sensitive populations like school-going asthmatic children has been challenging in this region. Given the substantial amount of time children spend within school microenvironments, assessing children's school-based exposures is essential for preventing children's health risks to air pollutants. Indeed, the importance of characterizing children's exposures in schools corresponds with the US Environmental Protection Agency's recent initiative to promote outdoor air monitoring network near schools. As part of a binational health effects study investigating the impact of traffic air pollution on asthmatic children, paired indoor and outdoor concentrations of fine and coarse PM (PM_{2.5} and PM_{10-2.5}), black carbon, and NO₂ were determined for 16 weeks in 2008 at four elementary schools in the international community of El Paso - Ciudad Juarez on the U.S.-Mexico border. Fifty-eight asthmatic subjects from these four schools were recruited. Health outcomes (weekly exhaled nitric oxide [eNO] measurements and daily respiratory symptoms) were recorded for the study period. Two schools (one in each city) were located in high traffic density zones and the other two in zones of low traffic density. Strong spatial heterogeneity in air pollutant concentrations existed in the region with all outdoor pollutant concentrations, in general, higher in Ciudad Juarez than in El Paso by two-fold or more. Concentrations of all pollutants, except PM in Ciudad Juarez, at high traffic density zones in both cities were higher than those measured at their respective low traffic density zones. Traffic-related PM pollution in Ciudad Juarez was confounded by the ubiquitous fugitive dust emissions from unpaved roads and regional unprotected bare soil such that both PM_{2.5} and PM_{10-2.5} measured

in the low traffic density zone surpassed those measured in the high traffic density zone. Aided by inter-site and intra-pollutant analyses, concentrations of NO₂ and black carbon were confirmed to be better indicators for traffic-related pollution. Indoor air pollution was found to be well associated with outdoor air pollution, although differences existed among all schools in student activities, building tightness, use of ventilation system, temperature control devices, and building materials. Routine cooking and food preparation in classrooms could result in high level of indoor NO₂ which pose unintended health risks to school children. Significant associations between the weekly (96-hr) averages of several measured pollutants and eNO with effects estimates ranging from 1 to 3% increases in eNO per interquartile range increases in pollutant concentrations were observed. Effect estimates from models using indoor pollutant school concentrations were generally more robust than corresponding models using outdoor school or ambient concentrations. This research characterizes the intra-urban variability (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Presents a study which aims to examine two ways that schools may encourage physical activity behavior, one, number of permanent play facilities and second, school policies related to physical activity like quality of physical education programs, promotion of physical activity, safety issues, and the adequacy of school facilities. The amount of permanent playground equipment at the school was significantly linked to physical activity levels, although school policies were not. Specifically, for every 10 additional playground pieces, children engaged in 3.2% more average physical activity and 8.3% more moderate-to-vigorous physical activity (MVPA) during recess. Physical activity outside of school hours was 5.6% higher on average and 10.5% higher for MVPA for every 10 additional pieces of play equipment. Building more permanent playgrounds and structures appeared to be a relatively cost-effective strategy for increasing physical activity behaviors both during recess and after school hours. N2 - This study examined sources of variability in preschool children's positive and negative engagement with teachers, peers, and tasks, and how that variability was related to both classroom activity settings (e.g., teacher-structured time, outdoor time, transitions) and child factors (age, gender). Participants were 283 socioeconomically and linguistically diverse children drawn from 84 classrooms, 34-63 months old (M = 50.8, SD = 6.5). Each child's engagement was observed and rated multiple times within a single day. Results suggested that children's engagement varied significantly across the preschool day. Activity settings that provided children with a greater degree of choice (free choice and outdoor time) were associated with more positive engagement with peers and tasks, while teacher-structured activities were associated with more positive engagement with teachers. Transitions emerged as a difficult part of the day, associated with less positive engagement with teachers and tasks. Older children were rated higher on peer and task engagement. These findings, together with previous research, suggest that both characteristics of the classroom setting and child factors are associated with children's classroom engagement throughout a day in preschool. N2 - The aim of the study was to describe and compare the school participation and social networks of children with physical disabilities and complex communication needs (Group CCN), children with physical disabilities only (Group PD), and children with typical development (Group TD). The 39 participants, 10-15 years of age, were observed for 4 hours at school. School staff and the parent and/or child provided information on children's social networks. A striking observation was that, while participants in Group TD continuously conversed and socialized with peers inside and outside classrooms; those in Group CCN rarely used aided AAC, were provided with limited communication opportunities at school, and had fewer acquaintances and friends. Findings warrant intervention at the participation level at school and in the community. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - As much as play is researched and discussed by people interested in children and childhood, studies often fail to examine closely the ways that kids accomplish their play. This study sought to answer the question of how children sustain their play interactions. By making use of qualitative methods to collect and analyze data, the play of elementary-age children was studied in the summer camp and school recess settings. In these settings, children were less closely supervised by adults and were freer to make their own decisions about their interactions, in comparison to more structured settings such as school classrooms or organized sports. Findings from this study revealed that kids worked to sustain their play interactions by creating a participation framework that included one participant being in charge within each interaction. The kid in charge played the role of the boss and managed the play activity. The other kids followed and took on support roles. In addition, findings revealed that unwritten rules around social interactions were important to the ways kids interacted with each other. Play activities were found to be made up of nuanced communication that was evidence of the work kids did to sustain their interactions. By managing their own play activity, kids worked to sustain interactions without the guidance of adults in the moment. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the chapter) Psychoanalysts listen and reflect on what they hear from their patients and on what they do with them. Child analysts also attend to the activity of the play with their young patients and to the symbolic representations in the play. Rarely have analysts-adult or child-learned from observational data in the meticulous manner of scientific researchers, and rarer still are attempts to gather this observational data and make it available for others studying the analytic process. All psychoanalysts would agree that what is communicated outside of language in the analytic hour has great value. How do other disciplines teach about what happens outside of language and symbols? One way is through watching videos. A tennis player can look at videos of Roger Federer and watch his strokes, yet eventually the player will have to develop 'muscle memory' to be able to implement the moves in a match. This is the focus of the current chapter. Here, I will use the case of a dyadic (mother-child) treatment to illustrate how videotape and particularly the microanalysis of the videotape can enhance our understanding of what goes on in psychotherapy and give us insights into therapeutic technique. In this chapter I will use the case of "Jose," a 3-year old to 4-year old boy, to demonstrate the value of videotape and microanalytic technique to the understanding of therapeutic change. The treatment was a dyadic treatment, in which the author saw mother and child together, using videotape in several different modes during the therapy. In each of the three examples of videotape from the case, a moment of new meaning created by mother and child together was accompanied by the 'music' of highly coordinated rhythms of vocal and action turns. N2 - The purpose of this study was to explore the use of bibliotherapy as an intervention to increase social problem-solving skills in young children, delivered by classroom teachers within a natural classroom setting. Previous research in this area has been limited to bibliotherapy interventions delivered by clinicians in small group settings. However, guidelines for delivering interventions in natural environments suggest that teacher-led, classroom-based, and child-initiated activities would provide the most natural, school-based setting for young children. The intervention for this study was delivered by classroom teachers and integrated into the classroom curriculum. The participants included 96 students from three kindergarten and three first grade classrooms in a demographically diverse elementary school located in a large urban school district. Classes were randomly assigned to either a treatment group or wait-list control group. The treatment group received the bibliotherapy intervention with reinforcement activities while the wait-list control group received no intervention during the intervention period. A one-way ANOVA, ANCOVAs, and correlations were used to analyze results across groups within a pre-post experimental design. After the intervention, the treatment group demonstrated significantly higher social problem-solving skills than the wait-list control group. Also, the results suggest that children who participated in the bibliotherapy intervention were able to maintain their social problem-solving skills and generalize their skills they to other situations. N2 - The aim of this study was to describe the overall play participation of children with cerebral palsy (CP) aged 9-13 years by measuring what activities they participate in using the Preteen Play Profile (Henry, 2000); and to explore variations in participation in different play categories based on each child's manual ability, gross motor function, CP distribution, age and gender. A mail-based survey was conducted of children with CP from three facilities in the United States. Of 252 surveys mailed, 15 were undeliverable because of the wrong addresses and 93 completed surveys were returned (39.2%). The children (58 males, 35 females) were aged between 9 and 13 years (mean age 11 years 1 month, SD= 1.06). Findings showed that children with CP participated in a wide range of activities in the past year. The majority of play activities were indoor rather than outdoor, sedentary rather than active, and lack structure. Watching television and listening to music was by far the children's major play activity. Play categories were ranked from highest to lowest in play participation as follows: indoor, creative, social, summer, outdoor, winter, sports and lessons. It was found that children with quadriplegia who are in Levels IV and V on both the MACS and GMFCS are the most at risk groups of

decreased play participation. The children's manual ability and gross motor function were the main predictors of play participation indicating the need for using both classification systems in practice and research. Children of both genders participated in similar play activities but when analyzing separate play categories, females achieved significantly higher scores than males in creative, lessons and social activities. The results of this study pointed to the need for integration of more outdoor, sports, and social play into the daily routines and curricula of centers, and schools that serve children with CP. The study concluded with some recommendations on how deficiencies and gaps in play participation can be filled through several proactive approaches that pediatric occupational therapists can take in conjunction with caregivers and community members to improve the lives of children with CP. N2 - Aim: According to the US Department of Health and Human Services (2008) and the World Health Organization (2008), regular physical activity is essential to the healthy development of children and contributes to the reduction of chronic diseases throughout their life span. However, coordinated comprehensive national and international programs to promote physical activity and sports participation are lacking. According to the German Sports Federation (2006), physical education (PE) classes at German schools are increasingly being canceled or taught outside the school. "fit for pisa" is a German intervention developed in response to the demand for scientific evaluation of interventions like daily physical education. Its goal is to provide quality management-secured, structured and standardized PE instruction by qualified instructors. Subjects and methods: The "fit for pisa" intervention has been implemented at five primary schools in Gottingen, Germany, since 2003. This daily physical education intervention is based on quality standards. At the five primary schools participating in "fit for pisa," students receive a supplementary 3 class hours of PE/week in addition to the mandatory 2 class hours/week for the entire school term. In other words, the children now receive one 45-min session of PE each school day. Daily physical education is now a part of their mandatory school curriculum. The curriculum content and teaching methods have been continuously developed and optimized based on the state guidelines for Lower Saxony. Results: Teacher training is held at the participating schools once a month to promote standardized implementation and quality management of the intervention program. Additional monthly meetings are held so that the teachers can discuss any problems, deviations or other issues occurring in the classes. Checklists are provided for the teachers and external trainers to document the content and objectives of each lesson. Supervisors evaluate the checklists at regular intervals. Using these instruments, the results of the 4-year intervention program were evaluated at the five participating primary schools. Conclusions: This study provides important data for recommendations to implement additional physical education in primary schools, for the corresponding quality assurance instruments and for the optimization of physical education guidelines for primary schools. N2 - This article discusses the way in which four-year-old children engaged in the complex co-production of rules and social governance in their primary school playground in Wales, UK. Through an inductive investigation into children's everyday social interactions at morning break time the child's view of their spatial affordances can be revealed. These affordances are the spaces the children talk into being (Heritage, 1978) and to what end. By making explicit reference to the wooden huts in their co-production of playground rules and governance the children talked those spaces into being and made them noticeable as important places for the practice of such agency in their everyday social organisation process. N2 - Social skills play an important role in young children's successes in and outside of school. For two decades, educators have used the Social Skills Rating System (SSRS; Gresham & Elliott, 1990) as a tool for describing children's social behaviors and for planning interventions to improve social skills. Although widely used, some researchers have criticized certain aspects of the preschool version of the SSRS. In 2008, a revision of the instrument, the Social Skills Improvement System-Rating Scales (SSiS-RS; Gresham & Elliott), was published. In this article, we examine the development of the preschool versions of SSRS and SSiS-RS and provide a comparison of the two rating systems, focusing on the content, structure, psychometric properties, and intended use of the instruments. We then describe the SSiS-RS within an assessment for intervention model. We conclude that the SSiS-RS is an improved assessment instrument over the preschool SSRS and provide recommendations for future studies that will contribute to the evolving validity evidence for the resulting scores and decisions made from them. N2 - Nearly all children receive abduction prevention training. Most traditional education programs increase the learner's knowledge, but often fail to produce concomitant behavior change. Behavioral Skills Training (BST) is a multi-component, behavior-based training strategy with empirical support demonstrating its effectiveness in teaching children safety skills, behavioral generalization and maintenance over time. BST, however, is restricted by financial, human and time costs and limited resources to implement the training protocol. These factors likely limit widespread adoption of the training model. This study examined the use of computer-based instruction that emphasized active responding and mastery level performance requirements to teach school-aged children abduction prevention skills. Computer-Based Instruction (CBI) was compared against traditional BST (instructions, modeling, rehearsal, feedback and in situ training) on measures of training effectiveness and efficiency. Forty children (Mage = 10 years, 2 months) were randomly assigned to the CBI experimental group or BST control group. Evaluation was conducted via in situ assessments in laboratory and naturalistic settings at baseline, post-training, two weeks and one month following training. Results revealed clinically and statistically significant improvements in child performance of target safety behaviors after training for both groups. Behavioral generalization to naturalistic settings and skill maintenance was demonstrated at follow-up assessments. Differences in child performance were not observed between training delivery models. Training

time and number of training trials to program/skill mastery was less for BST compared to CBI. Costs and resource needs were greater during the program development phase for CBI. Program implementation expenses associated with CBI were minimal and cost per unit of delivery decreased exponentially with successive implementation of the intervention. Per unit of delivery costs for BST were fixed and total investment associated with this model increased across successive implementations. Taken as a whole, CBI was as effective as BST in teaching children abduction prevention skills. Across multiple learners, the computer-based instruction program becomes a more economical delivery model. Findings are also discussed relating to child emotional response during training and assessment sessions and correspondence between the learner's verbal report of behavior during simulated abduction situations and behavioral performance during live assessments. N2 - The display of aggressive behaviours among the digital generation has modernized the traditional attributes of bullying. Cases of bullying are no longer confined to physical altercations between peers in school hallways or hostile verbal exchanges during recess periods. With the progression of technology, educators must recognize the changes of our students' behaviours as lives become modified by the digital era. The issues of cyber bullying have gained global visibility due to the disheartening publicized cases of the victims. While the families of victims mourn the loss of their children and earnestly seek to understand the cause of each account, researchers actively examine and implement preventative measures in hopes of educating individuals (e.g., general and special educators, parents, students, community professionals) to distinguish the warning signs of aggressive behaviours in digital forms. N2 - A central argument for the creation of Online Learning Environments is they permit learners to engage in social learning freed from the constraints of shared space and time (Hara, Bonk, & Angeli, 2000). However, other research suggests that location and work relationships (Hampton & Wellman, 2003; Koku & Wellman, 2004), as well as race, ethnicity and gender (McPherson, Smith-Lovin, & Cook, 2001), have an influence on the shape of social networks. Studies of late-elementary school children suggest that they have strong preferences for same-gendered interaction in classroom and playground settings. This research uses Social Network Analysis and Discourse Analysis to evaluate the effects of shared school location and gender on the social networks created by late-elementary students in Quest Atlantis, an international game-like social learning environment. Three different modes of computer-mediated communication interaction were sampled: synchronous public chat, asynchronous private e-mail, and asynchronous private telegrams. This study found that participants sent disproportionate numbers of messages to participants located at the same geographic site. This effect was most pronounced for mail messages, which were almost exclusively sent to same-site participants. Participants also disproportionately sent e-mail and telegrams, although not chat messages, to members of the same gender. Designers and managers of online social learning environments should consider that effective communication across sites separated by geography may require active mediation and team building beyond the existence of CMC utilities. Social network analysis can provide an useful tool for evaluating efforts to build online social learning environments. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In Texas, fifth grade students are required to pass both the reading and math sections of the Texas Assessment of Knowledge and Skills, or TAKS test, in order to be promoted to the next grade level. The purpose of this study is to describe parents' perceptions of the influence of the high-stakes TAKS test on the family lives of at-risk fifth grade students. Parents of students identified as at-risk for failure on the TAKS test

by their schools were given a 12-item survey with three components: the effects of TAKS on the student and family, the effects of TAKS on how students spend time outside of school, and parent attitudes about TAKS as a fair measure of achievement. A series of three one-way ANOVAS was used, comparing each independent variable (family, time, and fairness) to a series of dependent variables (gender, race, and attendance at a Title I school) to look for variability between these groups in their attitudes towards the independent variables. The results indicated that many parents perceive that the TAKS affects their families by causing their child and other family members to express concerns about passing the test and by causing the parent to worry about how their child is reacting to the pressures of the test. Parents perceived that the TAKS test affects how much time students spend playing with friends as well as watching television or movies. Many parents did not agree that TAKS is a fair measure of student achievement for their child or other children. The ANOVAs indicated statistically significant findings among race groups and their scores on "family" and "fairness." Asian/Pacific Islander parents indicated significantly less effect of TAKS on their student and family than did white parents. Asian/Pacific Islander parents also perceived TAKS as fairer measure of student achievement than did white parents. As well, Hispanic parents also perceived TAKS as a fairer measure of student achievement than did both white and Black/African American parents. Findings indicate that perhaps schools and teachers would be surprised to discover the amount of stress TAKS is causing families and students, particularly those at risk for failure as well as those groups that might not have previously been thought to "care" about school. The level of negativity caused by TAKS appears to be an undesirable unintended consequence of the assessment system, so educators may want to reconsider their policies and practices for TAKS-related parent engagement, homework, and test preparation. N2 - The study sought to determine if increased technology use affects the free-time choices of students. While technology options have grown exponentially, time remains a fixed commodity. Therefore, it is suggested that students who increasingly use technology must draw time from more traditional childhood activities. Students' free-time activities were examined to document discernable patterns among the activities valued by students who use technology extensively and the activities valued by students who use technology less frequently. Study participants were fifth and seventh grade students in a semi-rural suburban county in the southeastern United States. The data collection instrument was a self-reporting survey in which students were asked to specify their relative interest in six traditional activities in comparison to specific technology-based alternatives. Students were also asked to estimate the number of minutes per week they spent on traditional and technology-related activities. Based on their time estimates, high and low quartiles of technology use were established. The forced-choice responses of students in the upper quartile of technology use were compared to the forced-choice responses of students in the lower quartile of technology use to determine if there were differences in their

expressed preferences for the six traditional activities included in the study. Although findings revealed that students in the upper quartile of technology use were less interested in all six traditional activities studied than were students in the lower quartile of technology use, reading for fun, supervised activities, outdoor activities, and having a hobby were activities more readily relinquished than were spending time with family and playing with friends, indicating their relative value among the two groups. As students abandon traditional childhood activities to pursue technology-driven options, adults who are concerned about childhood development might explore alternative means for obtaining the benefits those six activities once provided. Recommendations are made for replicating the study among different populations. Although gender and grade level were two variables that were examined in this study, it would be beneficial to determine if findings would be similar among students with more or less access to technology, with divergent socio-economic means, and from diverse ethnic backgrounds. N2 - (from the chapter) Gender shapes human lives in large and small ways. Whether a person is female or male influences her or his clothing, hobbies, social interactions, occupations, and incomes. To consider the pervasiveness of gender in our daily lives, imagine what it would be like if a person tried to live outside of the categories "male" and "female." That is the premise of Lois Gould's fictional children's story about a child named X who was raised by its parents without revealing its gender to others. In the story, X encounters resistance from peers, teachers, and other parents who want to treat X as a girl or a boy. In the story's happy ending, the other children begin to emulate X once they realize that X is having twice as much fun as they are. That is, without being constrained by traditional gender categories, X has the flexibility to pursue a greater range of play activities. The idea of not revealing one's gender to other people may seem like something that could only happen in a children's story. However, a Swedish couple is not revealing the gender of their 2 & 1/2-year-old child named Pop. According to the mother, "We want Pop to grow up more freely and avoid being forced into a specific gender mould at the outset". The fictional story of X, as well as the real cases of Pop and Shane Whalley, bring into stark relief society's reliance on gender to define and constrain human experience. In the present chapter, we review some of the ways in which this occurs in children's lives. We describe children's gender development during three age periods: infancy and early childhood (approximately birth-5 years), middle childhood (approximately 6-12 years), and adolescence (approximately 13-18 years). Because children construct their own beliefs about gender and use these beliefs to guide their behavior, we focus on the role of children's

cognitions, affect, and behavior in shaping their gender development. At the same time, because children are born into a world in which gender has significant meaning, we highlight the ways in which other people's gender-stereotyped expectations and behaviors differentially affect girls' and boys' beliefs, goals, and behaviors. However, because gender affects virtually every facet of individuals' lives, we are unable to review every important aspect of gender development. We concentrate on subjects most closely linked to social development and hope that readers will be inspired to read more broadly on other related topics. N2 - Objective: To describe the design, measurements and fieldwork of the IDEFICS (Identification and prevention of dietary- and lifestyle-induced health effects in children and infants) physical activity and body composition validation study, and to determine the potential and limitations of the data obtained. Design: Multicentre validation study. Subjects: A total of 98 children from four different European countries (age: 4-10 years). Methods: An 8-day measurement protocol was carried out in all children using a collaborative protocol. Reference methods were the doubly labelled water method for physical activity, and a three- and a four-compartment model for body composition. Investigated field methods were accelerometers, a physical activity questionnaire and various anthropometric measurements. Results: For the validation of physical activity field methods, it was possible to gather data from 83 to 89 children, laying the basis for age- and sex-specific results. The validation of body composition field methods is possible in 64-80 children and allows sex-specific analyses but has only limited statistical power in the youngest age group (<6 years). The amount of activity energy expenditure (AEE) varied between centres, sexes and age groups, with boys and older children having higher estimates of AEE. After normalisation of AEE by body weight, most group-specific differences diminished, except for country-specific differences. Conclusion: The IDEFICS validation study will allow age- and sex-specific investigation of questions pertaining to the validity of several field methods of body composition and physical activity, using established reference methods in four different European countries. From the participant analyses it can be concluded that the compliance for the investigated field methods was higher than that for the reference methods used in this validation study. N2 - Playgrounds and play times offer valuable contexts for children to explore and learn about themselves and their social lives. This study sought to gather evidence of children's perceptions of their playgrounds and play times, specifically whether the playgrounds were seen positively or negatively and the types of activities in which they engaged. Child-oriented methods were adopted inspired by the Mosaic approach. The main themes from the focus group interviews were social play (friendship, loneliness/solitude and fair play); physical activity play (activities and rationale); risk (injuries and bullying); and gender (action/stillness and gendered roles).

Research suggests that segregation declines when adult supervision supports shared play, and our experiences suggest that such intervention is the most likely solution to the 'problem' of gender play in this setting.

N2 - This study considered how three groups of academically talented high school students—those who attended an academic summer program (TIP), those who qualified for the program but chose not to attend (QNA), and those who did not qualify (DNQ)—spent time outside the classroom. These groupings differentiated students by ability (QNA vs. DNQ) and attendance (TIP vs. QNA). Male-female comparisons were also conducted. By comparing participation rates across a variety of activities and by sex, the current study helps explain the lives of high-ability students outside the arena by which they are defined: their academic ability. Results reveal numerous group and sex differences based on how high-ability students spend their time outside the classroom. Females tended to participate more than males in activities that were generally positively associated with academic achievement, while also participating in more types of activities. Males, however, reported watching more TV and were less likely to participate in any activity. QNA students reported spending more time on academic-related activities, such as homework and academic clubs, than did DNQ students, indicating a generally higher interest in academic endeavors. However, the QNA and TIP groups differed only in their service club participation rates, indicating that attending a summer program is not associated with spending time outside the classroom differently during the school year. This research underscores the heterogeneity of different groups of high-ability students and suggests some caution when generalizing from research findings based only on program participants. Knowing how students spend their time can help parents, educators, and researchers understand and foster adolescent development. N2 - Research Findings: Forty-five child caregivers and 120 parents participated in this study to examine perceptions of childcare programs in Jordan. The researchers developed a questionnaire that consisted of 6 dimensions: health, education, parent-caregiver relationship, facilities, building/landscape, and playground. Moreover, interviews with 10 child caregivers and 20 parents were conducted. Results indicated that child caregivers expressed moderate satisfaction with the programs. In contrast, parents expressed lower satisfaction with the childcare programs. The results also revealed that caregivers and parents perceived the playground area as effective but found health and the parent-caregiver relationship ineffective. Practice or Policy: This study highlights the need to supervise childcare programs effectively and the importance of fostering a strong partnership between child caregivers and parents. N2 - This case study followed struggling readers as they moved through an enhanced fluency intervention which included explicit instruction in fluency, comprehension, and "good reading" behaviors. There were fourteen students in fourth and fifth grades who participated in small group reading classes outside their general reading class. The intervention used the commercially available text of Read Naturally, Master's Edition (Matsoff, 2006). The teacher provided explicit sequential instruction with each small group. Enhancements in fluency included instruction in text markings and prosody, teacher modeling, and a variety of readings. Enhancements in comprehension included explicit instruction in the reading strategies of predicting, clarifying, questioning, and retelling. Instruction on what "good reading behaviors" used "good reader" slogans and guided practice. Achievement data were collected using pre and post intervention measures. Student interviews and questionnaires were administered pre and post intervention to determine changes in the student's perception of him/herself as a reader. Questionnaires and interviews examined the student use of "good reading" behaviors. Parent and teacher observations were elicited through questionnaires to assess these behaviors. The enhanced fluency intervention had a positive effect on the struggling readers as the group means increased on standardized and curriculum-based assessments. Changes were noted as the students used the vocabulary of "good reading" behaviors on final student interviews. Responses on the final student and adult questionnaires reported "good reading" behaviors at home and at school but responses indicated students did not use the majority of "good reading" behaviors in their independent reading activities. N2 - This paper reports the background and findings of the community-based pilot program 'Rock Up' to school. The Rock Up program was directed at a niche section of young students in Grades 5, 6, and 7 to respond to identified risk factors associated with disengagement from formal education. The Rock Up approach was to energise these students' connection to learning as they approach the difficult stage of transition from primary school to secondary school. Ultimately, Rock Up aims to assist those students in their development of wellbeing, within and outside of the school environment. The operational measures of wellbeing covered; academic, social, emotional, behavioural, and school absence. Thirteen students, who had been identified by their respective teachers, were invited to participate in individual and/or group activities that focused on their wellbeing and developing their readiness for secondary school. Written and verbal feedbacks from students, teachers, parents, and the program facilitator, were in the main very positive. Analysis of the data of the first round of the program using a three-wave questionnaire and a participatory action research approach indicated the need to proceed to a new round using more refined processes. When fully developed, Rock Up is intended to be the vanguard for collaborative practice between the education and community sectors throughout Victoria and to be an example of an efficient and effective model of transition for this age-group. N2 - Imagine what it is like to be a child whose clumsy actions make it difficult to keep up with peers on the playground or to accomplish everyday tasks of daily living such as tying shoes or buttoning a coat. This special issue of Research in Developmental Disabilities is focused on the disorder that defines these children, known as Developmental Coordination Disorder. The papers presented here are selected from the VIIIth International Conference on Developmental Disorder which was held, for the first time in the United States, in Baltimore, MD, 2009. We have grouped the contributions into three sections. The first two sections represent the International Classification of Functioning, Disability and Health framework (WHO, 2001) - (1) Body Functions: Psychological, Cognitive and Neuromotor Function; and (2) Activities and Participation. The third section is titled - (3) Assessment and Measurement. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The impact of music activity on children's motor and cognitive skills has been investigated with music learning, instrument lessons and classroom music. While none have employed natural utterances, singing games or playground/street songs, these musical experiences of childhood are acknowledged as a major platform for child development. The current study isolated handclapping songs exploring the association of performance quality with classroom academic achievement and examined whether children who spontaneously engage in handclapping songs activity demonstrate improved motor or cognitive abilities. Finally, the study investigated the outcome of a two-group eight-week classroom intervention. The study found that: (1) children who were more skillful at performing handclapping songs were more efficient First Graders; (2) Second Graders who spontaneously engage in handclapping songs were advantaged in bimanual coupling patterns, verbal memory and handwriting; and (3) classroom handclapping songs training was more efficient than music appreciation classes in developing non-music skills among Second and Third Graders. N2 - In this study, a multiple baseline design across three young children with autism was used to assess the impact of individualized behavior support, implemented through family-school collaboration, on the children's appropriate and problem behaviors and adult-child interactions. A positive behavior support process was used to promote family-school collaboration and to design the individualized intervention. Data indicated that the children's target behaviors improved with the intervention during circle time at school and play time at home, and their behaviors generalized to nontargeted center time at school and play at the community playground. Teacher and mother positive interactions with the children increased while negative interactions decreased. Social validity indicated that the interventions provided through family-school collaboration were acceptable and effective. N2 - (from the cover) This monograph addresses the expanding field of family involvement to out-of-school time (OST). OST may be defined as time outside of state required time limits for compulsory school attendance but time in which students are engaged in planned academic or enrichment activities. During the past decade, OST programs have burgeoned across the US. OST programs are offered to children and youth, elementary through high school, as structured and safe venues to increase student academic achievement, and extend students' interests. (from the foreword) Family engagement in OST programs is vitally important because, as during state-required schooling time, family engagement in OST is linked to student academic achievement. Prior to the turn of the century, families had to secure privately funded OST opportunities for their children. Thus, OST programs were dependent on for-profit or nonprofit organizations and not available for all children and youth. In recent years, well-known sports and entertainment personalities publicly attributed OST to their current success. Increasingly, federal, state and local funds have been allocated to the development of a variety of afterschool programs and other OST learning opportunities across the United States. Thus, during the past decade, educational evaluators and researchers within the United States have expanded their attention to study OST learning opportunities. N2 - The Child Nutrition Act of 2004 mandated the creation of wellness policies in all school districts and encouraged youth participation in their creation. Initial reports show a lack of youth participation in community wellness discussions. This participatory action research study used qualitative methods (Photovoice and Literacy Through Photography), and aimed to demonstrate: the socially constructed meanings, or social representations, a purposive sample of youth (ages 9-11) gave to the concept "wellness" in their everyday lives, how their conceptualization of wellness changed over time using the methodologies; their personal impressions and shared understandings of how their settings affect their wellness; and their recommendations for the enhancement of their settings in order to promote wellness. For the purpose of data analysis, some a priori categories were utilized since wellness is a construct that already has dimensions defined in the literature. The participants' conceptualization of wellness fit with Prilleltensky & Fox's (2007) dimensions of wellness: personal, relational, and collective, and included: environment, physical activity, safety, food, freedom, self-directed learning opportunities, transportation, inner life/spirituality, and positive social relationships. Participants made recommendations to enhance their settings' ability to promote wellness. For example, participants stressed the need for access to nature, especially green space for physical activity, and active transportation opportunities. Recess, physical education, and healthy food options were identified as important in the school setting. Community settings and resources that create opportunities for self-directed learning and physical activity in a group setting were seen as critical. Participants acknowledged that wellness can be a social justice issue when their peers live in areas that promote violence rather than wellness-enhancing community assets. The results from this study demonstrate that youth view wellness as more than just nutrition and physical activity, the primary components of most school wellness policies. Consequently, any comprehensive wellness policy should be developed utilizing a more wholistic conceptualization of the term. Participants expressed that their settings can have an impact on wellness; a concept congruent with the social ecological approach in health promotion. This study's findings demonstrate that youth are able to conceptualize wellness and make a significant contribution to their community's wellness discussions. VL - Multicultural gifted education :

IS - 2nd ed.

N2 - (from the preface) In seeking to create gifted education programs and Advanced Placement (AP) classes that are multicultural, I address the following questions throughout this book: Why do all students need an education that is responsive in general and multicultural in particular? Why is a multicultural education essential for White and racially and culturally different students? What is an education that is multicultural? Which components are most important? When is a multicultural education needed? In what school settings is a multicultural education needed? How can educators implement multicultural education so that it does not become an add-on but instead becomes an integral and integrated aspect of the educational process for gifted and advanced learners? Finally, I focus not only on students, but also on educators by offering recommendations to help educators of gifted students to become more culturally competent-aware, knowledgeable, skilled, and responsive. I believe that being culturally competent is indeed a survival skill, both inside and outside the school walls. An important feature of the book is its use of vignettes, scenarios, and brief case studies. This book addresses what I think is needed in the two programs often used to serve high-ability students (i.e., gifted education and AP classes) if they are to truly become multicultural-if education is to affirm the dignity and humanity of traditionally disenfranchised students and open the minds and hearts of White students and educators about those who are different from them. School personnel in gifted education and AP classes must explore the need(s) and rationale for multicultural perspectives in assessment, research, curriculum, instruction, and counseling. Just as we address academic and intellectual diversity, educators of gifted students and other advanced learners must attend to racial and cultural differences. We must seek excellence and equity for all students, acknowledging in the process that all students are the future, worth educating, and deserving of an education that meets their interests and needs. Educators of gifted and AP students must be proactive rather than reactive in addressing this increasing diversity and difference(s); they must seek both excellence and equity-the two are inextricably bound! N2 - Presents a case report of an 11-year-old, right-handed male brought by his mother for treatment of ongoing psychotic symptoms. He began to have significant difficulties in reading and word retrieval. A few months later, he began talking and laughing to himself and was evaluated in the emergency room of a local hospital to rule out organic causes for these behavioral changes. He had a normal magnetic resonance imaging (MRI) scan of his brain, cerebrospinal fluid (CSF) exam, and electroencephalogram (EEG). He was diagnosed with depression and prescribed sertraline, which was not helpful. The patient was hospitalized for 7 weeks after he attempted to jump out of a car in response to auditory hallucinations. He was discharged on a combination of olanzapine, risperidone and lithium. He showed a gradual decrease in his psychotic symptoms and began reintegrating slowly back into the school and the community. Our patient is currently in partial remission on a combination of olanzapine, risperidone and lithium. He is attending therapeutic day school and is able to enjoy outdoor activities. VL - 71:

IS - 11-A

N2 - In this study, fourth and fifth grade students' physical fitness levels were compared to their academic achievement based on the idea that health and physical fitness have an impact on the ability to achieve academically. Because of the recent pressures of No Child Left Behind, many schools have opted to limit the amount of time students spend in physical education classes and recess. With the increased percentages of students who suffer from diabetes and other health related risks, eliminating or reducing physical activity from the school day is not the answer. Data was collected from 90 students (46 males and 44 females) during the 2009-2010 school year by using the President's Challenge Physical Fitness Test, STAR Reading Percentile scores, and Grade Point Averages (GPA's). Through multiple regressions, the researcher did not find statistically significant relationships between physical fitness levels and STAR Reading Percentiles or between physical fitness levels and Grade Point Averages. When physical fitness levels were combined with STAR Reading percentile scores, a significant correlation was found between these two variables and Grade Point Averages. A significant correlation was found between physical fitness levels and mathematics. Lastly, another significant correlation was found between STAR, Grade Point Averages, and sit ups. With these varying results, the researcher decided to retain the following null hypotheses of this study: there will not be a significant relationship between physical fitness scores based on the President's Challenge Physical Fitness Test and academic performance based on STAR Reading Percentile scores for fourth and fifth graders at the participating school, and there will not be a significant relationship between physical fitness scores based on the President's Challenge Physical Fitness Test and academic performance based on Grade Point Averages for fourth and fifth graders at the participating school. This study does not prove causality; therefore, the results should be interpreted with caution. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This paper offers ethnographic observations on the place of "agency" in the lives of Aboriginal children in Central Australia. The focus is on children's play and adult-child interaction in the remote community of Ernabella, the oldest settlement in the Anangu Pitjantjatjara Yankunytjatjara (APY) Lands, northern South Australia. The circumstance of Aboriginal children in remote areas is introduced as a contrasting picture: on the one hand, the life of Aboriginal families is shaped by their marginalised socio-economic position and dependency on the state, which has become especially evident in the recently intensified efforts by the government to "mainstream" Aboriginal communities deemed in "social chaos" in order to regulate and thereby improve children's lives; on the other there is the social fact that children enjoy a comparatively high level of autonomy within the Aboriginal domain. The much-observed "freedom" from parental discipline, however, does not simply mean that children assert their will without regard for certain social rules. Rather, it is suggested that it is precisely the relatively low level of direct instruction and reprimand by adults that fosters children's ability to pattern their behaviour in relation to one another and to structure their social world and understandings according to the meanings that they co-create. Agency of this kind often occurs through imaginative play and spontaneously. This paper does not address policy issues directly. However, it is relevant as a background paper on Aboriginal children's lives that contributes to the understanding and recognition of existing social capacities outside institutional settings. N2 - Recent, research has pointed to childhood maltreatment as a risk factor for adolescent and young adult sexual risk behaviors and sexually transmitted infections (STIs). Although several prospective studies have examined the long term effects of childhood maltreatment on adult HIV risk behaviors or sexual health outcomes, few have conducted research among representative samples of black women in the United States. Because of the disproportionately high rates of both childhood maltreatment and STI/HIV infection in this population, it is important to examine this association as well as the pathways by which these constructs are associated. Using data from The National Longitudinal Study of Adolescent Health (Add Health), a nationally representative cohort of adolescent black females (N = 1,552) who were in grades 7-12 during 1994-5 and followed into young adulthood, the overarching goal of this study was to develop and test two structural equation models of the simultaneous interrelationships amongst theoretically-derived variables as they relate to childhood maltreatment, and 1) adult sexual risk behavior and 2) number of sexually transmitted infections in young adulthood. The research for this dissertation was grounded in a conceptual approach that posits that factors outside the individual's control are associated with sexual risk behavior. Further it is posited that childhood experiences have long-term effects on the individual, and involve a cascade of influences culminating in risk behavior or acquisition of an STI. The primary finding of this study was that childhood maltreatment is significantly associated with adult sexual risk behavior and STI among black women living in the United States. These associations were found to be only partially mediated by adolescent and adult characteristics (emotional distress, alcohol use, age at first sex, adolescent attachment and religiosity). Lower adolescent attachment, early age at first intercourse, and adult alcohol use were each separate significant mediators of the relationship between childhood maltreatment and adult sexual risk behavior. Significant mediators of the relationship between childhood maltreatment and adult STI diagnosis were: lower age at first sex, and a path via higher adolescent and adult emotional distress. It was hypothesized that religiosity would be an important mediator in this study, providing protection against engagement in risky behaviors and also STIs. However, religiosity was not a significant mediator of either association, and was significantly directly associated with lower sexual risk behaviors, but not significantly associated with STI diagnoses. This was an unexpected finding and suggests that even if religiosity as a form of social control, plays a role in reducing risky behaviors, it may not be enough to protect black women from acquiring sexually transmitted infections. This finding contributes to the literature that suggests that high rates of STI/HIV are not associated with risky behaviors among black women. Public health interventions that address behavioral modification, should also include components that screen for and address past abuse histories. While some hypothesized pathways did not reach statistical significance in this study, variables included, such as emotional distress, alcohol use, and gang involvement and early sexual debut were associated with childhood maltreatment and also associated with sexual risk behaviors. Addressing the trauma from childhood maltreatment provides an opportunity to deal with the underlying reasons for risky activities, and may enhance the effectiveness of behavioral interventions. More research is needed to understand the burden of STI/HIV among black women. Interpersonal relationship characteristics, social networks and macro-level contextual variables should be included in future research addressing this crisis. N2 - This study was designed to investigate the reflective comments of 55 first grade children regarding their experiences in kindergarten and first grade. Data collection involved a conversational interview during which children voiced their reflections and comparisons on specific issues (e.g. friends, teacher, learning) they had encountered during kindergarten and were currently experiencing in first grade. The data was analyzed through Foucault's tenets of power. The aspects of the transition that empowered children were noted and further discussed, as well as aspects that were perceived as limiting. Specifically, children seem to find some things empowering: the newness of the experience; the challenging and hard work; the independence they have in a spacious school playground; the access to a canteen and separate bathroom areas and the opportunity to make more friends. On the other hand, children noted several limiting elements: the structure of the day and specifically the constant lesson-work model; the teacher's more stern behaviors and the scarcity of fun.

N2 - This study used increased physical activity during recess to reduce stereotypy in preschoolers with Autism Spectrum Disorder. Results indicate increasing physical activity can be used as an intervention to reduce automatically maintained stereotypy in preschoolers with ASD. The intervention had a lesser effect on a preschooler whose stereotypy was maintained by attention. Results show topographies of the stereotypy were differentially affected for each individual. Not all motor stereotypies were affected equally within the same individual, and for one child, vocal stereotypies appeared to become less variable. Social validity measures indicate teachers would be willing to use this intervention in the future. Implications for using physical activity as an intervention for preschoolers with stereotypy are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

IS - 9-A

N2 - The purpose of this study was to explore strategies that may increase children's motivation to engage in physical activity during unstructured in-school free-time, such as recess. One hundred and sixty-two students, recruited from three elementary schools and nine fourth grade classrooms, were randomly assigned to one of three groups: (1) a teacher's daily verbal persuasion to engage in physical activity during recess; (2) a modeling of active recess time games by a competent adult; and (3) a comparison group that received no treatment. Pre- and post-treatment self-efficacy and effort data were collected utilizing a recess time physical activity self-efficacy instrument and accelerometers. A Spearman's rank correlation analysis determined that, in the context of recess, self-efficacy and effort are not related. A series of 2 x 3 ANCOVAs with pre-treatment scores as covariates determined that following treatment, the verbal persuasion group participants, compared to the modeling group participants, had significantly greater self-efficacy and effort mean scores. A borderline significant gender by treatment interaction effect on effort indicated that verbal persuasion was slightly more effective at increasing males, compared to female's effort. A series of 3 x 2 repeated measures ANOVAs determined that from pre- to post-treatment only participants in the verbal persuasion group spent a significantly higher percent of their recess time engaged in moderate to vigorous physical activity. Lastly, a principal component analysis with varimax rotation indicated that the barrier self-efficacy scale utilized in this study consisted of two types of barrier self-efficacy: adult verbal persuasion barrier self-efficacy and other barrier self-efficacy. Given school districts current budget and curriculum constrains, this study provides strong evidence that one cost effective strategy for increasing children's daily physical activity levels is a small dose of social prompting in the form of a teacher's verbal persuasion. In light of evidence suggesting that physical activity is linked to lower obesity rates, and substantial health and academic benefits, social prompting may be a useful strategy for addressing the childhood obesity epidemic, and improving students' academic and health outcomes. N2 - (from the chapter) Early childhood education refers to all education and child care programs that serve young children from birth through age 8. As adults quickly learn when a young child surprisingly mimics a word intended only for adults to hear, children learn in all environments. Young children do not distinguish learning from playtime, so for young children all environments are learning environments. Therefore, whether a child is in child care for long hours each day or in a preschool a few hours a week, the quality of the experience is critical. Many young children are in some type of center-based early childhood program prior to kindergarten. The U.S. Department of Education estimated that 43% of 3-year-olds and 69% of 4-year-olds were enrolled in a center-based early childhood program in 2005. Outside of the home, prekindergarten children are found in care by relatives and family friends, family and center-based child care, public and private preschools such as Head Start, and Early Head Start, and early childhood special education programs. Unlike elementary and secondary education, which guarantees a free public education, parents with prekindergarten children are primarily responsible for finding and financing their child's education and care. The goal of early childhood care and education is to provide safe language-rich environments where infants, toddlers, and young children explore their world; deeply connect with materials, other children and adults; and develop healthy bodies and minds. This chapter surveys options for early childhood education and child care and addresses assessment of quality for programs serving young children. N2 - The study of children's occupation is receiving more attention in the occupational science literature. This trend corresponds with a global interest on child health and well-being. Research into the activity patterns of children in natural environments offers to advance knowledge about children's participation, health and occupational development. This study was conducted using time-use methods to explore and identify activities and environments of Irish children aged between 5 and 8 years in 2007. Findings support the need for environmental contexts to be taken into account when considering occupational development. Further study of

time-use methods is warranted for use in examining the children-environment-occupation relationship.

N2 - This study sought to determine individual factors that may influence adolescents' interests in various health behaviors and, by extension, their potential interest in programs that promote healthy lifestyles and reduce obesity. The sample consisted of 737 rural Pennsylvania (United States) middle and high school students not involved in either healthy exercise or dietary behaviors (a target group for health-promoting interventions). Participants completed a self-report measure of their general health functioning, including their interests in sports programs, outdoor recreation programs, weightlifting, weight loss and healthy eating/cooking. Nurses measured body mass indices (BMIs). The vast majority of the sample endorsed self-efficacy in healthy eating and physical activity, and this self-efficacy was associated with interest in a healthy diet and outdoor recreation. Interest in healthy activities was consistently higher among 7th graders (age mean 5 12.6 years) than 11th graders (age mean 5 16.3 years). Females were more interested in weight loss and healthy eating/cooking, whereas males were more interested in weightlifting. Higher BMI only predicted interest in weight loss. These results indicate that adolescent health interests vary on the basis of their gender, grade level, BMI and self-efficacy. These trends are potentially important to consider when seeking to match intervention programs to adolescent interests. N2 - The demographic and economic transition that many developing countries, including Jordan, are undergoing is producing important changes in diet and lifestyle that greatly impact the development of chronic illness. The health behavior of adolescents in developing countries constitutes one of the most serious global challenges we face. The purpose of this study was to explore the wellness appraisal of Jordanian adolescents. It specifically describes the (i) self-care and health history pattern, (ii) to assess physical activity and nutrition appraisal, (iii) quality of life appraisal and (iv) school and outside activities appraisal. A self-administrated questionnaire collected the data from adolescent groups (boys and girls.). A multi-stage stratified random sample was obtained from six public schools by first selecting the educational directorate located in the city of Irbid, which is located in the north of Jordan. A random sub sample of six individual schools was then selected. Individual classes were then selected. A total of 269 boys and 261 girls (12-17-year old) were included in the analysis. The results showed that the students engaged in risky health behaviors which could lead to short- and long-term health problems. The most alarming finding of this study was students' nutritional habits, including less than the daily requirements of fruits, vegetables, milk and meat, while the intake of fast food, soft drinks and sweets were higher than recommended. School-based health promotion and wellness programs should be established in Jordan to influence the health behaviors of adolescents and parents and to avoid further deterioration of their health. Jordanian school curriculum needs to integrate more precise health education programs about diet, exercise, self care and other life style behaviors. More detailed studies are needed with more elaborate instruments about food habits, physical activities and psycho social life. N2 - Child characteristics including age, gender, risk-taking behaviour and sensation seeking are thought to influence children's ability to appraise risks. The present study investigated children's risk perceptions and appraisals in the context of common outdoor physical play activities. Risk perceptions and appraisal of four- and five-year olds were assessed using a pictorial risk appraisal measure and through individual semi-structured interviews examining children's decision-making. Sensation seeking and risk-taking behaviour were assessed using self-and parent-report measures. Results revealed that the children were able to identify injury risk behaviours however differentiating the severity of the potential injury was less accurate. Furthermore, the children appeared to use these judgements in their play to inform their behaviour whilst using playground equipment. Whilst they actively sought out those activities that offered challenge and excitement, they were aware of their abilities and showed caution in engaging in activities that were beyond their current capabilities. The results have implications for the provision of calculated risk-taking in outdoor play and for adult responses to the risk-taking behaviour of children. VL - 5 2010, pp. 37-58.

N2 - Background: This article presents the results of two studies related to successful learning at school. Successful passing from pre-school to school activities depends on the mental maturity of children. Peculiarity of the development of the attention is important to successful learning at primary school. Aims and methods: The first study was aimed for evaluation of differences of learning different educational contents, and the Control Drawing Observation method was used. The second study had the aim to investigate the characteristics of attention of primary schoolchildren using the Black-Red Numbers Table method and interview with teachers. Results: Pupils learning different educational contents had the same mental maturity levels. But higher mental maturity level was related to concentration ability and work self-sustaining. There were found no gender or school motivation relationship with mental maturity, but girls and boys differed in school motivation. The main

problems for pre-school-aged children were related to the memorization and carrying out of instructions. It was found that intensity, concentration and displacement of attention and both ability to stand from the outside stimulus and the ability to listen and follow verbal instructions were significantly related to respondents' age. The intensity and concentration was also related to the level of progressiveness at school. The results didn't confirm the hypothesis that concentration of attention is related to the educational content. Conclusions: The mental maturity level is not related to the educational content. The progressiveness at school is connected to the intensity and concentration of the attention. All its features (intensity, concentration and displacement) develop according to the age of primary pupils. (PsycINFO Database Record (c) 2013 APA, all rights reserved) (journal abstract)

N2 - Reviews the book Talk and social interaction in the playground by Carly W. Butler (2008). Scholars who investigate the social lives of children can choose from among multiple lenses to frame their studies. Butler's work is based on 30 hours of recorded talk of 6- and 7-year-old children in an elementary school over a period of 1 month, but analysis in this work focuses on the interactions of 11 children on the playground at school during lunch. As Butler clearly articulates, these 3 days provide a rich and coherent corpus of material that allows for analysis by looking for recurring practices in the fairy club, as well as the detailed analyses of particular episodes of interaction in the club. This book adds to the work on children's social interaction and highlights the practices that allow children to engage in coordinated action. In this book, children's play is respected and honored on the terms of the children and never dismissed as mere child's play. Overall, Butler makes a significant contribution to a growing and important body of work in children's social studies. This book will be of interest to conversation analysts, ethnomethodologists, and children's communication researchers, but other scholars who are looking for clear and detailed discussions of research methods should also take a serious look at this book. N2 - This paper examines the measurement of childhood materialism using Schor's ([2004]) Consumer Involvement Scale. Schor treated consumer involvement empirically as a unidimensional construct, though she suggested that conceptually it may be multidimensional. Using confirmatory factor analysis procedures on data collected from children in the U.S. and U.K., the psychometric superiority of a three-factor structure is established, comprising dissatisfaction, consumer orientation, and brand awareness components. Additional analyses demonstrate distinct associations between each of these components and other constructs, including self-esteem, outside school activities, and child-parent relations. The scale's generalizability across boys and girls is also confirmed. The results suggest that Schor's Consumer Involvement Scale will be useful for researchers interested in studying the important topic of materialism in children. N2 - (from the chapter) This chapter examines several issues on obesity in early childhood that have direct practical relevance to supporting healthy weight gain in this critical period of life. The first fundamental issue for child health nursing practice is the definition of normal growth in early childhood, which leads directly into an examination of the assessment of at-risk growth patterns and other risk factors for later childhood (and adult) obesity. Appropriate feeding practices are fundamental to healthy weight gain in early childhood and these recommendations are reviewed as well as the importance of active play, motor skill development and reduced television viewing time. Patterns for all human behaviors are highly influenced by environments, and this is most true in the early childhood years. Thus, the many preschool settings outside the home environment are also examined as opportunities for implementing the policies and practices needed to promote healthy eating and active play. N2 - Background: The recent increase in childhood obesity is expected to add significantly to the prevalence of chronic diseases. We used multivariate multilevel analysis to examine associations between parks/green space and childhood overweight/obesity across communities in Calgary, Canada, a city characterized by intensified urban sprawl and high car use. Methods: Body Mass Index was calculated from measured height and weight data obtained from 6,772 children (mean age = 4.95 years) attending public health clinics for pre-school vaccinations. Each child's home postal code was geocoded using ESRI ArcGIS 9.2. We examined four measures of spatial access to parks/green space (based on Geographic Information Systems): 1) the number of parks/green spaces per 10,000 residents, 2) the area of parks/green space as a proportion of the total area within a community, 3) average distance to a park/green space, and 4) the proportion of parks/green space service area as a proportion of the total area within a community. Analyses were adjusted for dissemination area median family income (as a proxy for an individual child's family income) community-level education, and community-level proportion of visible minorities. Results: In general, parks/green space at the community level was not associated with overweight/obesity in Calgary, with the exception of a marginally significant effect whereby a moderate number of parks/green spaces per 10,000 residents was associated with lower odds of overweight/obesity. This effect was non-significant in adjusted analyses. Conclusion: Our null findings may reflect the popularity of car travel in Calgary, Canada and suggest that the role built environment characteristics play in explaining health outcomes may differ depending on the type of urban environment being studied. N2 - This study investigated the metalinguistic abilities of 91 prevocational and pre-academic students from 7th and 9th grade. To prevent educational influences, we measured comprehension of joking riddles, 'language of the playground', rather than typical academic language performance. Preacademic students performed better than prevocational students, 9th graders better than 7th graders and riddles which require linguistic knowledge to resolve the joke were more difficult than riddles requiring world knowledge. The study also revealed that vocabulary was an important predictor of metalinguistic abilities, and that riddle comprehension and appreciation were weakly correlated. Furthermore, metalinguistic abilities and vocabulary size of pre-academic 9th graders was larger than of their peers from 7th grade, but this was not the case for prevocational students. Because vocabulary, grade and school track were related, it can be concluded that linguistic riddle comprehension is a valid and appropriate measurement of metalinguistic abilities of young adolescents. N2 - The authoress makes reference to an educational practice realized in a day nursey, in order to manage a cognitive research about the children's routines in the framework of an educational path. In this institutional context occurs a series of experiences, which involve the body as well as its espressive language, articulated in a sequence of paradoxical messages of opposite value. Inside/outside, near/far, narrow/large etc... are topological dimensions drawn by childish gesture and by the educator that is "naturally" prepared to receive the projective movement. It is just in the orderly steadiness of an institutional structure that it is possibile the flexible modulation of child's impulses. If it will be given to the child the opportunity to meet someone able to "play" with him in a "frontier territory", inhabited by rapidly changing of emotions and sensations. N2 - This study investigates fifth, sixth, and seventh grade students' place preferences between indoor and outdoor non-classroom spaces during recess and their activity patterns in these spaces in three private elementary schools. The study explores whether differences in the variety and organization of the spaces of school facilities have an impact on the place preferences of students and whether students are aware of the reasons for their preferences. Students' place preferences and their activities were determined with field observations and a 30-item questionnaire with Yes/No and open-ended questions. A total of 173 students (n = 51 School 1; n = 70 School 2; and n = 52 School 3) participated in the questionnaire. The Chi-Square test, a non-parametric statistical analysis test, was used to analyze the students' answers to the questionnaire. The results indicate that students prefer places which offer variety and which are large enough to avoid congestion and that, in general, students are aware of the spatial features of their environments and make choices accordingly. When students are given a choice of outdoors or indoors, they tend to choose according to which is more conducive to their activities. If both outdoor and indoor spaces are conducive, students tend to use both. If neither is conducive to their activities, students either alter their behavior patterns, for example, developing a preference for stationary activities or staying inside the classroom, or they convert available spaces to accommodate their activities. It is concluded that students are good sources of information in the design and

planning of the environments they occupy. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The present study examined the types of settings in which students receive care after school and the activities in which students engage in these particular settings. Data were extracted from the National Household for Education Statistics 2005 data set using students enrolled only in 6th, 7th or 8th grade (N = 4,659). The variables of interest included student academic misbehavior and student academic performance, the type of care arrangement relative, non-relative, parent, center and self as well as the activities homework/school-related, computers, art, chores/work, outdoor play/sports, indoor play/sports, and television/videos/music, in which students are engaged within each after school care arrangement. Chi-square analyses were conducted to assess any differences in the activities in which students were engaged while at after school care arrangements to determine to what extent these activities contribute to students' academic performance and misbehavior. An over-all pattern in the data regarding the care arrangements showed a positive relationship between the parent care arrangement and the occurrence of student misbehavior. In regards to the activities in which students were engaged after school, a positive relationship was found between homework activities and student academic performance and misbehavior. These findings provide some information to assist parents in selecting the best possible environments for their children after school. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Background: Fast ripples (FR, 250-500 Hz) detected with chronic intracranial electrodes are proposed biomarkers of epileptogenesis. This study determined whether resection of FR-containing neocortex recorded during intraoperative electrocorticography (ECoG) was associated with postoperative seizure freedom in pediatric patients with mostly extratemporal lesions. Methods: FRs were retrospectively reviewed in 30 consecutive pediatric cases. ECoGs were recorded at 2,000 Hz sampling rate and visually inspected for FR, with reviewer blinded to the resection and outcome. Results: Average age at surgery was 9.1 + 6.7 years, ECoG duration was 11.8 + 8.1 minutes, and postoperative follow-up was 27 + 4 months. FRs were undetected in 6 ECoGs with remote or extensive lesions. FR episodes (n = 273) were identified in ECoGs from 24 patients, and in 64% FRs were independent of spikes, sharp waves, voltage attenuation, and paroxysmal fast activity. Of these 24 children, FR-containing cortex was removed in 19 and all became seizure-free, including 1 child after a second surgery. The remaining 5 children had incomplete FR resection and all continued with seizures postoperatively. In 2 ECoGs, the location of electrographic seizures matched FR location. FR-containing cortex was found outside of MRI and FDG-PET abnormalities in 6 children. Conclusion: FRs were detected during intraoperative ECoG in 80% of pediatric epilepsy cases, and complete resection of FR cortex correlated with postoperative seizure freedom. These findings support the view that interictal FRs are excellent surrogate markers of epileptogenesis, can be recorded during brief ECoG, and could be used to guide future surgical resections in children. N2 - A selection of common children's games were measured in a laboratory-based study to be enjoyable and to elicit sufficient physical activity energy expenditure (PAEE) in 3rd grade children to combat the purported chronic energy surplus of childhood obesity (~100 kcal/day⁻¹). PAEE during the games was similar for boys and girls, yet overweight children expended greater PAEE relative to body weight than healthy weight children. During a subsequent simulated recess program, the enjoyment declined over the 10-session program with no significant decline in PAEE. Using the enjoyable games of known energy cost in a structured recess program for 9 weeks successfully increased total daily PA compared to the control school who reported substantially greater amount of free-play time. The greater amount of acquired PA in the intervention school children did not affect the amount of time spent in sedentary pursuits but it did result in a smaller increase in body weight after 9 weeks. More research is needed to expand on this initial list of games that reduce the excessive weight gain in children when incorporated into a structured recess intervention. N2 - The purpose of the study was to expand the understanding of childhood obesity in American children by examining the associations between obesity in children and measures of social capital. Persons between 2 and 20 years of age are categorized as "obese" if their BMI is in 95th percentile or above for their age and sex using the Center for Disease Control and Prevention (CDC) BMI-for-age growth charts. Obesity prevalence has more than quadrupled in the last 40 years in the United States for children. The prevalence rate is 17.0% for children ages 6-11 years. Social capital, in the study of health, can be defined as resources accrued and/or accessed from social relationships/social bonds at multiple levels including the individual, family, neighborhood, community or nation. The research quantitatively analyzed the associations between the likelihood of childhood obesity and BMI with personal social capital, family social capital and neighborhood social capital. The research was conducted with a public use dataset from the 2003 National Survey of Children's Health. This survey is part of the State and Local Area Integrated Telephone Survey Program (SLAITS) conducted by the CDC's National Center for Health Statistics (NCHS) and was funded by the Maternal and Child Health Bureau (MCHB). A dataset for the study was created for the 10,018 10 and 11 year olds for whom height and weight was available. The study population had an obesity prevalence of 20.4. Logistic and OLS multiple regression models were employed for hypotheses testing. Eleven indicators were categorized as measures of personal social capital, family social capital or neighborhood social capital. The regression models clearly identified many individually significant measures of social capital but their (the regression models) were weak in their predictive power. Five individual indicators of social capital were particularly noteworthy for having consistently significant associations with the likelihood of obesity and BMI throughout the research. These include type of school

(private or public), moving, number of siblings, parents knowing friends and participating in activities outside of school. The research supports the idea that the study of children's social capital (personal, family and neighborhood) is a viable way to expand the understanding of the pathways behind the social patterning of childhood obesity in the United States. N2 - Several cognitive components are thought to explain the relation of rapid serial naming and reading ability including the constructs of phonological access, attention, automaticity, articulation, global processing speed, and visual acuity. One cognitive component that has gone understudied when investigating rapid serial naming is parafoveal processing. The goal of the present study was to examine the role that parafoveal information, information outside the direct visual focal point, plays in the rapid serial naming task. Two experiments explicitly varied the amount and type of information available to the right of the focal point in manipulated versions of the rapid serial naming task. The performance of forty-one first-grade students were examined for differences between manipulated conditions and relations with reading outcomes at three levels of processing, low-level visual processing, initial lexical access, and higher-order cognition. Results suggested that initial visual processing occurs for the letter directly in the focal area, as well as the letter immediately following it, and that children who were better at rapid naming were significantly more impaired by the lack of parafoveal preview than were the children at the lowest end of the distribution of rapid naming performance. N2 - Early detection of autism spectrum disorders (ASD) is crucial to optimizing child and family outcomes. Most research on the early diagnostic features of ASD has been done in the clinic environment; therefore there is a need for research on diagnostic features displayed in a natural environment. Observation of behaviors of young children in their home environment is a possible way to assist in earlier diagnosis in a less time consuming, less stressful, and more cost-effective manner for families. The primary purpose of this study was to explore and quantify red flags for ASD in the behaviors of young children between 17 and 36 months of age (N = 60) demonstrated in the home environment. Measures on the Systematic Observation of Red Flags for Autism Spectrum Disorders in Young Children at Home (SORF-Home; Wetherby & Woods, 2009) were coded from video recorded home observation samples of the child interacting with a parent or caregiver during everyday activities. Overall, the results of this study demonstrated that early red flags of ASD were evident in the home environment. Seven of the red flags identified by previous researchers to be evident in the clinic environment (lack of warm, joyful expression with directed gaze, lack of coordination of gaze, facial expression, gestures and sounds, lack of response to name, lack of communicative vocalizations with consonants, inappropriate eye gaze, lack of response to contextual cues, and lack of sharing interest or enjoyment) were also found to be demonstrated by a majority of children during the home observations. Examination of the relationship between the early red flags and developmental level revealed no significant correlations between the red flags and nonverbal cognitive developmental level and medium to large negative significant correlations between some red flags and verbal developmental level. Significant correlations were observed between many of the early red flags and ASD symptom severity on the Autism Diagnostic Observation Schedule (ADOS; Lord, Rutter, DiLavore, & Risi, 2002). No significant correlations were observed between measures of parent report of red flags and the early red flags measured in the home environment. The results of this exploratory study extend knowledge on the nature of red flags for ASD in young children to the home environment which adds valuable information for both practicing clinicians and families. The findings also provide promising information on the utility of the SORF-Home as an interactive screening measure for ASD and offer important implications for early identification of ASD. N2 - As a part of a larger international mapping exercise to examine students' motivation to study music as compared to other school subjects, this article draws upon data from a sample of 3037 students in the USA to

observe perceptions of values, competence and interest in music study (in school versus outside of school) among music learners and non-music learners. Students were grouped into three grade levels: (a) 6, (b) 7-9, and (c) 10-12. Music learners in the USA had significantly higher motivational profiles for music and some other school subjects as compared to non-music learners. Music interest inside of school was ranked significantly lower than for any other subject, while music interest outside of school was ranked second highest for any subject in grades 6 and 7-9, and highest of all subjects in grades 10-12. This article addresses cultural and contextual issues in the USA to consider how music advocates might better demonstrate the importance and usefulness of music study as an academic course. Practical recommendations include encouraging a broader emphasis beyond performance and competition, and promoting opportunities for autonomous music learning within the school setting. N2 - Increasing socialization opportunities for individuals with autism has been an ongoing educational process. There continues to be a need for a systematic approach to facilitate increases in social skills among students with autism in general education settings. One such model of instruction that has promising results is Pivotal Response Training (PRT) (Koegel & Koegel, 1995). PRT is a comprehensive service delivery model that uses both a developmental approach and applied behavior analysis (ABA) procedures, to provide opportunities for learning within the context of the child's natural environment (Koegel, Koegel, Harrower, & Carter, 1999). It focuses on providing opportunities for learning social behavior within the context of the individual's natural environment. The current study utilized peer-mediated PRT combined with self-management procedures, to support the independent use of social behaviors among students with autism. Three elementary-age students with autism from a self contained classroom participated. These students were trained to implement self-management procedures to assist these students. Six elementary-age general education students were trained in PRT. The effectiveness of these treatments in increasing social behaviors was evaluated using a multiple baseline across subjects designs. Probes were obtained during general education activities (e.g., lunch, gym) and in the school playground to assess generalization effects. Data were obtained via videotaped 10 minute sessions using 10-s partial interval recording. External validity was measured by the Social Responsiveness Scale (SRS) which was completed by the special education and general education teachers. The results of this study demonstrated that peer-mediated PRT combined with self-management procedures increased the social behaviors, maintained interactions, and initiated conversations by students with autism. It also had a collateral effect on the attention behaviors of supported and coordinated joint attention, and the strength of these results suggests that they can be generalized to general education settings (e.g., playground, lunch room, gymnasium). N2 - Focus groups explored the bullying prevention suggestions of 62 Grade 5 to 8 students. Discussions were transcribed and analyzed thematically. Students advocated a comprehensive approach including uniforms, increased supervision, playground activities, group restructuring to prevent social isolation, influential presenters, prevention skills training, solution-focused posters, and meaningful consequences. In addition, students suggested that parents should improve relationships with their children, respond to aggression, limit exposure to media violence, and support school-based discipline. The failure to respond effectively to students who bully in defiance of antibullying presentations, and who retaliate when reported or disciplined, undermines prevention programs by reducing the willingness of bystanders to intervene or report bullying, and influencing the attitudes of younger pupils. The approach advocated by students is supported by meta-analyses of the effective components of bullying prevention trials. N2 - This study chronicles the home and school technology practices of a group of 7th grade middle school students representing varying social and economic backgrounds for the purpose of exploring possible ways in which exposure to computer technology in the home helps to inform the ways in which children demonstrate technology literacy when using computers in an academic setting. Further, this study seeks to illustrate that differences in the quality of access to technology and familial support at home are reflected in the behavior, attitude and achievement levels that these children exhibit in school when engaged in technology-related academic activities. For the purpose of illustrating the exhibited differences in technological literacy skills of the students under consideration, the study describes in detail both the type and depth of computer use in the home; including familial support, parental and sibling knowledge and attitudes and other non-academic influences outside of school. The findings of the study indicate that students without home computer access are at a significant disadvantage in relation to their peers in terms of developing technological literacy. N2 - Concern about the level of physical skill development of young children has surfaced since the late 1900s due to the increase of childhood obesity and the decrease in opportunities for children to play freely outside. Increased usages of technology and changes in the way people live have also contributed to this concern. Project First Step began in 1991 to measure the physical skills of beginning kindergarten children to provide teachers with information on strengths and deficiencies in this domain. The focus of this research goes beyond a descriptive quantitative study looking at trends over the past 17 years of children's physical skills and includes aspects of a comparative descriptive design. In addition, an analysis of the physical skills that children possess during the final time period (2006-2008) will be addressed to assist teachers in developing strategies for young children's optimal learning. The works of Piaget and Gesell provide the theoretical base for this study. The results of this study showed that physical skill levels have dropped significantly from the 1991-1992 time period until the 2006-2008 time period. Significant drops occurred in 52 of the 66 t-tests, indicating that physical skill

levels are decreasing in all 10 areas screened and for overall skills as well. The scores were significantly lower in all areas in the 2006-2008 time period than in the 1991-1992 time period. The results of this study will help parents and educators to address the declining opportunities for children's physical skill development.

N2 - This dissertation presents research that investigated how first grade students' ability to construct solutions and to plan through drawing for engineering design problems is related to their participation in a LEGO-based engineering curriculum with two variations on the instruction for planning. The quasi-experimental design engaged two first grade classrooms in an urban K-6 Science and Technology elementary school outside of Boston, MA in a set of activities that asked students to construct solutions to engineering design problems inspired by the story of Goldilocks and the Three Bears. The planning classroom was provided with instructions on how to plan and students were required to plan through drawing prior to constructing their solution to engineering design problems. Students in the spontaneous classroom were not given instruction in planning and were allowed immediate access to materials to construct their solution. Students' drawings and constructed artifacts for engineering design problems during pre and post assessments as well as during the classroom were collected. The analysis of the classroom data found that students were able to successfully construct solutions to engineering design problems with increasingly number of requirements. Pre and post comparisons of students' performance on problems with materials they had had extensive experience with (LEGO) and craft materials (non-LEGO) found that students only made gains in constructing solutions to engineering design problems with materials they had prior experience with. The planning intervention appeared to have no relationship with students' ability to construct solutions that addressed requirements that were clearly presented to the students. However, there may be a relationship with less obvious requirements regarding aesthetics (as measured by symmetry of the artifacts) and material selection. In general, the findings suggest that planning through drawing may help students preserve their ideas but that first grade students do not use drawings for planning in the same manner as adults do. Implications for engineering education for early elementary are also discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The Hispanic academic achievement gap in California is often attributed to language difference, low economic status, and assumed cultural deficit within families (Neufeld & Fitzgerald, 2001; Saracho, 2007). When students who fit these descriptors achieve academic scores of proficiency and above, we can benefit from examining their repertoires of family literacy practices. This qualitative study examined the summer literacy practices within the nine Spanish-speaking families of a second grade cohort attending a small Title 1 urban school in Southern California. At home adult support was in Spanish, and material means were limited by low-income status, yet six of the nine achieved above average on state tests in English. In this descriptive, two-phase study I used semi-structured interviews and video elicitation to answer these questions: (1)What do Mexican-heritage children do during the summer vacation? (2)What funds of literacy are available to them? (3)How do home and community ecological and cultural-linguistic contexts influence their engagement with these funds of literacy? The goal was to identify patterns of literacy engagement with local resources as they emerged through daily family routines within an apparently homogeneous sample. I used the framework of ecocultural activity settings to capture literacy events involving adults and children in their naturalistic settings. Inductive analysis of multiple data sources revealed a wide range of practices and an abundance of literacy resources within each home. Four of the six higher achieving children were found to be involved in church or bible study community activities that required literacy in Spanish. Adults in these cases provided structure and engagement to summer practices, with the purpose of moral education. In two of the cases fathers were the dominant agents of literacy. In all cases older siblings mediated practices in English. These findings complicate the deficit assumptions associated with low-income, linguistic minorities by providing illustrating how families leverage local funds of literacy to support their children's overall literacy development. The study claims the need for a new framework of literacy research that integrates the role out-of-school literacy activities in overall literacy development, and the need to acknowledge the literacy resources Mexican-heritage students bring to the classroom. N2 - The purpose of this study was to investigate the effects of a portable play equipment intervention intended to increase the PA levels of preschool children during outdoor classroom time. The following hypotheses were formulated: (a) the intervention using portable play equipment will increase the PA of all children during their outdoor classroom period as measured by pedometer steps. (b) boys will be more physically active as measured by pedometer steps than girls during the preschool outdoor classroom period. The research questions addressed in the study were: (a) what types of activities do preschool children participate in during their outdoor classroom period? (b) what type of portable play equipment is used most often by preschool children during their outdoor classroom period? and (c) is there a difference in the activities and equipment participated in between preschool boys and girls during their outdoor classroom period? An ABAB reversal design was used to study the physical activity measured by pedometers (Yamax New Lifestyles Digi-Walker SW - 701) in preschool children when the portable play equipment was introduced to the outside classroom. The first intervention phase was using portable play equipment and the second intervention phase used a teacher to encourage active play for four randomly selected children. A modified version of the Observational System for Recording Physical Activity in Children-Preschool Version (OSRAC-P) (Brown et al., 2006) was used to code the activities and the intensity of the PA the children did during outside classroom time. A repeated-measure by time analysis was completed to see the differences between baseline phase and intervention phase data. The same analysis was done to see the differences between the teacher intervention phase and baseline phase. The significance level was set to $p < 0.05$. The PA change between the first baseline and the first intervention was statistically significant. The PA levels significantly increased when the portable equipment was introduced the first time to the outside classroom time. However, the change between the second baseline and the second intervention was not statistically significant. Finally the teacher intervention for the four randomly selected students was not statistically significant either. The results of the study do not support the first hypothesis even though there were statistical differences between the first baseline and the first intervention. The intervention using portable play equipment did not increase PA of all children during their outdoor classroom period as measured by pedometer steps. The second hypothesis is not supported by this study. Boys were not more physically active than girls as measured by pedometer steps. The amount of steps for boys and girls were similar throughout the study. The results indicate that portable play equipment with teacher encouragement has the potential to increase the physical activity levels of preschool children but more research is necessary to understand the complexity of behavior of this age group. N2 - Although much of the violence prevention literature has focused on evaluating intervention programs, few studies have included the perceptions of students in the effort to help them. The goal of this study was to deepen our understanding of their lived experiences and consider the implications for more effective school policies and programs. It is critical to understand what helps at-risk students feel connected to school and want to actively participate in the effort to establish safe learning communities. This study is based on a qualitative research design to include the voice of students on the problems they have experienced in traditional classes, as well as the supports to help them achieve success. Students were considered at-risk because they had experienced difficulty in the past with academics, behavior and their social interactions at school. The decision to focus on middle school students was made given the extent of bullying behaviors at that level and the need to understand what helps them care about their education and want to do well in their classes. The methods used to collect data included individual and group interviews, visual data in the form of photographs taken by students and two direct observations of their support program classes. All of the data in the study was managed and analyzed through the use of a qualitative data analysis software, specifically NVivo 2.0. It was then organized into an electronic project, called the E-Project, which contained all of the documents generated within the study, including raw data and interpretative memos, as well as specific codes and links within the data utilized for analysis. Each of the students initially provided examples as to why they had become so disconnected in their traditional classes and no longer wanted to achieve success. They repeatedly emphasized a lack of care as the most significant problem they experienced and the failure of teachers to establish meaningful connections with them at school. Although academic issues were at the inner core of their concerns, they expressed a significant problem with how their behavior was managed and the wider social dynamics that impacted all of their experiences. Students focused on the beliefs and actions of teachers who allowed them to experience a pattern of failure and utilized punitive discipline that further isolated them in their classes. They especially voiced frustration and anger at the hypocrisy of teachers who said they cared, yet blamed and humiliated them in front of peers without regard for their fundamental social and emotional needs. As all of the students in the study were participating in a support program, they were also able to identify the academic, behavioral and social experiences that helped them actively participate and become involved at school. Students emphasized the need for teachers to believe it is their responsibility to find solutions to the problems they experienced and take the actions necessary to make a positive difference in their lives. They wanted teachers to genuinely care about them and not accept failure as a choice they can make under any conditions. It was important for teachers to stop the bullying behaviors that prevented students from taking academic risks without the fear of being embarrassed or shamed in front of their peers. It was essential for teachers to establish a safe classroom so they could enjoy working together with a sense of community. Students consistently voiced throughout the data the importance of having teachers not only help them achieve academic success, but also recognize their lives outside of the classroom. They emphasized the profound need to be included and valued as important members of the school community and explained how their academic, behavioral and social needs are connected to each other. It was important to celebrate their accomplishments with traditions. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Aggression, in all of its forms, is a growing problem in today's schools. Relational aggression, the attempt to harm another person through manipulation and damage of relationships with others, is a specific form of aggression that is not only increasingly prevalent, but also undertreated (Crick & Grotpeter, 1995). Children gossip about peers, exclude each other from activities, and engage in name-calling, among other relationally aggressive behaviors. Females are more likely to engage in this behavior; males tend to engage in more physically aggressive behaviors (Yoon, Barton, & Taiariol, 2004). While frequently dismissed by teachers and administrators as "typical" childhood behavior, studies have shown that relational aggression can be as harmful as physical aggression (Bauman & Del Rio, 2006; Yoon et al., 2004). The purpose of this dissertation is to design and develop a classroom program for a central New Jersey public school to be implemented with third to fifth grade female students during lunch, an unstructured time of day during which children often engage in relational aggression with peers. The program is based on a thorough needs assessment conducted in the middle school for which the program is being designed (Maher, 2000). The program design also relies on Dodge's (1986) Information Processing Model as a foundation for its design (Lochman & Dunn, 1993). The needs assessment examined students' peer relationships and students' bullying behaviors through student and teacher questionnaires. The program consists of ten classroom-based lessons that address bullying, relationship skills, anger management, and problem solving. The other part of the program is a teambuilding component for implementation during lunch and recess. The dissertation includes detailed lesson plans as well as session outlines for teambuilding activities. Also included are introductory lessons, which provide school personnel with a clear lesson for introducing each component of the program to students. Finally, the limitations of the program, implications for the program's use, and future directions are also discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study compared fifth grade students' physical fitness levels to academic achievement based on the premise that health and physical fitness has an effect on one's ability to learn and achieve academically. Due to No Child Left Behind and the mounting pressures to reach Adequate Yearly Progress, many school officials view non-assessed activities like physical education and recess as unnecessary, consequently creating a case for the elimination of any subject that is not directly measured through standardized testing. Finding a link between fitness and academic achievement may cause educational leaders to reevaluate time spent during the school day. Data was collected for 113 students during the 2008-2009 school year by using the FitnessGram, STAR Reading and Math Percentiles, and Grade Point Averages (GPA's). Through multiple regression, the researcher found statistically significant relationships between physical fitness and two of the three measures used for academic achievement: STAR Math Percentiles ($p = 0.0063 < 0.05$; $R = 0.26 > 0.195$) and GPA's ($p = 0.0124 < 0.05$; $R = 0.23 > 0.195$). Therefore, the hypothesis was accepted, validating a link between fitness and academic achievement. This study does not prove causality; it is more probable that physical fitness and academic achievement influence each other in ways that are still vague. N2 - Despite increased media attention following high-profile school shootings, bullying continues to be defined as a nationwide problem. While researchers in a number of fields have studied this problem, much of the existing literature ignores information about how individuals in schools actually define and interpret bullying. In order to better understand these interactions, my dissertation is a multi-method study combining interviews with 53 students and 10 adults and over 430 hours of participant observation with fifth grade students at two rural elementary schools. Drawing on the sociological tradition of symbolic interactionism, these methods allow me to understand bullying from the perspectives of those in the schools. I argue that bullying is socially constructed by students and adults who take social contexts into account when determining whether or not an action should be defined as bullying and how they will respond. While adults in this study focused on outcomes, students focused on intentions and included a number of caveats in their definitions, stating that those who were joking, retaliating, or making fun of younger students were not engaging in bullying. Further, the images associated with the word "bully" in popular culture led a number of participants to hold views of bullying that focused on people rather than actions, thinking of bullies as those who were always mean. These person-centered definitions allowed them to "define away" bullying as a problem in their schools, despite the continued presence of interactions that fit typical definitions of bullying. Because they could not directly observe all of the interactions taking place in a classroom, at lunch, or on the playground, bullying often went

unobserved by adults. As a result, students were able to use the school rules as weapons against each other, selectively reporting rule violations by peers that they disliked, whether or not their peers were guilty of those violations. These findings demonstrate the ways that bullying is a part of the culture in these elementary schools. As such, solutions to this problem demand an understanding of and consideration for the larger school culture in order to improve students' daily experiences at school. N2 - Molecular family stability can be defined as the predictability and consistency of the daily activities and routines of the family, including activities in the home as well as activities occurring outside the home that are arranged and supported by the family. Previous research has demonstrated a relationship between the constructs of molecular family stability and child adjustment, with greater family stability associated with better child adjustment. The current study evaluates several control-related constructs as potential mechanisms through which the relationship between family stability and child adjustment may operate. Self-control and aspects of perceived control were assessed as possible mediators of this relationship. The specific aspects of perceived control included were perceived primary, secondary, and anxiety control. It was hypothesized that self-control and perceived control would mediate the relationship between family stability and child adjustment. Participants were 67 children in grades 3 through 8 and their parents. Children and parents were each asked to complete measures of family stability, self-control, perceived control, and adjustment. Multiple regression analyses were used to evaluate the hypothesized mediational model. Results generally support the hypotheses that self-control and perceived primary control mediate the relationship between molecular family stability and adjustment; however, the hypotheses that perceived secondary and anxiety control mediate the relationship between family stability and adjustment were not supported. Additionally, evidence emerged suggesting a suppression situation in which perceived primary control, child age, and family income appear to serve as suppressors revealing a significant and positive relationship between child-reported molecular family stability and one particular aspect of adjustment, anxiety symptoms. Results are discussed in terms of avenues for further research and potential clinical applications of the construct of molecular family stability. N2 - Children with Autism Spectrum Disorders (ASD) manifest a triad of deficits, in the areas of socialization, communication, and repetitive and stereotyped behaviors (American Psychiatric Association, 2000; Volkmar, 2005). Tailoring interventions to address these issues is important when working with children with ASD. It is critical to remember that although children with ASD share common deficits, each child is entirely unique. Interventions must be tailored to each child's specific needs and interests. The current study assessed the effectiveness of peer-mediated intervention on increasing social skills in a sample of 6, 5 to 9 year old children with ASD. The intervention was run class-wide, during students' recess time. Although perhaps the most naturalized setting to practice socialization goals, recess remains one of the least utilized times to address goals during the school day. Peer-mediated intervention addresses goals in the most naturalistic of settings, actual peer interactions, while minimizing cost in teacher time and expense to the district. Participants were paired and instructed to play with typically developing buddies. Buddy pairs were rotated to promote exposure to multiple peer exemplars. Intervention occurred in 3 weekly sessions over 6 weeks, for a total of 18 sessions. Prior to intervention, 2 weeks of baseline data was collected on participants' social bids. Social bids were adapted from those assessed in Baumringer's (2002) study. Doctoral students were trained in the fidelity of treatment, and once 80% reliable on the operationally defined behaviors, collected data on the target dyads. Data was collected on frequency of social bids and percent of time engaged with peers during baseline, intervention, and at follow-up. Social bids were defined as any behaviors that functioned to maintain or initiate peer interaction (Baumringer, 2002). In addition to direct observational data, teachers and parents completed The Social Skills Rating System (SSRS; Gresham & Elliot, 1990) prior to and following intervention. The study utilized a single subject (N=6), ABA design. Results were assessed via visual inspection of data. Busk and Serlin's (1992) techniques were also used to monitor effect sizes for each participant. It was hypothesized that following the intervention, participants would demonstrate: (1) an increased frequency of social bids; (2) an increase in percent of time spent engagement with peers; and (3) increased levels of overall social skills from pre to post assessment as measured by the SSRS-Teacher Form. Results demonstrated strong support for Hypothesis 1. Five of the 6 participants demonstrated increases in the frequency of bids. Results also demonstrated strong support for Hypothesis 2. All participants demonstrated significant increases in percent engagement with peers. Hypothesis 3 was not supported; analysis of teacher ratings did not indicate consistent gains in social skills. Implications for future research are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The effectiveness of an intervention is dependent on one's active implementation of key intervention elements. In the child mental health field, an intervention often requires parents to implement certain behavior modification strategies in the home. There are a number of factors that could influence whether intervention strategies are used outside of initial training. However, little research has examined the factors related to parenting adherence to treatment strategies. This study explored whether the same factors that are related to initial parental engagement (i.e., child, parent and family contextual factors) also influence subsequent use of intervention strategies presented in a one-time workshop. Participants were parents of children (3-5 years old) who reported difficulties at bedtime. Participants attended a one time workshop, completed pre and post workshop measures and were contacted two and four weeks post-workshop to assess their level of adherence to strategies and the degree of bedtime problems their child was experiencing. Cognitive variables, adapted from the Theory of Planned Behavior and The Health Belief Model, were expected to mediate the influence of child, parent and family factors on adherence. Contrary to hypotheses, perceived benefits, barriers and parent expectations did not significantly mediate the path to adherence. A decrease in bedtime problems was seen across groups. Those parents who most closely adhered to the evidence-based strategies saw the greatest amount of improvement four weeks after the workshop. Limitations of the current study and suggestions for future research are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - A six-week sciencing programme, directed at stimulating exploratory play, was implemented with 2- and 3-year-olds in a day-care centre. The core of the programme consisted of guided play with children in the centre's sandpit. The effectiveness of the programme was determined with ecologically valid methods consisting of pre- and post-observations of children's exploratory behaviour during free sandpit play in the experimental group as well as in a control group. A systematic observation scheme for exploratory play, the Exploratory Play Scale, was used for this purpose. The experimental group showed an increase in level of exploratory play from pre- to post-observations, while the control group did not. This study shows that a small-scale sciencing

programme can have an effect on children's level of free exploratory play. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Physical activity is an essential component for lifelong wellness and the quality of life. Over the past years, childhood obesity has dramatically increased. Data supports that young children are adopting sedentary behaviors within and outside of school hours that may contribute to obesity and other health-related diseases. This paper provides early childhood practitioners with an overview of physical activity recommendations for young children between the ages of three to five and cost-effective means to assess physical activity through step count pedometers. Finally, some pedometer activities are provided along with a description of the children's reactions and behaviors to the integration of pedometers. Both the activities and pedometer appear to be easily incorporated into any classroom or recess settings to get your children moving and active. VL - *Playing for keeps: Life and learning on a public school playground.* xiii, 127 pp. New York, NY, US: Teachers College Press; US.

N2 - (from the cover) Why is play important in the lives of children? What crucial aspects of learning are being neglected in the current near-elimination of recess time in public schools? *Playing for Keeps*, coauthored by the well-known writer and educational leader Deborah Meier and two colleagues with equally long experience in schools, explores these questions. Based on close observations on a public school playground, the book shows children at play in a relatively natural, unstructured environment. The reader is virtually there, seeing, listening in, able to appreciate the children's curiosity, humor, intelligence, and inventiveness. Readers will recognize the children's voices and ways of thinking, and perhaps be reminded of their own childhood, their own children, or the children they teach. The authors comment on the observations, adding to the reader's own perceptions. This lively, engaging book makes a strong case for the importance of free exploration, wonder, imagination, and play to the learning and growth of children. N2 - Low levels of physical activity (PA) and high amounts of sedentary behavior (SB) contribute to the onset and maintenance of various chronic diseases. we report on both PA and SB data in a representative population-based sample in Hong Kong children. Using self-reported data on weekly frequency and average duration of participation in Moderate-to-vigorous physical activity (MVPA) in and outside-school, weekly minutes spent on in-school, outside-school, and total MVPA were computed for each study participant. For sedentary activities, we computed total weekly minutes spent on: TV/video viewing; homework and other educational activities; computer use; electronic sedentary games; non-electronic sedentary games; and all types of sedentary activities. Children reported spending more time on outside-school than in-school MVPA, with the total amount of MVPA falling short of the PA recommendations for children of 420 min per week. A greater proportion of boys than girls were found to invest more time in computer use and electronic and non-electronic sedentary

games, while girls were likely to engage in homework/educational activities. The prevalence of SB associated with electronic media use is very high, with Hong Kong children spending nearly twice the time on such activities than on MVPA. Intervention should focus on the reduction of SB related to the use of electronic media. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

VL - Social and emotional learning in the classroom: Promoting mental health and academic success. xviii, 174 pp. New York, NY, US: Guilford Press; US.

N2 - (from the book) Social and emotional learning (SEL) in the classroom is our message in this book for promoting mental health and academic success. Although the specific techniques, strategies, and concepts of SEL are not new, it has only been the past few years—perhaps since the mid-1990s—that SEL has been articulated as a cohesive framework and has gradually evolved into a field with a huge potential reach and influence. Through the efforts of individual prevention scientists and practitioners, such as those who founded the Collaborative for Academic, Social, and Emotional Learning (www.casel.org), SEL has matured and expanded to the point where it is beginning to make a significant difference in our schools and communities. As you will see in the research cited, the potential impact of SEL is most impressive, although still in its nascent stages. Hence, we see this book as an "A-to-Z" guide to spur educators and mental health professionals to start using SEL in a cohesive and structured way in schools and related settings. The eight chapters of this book are not exhaustive by any means, but they will take you through almost every aspect of using SEL, from planning and getting support for it, to selecting curriculum tools, to delivering content in a way that fits your students and communities, to measuring and evaluating the outcomes that you produce. Chapter 1 introduces and defines SEL and realistically assesses what it can offer you and your students. Chapter 2 includes an overview of several of the most widely used and researched SEL programs currently available for adoption. Chapter 3 covers the essentials of using SEL in the classroom, including a wide variety of practical material ranging from preparing your students and selecting materials to developing your own plans for SEL activities if you are not

using a packaged program. Chapter 4 explores the link between SEL and academic learning in schools and contains many practical examples and suggestions for how SEL programs and strategies can be woven into the fabric of the curriculum in a manner that supports academic learning. Recognizing that delivery of SEL programming in schools occurs in a complex and increasingly diverse and pluralistic social context, Chapter 5 addresses the need for adapting SEL content to make it culturally appropriate in specific settings and includes a practical, step-by-step guide for doing so. Although we obviously highly value SEL as a mental health promotion tool in schools, we recognize that basic classroom-based SEL programming alone is not enough to fully meet the mental health needs of our students with the most severe and complex problems. Thus, Chapter 6 focuses on enhancing SEL to maximize its benefit to the most distressed students and examines practical ways to help link those students with expanded mental health programming in the broader community. Chapter 7 is a basic primer on using social-emotional assessment, measurement, and evaluation strategies within SEL and briefly overviews some exciting new tools and innovations in this area, some of which are literally "just out the door." And finally, Chapter 8 delves into the intricacies of using SEL within complex organizations such as schools, providing a solid foundation for understanding how systems change, as well as practical strategies for planning and gaining support for using SEL in your own organization. N2 - This study examined young children's access, perceptions and use of technology within and outside of school settings. One hundred sixty seven children from varied ethnic and socio-economic backgrounds participated in the study. Regardless of gender, socio-economic status or ethnic group, most children had access to computers in and outside of schools. In both settings, pre-K through grade 2 children report that they primarily use computers to play games. Children's attitudes toward computers are positive. Older children tend to use the computer more often, are better able to operate the computer and their attitudes towards computers are more positive. Boys' attitudes towards computers are more positive than the attitudes of girls, but no gender differences were found for computer use nor ability level. While no significant differences were found between the attitudes of Dutch and immigrant children, the latter group indicated more frequent use. Also, children from a lower socio-economic neighborhood had more positive attitudes towards computers and used computers slightly more often than middle class children. The findings of this study inform the debate on the desirability of young children's exposure to computers at home as well as in educational settings. Further, these findings may help educators and parents to both critically assess their current practices (e.g. the relative value of the most frequently used applications-games), and strive to integrate developmentally appropriate uses of technology at home and in classrooms. N2 - Students' perceptions of school safety and experiences with bullying were examined in a large Canadian cohort of 5,493 girls and 5,659 boys in Grades 4 to 12. Results indicate notable differences in when and where students felt safe based on their own perceptions of safety and their own experiences with bullying, particularly across elementary and secondary schools. For elementary students, especially those involved in bullying, the playground/school yard and outside recess/break time were particularly hazardous, whereas for secondary students involved in bullying, the hallways, school lunchroom/cafeteria, and outside recess/break were considered especially dangerous. The commonality across student-identified unsafe areas is that they tend to not be well supervised by school personnel. Accordingly, the present results underscore the need to increase adult supervision in areas in which an overwhelming majority of students report feeling unsafe. N2 - (from the chapter) Working with a child with selective mutism requires knowledge of the characteristics of the disorder, training in appropriate therapeutic techniques, the ability of the therapist to project personal qualities of patience and acceptance, and the therapist's ability to work as part of a team within the school. Behavioral contracting, use of classroom and curriculum modifications, determination of test accommodations, provision of parent and teacher training, and coordination of related services are all likely elements in an overall plan at one time or another and may fall within the play therapist's arena if she takes on a consulting role. Likewise, information from outside sources (i.e., psychotherapy or psychopharmacology) may filter through her. The play therapist has the unique position of understanding the student and gaining his or her trust, as they work to minimize the impact of the disorder and facilitate typical social patterns. She will be the conduit for change in the child as well as the facilitator of generalization of these behaviors to the classroom setting. The play therapist's application of unique skills, position within the school team, knowledge of selective mutism, and personal involvement, will be the variables responsible for increasing mainstream social behaviors in the child who could not do it alone. N2 - (from the chapter) "You mean you're just going to let us play?" asks a fifth-grade boy who is just beginning his first session in a sand tray friendship group at school. He and five other boys are going to play together for an hour using small trays of sand and miniature figurines. They will meet for the next 12 weeks to create scenes in their sand trays and then tell stories about their worlds if they choose. It is hard for the boys to believe they are actually going to play during school time. Unless it is recess time, the idea of play with other children during school hours is a surprise for many children and for adults as well. Even more surprising is the idea that fundamental behavior changes can occur in children in a relatively short period of time through playing

together and telling stories to one another. Several months after one sand tray friendship group ended, the school principal noticed that the boys from the group had not been referred to her office since they had participated in the group. She was surprised. This group of fifth-grade boys, referred primarily for fighting on the playground and disruptive behavior in the classroom, had been frequent visitors to her office before they started the sand tray group play. The principal was especially impressed by their ability to maintain their behavior changes several months after the group ended, and as a result, she requested a significant increase in the number of friendship groups for the following school year. Once again, the principal noted a dramatic decrease in referrals to her office among the children who participated in the expanded group sandplay program. Although the structure of the friendship groups is simple in form and function, the underlying concepts are grounded in current neuroscience and theoretical principles. Why and how these sand tray friendship groups work is the focus of this chapter. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the chapter) Any school-based assessment, whether it is time limited for a specific purpose or ongoing, is an inescapable feature of education. Assessment occurs daily within the classroom as children work through the curricula. Teachers monitor growth using multidimensional curriculum tools such as Rubrics to measure acquisition of readiness skills and then the academic skills themselves. When learning is not occurring at the hoped-for rate, staff teams, often called Child Study Teams, meet to suggest and design individualized remediation models. Sometimes, the interference with learning is related to social-emotional-behavioral problems of the target child, the child in his or her classroom setting, and/or the child in his or her family. The tools of play therapy can be a more informative venue than that of typical social-emotional assessment tools. The principles and techniques of play assessment are widely applicable and developmentally appropriate to use to observe the target child across multiple settings in the elementary school, including the playground; to assist the Child Study Team in developing recommendations for remediation; for more formal processes such as developing a functional behavioral assessment and a Behavior Intervention Plan, a school intervention plan (now called Academic Intervention Services), a Section 504 Plan, or for developing a Committee on Special Education Individualized Education Plan. The focus of this chapter will be on using a play assessment process for the Committee on Special Education (CSE) because these evaluations are the most comprehensive of the school-based assessments. N2 - Recent psychological research has examined the beliefs that individuals hold about their relationship with the natural world. This article builds on the previous literature on connectedness with nature and we introduce a new game version of the Implicit Association Test (IAT), known as FlexiTwins. The game is intended to facilitate research using the IAT and provides a flexible platform for measuring implicit associations. In this paper, we report three studies in which we use the game to measure self-nature associations. Study 1 reports the development and validation of FlexiTwins with a college sample. Study 2 further validates the game using a known-groups sample of environmental activists. Finally, Study 3 examines the implicit connectedness of a sample of 30 grade school children. Across all three studies, we find good evidence for reliability, as well as theoretically meaningful results. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the cover) Current research shows that regular physical activity helps children and teenagers perform better in school. Taking physical activity beyond gym class and recess, this inspiring book shows how to integrate movement with classroom teaching and learning. Drawing on cutting-edge educational research, the authors describe how regular physical movement increases attention span and helps the brain master new information. Readers will learn how to use short activity breaks to refocus students and movement-based games to reinforce the academic curriculum. This resource includes (1) User-friendly information on the influence of physical activity on the brain and how combining it with academics contributes to student achievement Hundreds of movement activities that can be easily implemented in the classroom, many requiring two minutes or less; (2) Discussion of how movement can contribute to classroom management and community; and (3) Illustrations of action sequences for gross motor activities. With an emphasis on teaching the whole child, *The Kinesthetic Classroom* shows how movement can improve students' mental and physical well-being and contribute to their joy in learning. N2 - Virtual worlds have become the new playground for millions of tweens but we know little what it takes to become a player in a virtual community. This paper focuses on one virtual world, called Whyville.net, which at the time of our study hosted over 1.2 million players ages 8 to 16 years, with the average player 12.3 years old. Girls represent over 68% of all players. A guided tour to the various places in Whyville, the different types of science games, and the range of players' activities provides insights into what players talk about, with whom they socialize, what they like to play, and how they engage in investigations. In 2005, a group of researchers set out to study Whyville by recruiting hundreds of participants online and offline in classrooms and after school clubs and by conducting observations, surveys, and interviews about their online activities. In addition, we collected log files that captured their online movements and chat interaction during a six month period. We discuss ethical issues of conducting research as adults in tween virtual communities and limitations of capturing the complexities of interactions simultaneously in online and offline spaces. The paper concludes with an overview of following papers in the special issue that cover players' avatar designs, representation of race, cheating practices, learning how to throw virtual mudballs, and participation in virtual epidemic. N2 - This paper reports on a pilot study in which children aged 7-12 (N = 68) had an opportunity to study in a novel formal and informal learning setting. The learning activities were extended from the classroom to the playful learning environment (PLE), an innovative playground enriched by technological tools. Curriculum-based learning was intertwined with game co-creation, play, and computer games in the PLE. The results indicate that the children considered learning in groups, through co-creation and turning fact into fiction, to be a rewarding way to learn, practice group work and use their imagination for a common goal. Teachers felt their role was important and challenging, especially in terms of the amount of tutoring and lesson planning. The study shows that one way to foster activity, creativity, imagination, and group work skills-along with academic achievement-is to integrate fact and fiction and a playful learning environment in teaching, studying and learning. N2 - This study examined literacy motivation among middle-school students in English for speakers of other languages (ESOL) classes by using a 20-question survey and semi-structured interview. The survey results identified similarities among students of different genders, but differences between the beginning ESOL group and the more advanced groups, with the beginning group exhibiting higher motivation in the subsection of "valuing" of reading. Multiple linear regression with gender, ESOL group, and self-concept as reader predicted value of reading, with ESOL group having the highest prediction power. The eight students interviewed generally reported a strong interest in reading and writing, particularly outside of school, and a wide array of literacy activities within the family in which the students were both learners and teachers. N2 - (from the chapter) Consider how much time we spend thinking of others. Almost every expressive act of communication (except maybe for exclamations!) requires that we think of the listeners or readers of our messages. All forms of social interaction demand some thought of those around us; we need to consider their expectations and anticipate their reactions. Failure to think of others is often problematic. And, when it comes to analyzing events or situations, a complete understanding often involves looking at a problem from different points of view. Considering different points of view is so common that many of us may take perspective-taking skills for granted. Yet, the ability to take the perspective of others is not always an obvious part of our psychological response, and very young children often show marked limitations in being able to see the world from another's point of view. The game of hide-and-seek is a consummate example of the need for perspective taking. One child covers her eyes while a second child finds a hiding place; after a prearranged time (say, until the count of 10), the first child seeks the second child, who should be hidden out of view. In order to successfully hide you need to think of what the seeker can and cannot see; in order to successfully seek, you need to imagine where someone might hide outside of your perspective. When very young children play hide-and-seek, sometimes their lack of perspective taking is obvious. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

VL - Resilient playgrounds. x, 173 pp. New York, NY, US: Routledge/Taylor & Francis Group; US.

N2 - (from the introduction) A special connection exists between students' social competence and the playgrounds that schools provide for them. Some of the social success that students experience can be attributed to the physical setting of the playground, the social climate created with their peers, and the caretaking environments that are fostered by school recess practices. Strengthening playground settings can be an important first step toward fostering students' social success and ultimately their social competence. These, then, are my two overarching goals for this book, Resilient playgrounds: (a) to provide a conceptual framework for understanding playground contexts and their relation to students' social success, and (b) to articulate a strategy for assessing playgrounds, identifying features that might disrupt students' social interactions, intervening to modify these features, and monitoring to ensure that the interventions have led to more successful peer relationships. (from the cover) This book provides tools and strategies for school mental health professionals, teachers, and administrators to evaluate and improve the recess experience in order to ensure that children benefit as much as possible from this important time. An accompanying CD contains forms, examples, PowerPoint presentations, and other resources to support the procedures discussed throughout the book. N2 - This study deals with the development of system thinking skills at the elementary school level. It addresses the question of whether elementary school students can deal with complex systems. The sample included 40 4th grade students from one school in a small town in Israel. The students studied an inquiry-based earth systems curriculum that focuses on the hydro-cycle. The program involved lab simulations and experiments, direct interaction with components and processes of the water cycle in the outdoor learning environment and knowledge integration activities. Despite the students' minimal initial system thinking abilities, most of them made significant progress with their ability to analyze the hydrological earth system to its components and processes. As a result, they recognized interconnections between components of a system. Some of the students reached higher system thinking abilities, such as identifying interrelationships among several earth systems and identifying hidden parts of the hydrological system. The direct contact with real phenomena and processes in small scale scenarios enabled these students to create a concrete local water cycle, which could later be expanded into large scale abstract global cycles. The incorporation of outdoor inquiry-based learning with lab inquiry-based activities and knowledge integration assignments contributed to the 4th grade students' capacity to develop basic system thinking abilities at their young age. This suggests that although system thinking is regarded as a high order thinking skill, it can be developed to a certain extent in elementary school. With a proper long-term curriculum, these abilities can serve as the basis for the development of higher stages of system thinking at the junior-high/middle school level. N2 - British children start school at a very early age - they are among the youngest in Europe when they begin formal schooling as 4-year-olds. Today, the majority of pre-school children spend at least part of their day away from their families, and early education outside of the home is increasingly being offered to children under the age of 3. In recent years the UK Government has begun to see Children's Centres and early years policies as a way to reduce the impact of social disadvantage before school entry. Partly as a result of policy and practice changes over the last decade and a half, early years education in the UK is now a rapidly growing academic field which draws on multiple disciplines - sociology, education, philosophy, psychology, and linguistics among others. Most of the papers in this edition address three main issues; the views that teachers and early years practitioners hold of children's play activity, the nature of learning in the early years, and the psychology of young children's communication. N2 - This article presents a model for the development of an environmentally oriented unit designed to be implemented as an integral part of the science core curriculum. The program's main goal is encouraging students at the junior high-school level to develop systems-thinking and environmental insight as a basis for environmental literacy. A design-based research was employed in order to construct the learning program and improve it in consecutive cycles. The findings indicate that junior high school students who were involved in the learning process-through knowledge integration activities, scientific inquiry, and outdoor learning-achieved a meaningful improvement of their cyclic and systemic understanding of the water cycle. The article concludes with a summary of the program's design elements we recommend using in other programs seeking to foster students' understanding of natural cycles within the context of their influence on people's daily lives, rather than in the isolation of their specific scientific domains. It is suggested that an environmentally based science curriculum should involve authentic, real environmental topics, and at the same time, it should emphasize the role of scientific knowledge and skills that are needed for the development of environmental literacy.

N2 - Background: A number of studies indicate higher prevalence of overweight and obesity among rural school children. The purpose of this study was to examine the differences in personal, social, and environmental correlates of physical activity between school location (urban versus rural) and gender. Methods: Middle school children (N = 676) from different districts in Cyprus completed questionnaires assessing physical activity and potential correlates. Results: Children from rural schools reported higher friend support for physical activity and more ease of walk to a bus station from their home. Urban school children reported higher presence of sidewalks in their neighborhood. Boys reported more hours per day playing outside and higher enjoyment and friend support for physical activity than girls, whereas girls reported higher means in the variable 'I see a lot of people walking or being physically active in my neighborhood'. Significant two-way interactions between gender and school location were noted with rural school girls having less favorable scores in a number of correlates of physical activity. Conclusions: More studies are needed to further understand the higher incidence of overweight and obesity observed among rural youth. Girls from rural areas may be targeted as a priority group for promoting physical activity. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Early childhood assessment has evolved to an environmental model encompassing not only child attributes, but ecological factors relating to child functioning within systems as well. The purpose of this article is to describe the successful use of a diagnostic classroom model for preschool assessment in a public school district in southeastern Virginia. The diagnostic classroom model is a structured learning environment where dynamic assessments of children aged 3 through 5 can occur by allowing children to be observed in a more natural setting over time. As a mode for assessment, the diagnostic classroom addresses two key features of best practices of early childhood assessment: families play a vital role in the process and methods accommodate children's developmental status. Descriptions of the classroom and stakeholder satisfaction data are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

IS - 6-A

N2 - The primary purpose of this study is to examine the relationship between the independent variables self-esteem, campus climate and parental involvement compared to the dependent variables grades and academic performance in African American Boys. This study will include Private school and Public school students from a large city. African American boys (age 11-16) will be selected to participate in the study, also previous academic performance will be obtained. Additionally, this examination will include the use of the follow instrument. (1) Stanford 10 Achievement Test (Stat 10) (Klein, 1993) achievement test which provides information on student performance; (2) Rosenberg Self-Esteem Scale (SES) (Rosenberg, 1965) for the purpose of obtaining a measurement of global self-esteem, and the Campus Climate Survey (McBrien, & Brandt, 1997). Self-esteem has become a household word. Teachers, parents, therapists, and others have focused efforts that may cause many positive outcomes and benefits. Self-esteem is literally defined by how much value people place on themselves (Baffle, 1991). It is the evaluative component of self-knowledge. High self-esteem refers to a highly favorable global evaluation of the self (Baffle, 1990). Low self-esteem, by definition, refers to an unfavorable definition of the self. Self-esteem does not carry any definitional requirement of accuracy whatsoever. School culture and climate refers to the sum of the values, cultures, safety practices, and organizational structures within a school that cause it to function and react in particular ways. Some schools are said to have a nurturing environment that recognizes children and treats them as individuals; others may have the feel of authoritarian structures where rides are strictly enforced and hierarchical control is strong. Teaching practices, diversity, and the relationships among administrators, teachers, parents, and students contribute to school climate. Although the two terms are somewhat interchangeable, school climate refers mostly to the school's effects on students, while school culture refers more to the way teachers and other staff members work together. Parental involvement is linked to children's school readiness. Research shows that greater parent

involvement in children's learning positively affects the child's school performance, including higher academic achievement (McNeal, 1999) and greater social and emotional development (Bredenkamp, & Copple, 1997). Simple interactions, such as reading to young children may lead to greater reading knowledge and skills (Snow, Burns, & Griffin, P., 1998). And, children with richer home literacy environments demonstrate higher levels of reading knowledge and skills at kindergarten entry. Parent involvement outside of home, such as participation in extracurricular activities, relates to their reading, general knowledge, and mathematics knowledge and skills (Reaney, 3 Denton, & West, 2002). However, more information is needed to examine what specific types of parent involvement are related to kindergartners' early literacy and how the relationship varies for children from diverse backgrounds. Procedures. Academic data was obtained from participating schools in a large city. Volunteer African American boys who participate in this research will be selected from two schools, one private and one charter. Test and surveys will be administered by researcher to students selected from the sixth grade class. The research analyses will be performed using SPSS Graduate Pack 11.0.1 for Microsoft Windows. The statistical analysis which will be utilized, is the T test and Spearman Rank Correlation Test. This test will determine if a relationship exist for questions 1-3. Question 4, 5, and 6 will be analyzed using a T Test for independent groups, Question 7 will be analyzed using the appropriate multiple correlation technique. N2 - The United States is facing a dilemma related to the wellbeing of today's children and adolescents. Youth, on a broader scale, are increasingly afflicted with what author Richard Louv, in his book *Last Child in the Woods* (2005), has labeled "nature deficit disorder" (NDD). The NDD phenomenon is considered to have emerged as a result of children and adolescents not having as many direct experiences with or exposure to nature. Estimations are that from the years 1997 to 2003 there was a 50% drop in the number of youth who participated in outdoor activities, including walking, hiking, and fishing ("*Mother Nature Knows Best*", 2007). Furthermore, only six percent of children age 9 to 13 plays outside on their own (Louv, 2007). Play, however, is considered an essential part of the learning process throughout life and should not be neglected (Rieber, Smith, & Noah, 1998). In addition, there is growing evidence indicating that there are healthy outcomes associated with unstructured play in nature and that although children only play outdoors for limited amounts of time, they enjoy playing outdoors, and given more choice and/or opportunity, many would play outdoors more than they currently do (British Market Research Bureau, 2005; Ericson, 2001; White & Stoecklin, 1998). The purpose of the study was to further investigate the premise that structured integrative health and wellness programs in an out-of-school setting can play a significant role in helping young people adopt physical activity habits and behaviors, as well as influencing dietary choices. This study focused specifically on the evaluation of the Sajai Wise Kids Outdoors program to gain an increased comprehension of the effects that may result from intentional out-of-school time programming with wellness and outdoor exploration focus areas. The program was designed

to be fun, experiential, and educational in promoting nature based play and nature appreciation in youth ages 6 to 11 years of age while teaching them basic wellness concepts. The research design used to evaluate the program's effects is best described as a mixed-methods approach. The study is based on a quasi-experimental, repeated measures design that utilized a collective (multi-site) case study technique with pre-, post- and follow-up assessments. Multiple sources of evidence were used in the study, including surveys, observations, and focus groups with youth and staff. The Theory of Planned Behavior (TPB) served as the theoretical framework as the latent constructs of the TPB have been indicated in the literature as being predictive of behavior related to physical activity and dietary choices. Although program enrollment in the cities of St. Paul and San Francisco totaled 170 participants, 67 youth ages 6 to 13 from diverse socio-economic and cultural backgrounds completed all three phases of data collection. Quantitative measures were administered to assess change in adolescent outcomes related to the latent constructs of the TPB. While results of the quantitative analysis did not show significant differences across the three measures of the study, youth were found to display significantly higher than average means at baseline. This supports the possibility that youth who showed a higher affiliation towards the constructs measured at baseline, as well as at the end of implementation, will have a continued or greater desire or intention to spend time in the outdoors, thus leading to increased physical activity. Triangulation of qualitative and quantitative findings provided further evidence that out-of-school time programs that are intentionally designed to engage youth with concepts focused on wellness and the natural environment, such as Wise Kids Outdoors, have the ability to serve as a gateway of opportunity for youth to explore and discover a relationship with nature. N2 - Emotion language use provides insight into a person's emotional landscape. However, little is known about how preschool aged children and their parents use emotion language in their real world interactions. To address the shortcomings of the current body of empirical work on naturally occurring emotion language, this dissertation asks the following four research questions: (1) How do children and parents use emotion words in their daily lives?; (2) How is children's emotion language related to parents' emotion language?; (3) How is emotion language use related to emotional functioning?; and (4) How does emotion language in a lab setting compare to a natural setting? The first question relates to descriptive information that is unknown about emotion language use in real world interactions of young children and parents. Points of interest include whether family members differ in rates of emotion language use, whether use of positive and negative emotion words are related within a family member, and how stable emotion language use is over a one year interval. The second question addressed by this dissertation relates to the relationship between parent and child emotion language use. From a social learning theory perspective, it would be expected that children's emotion language use will be related to parents' emotion language use. However, gender plays a large role in emotion socialization so will likely impact the correspondence between parent and child emotion language. The third goal is to examine what

the emotion language used by an individual illuminates about his/her emotional world. Two competing models are possible: emotion language as a reflection of emotion experience or emotion language as an emotion regulation strategy. The reflection model posits that emotion word use simply mirrors an individual's emotional experience, leading to the prediction that individuals who use more emotion language, particularly negative emotion language, demonstrate more emotional dysfunction. The regulation model, on the other hand, suggests that using emotion words acts as an emotion regulation technique, leading to the prediction that people who use more emotion language would actually be expected to show less emotional dysfunction. The last goal of this dissertation is to evaluate the ecological validity of emotion language measurement in traditional lab settings. The vast majority of research on parent-child emotion language comes from laboratory based paradigms. To date, no empirical work has measured emotion language in naturally occurring parent-child interactions to see if use in the lab corresponds to use in everyday life. The methodology of this project will be able to answer this question because emotion language use by families is measured in both settings. This dissertation implements a naturalistic methodology tool to answer the above questions. Thirty-five preschool aged children and their parents were recruited to participate in a two-wave longitudinal study in which the children wore a digital recording device for one day at each of the time points to capture acoustic information about the emotion language and behaviors they and their parents use in their daily lives. Additionally, participants completed a traditional laboratory based paradigm used to study emotion language within families. Parents also completed self-report measures related to emotion functioning for themselves and their child. Results indicate that children and their parents use high rates of positive emotion but very low rates of negative emotion in their naturally occurring interactions. This is different from lab based paradigms that elicit high rates of both positive and negative emotion language from children and parents. N2 - Research in the field TESOL has focused on the identity issues for a decade. Chinese English language learners have been regarded as high achievers in U.S. school traditionally. The neglected view has been the perspectives of Chinese English language learners themselves and their relationship with social environments in their learning process. My purpose of this case study is to conceptualization the factors influencing act Chinese English language learners' identity. Through the perspectives of students, parents, and their school teachers and counselors, conceptualization of learning English as struggle over identity, meaning, and social position, and being accepted was accomplished. I studied with four participants who had been in the U.S. for no more than five and half years. They had finished their elementary schools in China and came to the U.S. with their parents. Six parents agreed to talk with me about their parental involvement in both China and the U.S. Twelve school teachers and two counselors share their perspectives with me. I observed Chinese English language learners seven days each in their own ethnic community after they finished school or at weekends. I observed them three days of each in their school environment such as classroom, library, gym, hallway, cafeteria and playground.

My field notes and reflective journal were my important source of data. I interpreted and presented my findings in terms of themes. There were six themes evolved from data: learning English in China and U.S. Secondary School, Being Pressured to School Success, Societal Status of Chinese ELLs in Secondary school, Acquiring Societal Status in the U.S., Maintaining identity in Chinese Community, Linguistic and Cultural Navigation in the Borderlands. Through these themes, the linguistic, cultural, societal, community, and geographical factors were found that influence the identity of Chinese English language learners. N2 - This study examined the effectiveness of an eight-week intervention program that was developed to increase children's physical activity in early care and education settings. Social learning theory and the dynamics systems approach were used as the guiding theoretical frameworks in this study. Seven hypotheses were made to guide the evaluation of the intervention program. The intervention took place from November 2006 through January 2007 in the three-, four-year-old, and kindergarten classes at the University of Delaware Laboratory Preschool. One component of the intervention was physical activity curriculum for teachers to implement in children's daily routines. The other component was short energy burst activities also known as Planned Energetic Play (PEP) that teachers could embed in their existing curriculum. For the evaluation of the intervention program, data were obtained from the participants on four occasions: baseline (T1), mid-point of the intervention (T2), immediately following the completion of the intervention (T3), and four months following the completion of intervention (T4). The Actical accelerometer was used to measure children's daily, indoor, and outdoor physical activity at the four times. Repeated Measures Analysis of Variance (ANOVA) was performed to compare children's activity energy expenditure (AEE) and moderate and vigorous physical activity (MVPA) obtained across the four times of measurement. In addition, class, gender, and children's BMI at the beginning of the intervention were entered as between-subjects factors in the Repeated Measures ANOVA. Children who had the lowest level of physical activity at baseline were compared with the rest of the participants regarding the impact of the intervention program. The results showed that this center based intervention appeared to have a capacity for having an effect on increasing children's physical activity in the early care and education setting. The effectiveness was associated with class and the participant's activity level at the beginning of the intervention. Children's gender and weight status were not significant predictors of the outcome of the intervention. The implementation and effectiveness of this physical activity intervention program had implication on many factors related to early childhood education. Factors at the micro level included teacher attitudes and values, early childhood curriculum, and facilities of early care and education programs. At the macro level, early care policies and regulations had a strong influence on children's physical activity and their participation in programs that aimed at preventing childhood obesity. N2 - This paper explores the effectiveness of a school-based mental health project. Research has identified limitations in mental health care for children in the U.S. The provision of services in naturalistic settings geared toward preventing illness and promoting health is currently gaining support across political, social, and educational sectors. Therefore, the purpose of this study was to evaluate the effectiveness of the Primary Project, a school-based indicated prevention program grounded in developmental ecological theory, designed to increase the capacity of schools to identify and provide intervention for at risk children. The research question focused on determining whether or not participation in the program resulted in a decrease in targeted behavioral problems and an increase in competencies. The study addressed limitations of an earlier multi-year study of the Primary Project and included semi-structured resiliency activities in an attempt to strengthen the intervention for children with externalizing behavior problems. Children in the treatment group participated in 12 individual play sessions conducted by paraprofessionals. Archival pre-post test data for 54 treatment and 54 control-wait group children enrolled in grades K through 3 was analyzed using a MANOVA with repeated measures. Results did not support hypotheses; no significant overall condition x time effect between group difference was found. The current study has important implications for prevention research, and social change. Program evaluation is critical for social-policy development. The rigorous design of this study provides a replicable model for future program evaluation research useful for psychologists searching for direction in the investigation of cost-effective school-based mental health programs for at risk students. N2 - (from the chapter) Theories of achievement and motivation in physical education have experienced a significant transformation during the past two decades. Learning achievement in physical education, traditionally characterized by proficiency in playing sports and developing sport-related skills, is being replaced gradually by a demonstrated mastery of knowledge and skills related to healthful living. Similar to the study of motivation in learning academic subject matter, learner motivation in physical education has been viewed through multiple theoretical lenses beyond the behaviorist perspective (e.g., using win/loss as rewards for motivation). Currently, researchers are examining how achievement and motivation strategies can be used to help learners achieve the goals of developing and sustaining a physically active lifestyle. In this chapter, we will frame our discussion of learners' achievement and motivation in physical education in the broad context of curriculum and student learning to explore the critical relationships among content, motivation, and learning achievement. We will (a) discuss the impact of major achievement motivation theories on research in physical education, (b) review and critique major research findings, and (c) discuss possible challenges for future research in physical education. We have focused this review on research conducted with K-12 students in physical education, rather than physical activity associated with sport or recess. Although all three are beneficial to students in school, the meaningfulness of achievement in sport is limited to a small group of highly skilled students, while recess does not represent a meaningful achievement setting. The emphasis on physical education allows us to examine achievement in physical education learning environments within a domain specific context. Thus, the studies reviewed in this chapter were conducted in physical education settings, rather than in youth sport or recess. For sport-related motivation issues, we refer the reader to an excellent collection of reviews on motivation edited by Roberts (2001). (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Background: The Active Living Logan Square target audience is the community of the southwest corner of Logan Square, an urban Chicago community of 84,466 residents, mostly Latinos. Through the Active Living by Design (ALbD) initiative, the Logan Square Neighborhood Association leveraged its 48 years of existence in the neighborhood to create opportunities and build partnerships. Intervention: Activities addressed three primary goals: (1) enhance school environments and practices to support physical activity before, during, and after the school day; (2) encourage individuals and families to enjoy outdoor activities in their own communities; and (3) create safe, inviting places for activity that connect to surrounding communities. The partnership's participatory

approach involved a variety of community stakeholders in developing and implementing affordable, accessible, culturally acceptable, and sustainable physical activities for children and their families. Results: The partnership successfully piloted Open Streets (temporary street closures) and advocated for development of the Bloomingdale Trail, an elevated rails-to-trails project. In schools, the partnership changed the culture at McAuliffe Elementary to support healthy behaviors through new policies, physical projects, and programs. Lessons learned: Vital components of the project's success included a full-time coordinator with strong community ties; time to build healthy relationships within the partnership and community; the use of culturally relevant strategies; and flexibility to welcome complementary opportunities. Conclusions: The partnership intentionally did not produce a single community-recognized campaign; instead, it chose to use limited resources to promote tangible programs and projects that led to sustainable and replicable changes that promote physical activity. N2 - Empirical and anecdotal evidence suggests that landscapes with more vegetation have a positive impact on children's focus, attention, and cognitive development. In school, children are able to regain focus, suppress impulses, and pay attention in class longer after exposure to natural settings. Because children spend much of their time in school, the amount and types of vegetation on school grounds may influence their development. Public elementary schools in the Commonwealth of Virginia (N =988) were surveyed to examine correlations between school ground vegetation and outside recess. The number of trees on school grounds, the size of the school grounds, and the presence of sports fields were modestly correlated with greater outside recess time. These correlations support common sense because sports fields facilitate supervised play and larger school grounds provide space for sports fields and playgrounds and additional opportunities for free play. More trees on school grounds provide a welcoming environment for students and teachers, and encourage outside play. These results may help school personnel design and maintain school grounds that increase outdoor recess time. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study explores preschool children's outdoor play preferences. The sample was 40 (20 male, 20 female) primarily European-American three and four year olds. Data were collected via naturalistic observation and analyzed using repeated measures ANOVAs and MANOVAs. The independent variable was sex of child; dependent variable was play space (riding, sandbox, slide, jungle gym, open space, castle/play house, swings). Findings revealed a significant effect of sex of child on choice of play space-boys preferred to play on the jungle gym and swings, whereas girls preferred the sandbox more than boys. These findings both support and contradict existing literature. Future research should pursue children's use of micro spaces in their play environments. N2 - Research Findings: Research on early literacy development within the family focuses primarily on parent-child interactions as they use literacy materials, typically books. However, features of the home environment

and organization of family life, which provide the framework within which these interactions occur, are rarely investigated. These variables include space; time; family members' roles, responsibilities, and relationships; whether literacy activities are routines; and influences of community and culture. In this exploratory study, these physical, social, and symbolic resources of the family environment were measured using a home tour, photographs, book-reading observation, and an interview during two visits to six families who had children with mild to moderate disabilities. The data generated by these methods were then used to complete a summary measure, the Home Literacy Resource Checklist, for each family. The results indicated that the families who had previously reported reading to their child 1 to 3 times per week differed from those who had reported reading daily in resources such as help from people outside of the immediate family, existence of book-reading routines, a predictable daily schedule, use of the library, and presence of literacy materials. Practice or Policy: Further development of these measures and their use with a larger and more diverse sample are warranted so that practical knowledge about home and family life can contribute to interventions designed to improve the quantity and quality of family book reading. N2 - (from the chapter) The use of toys as an integral and essential part of therapy for young children with delay and disabilities has stimulated published resources that describe or advertise toys suitable for early intervention. Such resources show how toys may be used in both assessment and treatment (Schwartz, 2004). How toys are altered, adapted or used depends on the child and the nature of the disability or disorder. Toys may help infants with special needs "tune in", "reach out", "make discoveries", or increase "sensory awareness" (Segal, 1988). Some toys may be adapted for children with physical or visual challenges, for instance, through the use of activation switches, modified knobs and handles, or securing a toy to a stationary surface (Musselwhite, 1986). Early intervention services to children aged 0-3 years support the child and the family in enhancing the child's skill development. Intervention builds on the child's strengths and improves those developmental domains (such as communication or locomotion) to help the child reach full potential. As early intervention services became federally mandated to be provided in the child's familiar or "natural environment," professionals typically carried toys and materials in a "toy bag" to a home or day-care. The theoretical rationale for the role of toys as part of play in early intervention, the history of this aspect of the material culture of early

intervention, and the changed focus of early intervention services related to the use of toys are the topic of this article. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - As new media continue to be introduced, they become especially troubling for educators, who fear that children will grow up as zombies, lacking creativity, inspiration, and literacy-and becoming sedentary and overweight. This brief article analyzes how media use is nested in children's everyday lives. In particular, it focuses on the hypothesis of media displacement of other activities. According to the displacement hypothesis, media displace creative activities (such as free play), achievement-related activities (like reading and studying), and physical activities. In this article, "play" refers to unstructured noncomputer leisure-time activities not directly related to school, including indoor and outdoor play. Achievement-related activities (such as studying and reading) are the "work" of children in middle childhood. Physical activities include time in structured sports and in walking/hiking outdoors. Time spent in a new activity has to come from another previous activity, leading to the expectation that many other activities will decline. The results support the concerns of those who fear that media interfere with other activities. Of particular concern is that in both years, children's nonmedia play hours and their sleep hours are shorter with greater media use. Play and sleep both seem to offer large blocks of children's time from which new activities can be carved out. Video game playing and television viewing are negatively associated with reading, study and outdoor activities, again suggesting potential negative effects on achievement and physical activity of extensive media use. The large amount of time spent watching television provides a large pool of available time from which to expand new media and may reflect a medium that will decline in the future. N2 - The German youth is relatively well informed about healthy eating, but does not act in accordance with this knowledge. It is also known from empirical studies that there is an association between lifestyles, food knowledge and the eating patterns of older teenagers. However, is there a similar correlation in regard to younger children? This article shows results of a study addressing this issue by empirically investigating leisure time activities, food intake and food knowledge. The study conducted with 907 children, on average 12 years old, out of an urban region in northwest Germany using a written questionnaire, implies that food patterns and food knowledge have to be improved because they are on average only marginally acceptable. On this level, they are not in line with a healthy future. For the first time in Germany, food patterns and food knowledge of seventh grade pupils were analysed in relation to their lifestyles. The study revealed four lifestyles. One family-oriented lifestyle and three non-family oriented lifestyles: outdoor and sociable youth, culture-oriented youth, and multimedia kids. The family-oriented lifestyle influences the children's food patterns in a positive way; the three found non-family-oriented lifestyles lead to less preferable food patterns. The results imply that there is a phase of unhealthy food patterns at the beginning of the second life decade, which seems to be linked to the detachment from the parents and the gained independency, expressed by the first self-chosen lifestyles. As lifestyles have such a vital influence on healthy eating, and family is no longer the place where children get their everyday competencies, school has to enable pupils to make healthier food and lifestyle choices. N2 - This study investigated the application of an expectancy-value model to children's activity choices on the playground at recess. The purpose was to test the prediction that expectancies for success and subjective task values are related to decisions to engage in specific recess activities such as climbing, playing soccer, or skipping rope. Participants included 242 children in grades IA from five schools. Participation in playground activities was assessed using the Activities for Daily Living in Physical Play (ADL-PP) (Watkinson et al, 2001).

Task-specific expectancies and values were measured on the playground activities contained in the ADL-PP. The results indicated that children's perceptions of competence were significantly higher on playground skills that they had identified as most important compared with least important ($p < .001$). Multivariate prediction analyses revealed that the data supported the predictions of the model ($p < .0001$) suggesting that recess can be an achievement context. N2 - The purpose of this article is to qualitatively explore the affordances for risky play in two different preschool outdoor environments, an ordinary preschool playground and a nature playground, based on Gibson (The ecological approach to visual perception, 1979) theory of affordances and Heft's and Kyttea's (Heft in Children's Environ Qual 5(3) 29-37, 1988; Kytta in J Environ Psychol 22:109-123, 2002, Kytta in J Environ Psychol 24:179-198, 2004) extended work on this theory. Observations of risky play in two Norwegian preschools, one ordinary preschool (where play took place on an ordinary playground) and one nature and outdoor preschool (where play took place in a nature area) were conducted. In addition, the children were interviewed about their actualized affordances of risky play, their mobility license, and the constraints on risky play. The results show that both play environments afford an extensive amount of risky play among the children, and that the degree of mobility license tolerated by the staff is an important factor for the children to actualize these affordances. Differences in the qualities and features in the two play environments were found to have an impact on the degree of riskiness in the play situations. As such, the nature playground afforded a higher degree of risk in children's risky play. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - In this paper, we report the findings of our qualitative inquiry conducted with two male and two female sojourner students in their early teens living in the United States. Sojourner students, an under-researched population in literacy studies, refers to expatriate children who reside and study abroad for a number of years because of their parents' jobs and who anticipate eventual return to their home country. Our participants were Japanese sojourner students. Drawing on multiple sources of data, including the students' literacy logs that documented their reading and writing activities in Japanese and English, interview transcripts, and literacy artifacts, we investigated what kind of literacy practices they engaged in outside school and what developing bilingual and biliterate competences meant to them as individuals. Our findings indicate that (a) although the four students spent much time on academic literacy in Japanese and English outside school, they also had active literate lives of their own; and (b) gender affected not only how they perceived their competencies in the two languages but also how they allocated their time outside school to engage in literacy practices in each language. While there is little investigation of this student population from the perspective of gender, we suggest that it is an important issue to take into account in future research. N2 - This article focuses on a bookmaking project that was conducted with pre-adolescent Serbian and Bosnian girls at a summer camp outside Sarajevo, Bosnia in 2005. During this camp, children from Bosnia, Serbia and Croatia were brought together by the Global Children's Organisation to engage in a variety of activities, including conflict resolution, art, athletics and academics. The literacy workshops that were offered gave the children the opportunity to write, illustrate and construct their own books about topics such as peace, friendship and the preservation of nature in Bosnia. The workshops were conducted in English and Serbo-Croatian, using a variety of pedagogical strategies. Upon completion of their books, the girls hosted a 'story hour' for the younger children at the camp and their stories were read aloud and discussed. This article explores the story telling of children in post-war Bosnia (through writing samples) and discusses the powerful social component of literacy events and their ability to unite and heal disparate groups. Additionally, this article explores writing as a means of imagining a more hopeful future and how as writers, children are shapers of their own cultures and of their individual and collaborative identities within those cultures. N2 - This paper outlines the role that Forest School can play in children's development. With over 100 Forest Schools in England, 20 in Scotland and 20 in Wales, this concept is growing across Britain. Forest School involves children having regular contact with woodland over an extended period of time; it allows them to become familiar, and have contact, with the natural environment. The recent Learning outside the classroom manifesto highlights the importance of children and young people gaining experience of the world beyond the classroom. Twenty-four children from seven schools in Oxfordshire, Shropshire and Worcestershire were observed over an eight-month period as they attended Forest School. Improvements in the children's confidence, motivation and concentration, language and communication and physical skills were recorded by teachers and Forest School leaders. Changes took time to occur, highlighting the need for repeated and regular contact with the natural environment, especially for children who do not have access to nature as part of their everyday lives. N2 - For many researchers, the concept of a power imbalance is central to the understanding of bullying, and its presence in the bully-victim relationship is a prerequisite condition that needs to be fulfilled before bullying is deemed to have taken place. Despite the concept's central importance in many definitions of bullying, the nature of the power imbalance in many types of interpersonal aggression invariably labelled as bullying remains unexplored and unclear, and the concept itself has not received much empirical investigation. One major reason for the absence of experimental data on this important issue in bullying can be attributable to the over-reliance on anonymous questionnaires in the extant bullying literature. From the data collected using a newly developed non-anonymous instrument, Chan (2002) found that in the elementary school sample surveyed, a large percentage of bullying was carried out by one's peers or age-equals, and not by someone outside of one's class. The importance of these findings was examined in the context of the conceptual difficulties ensuing from the power imbalance assumption, as well as the implications for school management (e.g., play-time arrangements) and teacher training. N2 - Objective: In the general population, attention is reliably enhanced after exposure to certain physical environments, particularly natural environments. This study examined the impacts of environments on attention in children with ADHD. Method: In this within subjects design, each participant experienced each of three treatments (environments) in single blind controlled trials. Seventeen children 7 to 12 years old professionally diagnosed with ADHD experienced each of three environments-a city park and two other well-kept urban settings-via individually guided 20-minute walks. Environments were experienced 1 week apart, with

randomized assignment to treatment order. After each walk, concentration was measured using Digit Span Backwards. Results: Children with ADHD concentrated better after the walk in the park than after the downtown walk ($p = .0229$) or the neighborhood walk ($p = .0072$). Effect sizes were substantial (Cohen's $d = .52$ and $.77$, respectively) and comparable to those reported for recent formulations of methylphenidate. Conclusion: Twenty minutes in a park setting was sufficient to elevate attention performance relative to the same amount of time in other settings. These findings indicate that environments can enhance attention not only in the general population but also in ADHD populations. "Doses of nature" might serve as a safe, inexpensive, widely accessible new tool in the tool kit for managing ADHD symptoms. N2 - Background: With limited opportunities for physical activity during school hours, it is important to understand the contexts of physical activities done outside of school time. Given the importance of physical and social aspects of environments, the purpose of this study was to describe where and with whom girls participate in physical activities outside of school. Methods: Participants were 1925 sixth-grade girls in the Trial of Activity for Adolescent Girls (TAAG). At baseline, they completed a 3-day physical activity recall (3DPAR), reporting the main activity performed during 30-minute intervals and the physical and social contexts of physical activities. Results: The most frequently reported physical activities done outside of school time were house chores, walking (for transportation or exercise), dance, basketball, playing with younger children, and running or jogging. The most common location for these activities was at home or in the neighborhood. With the exception of household chores, these activities were typically done with at least one other person. Conclusions: Interventions that promote physical activities that can be done at or around home or developing supportive social networks for physical activity would be consistent with the current physical activity contexts of adolescent girls. N2 - Altruism can evolve through assortment if the selfish advantage of egoistic individuals is outcompeted by the benefits of mutual cooperation between altruists. This selection process is possible if (a) individuals can distinguish altruists from egoists and (b) altruists cooperate electively with other altruists, leaving egoists no chance but to mingle with each other. This study investigates whether these two conditions are fulfilled in a natural setting. One hundred twenty-two students of six secondary school classes (age 10 to 19 years) played an anonymous dictator game, which functioned as a measure of altruism. Afterwards and unannounced, the students had to estimate their classmates' decisions and did so better than chance. Sociometry revealed that the accuracy of predictions depended on social closeness. Friends and disliked classmates were judged more accurately than liked classmates or those met with indifference. Moreover, altruists were friends with more altruistic persons than were egoists. The results confirm the existence of the two prerequisites for the evolution of altruism through assortment: the predictability of altruistic behavior and the association of altruists.

N2 - (from the chapter) Without question, the education of America's students in science, from kindergarten through Grade 12, stands at a critical crossroads. The generally inadequate outcomes from science teaching and learning in recent years are well documented on both national and international testing yardsticks: too many students have neither the skills nor the understanding in science to enable them to compete in the increasingly scientific and technically oriented global workplace or to successfully pursue higher education in science or science education. This book represents the collective experiences of half of the eight "dissemination and implementation" centers that were funded by the National Science Foundation (NSF), begun between 1997 and 1999, to foster the understanding and use of exemplary mathematics and science instructional materials. Four centers were created to focus on math instructional materials exclusively, three were funded to do the same for science materials only, and one dealt with both subject areas. This book covers the activities of the latter four centers' work in science. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - For young children with autism enrolled in community-based inclusive child care programs, outdoor play can be a major challenge. The aim of this music therapy intervention was to improve peer interactions and meaningful play on the playground for four boys with autism by adding an outdoor music center and using original songs composed for each participant. A collaborative approach was used to support the implementation

of the intervention by the children's teachers, engaging classroom peers as formal and informal helpers. The effects of the interventions were examined using a multiple baseline design with four conditions replicated across the four children. The results indicate that the musical adaptation of the playground itself did not improve social interactions of children with autism significantly, but it facilitated their play and involvement with peers by attraction to the sound and opportunity to use the instruments. The song interventions produced desirable peer interaction outcomes, and the collaborative consultative approach enabled teachers to implement interventions successfully in ongoing playground routines. In addition, peer-mediated strategies increased peer interactions and meaningful play on the playground. (PsycINFO Database Record (c) 2014 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) The current chapter will review a theory of how children interpret and process social situations and how these processes can be biased in a way that leads the child to aggression. Children are in school for 8 hours of their day. Most of their social interactions occur there, when they are in classrooms or on the playground with other children. Mistakes and biases in the social information processing steps often manifest at school. By possessing an understanding of these steps, one would be in a better position to prevent aggression from happening. The current examination will consist of a review of a theory of social information processing and research connecting biases in processing to aggression. Finally, we will present a scenario exploring how social information processing theories can be used to treat and prevent school violence.

VL - :

IS - 2006

N2 - (from the chapter) More than 6 million adolescents who have become addicted to tobacco will die of tobacco-related illness as adults. As tobacco use remains the leading preventable cause of morbidity and mortality in the United States, developing even more vigorous prevention programs is an important public health priority. Each day about 4,000 youths, age 12-17, will try a cigarette for the first time and about half will become daily smokers. From a socioecological standpoint, there are individual as well as contextual factors related to adolescent smoking. However, there are two important factors that deserve particular attention for their strong influence: peer and parental influence. While there is debate as to whether parents or peers have more influence on smoking (especially in late adolescence), parenting behaviors can affect affiliation with smoking peers. Previous research has identified several parental characteristics associated with adolescent's smoking such as perceived parental influence, smoking status, smoking-related prompting, parental monitoring, and expectations not to smoke. Parents who smoke are encouraged to quit while their children are young; nevertheless, children of smoking parents have lower rates of smoking when parents communicate strong anti-smoking messages and establish household smoking ban rules. Information and guidelines available to parents about smoking prevention typically emphasize the importance of teaching children how to say no or walk away from cigarette offers, ensuring child involvement with sports or other extracurricular activities, talking with children about tobacco in the media, establishing household rules, and being aware of with whom and where children spend their time outside of the home. Healthy Generations, a study examining parental influences and adolescent smoking, found that parents are aware of some smoking prevention strategies (e.g., talking to children about smoking and involving them in extracurricular activities), but not all (e.g., knowing who their friends are). Our research has also shown that what parents do know about prevention does not always translate into the actions they actually take against adolescent smoking. Despite the majority of parents in our study reporting that they discouraged their children from smoking by talking to them about its harmful effects on the body, less than 10% of the parents mentioned teaching their children to say no, knowing who their friends are, talking about family experiences, and keeping them occupied with sports. The majority of parents in our study were willing to participate in smoking intervention programs; however the biggest barrier in being able to do activities with their children was lack of time due to work. Future research on factors that can help facilitate implementation of smoking prevention strategies by parents is important for developing parent-related program components to reduce incidence and prevalence of adolescent smoking. N2 - (from the chapter) This chapter describes a neuropsychological assessment case report of an 8 year old girl who was very seriously mauled by two large dogs. She had been to her mother's friend's house many times and was familiar with her mother's friend's dogs. When the women stepped outside during one visit, Anna thought the two dogs might like to play together, so she took down the gate that separated them from each other. She remembers reaching for the rope toy, thinking she would play with them. She remembers the sounds as first the male full-grown dog attacked her and then the adult female joined in, biting her severely, mauling her head and neck. She remembers being dragged across the room and calling out for help. During 9 hours of surgical intervention to stabilize her injuries, Anna experienced pulmonary distress and required resuscitation. The attack had focused on the right side of her face and neck. Her injuries included nearly complete occlusion of the right internal carotid artery and focal injuries to both vertebral arteries. Her right ear was severed, the facial nerves on the right side of her face were injured, and her right eye was dislodged from its socket. Facial bones required reconstruction, and plates were placed in the right eye socket and across the bridge of her nose. Anna also experienced two cerebral infarcts. The first was during the attack itself. Emergency computerized tomography (CT) and angiogram revealed an embolic stroke at the distribution of the middle cerebral artery on the right. The second stroke came immediately following the completion of her surgery in the right mid-parietal lobe. Three years later, Anna was demonstrating problems with coordinated motor movements. Physical therapy had been completed some time ago; however, like most adolescents, Anna began having trouble remaining compliant with her home exercises. Her parents described her as "sassy" at times, with some "normal" adolescent defiance and occasional giddy behavior. They portrayed her as an affectionate girl, invested in her family, friends, teachers, and church. At the time of evaluation, they stated that Anna had continued concerns regarding her vision and her difficulty using her left hand. However, they clearly stated that they and Anna had no problems with her scars, her physical appearance, or remorse about the injury. The family was interested in seeking neuropsychological evaluation only to determine whether there were any "permanent" cognitive sequelae. N2 - Introduction: At the moment we can find a great conscience on the benefits that the regular practice of physical activity contribute, together with healthy feeding habits, can help to avoid or slow down the manifestation of certain diseases. In this sense the analysis of the body composition and the physical activity levels in the childhood will allow, if we are able to act consequently, to define the styles and the quality of life in the adult stage. Method: A total of 211 subjects were analyzed, ages between 8 and 12 years (n1 = 96 boys; n2 = 115 girls) of the Sevillian population of Fuentes de Andalucía. Once grouped based on the physical activity level, the kinanthropometric variables and body composition were measured. Results and Discussion: Of the analyzed sample only 34,60% were physically active. The average fat percentage of the masculine group was 15,77% (SD = 8,23), whereas for the girls it is of 22,37% (SD = 6,79). On the other hand, 46,92% of the analyzed sample shows overweight or obesity. Conclusion: The children population of Fuentes de Andalucía that are regularly active outside the physical education classes have less body fat and also less overweight than those who don't practice any physical activity. N2 - The purpose of this study was to identify patterns of process characteristics capturing the essence of children's experiences in their natural environment and their possible association with health and well-being operationalized as engagement for young children with and without developmental delay. Data were gathered from 1035 children between 1 and 3 years in community-based preschools. Teachers and parents responded to

questionnaires concerning interaction, activity, and engagement, as well as demographic and biopsychosocial information. A cluster analysis was conducted to find homogenous patterns related to engagement. Five distinct patterns were identified, all related to different levels of engagement. Several factors, within both the child and the environment, were associated with high levels of engagement. Interaction skills and availability of activities appear to be strong predictors of high-level engagement, regardless whether or not the child has been identified as developmentally delayed. N2 - Background: The decision among young people to drink is complex and reflects multiple domains of influence. This paper applies the results from a previous test of an externalizing-based model predicting heavy drinking and alcohol problems in the probands from the San Diego Prospective Study to evaluate how similar characteristics relate to the decision to drink in their offspring. Methods: Data were generated from multiple sources for 152 offspring with a mean age of 17.2 years. Information on the family histories, personal alcohol and other substance use, socioeconomic stratum, the child's gestational problems, and additional characteristics were gathered from face-to-face interviews with a parent approximately every 5 years between their mid-20s and mid-40s. Data regarding the drinking status and additional variables applicable to the offspring were extracted from the 25-year (T25) epoch of the family evaluations using data supplied directly by the offspring. The relationships of variables to the drinking status in that generation were determined through correlations, regression analyses, and an AMOS-based structural equation model (SEM). Results: Significant correlations to the drinking status in offspring were observed for age, but not for sex. Using age-adjusted backgrounds and data supplied by the offspring at T25, the most robust correlations to the drinking status were seen for a disinhibition measure, peer drinking, expectations of the effects of alcohol, and the history of having worked outside the home. When placed into an SEM, the former 3 variables performed in a manner similar to that observed in the original probands in the prediction of the drinking status, in a model with good fit characteristics. Conclusions: These data from a prospective study support the importance of similar domains across 2 generations in characterizing age-appropriate alcohol-related outcomes. N2 - This article investigates the role that parental socioeconomic status plays in forming the racial gap in home computer use among young school-age children. Descriptive statistics from time diary data of 6- to 11-year-olds in the Panel Study of Income Dynamics, Child Development Supplement, reveal that Black American children spend substantially fewer minutes on the computer than do non-Hispanic White children; however, the racial gap in percentage terms has narrowed between 1997 and 2003. Multivariate analyses indicate that the extent to which parental socioeconomic status explains the racial gap declined between 1997 and 2003-in 2003, less than 10% of the gap is explained by family income and household head's education. The pattern of decline is not observed when analyzing the racial gap in reading time. As home computer ownership approaches saturation, the racial gap in computer use time may increasingly reflect the underlying racial boundaries rather than parental status differentials. N2 - The purpose of this study was to investigate the effects of computer-presented Social Stories and video models on the social communication skills of three children with High-Functioning Autism/Asperger's Syndrome (HFA/AS). Using a multiple-baseline across-participants design, computer-presented Social Stories and video models were implemented and direct observations of the participants' identified target behaviors were collected two times per week during unstructured school activities (e.g., recess). Overall, data demonstrated that the combined treatment package was effective for improving the rates of social communication for the participants, although modifications to allow access to social reinforcement were needed in two cases. In addition, all three participants demonstrated maintenance of skills at a 2-week follow-up. However, generalization of skills was only observed for one participant. This research adds evidence that a combined intervention presented via computer may be a beneficial method for remediating social skill difficulties for individuals with HFA/AS. N2 - The correlation between the communicative intent of parents, in terms of their expectation of a response and the response patterns of young children aged 23-25 months during parent-child interactions, was investigated. An Observational Framework was used to code these parameters in interactions between 36 children and their mothers. The children were assigned by cluster analysis to 'advanced', 'typical' and 'delayed' language groups and their responses were coded with respect to the degree of correctness or appropriateness within the interaction. Differences in both the parental response expectations and the children's response patterns across the three clusters are discussed. N2 - The authors explored the influences of 3- and 5-day residential environmental education programs at the Great Smoky Mountains Institute at Tremont (TN) on participants' connections with nature, environmental stewardship, interest in learning and discovery, and awareness of the Great Smoky Mountains National Park and biodiversity. The authors found significant positive, short-term effects on all outcomes of interest. Also, 3-month delayed posttests indicated retention of significant gains in environmental stewardship and awareness, whereas other gains faded. Longer stays and active engagement of visiting teachers in on-site instruction enhanced most outcomes. The authors discuss the influences of previsit preparation and group size on participants. N2 - Anti-bullying interventions in schools favour approaches that practically tackle the problems in the classroom as well as the playground. However, the effectiveness of curriculum-based interventions is often context specific. A Positive Psychology (PP) approach to tackle bullying focuses upon the individual strengths of pupils rather than behaviours. It foregrounds the greater involvement of pupils in problem-solving the issue of bullying, and promotes development of personal qualities that are valued both socially and individually. In this study, a positive psychology intervention programme was designed for implementation in a school's year seven Personal, Social & Health Education (PSHE) lessons, with a control group recruited from another school. The effectiveness of the programme was measured both pre- and post-intervention using self-report questionnaires which included items on bullying behaviour, general well-being and mental health. Results indicated that, among those pupils who experienced the PP intervention programme, levels of bullying reduced and they scored marginally better in terms of general well-being but not mental health. Further developments in the programme are underway. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract) SN - 0267-1611

N2 - Research on aggression commonly cites that boys engage primarily in physical aggression, as characterized by the pursuit of dominance via hitting, kicking, and threatening while girls engage primarily in relational aggression, which includes a plethora of behaviors geared toward manipulating others' social interactions and inflicting harm on peers so as to cause damage to peer relationships. Although most research suggests that girls engage in relational aggression more than boys, contradictory findings suggest that there is no significant difference between boys' and girls' perpetration of, or victimization by, relational aggression. In fact, some studies indicate that boys engage in relational aggression at a higher rate than girls. Further, it is found that boys involved in relationally aggressive acts exhibit significantly higher degrees of social-psychological maladjustment than girls involved in relational aggression. Despite these findings, however, there has been relatively little focus on the experiences of relational aggression in boys. This is perhaps due to the attention given to overt physical aggression in boys and their tendency to ignore a relational aggressor or respond with a physically aggressive act in return, both of which lead the relationally aggressive act to go unnoticed. In any case, given that boys are involved in relational aggression and suffer its consequences, studying their perception and experience of relational aggression is warranted and is the goal of the current research. As a sub-project of grant-funded research at The Children's Hospital of Philadelphia, a focus group methodology was employed to study boys' perceptions and experiences of relational aggression. Twelve 5th grade children (6 males in one group and 6 females in another group) at a West Philadelphia elementary school participated in the focus group study over the course of seven weeks. All participants were of low socioeconomic status, African American, and from regular education classes. Boys in this study provided initial evidence that they experience some aspects of

relational aggression in similar ways as girls. For example, for both boys and girls, relational aggression includes gossip, rumors, and exclusionary behaviors, is a common problem, is typically enacted in unstructured and unsupervised settings, and is carried over from one location to another. For both sexes, there is a link between physical and relational aggression. Finally, adults' feelings toward males and females involved in relational aggression tend to vacillate and their responses to relationally aggressive behaviors are inconsistent at best. On the other hand, this study provides critical data on the ways in which boys and girls perceive and experience relational aggression differently. For instance, the primary functions of relational aggression in boys are to show off and to expel anger, while for girls relational aggression tends to be enacted out of jealousy or revenge. Second, male perpetrators of relational aggression are not popular, while female perpetrators are popular. This may be due to a gender-based stigma that exists for boys who are involved in gender non-normative behaviors, but not for girls. Finally, although both boys and girls perceive relational aggression as a problem and can identify its negative implications, boys do not see as much of a need for help as girls do. Results from the study enhance the literature on girls and relational aggression, provide critical information on boys' perceptions and experiences of relational aggression and treatment needs, and can contribute to aggression prevention programming for youth, as well as parent, teacher, and playground supervisor training programs. N2 - This study brings us inside a contemporary public junior high school in Kobe, Japan, providing a window on students' everyday experiences and struggles with growing up and learning the principles and responsibilities of becoming a member of Japanese adult society. On the one hand demonstrating teachers' ethnopedagogical schema of curriculum and pedagogy that is strongly linked to cultural notions of developmental readiness, this study on the other hand explores how student participation in an increasingly complex series of lessons, activities, and practices shape their identities over time as junior high school students and as members of Japanese society. Social discourses and conditions in broader society emerge in teacher practice and surface in students' conversations and writings that offer glimpses of how they see themselves and their futures vis-a-vis these received views. As they navigate between the worlds of school and of broader society, school events such as school excursions and "Let's Try Week" challenge students to extend concepts of selfhood by providing opportunities for performing emerging concepts of self and society outside the school perimeter. VL - 69:

IS - 4-B

N2 - Background. The prevalence of childhood overweight in the United States has increased by 50% in the last two decades (Schumann, Nichols X Lingston, 2002) and 25% to 30% of U.S. children between the ages of 6 and 17 are obese (Moran, 1999). Several studies show that sedentary activities such as television viewing, using a computer, and playing video games increase the risk of childhood obesity (Ebbeling, Pawlak & Ludwig, 2002; Dennison, Erb & Jenkins, 2002; Yackel, 2003). An innovative means of reducing sedentary activity in children through the use of video "exergames" or "exertainment" is becoming a popular means of increasing physical activity in children. A limited number of studies show that "exergames" can make a positive contribution to players' stress management, weight management, fitness, and health (Lieberman, 2006). More research is needed to determine if and how these interactive video games improve physical activity and overall health in children at high risk for obesity. Purpose. The purpose of this pilot study was to assess the effects of a four-week interactive video "exertainment" program in underserved children, as part of an after-school program based on social cognitive theory. Method. Participants consisted of 58 children recruited from an existing after-school program in the San Bernardino City Unified School District. The participants were children ages 7-12 years of lower socioeconomic status living in Southern California. Pre- and post-assessments were made to see if there were improvements in attitude, self-efficacy, outcome expectations, body composition, cardiovascular endurance, body image, physical activity outside the intervention, absenteeism, and academic achievement. Analyses. Results from this study showed that there was a 16% decrease in resting heart rate from baseline to post-intervention for males ($p=le;.001$) and a 12.9% decrease in resting heart rate for females ($p=le;.001$). Average active heart rate decreased for all subjects post-intervention representing a 7.16% decrease for males ($p=041$) and 5.2% decrease for females ($p=053$). Absenteeism rates improved significantly for students participating in the intervention. The mean number of days students were absent during the intervention (3.73, $p=020$) decreased compared to prior to starting the intervention (000, $p=000$). Academic scores showed significant improvements in the students' mean math performance while participating in the intervention ($t=3.63$, $p=001$) compared to non-participants ($t=2.16$, $p=.042$). The average percent body fat in males showed a non-significant decrease by less than 1% ($-.89$, $p=.295$). There were no significant changes on the other study variables. Application to Health Education. The "U Got 2 Move It" program focused on promoting healthy lifestyle modifications in America's youth as a means of reducing the risk of obesity in underserved children by introducing an appealing format for activity-interactive video games in after-school programs. The results from this pilot test will serve as a model for health educators to partner with schools and community-based organizations to develop future health-related programs focusing on preventing or reducing the threat of obesity and related health problems in high risk children. N2 - The idea of student engagement has come to the forefront of the United States educational system over the past decade. Student engagement requires learners to be actively involved in all stages of the learning process. This study focuses on the use of online quizzes in the chemistry classroom as a means to help students become more engaged in their learning outside of the classroom. Students were given three different types of online quizzes over the course of a chemistry chapter. Student scores on end of the chapter examinations was used to determine whether there was a significant difference in the amount of learning that occurred when a student took each of the three types of online quizzes. Students in a private parochial high school chemistry class completed online quizzes over the course of a semester. The quizzes were taken after completing assigned readings from the chemistry text. After each reading, a third of the students took online multiple-choice quizzes, a third took a paragraph quiz, and a third took no quiz. Scores received from end of chapter tests were evaluated to determine if the impact each of the quiz types had on the learning. All statistical analysis was done using SPSS using two-way split plot ANOVA with condition (paragraph, multiple-choice, nothing) as the within subject factor and group (A, B, C) as between subject factor. The data indicates that there was no significance within the condition $F(1.877, 90.087) = .996, p > .05$, or the interaction results. $F(3.754, 90.087) = .509, p > .05$. The data indicated that the effect of group was not significant either. $F(2, 48) = .981, p > .05$. Interviews undertaken to explain this outcome discovered that students did not become engaged with the content until the night before each test. When they did so, they used a teacher-provided study guide as their primary learning tool. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Using the concept of resilience, as well as its processes and mechanisms, this study proposed to investigate the possible relationship between resilience and leadership. More specifically, the purpose of this research was to explore the possible relationship between parents' perceptions of resilience and their daughters' standardized leadership scores per the Roets Rating Scale for Leadership (RRSL) instrument. This research utilized a correlational design to determine whether, and to what degree, the resilience variable was related to leadership. The possibility of a relationship between the two variables was suggested by research conducted on leadership (French & Stright, 1991; Jablin, 1997; Landau & Weissler, 1991; Thompson, 2000; Trawick-Smith, 1988), parenting (Arntson & Turner, 1987; Bellinger & Gleason, 1982; Hartup & Moore, 1990; Huang, 1999; Teichner, Ames, & Kerig, 1997; Whorton & Karnes, 1992), and resilience (Fraser, 1997; Krovetz, 1999; Lugg & Boyd, 1993; Masten, 2001; Masten & Coatsworth, 1998; Smith & Prior, 1995) as well as derived from experience and observation. Method. The research design selected for this research study was a correlational design with the quantitative paradigm as its primary methodology. This methodology was chosen to explore the magnitude and the direction of the relationship between the variables of leadership and resilience in the hopes of helping the field of leadership to solve practical problems such as closing the gap between the "theories that integrate the process of leader development with that of leader performance" (Chan & Drasgow, 2001, p. 481). Additionally, the study was designed as correlational because this quasi-analytic design provided the greater ecological validity by being more easily applicable outside laboratory settings. The procedures for this study indicated the need to obtain two group scores, one for each variable of interest. Resilience ratings were used as the independent variables and the total leadership score served as the dependent variable. The resilience measures included four resilience behavior factors and a total resilience behavior score as well as the four social support factors and total social support score. Mediating variables of age, GPA, and type of parents' biological relationship, and mother vs. father ratings were also addressed. Scores for the narrative section of the RRSL were calculated by assigning a code to the girls' responses. 153 participants were recruited from four different public schools in Regions I, III, and IV of Miami-Dade County Public Schools. The data collection for the leadership variable (RRSL) occurred in a natural setting, while the data collection for the resilience variable (RRAPRS) occurred in the participant's home. The mother and the father, or the two primary caregivers, of each participant were asked to complete the rating scale separately. Both an English version and a Spanish version of the RRAPRS instrument was sent together for parents to choose the one they preferred. Major findings. Although a significant relationship between the concept of leadership and resilience could not be established across the border, the findings regarding father and male caregiver influence, and the variables of academic achievement, resilience, and grade, seem to pose interesting implications for families and educators. More specifically, when correlating the constructs of leadership and resilience, the literature suggests strong environmental or situational components affecting both of them. While there was a lack of statistical significance when correlating leadership and resilience, this could have been due to both constructs been difficult to measure objectively since so many factors play a role in their development and manifestation. IS - 2-A

N2 - The purpose of this study was to describe the daily pedometer-determined Physical Activity (PA) patterns of 4th and 5th grade children during the segmented school week (i.e., recess, Physical Education, lunchtime, school day, outside of school, weekdays, and weekends). Eight hundred and twenty-nine children from six Southwestern United States elementary schools participated by wearing pedometers (Yamax Digiwalker SW-200) for seven consecutive days (5 school days and two weekend days). Students recorded their steps at arrival and departure from school as well as before and after Physical Education, recess, and lunchtime. They used a recording sheet independently over the weekend. Results showed that boys took significantly more total steps/weekday than girls, outside of school steps, steps during lunchtime, steps during recess, and steps during school. During Physical Education, both boys and girls accumulated a similar number of steps. For boys, lunchtime represented the largest single source of daily PA (13.4%) obtained during school, followed by PE (12.7%) and recess (9.5%). For girls Physical Education was the largest single source (14.3%), followed by lunchtime (11.7%) and recess (8.3%). Significant differences were also found across ethnicity/racial groups, Body Mass Index cut points, and schools. A similar number of steps were also accumulated on weekend days. This study is critical, as it was the first with a large diverse sample investigating students' PA patterns across various activity segments. The daily steps/day patterns of fourth and fifth grade children are variable; however, an understanding of the contributions of the in-school segments can serve as baseline measures for practitioner and researchers to use in school based PA interventions. N2 - Using the Internet as a source for learning is rapidly transforming how we work and live. Internet-savvy children are vigorously participating in this new activity-largely outside of the classroom. A better understanding of these students' attitudes, beliefs, and behaviors will help guide educators in making the necessary pedagogical changes to meet 21st century social, cultural, and economic change. This study investigated the construct of Internet-savviness exhibited by academically talented and well-abled youth, ages eight through fourteen. Grounded in learning theories of social constructivism and distributed intelligence, a survey scale was developed to measure Internet-savviness and to elicit these children's Internet-related attitudes, beliefs, and behaviors. Reliability and validity analyses of the scales revealed satisfactory levels of internal consistency. An exploratory factor analysis revealed a clear, underlying structure of the following dimensions: (1) computer mediated communication, (2) creative expression, (3) information gathering, (4) Internet fluency, (5) Internet-self efficacy, and (6) social collaboration. ANOVA, MANOVA, and Regression analyses along with correlation and descriptive statistics analyses were applied to other variables of interest including Internet access speed, age, gender, frequency of Internet use, and type and location of access. Internet-savvy scores

corresponded to self reports of Beginner, Intermediate and Advanced Internet users. Thirty-three percent of youth rated themselves as Advanced users which aligns with previous research on Internet-savvy teens. Although females and males differed in Internet activities and scored below males on Internet-savviness, they closed the gap by age 12. Regarding gender, there were no statistical differences on dimension or total IS scores in this study. Doing something creative, exchanging images, access speed, age and access at home and at a friend's house were statistically significant predictors of IS scores. Effect sizes were reported. Narrative data was collected from the participants, analyzed and summarized as a way to identify central themes regarding Internet use in and outside of school and to triangulate on the multidimensional nature of Internet-savviness. N2 - Genetic factors play an important role in the etiology of anxiety disorders. Williams syndrome (WS), a genetic disorder caused by a deletion on chromosome 7q11.23 and associated with increased prevalence of anxiety disorders relative to the general population and other genetic disorders associated with intellectual disability, can be used in the search for susceptibility genes for anxiety disorders. This study examines the prevalence of anxiety disorders in children with WS, their mothers, and their siblings as well as predictors of anxiety in these groups, in order to facilitate the use of WS in studies of genetics of anxiety disorders. Anxiety disorders were assessed in 109 children with WS ages 4-16 years, 106 mothers, and 72 siblings in the same age range. Prevalence was compared to that in the general population. Children with WS had a significantly higher prevalence of specific phobia, generalized anxiety disorder (GAD), and separation anxiety in comparison to children in the general population. The mothers had a significantly higher prevalence of GAD than women in the general population, but the prevalence rate for GAD in this group prior to the birth of the child with WS was comparable to that for women in the general population. The siblings had a significantly higher prevalence of specific phobia in comparison to children in the general population, but it was similar to the rates reported in other studies of specific phobia in typically developing children. The odds of a child with WS having an anxiety disorder increased with age and the severity of maternal anxiety. The odds of mothers having an anxiety disorder increased if the mother was not employed outside of home and if the child with WS was a male. The elevated prevalence rates of anxiety disorders in children with WS suggest a connection between the deletion found in WS and anxiety disorders. Given the increased prevalence of anxiety disorders in children with WS, genetic studies examining possible links between particular gene(s) deleted in WS and anxiety are warranted. It would also be worthwhile to investigate relations between genes deleted in WS and genes previously implicated in anxiety disorders. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of this study was to investigate how much funding a site-based managed school allocated toward promoting effective professional development at an elementary school level. Additionally, the study examined a district and school's practice of allocating resources for professional development and determined how funding and where the funding for professional development originated. Furthermore, an evaluation process was used to identify the strengths and weaknesses of the school's professional development programs as they compared to an evidence-based professional development model. This study used conceptual frameworks adapted from the research literature to guide data collection and analysis for four research questions: (a) How are personnel used for the delivery of professional development? (b) How are resource allocation decisions for professional development determined? (c) How much funding is directed toward professional development and from what sources do these funds originate? (d) How is professional development used to promote organizational capacity and student achievement? This descriptive-analytic case study was conducted in one elementary school, Sutherland Elementary, in a decentralized unified school district, Glenn Park Unified, located just 30 miles outside of Los Angeles' metropolitan area in Southern California. The district and school were selected on the basis of: (a) implementation of innovative professional development; (b) evidence of administrative freedom to allocate funds to professional development; and (c) significant gains in the school's Academic Performance Index (API) over the last 5 years. Data analysis revealed that Sutherland Elementary and Glenn Park Unified School District employed several research-based strategies pertaining to professional development that aimed at building the capacity of the organization and the individuals. Additionally, the data uncovered that while Sutherland Elementary had the autonomy to decide upon professional development activities, the district supported the school site. An evaluation of Sutherland's allocation practices for professional development revealed a disconnect with the research provided by the evidence-based model. However, the data also highlighted that Sutherland Elementary and Glenn Park Unified School District received a greater amount of professional development resources than could be accounted for in the school and district's expenditures due to partnerships with universities and educational foundations. The study provided conclusions addressing the six core strategies of the conceptual framework, the role of the district office in a decentralized setting, and the analysis between the decentralized setting of Glenn Park Unified as compared to a centralized management style. Five major themes surrounding professional development practices appeared to illustrate the overall success of the school and district: (a) a vision for learning; (b) data-driven decision making; (c) effective utilization of resources; (d) collaboration; and (e) site autonomy. Recommendations for successful professional development practices at other schools and districts included: (a) establishing a clear vision and goals for teaching and learning; (b) utilizing data to make professional development decisions; (c) establishing the needed access to ongoing, on-site, fulltime coaching; (d) adopting a financial plan that mirrors those used in the private sector; (e) collaboration across the school and district; and (f) encouraging site autonomy for professional

development decisions coupled with district support as needed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Neighborhood research, the body of work exploring the link between the neighborhood context and residents' behaviors, has received growing attention in recent years. Although this literature is rapidly expanding, there is currently no consensus on how researchers should measure the neighborhood space. Many researchers rely on census data that have been shown to be problematic, while others conduct independent observations of neighborhoods and interview residents about their perceptions of neighborhood conditions. Unfortunately, the few studies that incorporate residents' perceptions of neighborhoods generally rely on adult ratings even if the outcome of interest is concerned with children. As this poses a potentially serious methodological issue in neighborhood research, this dissertation gave voice to children using a mixed methods design. First, ten preadolescent children enrolled in after-school programs in two New York City neighborhoods participated in open-ended interviews and walking tours of their neighborhoods. Qualitative findings revealed that children frequently discussed the following elements: neighborhood quality, safety, social, and physical disorder. These findings informed the design of a survey assessing children's and parents' perceptions of their neighborhoods and children's mental and physical health. 126 children, aged nine to 13, enrolled in after-school programs in three neighborhoods and 117 parents completed this survey. The children also listed five blocks around their home that constituted their neighborhoods. These blocks were observed by two outside raters and census data were collected at the block group level of aggregation. Results from the quantitative study phase suggest that children and parents showed some overlap in their perceptions of neighborhood conditions but these subjective ratings did not relate to the neighborhood observations and census data. Subjective ratings of neighborhood safety mediated the relationship between neighborhood disorder and neighborhood quality and child-rated perceptions of neighborhood conditions predicted their ratings of mental health. Neither parents' neighborhood perceptions, neighborhood observations, nor the census data directly related to children's mental health. On the other hand, observed physical disorder and child-rated neighborhood safety predicted physical health. The dissertation supports the hypothesis that subjective perceptions of neighborhood conditions related best to children's health and that children should be actively recognized in research concerning them.

N2 - The growing ethnic diversity of the United States has created a need to reinvestigate older concepts, such as the relations between autobiographical memory and the reminiscence bump, in new ways shaped by the shifting demographics of the American population. In keeping with these shifts, an investigation of the autobiographical memories produced by adult participants in terms of the ratings they provided for the level of positive affect, emotional intensity, and identity salience for each memory, and how these factors are impacted by cue word type (Civil Rights Targeted or Era Neutral), participant ethnicity (African American or European American) and participant age (child versus adolescent during the Civil Rights Movement) was carried out. It was found that African American participants reported memories that differed significantly in both their timing and their ratings from those provided by European Americans. African Americans tended to provide memories from an earlier point in their lives, with an emphasis on the first half of the reminiscence bump (ages 11-20). European Americans tended to place an equal emphasis on each half of the entire reminiscence bump (ages 11-30). There were also variations in their memory ratings. With the exception of ratings of affect, ratings by African Americans of the emotional intensity and identity salience of their memories were higher than those of the European Americans. It was concluded that ethnic identity can play a major role in how we perceive our autobiographical memories, as well as what period of life those memories are drawn from. An exploratory structural equation model was also run to investigate the relations among the ratings of affect, emotional intensity, and identity salience for the memories that were located either within the reminiscence bump or outside of this time period. This was performed in order to investigate which, if any, of these factors was the best predictor of the type of memories represented in the reminiscence bump. The generally weak relations between location relative to the reminiscence bump and the participants' ratings of their memories indicated that the model should be revisited and that other factors should be considered. N2 - Collecting assessment information on child characteristics and social emotional behaviors has predominantly relied on the use of adult informants. However, there has been an increase in the recognition of the importance of obtaining information directly from the child to supplement other assessment methods. This increase has been due in part to the improvement of the technical adequacy of recent self-report measures, and the understanding of the important role of self-perceptions on children's behavior through motivation. Limited self-report measures have been available in the past for assessing the concept of young children age 7 and below. This study investigated the Computer Assisted Child Interview (CACI) as a self-report measure of children's academic performance and school performance to determine its validity. The CACI is a computer assisted self-report assessment tool for children 4 to 10 years of age. It is used to obtain child perception of two broad areas: their perceptions of parenting behavior and strategies, and their own behavior and experiences. This study utilized a non-experimental within-subjects correlational design. The reliability of the CACI was established from a prior pilot project. The main focus of this study was to determine the relations between the predictor variables, particularly the CACI subscales of School Experience and Education Support, which solicited child input on their school difficulties and performance and the dependent variables such as parent and teacher reports. The Child Behavior Checklist (CBCL), the Teacher Report Form (TRF), the Peabody Picture Vocabulary Test-III (PPVT-III), and playground observation were used as criterion measures. Results indicated significant relations between child report on CACI School Experience subscale with the CBCL School Competence, and three TRF academic subscales. The CACI School Experience also correlated significantly with the Peer Rejection and Antisocial subscales of the Teacher Perception of Risk measure. No significant correlation was found between the CACI School Experience and the PPVT-III. Education Support scores predicted PPVT-III and positive playground behavior in the opposite direction. Scores from the CACI School Experience significantly predicted a combined construct of parent and teacher perception of student academic performance. Finally, hierarchical regression analyses indicated that the CACI school subscales contributed unique variance in predicting different models of outcome construct. N2 - Reviews the book, Volume I Songbook: Songs & Laughter on the Playground by P. Kern and A. M. Snell (2007). True to its title, this volume shares songs but also detailed information on strategies and interventions for turning playground time into a fun-filled as well as therapeutic music time. The book is a continuation of the work begun by author Petra Kern on incorporating music, music therapy and music instruments on the playground. The beginning Preface and Introduction are short statements but should be read very carefully for they contain the fundamental philosophy of practice of the two authors. The focus is in keeping with current trends in education which emphasize least restrictive environment and opportunities for inclusion and generalization. The music composed by both Kern and Snell is appropriate to the age and abilities of young and early school age children. The songs are simple, but not simplistic, with catchy melodies and rhythms. Each uses language that is functional outside of the song and can be generalized for use in everyday communication. Within this simplicity though, many of the songs contain some rhythmic or harmonic surprise that will appeal to the adults who work with children-supporting the author's stated purpose of encouraging others "to make music a part of their everyday lives". N2 - This study was based on the Cyprus data from both the student questionnaire and the tests of the Progress in International Reading Literacy Study (PIRLS), undertaken in 2001 under the auspices of the International Association for the Evaluation of Educational Achievement (IEA). The sample included 3,001 fourth-grade students from Cyprus, whose average age was 9.7 at the time of testing. The statistical analysis used to distinguish the more and less effective schools was based on the residuals. From this analysis, 6 factors explaining school differences in reading achievement were identified. The 1st factor, which is the strongest one, is related to class activities subsequent to the reading class. The 2nd most important factor is related to reading outside school. The 3rd factor is related to the time spent on homework. The 4th factor relates to attitudes toward reading. The 5th and 6th factors are activities during teaching and school climate. N2 - In this article, we examine U.S. and Italian parents' discourses on family time in parent-filled weekly activity charts and interviews with parents. Analysis indicates that in Los Angeles, California, parents talk about sheltering and isolating their nuclear family from the outside world and from everyday routine by creating special times and special activities for the nuclear family. In contrast, Roman parents' discourse allows for spontaneous times with the family that are diffused within routines and merged with other community members, institutions, and social spaces. We argue that differences displayed in parents' discourses are shaped by culturally specific orientations toward time, family, and individual versus shared responsibility. Through this cross-cultural comparison we contribute to the understanding of how local cultural models shape different ways in which parents interpret time spent in family and influence individuals' perceptions of their everyday lives.

N2 - This study investigated the physical activity (PA) levels of 6- to 8-year-old children over a seven-day period. The participants consisted of 35 girls and 36 boys in kindergarten and 113 girls and 131 boys in 1st grade. Physical activity (PA) is defined as "any body movement produced by skeletal muscles resulting in energy expenditure" and measured in this study using a Caltrac accelerometer. In addition to the data produced by the accelerometer, a detailed activity log was kept for each participant. The results revealed no statistically significant difference in PA levels between kindergarten and 1st-grade participants, $F(1,311) = 1.16$, $p = .282$. However, boys were more physically active than girls $F(1, 311) = 66.10$, $p < .001$, $\eta^2 = .17$, and the level of PA was higher on school days than on free days for both sexes, $F(1, 311) = 20.45$, $p < .001$, $\eta^2 = .06$. Finally, the data on the children's PA at school strongly supports the importance of physical education lessons (PE lessons) and recess periods in the daily school routine. N2 - Outdoor school environments are sites for play and physical activity for many children, and shortcomings within these environments are considered significant factors that contribute to children's inactive lifestyles and high levels of childhood obesity. This study explores the associations between the physical characteristics of schoolyards and the physical activity of third and fourth year students in five Turkish primary schools. Data were collected through multiple methods, including behavior mapping of student activities during recess, physical assessments of schoolyards, and interviews with students, teachers and administrations. The findings show similarities in the landscape features and physical qualities of schoolyards, particularly in the types of play and activities in which students engage. Results indicated that active students who walk to and from schools have lower body mass index (BMI) values than passive students, and students in schools with larger yards have lower BMI values. Most of the students prefer spacious and vegetated yards. A major concern is the crowdedness of the yards during recess that limit children's activity. Schoolyards with advanced landscape features are preferred more, and this in turn affects students' positive satisfaction. Outdoor school environments have a correlation to health outcomes and should be designed to promote more activity. Improving the physical and landscape qualities of the public schoolyards should be the primary concern of the designers in order to increase awareness of natural environment and more important, increase the health of children. N2 - This paper is an extension of previous work on capturing and modeling the affective state of entertainment ('fun') grounded on children's physiological state during physical game play. The goal is to construct, using representative statistics computed from children's physiological signals, an estimator of the degree to which games provided by the playground engage the players. Previous studies have identified the difficulties of isolating elements of physical activity attributed to reported entertainment derived (solely) from heart rate (HR) recordings. In the present article, a survey experiment on a larger scale and a physical activity control experiment for surmounting those difficulties are devised. In these experiments, children's HR, blood volume pulse (BVP) and skin conductance (SC) signals, as well as their expressed preferences of how much 'fun' particular game variants are, are obtained using games implemented on the Playware physical interactive playground. Given effective data collection, a set of numerical features is computed from these measurements of the child's physiological state. A comprehensive statistical analysis shows that children's reported entertainment preferences correlate well with specific features of the recorded signals. Preference learning techniques combined with feature set selection methods permit the construction of user models that predict reported entertainment preferences given suitable signal features. The most accurate models are obtained through evolving artificial neural networks and are demonstrated and evaluated on a Playware game and a control task requiring physical activity. The best network is able to correctly match expressed preferences in 69.64% of cases on previously unseen data (p-value=0.0022) and indicates two dissimilar classes of children: those that prefer constantly energetic play of low mental/emotional load; and those that report as fun a dynamic play that involves high mental/emotional load independently of physical effort. The generality of the methodology, its limitations, its usability as a real-time feedback mechanism for entertainment augmentation and as a validation tool are discussed. VL - 3:

IS - 2

N2 - Using data from a cohort of school going children, their households and caregivers (the Amajuba Child Health and Wellbeing Project, ACHWRP) in KwaZulu-Natal, South Africa, we compared demographic characteristics, care burden, health, physical function and social capital of caregivers of orphans (n = 300) with those of non-orphans (n = 298). This analysis presents cross-sectional findings from questions for caregivers that were added for the study's second round, conducted between September 2005 and June 2006. Caregivers of all children were overwhelmingly women (87%). Compared to non-orphan caregivers, caregivers of orphans were on average older (49.5 vs. 45.2 years, $p = 0.0002$), had fewer years of education (6.7 vs. 7.8 years, $p = 0.0042$) and were less likely to be married or cohabiting (29% vs. 46%; $p < 0.0001$). Caregivers of orphans reported caring for more children than those of non-orphans (4.8 vs. 3.8 children, $p < 0.0001$). A larger proportion of orphan caregivers reported having cared for an ill adult in the previous year (28% vs. 19%), and for that adult to have been a biological child ($p = 0.0531$). There was a high prevalence (55%) of self-reported poor health among all caregivers; caregivers of orphans were more likely to report poor general health and chronic illness. Although there was a high prevalence of functional impairment (self-reported inability to perform primary activity) among all caregivers (59%), there was no difference between groups. In terms of social capital, although similar proportions of orphan and non-orphan caregivers reported having friends outside the household, orphan caregivers were less likely to have a source of a small emergency loan [51% vs. 63%; adjusted odds ratio: 0.60 (0.41-0.88)]. Our results suggest that orphan caregivers are indeed more vulnerable, and that their particular limitations and needs must be considered when developing strategies for assisting vulnerable households to ensure better support for both caregivers and the children in their care. N2 - To understand the different relations children establish with the environment, an investigation on the use of several areas of a school patio and the interaction between children, (three to seven years old), during recreation time was performed. Data were collected through systematic observation, and place-centered mapping, which is an observational technique used in Environmental Psychology. According to the observed: playing in group was predominant, specially in areas with multiple-utility equipments, sports court, and in large open shady areas; differences in the use of the spaces were found related to children's age and gender. The implications of these results appoint to the need of planning outdoor areas that allow diverse activities, and promote quality of life for children regardless their age or gender. N2 - Participating in leisure activities provides important benefits for all people. However, there is a substantial reduction of (green) leisure opportunities in cities, and the green spaces that are available often are poorly accessible. The purpose of this study is to analyze the diversity of participation in various types of leisure activities and to determine the relationship between leisure activity participation and characteristics of the residential environment depending on socio-demographic characteristics. Diary data from 803 respondents

living in the Eindhoven region in the Netherlands were used. Four segments were identified that differ regarding their leisure activity participation, and a modest impact of green space accessibility was found. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Most of the existing ecological studies have been conducted during class instructional time. The purpose of this qualitative study was to describe (a) how students (N = 102; grade 2-4) engaged in a strategy named Health Passport taking place mainly outside of school time and (b) how four physical education teachers held students accountable for their involvement in physical activity during a long period of time (3-7 months). An inductive approach guided the data analysis, based on observational notes, interviews, and the content of the students' Health Passport. The results indicated that children displayed five different profiles of involvement in the completion of the tasks related to their passport. Physical education teachers chose to trust students' self-management capacity instead of using a formal evaluation to hold them accountable. The experiment of the Health Passport showed that physical education teachers can put together and implement accountability strategies to support students' regular practice of physical activity at home. N2 - Rates of problem behavior at urban elementary school playgrounds are of growing concern. The purpose of this study was to examine how the implementation of a recess intervention within the context of School-wide Positive Behavior Support (SwPBS), a systemwide, team-driven, data-based decision-making continuum of support, affected disruptive student behavior and teacher supervision on the playground in an urban elementary school. Specifically, this study replicated investigations conducted by Lewis and colleagues through teaching recess-related behaviors to students and using group contingencies to reinforce appropriate student behaviors. A multiple baseline design was used to assess the effects of SwPBS on the frequency of five target behaviors. Results indicated decreases in disruptive behaviors across three grade levels and increases in active teacher supervision. N2 - One of the goals of Healthy People 2010 is to eliminate health disparities of people with disabilities. However, there is a deficit of information on physical activity levels in children with mental retardation (MR) in both the school and out of school environments. The purpose of this study was to investigate the physical activity levels of elementary school-aged children with and without MR in both school, after-school and weekend environments. Accelerometers were used to record physical activity levels of nine children with mild MR and 33 children without (NMR). Four multiple regressions were performed to identify the difference between groups while accounting for age, gender and BMI. While at school, physical activity levels for children with MR were significantly lower during both recess and physical education, $p < 0.001$, $p < 0.001$ respectively, After school and weekend physical activity levels for children with MR were significantly lower, $p < 0.001$, $p = 0.006$ respectively. The findings of this study indicate that the disparity in physical activity in individuals with MR begins as early as the elementary school years and is measurable across environments. N2 - Drawing on time use data from the Child Development Supplement of the Panel Study of Income Dynamics, this study identified five different profiles of shared time between parents and young people at different stages of development. In childhood, all profiles had high rates of shared television viewing, but some were oriented toward in-home activities and others toward activities outside the home (e.g., cultural events). These latter profiles tended to be higher in socioeconomic advantage, and the young people in them tended to demonstrate greater gains in math, but not reading, achievement across the transition into adolescence. In adolescence, shared activity profiles favored low amounts of shared time between parents and adolescents across activities and disfavored shared time in public domains. N2 - We evaluated a social skills intervention with four children who had autism during interactive play with typical peers at a public elementary school. Paraprofessional staff (classroom assistants) used preteaching, rewards, and prompting to increase social initiations by the children toward peers. The children's social responses to peer initiations also were measured and rewarded. Intervention was introduced in a multiple baseline design and produced increases in social interactions between the children and peers. The application of social skills training in naturalistic settings and topics for future research are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Reviews the book, *Socioemotional development in the toddler years: Transitions and transformations*, edited by Celia A. Brownell and Claire B. Kopp (see record 2007-15136-000). Many might argue that toddlerhood, like middle childhood, has been relatively neglected by developmentalists. While infants, preschoolers, and adolescents have been the focus of broad developmental theory and research for a long time, toddlers (one- and two-year-olds, called "knee babies" or "knee children" by Margaret Mead) have received attention only in specific domains, such as language development and attachment. However, it is clear with this book that their time has come. Clever experimenters have found ways to tap the toddler mind, and modern theories make what goes on from ages one to three important. Sociocultural theories, with their emphasis on language and communication, and epigenetic and dynamic systems theories, with an emphasis on behavioral organization within a biological perspective, see these early years as crucial. Most of the contributors to this book use some version of sociocultural or epigenetic theory to explain what is going on during the toddler years. The contributors are good about organizing their chapters by telling readers what they have to say, saying it, and telling them what they said. However, the chapter authors clearly did not read each other's contributions, so there is considerable unnoted redundancy throughout. The editors weave the contributions together nicely in their introductory chapter, but that integration occurs before the reader has seen the chapters. Other concerns include the lack of an author index and too little use of descriptions of toddler activity in natural environments. Finally, several authors allude to the role of objects and the physical environment in the interactions with others. Yet the picture of toddlerhood presented in this book is peculiarly underrepresented by key toddler activities such as object play, exploration, and problem solving. Despite these quibbles, this is an excellent book. The authors collectively make a convincing case for the importance of toddlerhood in social and emotional development. N2 - (from the chapter) Behavioral assessment has evolved rapidly since Hersen and Bellack (1976) first surveyed the field over 30 years ago. Child behavioral assessment (CBA), in particular, has grown increasingly complex. Whereas the earliest treatments of behavioral assessment focused on broad areas of concern such as "behavioral excesses" and "behavioral deficits," contemporary efforts "suggest a field that is becoming more inclusive, and at the same time more highly specialized" (Reitman, 2006, p.3). Much of the growing specialization in behavioral assessment has been fueled by the Diagnostic and Statistical Manual of Mental Disorders (DSM; American Psychiatric Association, 2000). Indeed, Child Behavioral Assessment (Ollendick & Hersen, 1984) devoted only a single chapter to diagnostic issues. By contrast, a recent special section of the Journal of Clinical Child and Adolescent Psychology (see Mash & Hunsley, 2005) emphasizes the DSM taxonomy yet reveals limitations in DSM-focused assessment that has broad implications for CBA (see Kazdin, 2005; Pelham, Fabiano, & Massetti, 2005). In this overview, we discuss CBA past and present and offer some perspectives on the future of research and practice in this ever-developing field. Behavior therapy has undergone many changes since its inception in the 1950s. During its formative years, behavior therapy focused heavily on the development of more effective treatments, but the importance of behavioral assessment practices was relatively unappreciated until the late 1970s and early 1980s. Since the early 1980s, trends in therapy have continued to drive changes in assessment practices. Most recently, concerns have arisen over the merits of some forms of behavioral assessment. Specifically, questions have arisen about diagnostic assessment, especially in the realm of treatment monitoring and outcome evaluation. As a result, the next decade may well feature more research evaluating the utility of functional behavioral assessment and greater appreciation for the diverse functions of behavioral assessment in child behavior therapy. Finally, as with the evidence-based treatment movement, there appears to be a large gap between the assessment practices utilized by university and grant-funded researchers and assessment activities in clinical practice settings. The greater empirical scrutiny that is being brought to bear on assessment in clinical practice appears consistent with societal trends emphasizing demands for accountability outside of and within the mental health system (Lambert & Hawkins, 2004). Although preliminary data suggest the need for changes in assessment practices to accommodate the realities of clinical practice, there are only limited data concerning guidance on empirically based assessment as it should be practiced in the field. N2 - (from the chapter) In this chapter, I focus on the physical activity patterns of some of the two- and three-year-old boys during transition times while they waited in the classroom to go play outside or in the hallway. It appeared that these boys regularly sent their teachers nonverbal, gender-related messages. I will discuss (1) how socialization of two- and three-year-old boys and girls into their gender roles seemed to be influenced by the sociocultural context of their particular setting, a classroom in a childcare center; (2) how a small group of toddler boys seemed to transform unintentional physical body contact activity into intentional body contact activity, which resulted in gaining earlier access to space and resources and receiving more teacher attention; and (3) how a year later, in response to a different set of sociocultural expectations, some of the three-year-old boys seemed to transform body contact activity into a more socially acceptable, noncontact activity, aided by voice and hand gestures. They similarly gained earlier access to space and resources and received more teacher attention. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the chapter) Our chapter will present an analysis of different activities available in Whyville, in particular casual, collaborative, and community science-related games, and the potential they hold for science inquiry in informal settings. In our evaluation, we were interested to find out where players spend their time and to what extent they become engaged in Whyville's various science games. We worked with two classes of sixth-grade students aged 10-12 and asked them about their activity preferences in Whyville at different time points during their three months online at school and at home. Our analyses have shown that multi-user virtual environments (MUVES) such as Whyville offer a promising informal place for children to learn and play with science in multiple ways. The categorization of different science game genres helped us to identify Whyvox as a distinct feature of MUVES because it facilitated the immersion of the whole community rather than individual players, it is clear that these immersive features in MUVES deserve further design efforts and study in how they can lead to greater engagement in science and technology that possibly might lead to improved understanding of science and technology ideas. N2 - A semi-structured experiment was conducted to identify children's acquisition processes when learning playground game songs. Participants in the study were 20 pairs of children aged 4, 5, and 6 years, with each pair consisting of a younger child-learner and a senior child-teacher. The pairs were divided into two groups; Group 1 was observed by a researcher and a video-recorder, while Group 2 was observed using only a video-recorder. All child-teachers were well-acquainted with how to play the games, however the games were unfamiliar to the child-learners. Results suggest that child-teachers change their strategy of teaching depending on the conditions of instruction. Child-teachers in Group 1 used a variety of strategies including: demonstrating; playing and singing with the learner; slowing down; and, instructing. In contrast, child-teachers in Group 2: demonstrated; frequently played with the learner; sang alone; and, increased the tempo and rate of repetition even though the child-learners did not understand. In Group 1 over 50% of the time was devoted to demonstration by child-teachers, 40% to children playing together, and 5% to dialogue. In Group 2, over 90% of the time was devoted to the children playing together, and approximately 10% to demonstration by child-teachers. The article suggests that this latter instruction mode is not only a common feature of child-teachers' teaching in Group 2, it is also reflective of the teaching strategies of the masters of Japanese traditional music. N2 - The authors constructed an 11 x 17 in. tactile map to teach routes in an outdoor play environment to a 5-year-old blind child. After learning the routes on the tactile map, the child independently navigated them in the outdoor play environment. With practice, the child reduced the time necessary to learn and navigate the routes. The authors identify some concerns about the design of the project and suggest ways in which future researchers could resolve those issues. N2 - This thesis presents three studies of parental bookreading in low-income families. The first study examined differences between fathers and mothers in reported frequency of bookreading at child ages 24 and 36 months and in the summer before children entered Kindergarten. This study also looked at differences (e.g., education, race/ethnicity, language) between families where both parents report reading frequently to their toddlers compared to families where only mother reports reading frequently. The second study investigated

whether paternal bookreading makes an additional contribution to children's language and literacy, over and above maternal bookreading. The third study examined differences and similarities in style between fathers and mothers when reading to their toddlers. Results indicated that mothers reported reading more frequently to their toddlers than fathers. Furthermore, fathers in families where both parents reported reading regularly to their children were likely to have higher levels of education than fathers in families where only the mother did so. Children in families where two parents read to them had higher scores on measures of cognition and language. Paternal bookreading, in addition to maternal bookreading, predicted children's emergent literacy skills and oral language skills assessed prior to kindergarten entry. Both fathers and mothers actively engaged their children in the bookreading interaction. Fathers used more non-immediate talk (talk related to objects and events outside the book) than mothers did. Fathers were also more likely to help their child decode the text at preK. Mothers on the other hand were more likely to engage their children by eliciting text segments. Both parents engaged in talk about the book itself. The findings in this thesis emphasize the importance of including fathers in research studies when examining child development in a family context. Most of the research on bookreading has focused on mothers since they are often still the primary caregiver of the child. The results from these studies demonstrate that fathers do make a difference in children's language and literacy development. More research is needed to investigate fathers' unique contributions to child development. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Metabolic syndrome (defined by three or more of the following traits: elevated triglycerides, low HDL, abdominal overweight, elevated fasting plasma glucose, and elevated blood pressure) has been linked to an increased risk of type-2 diabetes and cardiovascular disease. Cook and colleagues (2003) demonstrated that Mexican American have the highest prevalence of metabolic syndrome among adolescents. Thus, understanding the factors associated with an elevated risk for metabolic syndrome in this population is paramount. This study examines the role of acculturation on the risk of metabolic syndrome and its antecedents, physical activity and dietary intake, in Mexican-American adolescents. A pooled cross-section (N=1831) of adolescents (12-19 yrs.) was taken from the NHANES 1999-2002. Logistic and linear regression models were used to examine the relationships between acculturation and metabolic syndrome, physical activity, and dietary intake controlling for other known correlates. The overall prevalence of metabolic syndrome was 4.8% or approximately 1.5 million U.S. adolescents. Mexican American ethnicity, overweight, gender, and inactivity, were associated with a higher prevalence of metabolic syndrome. Mexican-American adolescents were more likely to be overweight and inactive compared to Caucasians. Acculturation did not have a direct association with metabolic syndrome, but higher levels of acculturation were associated with increased physical activity and increased daily intake of calories, carbohydrates, saturated fat, and the number of times eating meals outside the home. Mexican American males were the most likely to have metabolic syndrome. Acculturation seems to be playing a role in

the risk profile of Mexican-American adolescents, which increases their daily dietary intake that may contribute to metabolic syndrome via overweight. Acculturation also increased the likelihood of physical activity, but this association may be insufficient to override the other risk factors. These results suggest that acculturation should be considered when designing and implementing interventions or policies aimed at Mexican-American adolescents to reduce overweight, increase physical activity, and promote healthy dietary options. This may help to reduce the treatment costs associated with overweight and type-2 diabetes. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study examined the connections between language brokering, social cognition, and academic achievement for preadolescent Latinos. Gender differences in language brokering activity, theory of mind ability, and academic achievement were also examined. There is a paucity of research on theory of mind development in older children from low SES and ethnic minority communities, as well as children from cultures outside the United States and Western Europe. There is no research on the relation between language brokering, theory of mind ability, and academic achievement. This study uses both a cultural approach and a theory of mind approach to study the socio-cognitive development of Latino preadolescents from immigrant families. Participants were 117 Mexican American 6th graders (M = 11.33 years; 56 girls, 61 boys) from a semi-rural agricultural community in Oregon. Each participant completed a questionnaire consisting of the Language Brokering Scale, the Short Acculturation Scale for Hispanic Youth, the Parent-Child Bonding Scale, and demographic information. Participants also completed tests of receptive English vocabulary (PPVT-III), receptive Spanish vocabulary (TVIP), and responded to two theory of mind vignettes developed to assess higher order theory of mind ability. Participants who reported being chosen as the primary language broker out-performed non-primary language brokers on theory of mind ability, things brokered, GPA, and reading achievement test scores. Girls out-performed boys on theory of mind ability, biculturalism, Spanish vocabulary, and GPA. Non-primary girls language brokered for more people than primary girls, and non-primary boys language brokered for less people than primary boys. Non-primary girls also reported more biculturalism than any other sub-group. English vocabulary, language broker order, and feelings about brokering were positively related to theory of mind ability for boys. Language broker order and biculturalism were positively related to theory of mind ability for girls. The relationship between theory of mind ability and academic achievement was non-existent for girls, and seemed to be masked by language brokering variables for boys. These results are discussed in relation to cultural variation in theory of mind, and traditional Latino gender socialization goals. Implications for the classroom and suggestions for future research are also discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Declines in physical activity-related beliefs and behaviors have been observed in the physical education setting as students move through middle school (Parish & Treasure, 2003). According to the stage-environment fit hypothesis (Eccles & Midgley, 1989) and self-determination theory (Deci & Ryan, 1985) these declines may be due in part to change in students' perceptions of the physical education context. Certain changes in the social context may undermine key individual perceptions that impact self-determined motivation, affect, and behavior. The purposes of this dissertation were to: (a) examine the relationships among and change in students' perceptions of the classroom climate, individual perceptions (competence, autonomy, relatedness), self-determined motivation, and enjoyment in physical education and physical activity outside of school and (b) explain change in these variables as students move into the first two years of middle school. Students completed a multi-form questionnaire with psychometrically sound measures of study variables as 5th and 6th graders (n = 518) and again the next school year (n = 449). Results from structural equation modeling analyses revealed that perceived teacher support mediated the positive relationships between perceived mastery climate and individual perceptions. Perceived competence, autonomy, and relatedness partially mediated the positive relationship between perceived teacher support and self-determined motivation. Further, students' enjoyment in physical education mediated the positive relationship between self-determined motivation and physical activity outside of school. Group difference analyses showed that students' perceptions of teacher support (older cohort who changed teachers only), enjoyment in physical education, and physical activity behavior declined from one school year to the next. Finally, results of structural models of change in study variables supported cross-sectional analyses. This study extends past research by including perceived teacher support in an examination of the physical education classroom climate, providing a description of motivation-related variables in physical education as students move into middle school and demonstrating the link between students' physical education experiences and their physical activity behavior outside of school. Developing strategies that help students feel supported by their teacher and socially connected in physical education may promote self-determined motivation in physical education and, in turn, greater physical activity outside of school. N2 - Young children learn by actively interacting with their environment. They explore their surroundings to play with objects and with other people. Through these interactions, they gain new knowledge and understanding which contributes to their social and cognitive development. Young children with autism may have difficulties interacting with their environment because of their specific deficits in symbolic play and joint attention. The purpose this study was to provide information on play and joint attention behaviors in a naturalistic environment, the preschool special education classroom, for children with autism (N=27) as compared to children with mental retardation or other developmental delays (N=28). The participants were observed in their classroom environment for approximately two hours over three separate days. The children were also assessed individually on visual, motor, receptive, and expressive language skills as well on play and joint attention. The children ranged in age from three to five years old and their mental ages ranged from 18.5 to 59 months. Child characteristics and demographics were not significantly different between the two groups. Results show that children with autism spent more of their time in an unengaged state than in any other engagement state, which directly translated into fewer symbolic play and joint attention behaviors. Additionally, children were not showing their optimal levels of symbolic play at school, nor were their teachers targeting those levels. Compared to children with mental retardation or other developmental delays, children with autism displayed fewer responses to and initiations of joint attention. Finally, the findings indicate that although teachers seldom focused on symbolic play and joint attention in their teaching, when they did, it was rarely for the purposes of increasing symbolic play and joint attention skills. These findings suggest the importance of teachers targeting play and joint attention skills in their preschool special education classes, specifically for children with autism. N2 - Schools have long sought measures to improve student behavior. Positive Behavior Support (PBS) aims to provide students with clearly defined, carefully taught, and consistently rewarded behavioral expectations, as

well as punishers consistent with the level and function of misbehavior. School-wide PBS addresses student behavior in the public areas of the school, such as the hallways, cafeteria, playground, and so on, through PBS practices and the use of office discipline referrals for evaluation and decision making. This study assessed the influence of school-wide PBS in middle schools using student surveys collected by the Oregon Healthy Teens project. The research hypotheses posited that (a) school-wide PBS would improve school context measures, such as teacher praise; (b) school-wide PBS would improve student target behaviors, such as delinquency and truancy; (c) school-wide PBS would not necessarily change measures of student competence, such as social skills; (d) student competence would moderate the effect of school-wide PBS on student target behaviors; and (e) if the target behaviors were associated with school-wide PBS, then school context measures would mediate those effects. The analyses compared student reports of school context, target behaviors, and competence in a quasi-experimental design with 103 randomly selected middle schools across three years, among which 32 received training in school-wide PBS. Student survey data and office discipline referrals were also correlated with measures of school-wide PBS implementation collected in 19 schools. The longitudinal, multilevel statistical models accounted for the nested structure of the data, which included student, cohort, and school levels. The results failed to support the research hypotheses, as no tests of context, target behaviors, competence, or moderator effects obtained statistical significance. With no differences in target behaviors, mediational analyses were not applicable. A thorough appraisal of this investigation revealed that the lack of support for the research hypotheses likely arose from limitations of the quasi-experimental design as well as survey questions that inadequately measured the changes in behavior expected from the implementation of school-wide PBS. N2 - Bullying negatively impacts the mental and physical health of student victims, bullies and bystanders. The Olweus Bullying Prevention Programme is an internationally recognized school based programme demonstrated effective in research. The purpose of this study was to determine if the Bullying Prevention Programme was effective for urban youth from diverse ethnic backgrounds. The programme was implemented in one large urban school district in the United States. Bullying incident density was used to evaluate programme outcomes. An independent evaluator performed 319 observation sets, 7,589 minutes. Data were standardized to incident density and reported back to school committees who developed and implemented culturally and developmentally relevant interventions based on the Olweus model. At baseline, incident density was 65 incidents per 100 student hours. After four years, incident density decreased by 45 percent to 36 incidents per 100 student hours. Programme components associated with decreased incidents were posting of rules, consistent enforcement of positive and negative consequences and training adult monitors to engage students in activities. Supplementary strategies were socialized recess, providing pro-social activities, reorganization of lunches and recess and separation of grades or genders. Results suggest that the Bullying Prevention Programme reduces

incident density by up to 65 percent. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Background: Research has sought to understand how environmental factors influence adolescent physical activity, yet little is known about where and with whom adolescents are physically active. Purpose: This study used electronic ecological momentary assessment (e.EMA) to map the social and physical contexts of exercise and walking across adolescence. Differences in physical activity contexts by gender, grade in school, day of the week, and season were examined. Methods: Twice a year between 9th and 12th grade, 502 adolescents (51% female) of mixed ethnicity (55% White) participated in 4-day e.EMA intervals (Thursday-Sunday) where their primary activity (e.g., exercise, TV, homework), social company (e.g., friends, family, class), and physical location (e.g., home, school, outdoors) were assessed every 30 (+10) min during waking hours. Results: Overall, greater proportions of exercise and walking were reported with friends, outdoors, and at school. However, boys were more likely to report exercising and walking in outdoor locations than girls. Exercising with classmates, family, and at school decreased across high school. Walking with family, friends, and outdoors also decreased. On weekdays compared to weekends, students reported a greater proportion of their exercise and walking at school. Students were more likely to report exercising and walking outdoors in the fall and the spring than in the winter. Conclusion: e.EMA showed that the social and physical contexts of adolescent exercise and walking vary as a function of gender, grade in school, day of the week, and season. Understanding the contexts of physical activity during the high school years can be helpful in designing interventions during adolescence. N2 - There is little research regarding interventions for children with internalizing behaviors in schools, both within classrooms and in nonclassroom environments. In response to this need, a nonclassroom treatment package, consisting of (a) social skills instruction, (b) mediated self-management, and (c) a reinforcement system, was implemented to modify the socially withdrawn behavior of 3 elementary students. The effects of this treatment package were evaluated on the school playground--during recess--by recording both the number of communicative acts and the total time spent engaged in appropriate peer play for each target student. All target students showed marked improvement in their playground, social interaction. Future research should be conducted with similar populations, using variations of the described methods in other school settings. VL - Socioemotional development in the toddler years: Transitions and transformations. xi, 497 pp. New York, NY, US: Guilford Press; US.

N2 - (from the jacket) The second and third years of life are a time of momentous growth and change. Leaving infancy behind, toddlers become increasingly independent as they begin to speak, walk, and participate actively in their widening social world. This volume brings together leading investigators to examine the key social and emotional transitions that characterize this pivotal period. Illuminating the pathways by which children develop socioemotional competence, how specific abilities emerge, and the nature and significance of individual differences, this is an authoritative reference for anyone studying or working with very young children. The introductory chapter provides an integrative overview of socioemotional functioning in toddlerhood and identifies basic issues and questions to be addressed. Subsequent sections scrutinize typical and atypical developmental processes on multiple levels, from evolutionary foundations and neurobiology to attachment and peer relationships. Tightly written chapters yield compelling insights into toddlers' emotions, pretend play, communication, prosocial behavior, self-control, autonomy, and attempts to understand themselves and others. Current empirical literature is reviewed; innovative research methods and findings are explained, including concrete examples; and implications for early intervention and prevention are considered. Throughout, the book emphasizes that no single behavior can be used as a yardstick of socioemotional competence and that it is the continuing interplay among codeveloping systems that moves the toddler forward. The final chapter presents a systematic framework for socioemotional assessment. Accessible and thought provoking, this timely work offers state-of-the-art information and ideas for developmental psychologists and early childhood educators, as well as graduate-level students. It will also be of interest to child mental health practitioners. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This research was carried out during a study which focused upon the rough and tumble play of children in the early years department of a suburban primary school in northern England. The child sample's playtime activities were ethnographically observed over a period of 18 calendar months, during which time interviews were also carried out with the children's class teachers and several other adults taking part in the children's daily school routines. It was found that the narratives created by a cohort of four-and-a-half- to six-and-a-half-year-old boys around their football (soccer) play were socially and symbolically complex, providing evidence that such play is a highly valuable developmental activity. However, the interview data indicated that owing principally to very low adult:child ratios in playground supervision, the focus of the adults was strongly directed towards negative aspects of outdoor free play. N2 - This study examined relationships between teacher implementation of a comprehensive bullying prevention program and student outcomes. Implementation in third- through sixth-grade classrooms (N = 36) was measured by observation and teacher report. Student outcomes were measured by student surveys and teacher ratings of peer social skills (N = 549) and observations of playground behaviors (n = 298). Multilevel modeling showed that teacher coaching of students involved in bullying was associated with less observed victimization and destructive bystander behavior among students engaged in these problems at pretest, and less observed aggression among fifth- and sixth-grade students. Support for skill generalization related to reductions in observed aggression and victimization among older students. Adherence to lessons was associated with higher ratings of peer social skills. Quality of lesson instruction corresponded to greater self-reported victimization, as well as more perceived difficulty responding assertively to bullying. Implications for school-based practice and future research directions are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study examined the effect of a social-behavioral learning strategy intervention (SODA) on the social interaction skills of 4 elementary school children with Asperger syndrome (AS). More specifically, the study investigated the effect of SODA training on the abilities of 4 children with AS to participate in cooperative learning activities, play organized sport games, and visit with their peers during lunch. A multiple-baseline-across-settings design (Tawney & Gast, 1984) was used to analyze social behavior without SODA (baseline) and with SODA (intervention) during fourth- or fifth-grade social studies cooperative learning activities, noon recess, and lunch. Maintenance probes occurred once a month for 5 months following completion of the intervention. The participants benefited from the SODA intervention. They presented increased percentages of time spent learning cooperatively, playing organized sport games, and visiting during lunch when SODA training began. When SODA training discontinued, they maintained high performance across all study conditions, nearly matching those achieved by 4 peers without disabilities. In addition, the participants presented long-term memory of SODA 1 month after maintenance. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (create) I believe a requirement of any effective Urban Education program is instilling in students the ability and knowledge to critically deconstruct the world that constructs them. Students in Urban environments are subjected to a myriad of issues that they do not always understand. Although they are aware of the poverty that surrounds them, the knowledge to analyze the reasons of the poverty may not be in their immediate grasp. Without such knowledge they mistakenly believe poverty is only the fault of the individual because they are not aware that in 2005 the Black unemployment was 10.8% compared to 4.8% for White unemployment or that the causes of high unemployment are due in part to outsourcing, systemic racism that attempts to ensure that even if qualified they will not be hired, poor schools that either do not adequately prepare students for the job market or are so problematic that students drop out before graduation. The student is not aware of the governmental policies that create and maintain the condition under which they live/survive. As a teacher committed to social justice for Black students, I work to make my curriculum such that it forces students to think in new ways. I know the phrase "thinking outside the box" is overused, but it provides the perfect conceptual intent I want my students to visualize. The box is that place that confines the mind and body of the students, subverts their drive toward realizing their full humanity. When students think outside of the box, their thinking is not at the margins but at the center. They succeed in turning the box inside out. I so wish I could provide a fail-safe lesson plan to be used in any and every situation. But of course that is impossible if we understand and accept the changing nature and fluidity of critical thought. Instead, I offer an assignment I have given my students, which provides the space to question and reflect on a specific issue utilizing critical thought/critical cognition as the vehicle to

understanding. When working with my students on issues that are difficult to understand, I ask them to write a dialogical play, complete with stage directions. The play is written in the questioning Socratic method and the characters (preferably only two) represent the confusion the student feels about the subject matter. Writing in dialogue allows the students to talk to themselves, question what they have just written, think in deeper ways about the parts that make up the issues they are writing about. Like a two-year-old, the dialogical play provides them the opportunity to constantly ask 'why'? Besides that, it's fun and allows the students to stretch their creative juices by tackling sensitive issues as another person. Inform your students that the stage directions should convey in a literal and metaphorical way both the mystification and enlightenment the characters (and by extension the students) experience. The process of conceptualizing and writing the play allows students to question themselves, constantly delving deeper into obscure meanings. As a conclusion for this exercise, you can either have certain students perform their play for the entire class, or depending on class size and time available, all of the plays can be performed in a culminating event for the class. N2 - In this study we examined the relationships among parental social supportive behaviors for children's weekday and weekend outdoor physical activity (OPA). Thirty-nine girls and 29 boys 8 to 11 years wore pedometers for 7 days. Sixty-five mothers and 50 fathers responded to a social support questionnaire about OPA that was comprised of four dimensions: encouragement, playing with, use of activity as family recreation, and watch. After controlling for age and sport participation, regression analyses indicated that mothers' use of activity as recreation was positively associated with girls' weekday OPA. On the weekend, fathers' play with son was positively related to OPA. The effectiveness of family-based activity interventions depends on when parents have opportunities to be present for their child's activity and gender differences in the support provided. N2 - We conducted three studies which examined the performance vs. skill acquisition model of social skills deficits. In Study 1, baseline social behaviors for a random sample of 12 boys with comorbid emotional and behavioral disorders (EBD), learning disabilities (LD), language delays, and Attention Deficit Hyperactivity Disorder (ADHD) revealed that prosocial behaviors as well as inappropriate behaviors exist comorbidly in behavioral repertoires, supporting a performance rather than acquisition model of social competence difficulties. In Study 2, an ABAC design was used to examine the efficacy of a self-management intervention with noncontingent (B) and contingent (C) reinforcement for three elementary aged boys with EBD. Generalization was demonstrated in natural settings for the contingent reinforcement phase only, but was not observed over time. Study 3 replicated Study 2's procedures using an ABAC multiple baseline across participants design with a sample of adolescents with varying degrees of mental retardation. Two of the three participants responded favorably to the self-monitoring training and showed marked improvements in prosocial play skills during recess; for the third participant, no behavioral changes were observed. Results from all three studies are discussed from a social learning theory perspective. The efficacy of the data collecting procedure and implications of the results are discussed. N2 - The psychometric properties of a Spanish translation of the Buss and Perry aggression questionnaire adapted for pre-adolescents and adolescents have been studied. A maximum-likelihood confirmatory factor analysis corroborates Buss and Perry's four-factor structure. The internal consistency of each factor and of the total score has proved to be satisfactory. The four factors are more closely interrelated in pre-adolescents than in adolescents. A second aim of this work has been to further our understanding of the possible relationship between aggression scores and certain outside-school activities of the subjects studied. Two thousand two hundred and eight students filled in the questionnaire together with a self-report concerning their habits. The results show that the aggression scores rise concomitantly with time spent watching television and playing video games and decrease the greater the time devoted to extra-curricular reading or moderate amounts of homework. Statistically significant differences relating to age and gender were also found. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) Raising young children in this country has become an increasingly challenging endeavor. Many families across the economic spectrum do not live in communities with established child-rearing networks. The mobility of families, which often reduces access to extended kin, and the financial realities, which often require both parents to work outside the home, are just two of the factors that have limited the transfer of child-rearing techniques and strategies across generations and across town. In many places, the pressures to focus on achievement-oriented activities at a young age have limited parents' time and desire to attend to more basic developmental concerns. Early childhood centers are in a unique position to bridge this gap. Once viewed as playful and optional additions to family life, preschools and child care centers fill important educational and economic demands in this country. Young children are especially vulnerable to the disruptions caused by traumatic events because they do not have well-developed physical or psychological resources to defend against them. They depend on adults to help them make sense of the trauma, heighten their

resilience, and shield them from its ill effects. When their primary caregivers are also affected, they are less available to provide reassurance to their young children and to help them re-establish their sense of safety and security. As a result, the burden of care for these children often shifts, at least in part, to caregivers outside their home. The child care center often takes on added significance for children affected by trauma who crave consistency and nurturance and are looking for a safe haven where they can play and learn and focus on more age-appropriate tasks of development. N2 - The purpose of this study was to explore whether or not adolescents who are deemed underachievers and who struggle to read school-assigned textbooks will engage with popular culture texts of their own choosing (e.g., magazines, comics, TV, video games, music CDs, graffiti, e-mail, and other Internet-mediated texts). The 60 student participants, who were enrolled in grades 7-9 in a small city school district in the southeastern U.S., self-identified mostly as not being interested in reading. Thirty attended weekly meetings of an out-of-school time media club and kept a daily out-of-school time activity log for 14 weeks (the intervention group); the other 30 were assigned to a comparison group and did not attend the weekly media club meetings but did keep a daily out-of-school time activity log for the same 14-week period. Independent t-tests applied to data from the daily activity logs revealed several interesting contrasts between the two groups. One unexpected finding was the relatively large amount of time that participants in both groups reported they spent reading outside of school. N2 - During a flight of 50 minutes in a non-analytic relational field, a sequence of scenes occurred between the 6-year-old Farah and the author, increasingly taking the shape of a message. Diverse vulnerabilities--whether belonging to infantile neurosis in a wider sense or not--were just as clearly observable in the playful dialogue as the unswerving integrative efforts of the child. This event motivated the author instead of considering as usual the chasm between pathology and normality to look this time into the opposite direction onto the continuum between normality and pathology. Beside theoretical preoccupations it was the emotional effect of the long-term aesthetic presence of this experience which led to its publication. N2 - Background: Many researchers are concerned with the proficiency of children in movement education. They are expressing this concern through the assessment of fundamental motor skills, owing to the established links between the proficiency of fundamental motor skills and subsequent involvement in sport and physical activity. The assessment of fundamental motor skills has predominantly employed a qualitative approach. Another form of assessment involves quantitative measurement; however, the relationship between process and product assessment paradigms is largely unexplored. Purpose: To investigate the relationship between the movement process and product measures of fundamental motor skill performances for primary school-aged children. The relationship between process and product assessment of fundamental motor skills is at the centre of this research. Participants: included 161 six to ten year-old children including 86 girls and 75 boys. The primary school-aged children participated in the study after parental permission and university ethics approval for the research were granted. Research design: involved a cross-sectional design which involved collecting data in an 'ecologically valid' environment--a school playground. Children were withdrawn from class three at a time and individually asked to strike the ball from a batting tee for three warm-up trials. Six trials for each child were measured in terms of process and product performance. Data collection: occurred in the school. The students were video recorded as they performed six trials of tee-ball striking, responding to the task goal of 'hit the ball as far as you can into the batting V'. These recordings were later coded using a (process) amalgamated striking

instrument that is comprised of three levels of efficiency for 10 components of the strike. The components of the process instrument were derived from both the Component Approach and the Total Body Configuration models. The distance or product scores were measured from the batting tee to the resting place of the ball. Data analysis: The six trials for the 161 children were analysed by firstly taking the process observations and coding them using the amalgamated striking instrument. These process codes were analysed using the partial credit form of Rasch (Quest) analysis. Subsequently, Quest provided case estimates, transforming ordinal observations to interval data. These process data were then compared to other interval measures--the distance measured in metres represented the product of the performance. Process scores (case estimates) were compared to product (metres) data to find the relationship. Findings: A significant correlation between the process and product measures for each of the six trials ($r = .51 - .66, p < .0001$) indicated there is a positive relationship between the process and product measures of the fundamental motor skill performance of the strike for each of the six trials. Conclusion: The application of the Rasch model allows for investigation of two different forms of data (ordinal and interval). The exploration of the relationship between process and product performance indicates the significant correlation between the two performances for these data. Choice of assessment technique now is more open, with some confidence in the association established for these two techniques. With considerable variance still unaccounted for, further exploration of this type of investigation would be prudent. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Background: To compare and contrast youth physical activity (PA) and inactivity patterns in two developing Asian countries: the Philippines and China. Methods: Comparative analysis of 1997-1999 Cebu Longitudinal Health and Nutrition Survey and the 1997 China Health and Nutrition Survey, large-scale surveys that included questions on type, frequency and duration of: commuting mode to school, sports/exercise in and outside of school, select sedentary activities and chores. Results: Filipino data included 760 males and 872 females aged 14-16 years. The comparable Chinese sample consisted of 202 males and 197 females. Active commuting is proportionately high in both countries (70-71% in the Philippines vs. 77-90% in China), although commuting by bicycling is rare in the Philippines (<1%) vs. China (35%). Patterns of school sport/exercise participation differ between countries by gender; more Filipino males report school sport/exercise than females (63 vs. 49%) vs. China, where more females participate than males (75 vs. 69%). Sport/exercise outside of school is proportionately low (6-12%) for youth from both countries with a single exception: 74% of Filipino males participate in extra-curricular sport/exercise. Although a higher percentage of Filipino youth report watching television > 4 h/day (< 10%) vs. Chinese youth (< 1%), both are lower than comparable US reports. Conclusion: In the Philippines, continued modernization augurs a decrease in local primary PA sources (chores and active commuting). In China, where youth already are not expected to perform chores, shifts to more

passive commuting modes (i.e. increased motorized transportation) are anticipated. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) The National Association of School Psychologists (NASP), recognizing the importance of early identification and intervention for young children's psychological and developmental difficulties, adopted a position statement on early childhood assessment to guide the fair and accurate identification of the developmental needs of young children (Bracken, Bagnato, & Barnett, 1991). This position statement was later revised in 2005 (National Association of School Psychologists, 2005). The current NASP position endorses multidisciplinary team assessments within an ecological model that includes multiple procedures, multiple sources of information, across multiple settings, and across time in order to yield a comprehensive viewpoint of the child's abilities. These multidimensional assessments should be linked to intervention strategies and should be conceptualized using more than a single methodology or theoretical framework. Furthermore, the position also underscores the importance of the full integration of parents and/or caretakers into the assessment process, including systematic data gathering in the natural environment. The foundation of the NASP statement on early childhood assessment practices is based on evidence garnered through research and professional practice. This chapter will discuss several critical issues that have emerged as psychologists in preschool settings strive to promote best practice during assessment activities. VL - The neurobehavioral and social-emotional development of infants and children. xii, 571 pp. New York, NY, US: W W Norton & Co; US.

N2 - (from the jacket) Over the course of his esteemed career, author Ed Tronick has received funding for hundreds of key studies in the US and abroad on normal and abnormal infant and child development--including his Mutual Regulation Model and Still-Face Paradigm, which revolutionized our understanding of infants' emotional capacities and coping--all of which led to critical contributions in the field. Organized into five parts--(I) Neurobehavior, (II) Culture, (III) Infant Social-Emotional Interaction, (IV) Perturbations: Natural and

Experimental, and (V) Dyadic Expansion of Consciousness and Meaning Making--this book represents Tronick's major ideas and studies regarding infant-adult interactions, developmental processes, and mutual regulation, carefully addressing such questions as: (a) What is a state of consciousness? (b) What are the developing infant's capacities for neurobehavioral self-organization? (c) How are early infant-adult interactions organized? (d) How can we understand the nature of normal versus abnormal development? (e) How do self- and mutual regulation relate to developmental processes? (e) Is meaning making purely a function of the brain, or is it in our bodies as well? In an introduction to this compilation of work, Tronick writes, "...the focus of my research has been on the nature of how people live in the world and how they change both themselves and their relation to the world over moments, hours, days, and years." The neurobehavioral and social-emotional development of infants and children demonstrates these aims in one simple volume, and offers readers a first-ever look at the important repertoire of a highly respected clinician and researcher. N2 - This study was designed to compare how 5- to 13-year-old children's leisure activity preferences differ with age and gender. Responses from 60 boys and 60 girls about their favorite toys, television shows, computer games, and outdoor activities were compared across leisure categories. The results showed that gender was a significant factor. Overall, boys spent more time in these leisure activities than girls did. They spent the most time engaged in sports, watching television, and playing computer games, whereas girls spent the most time watching television. Results from a gender index for all activities indicated that boys' leisure preferences became slightly more masculine with age. For girls, preferences for television shows became more feminine with age, but preferences for toys, computer games, and sports became less feminine. These self-chosen preferences may provide differential opportunities for the development of visual-spatial skills, achievement, initiative, self-regulation, and social skills. N2 - Scope and method of study. This study was designed to assess and follow the presence of posttraumatic stress disorder symptomology in children exposed to a tornado and compare that to the same symptomology in demographically similar children who had not been exposed to a tornado. This was done to examine the differences between these groups, both of whom live in a disaster-prevalent area, inside and outside of tornado season. The study also examined the roles that re-exposure to environmental cues, exposure to disaster-related media, attributions, and other factors play in maintaining a child's level of distress, as well as the children's general behavioral and emotional functioning. Participants in the study were 95 exposed children and 70 non-exposed children ages 8-12. The exposed children had at least one tornado strike their hometown in late May or early June 2004, while the non-exposed children's hometown had not had a tornado within 10 miles of it in the past five years. Each participant and their parent completed a series of questionnaires designed to measure the above variables in November 2004 (6 months post tornado and outside tornado season) and May 2005 (12 months post tornado and inside tornado season). Findings and conclusions. The current study supported the proposed stability of posttraumatic distress symptoms in tornado-exposed children, showing no decrease from six to 12 months post tornado. Also supported was the difference in posttraumatic distress symptom level between exposed and non-exposed children, with non-exposed children displaying significantly lower amounts of tornado-related PTSD symptoms both outside and inside tornado season than exposed children. The degree of difference between these two groups, while statistically significant, was not as large as expected, as the non-exposed children did show mild levels of posttraumatic distress. In contrast to expectations, results showed that tornado-specific distress was not related to more global behavioral or emotional functioning. The current study also supported the relationship between the factors of exposure, attributions, and distress. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Building on a number of recent studies examining verb development in natural and experimental contexts, this dissertation is the first to have examined in the same population children's naturalistic verb performance and their ability to generalize novel verbs in an experimental setting. In addition, this study investigated the role of discourse context on children's novel verb usage. Twenty-three 2- to 4-year-old children (eight 24-29 month-olds, eight 30-35 month-olds, seven 36-43 month-olds) and their primary caregivers participated in two observation and novel verb training sessions over the course of one week at their homes. Caregiver and child dyads first were observed in naturalistic play and subsequently each dyad engaged in a novel verb training task with the experimenter. At the end of the second visit all children participated in an elicited production task. Analysis of the naturalistic productions indicated that as the children became older they were more able to use transitive constructions in diverse ways (measured in terms of the number of verb types and tokens used, as well as the range of grammatical frames employed). In contrast, intransitive verbs were used in restricted ways across age groups. An examination of age differences in use of novel verbs in the experimental setting provided evidence for age differences in the contexts (training vs. elicitation) where children produced novel verbs. Nevertheless, in contrast to predictions, there was little evidence of children (regardless of age group) being able to produce a novel verb in a way it was not modeled in the input, suggesting that the children lacked full generalization abilities. A comparative analysis of the relation between verb productivity in natural and experimental contexts indicated a relationship between the ability to use verb constructions diversely in natural settings and ability to generalize novel verbs. Discussion focuses on how an understanding of a child's natural language diversity may affect interpretation of novel verb training studies and why so few instances of generalization were found in the present study in contrast to prior research. N2 - Aggression negatively impacts children's psychological and academic well being. The playground environment is more susceptible to aggressive behavior than more structured academic settings like the classroom. In this study, the relation between staff and student reports of student playground aggression was examined. Then, the relation between environmental playground factors (i.e., playground activities, playground supervisor ratios, active supervision, and playground rules) and student reports of aggression was examined. Finally, the relation of playground aggression to student self-reports of playground worries was evaluated. School Climate Theory provided the conceptual framework for evaluating playground characteristics, student aggression, and worry. Participants included 767 third, fourth, and fifth grade students and 57 playground supervisors from 10 Midwest elementary schools. Participants completed reports of aggression (students and staff), playground worries (students only), and playground environmental factors (staff only). Bivariate correlations were used to examine the relation between staff and student reports of aggression. Hierarchical Linear Modeling analyses were conducted to examine the relation among playground factors, aggression, and playground worries. This study used a novel approach to measuring the predictive relation of aggression on

children's worries through student self-report measures. Results of this study showed that staff and students reports of playground aggression were inconsistently correlated. Although overt physical and verbal playground aggression scores were significantly correlated, relational playground aggression and playground conflict were not associated. Additionally, four playground characteristics were linked to playground aggression: cooperative games, supervisor ratios, active monitoring, and playground rules. Finally, when students reported more playground aggression, their reports of playground worry were higher. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study explores the lives of children on the school playground to examine what happens and how children's social worlds emerge. Recess is an important part of the school day when social and moral actions are constructed in the midst of activity (Goodwin, 2002). Based on a 10-month school year, this ethnographic study of 5th-and-6th-grade children in a private Christian school in Southern California focused on peer interactions, especially when something unanticipated happens and moral dilemmas ensue. By attending to significant and situated social, cultural and historical events of mediated action (Wertsch, 1998), this study addressed children socially occupied (Lawlor, 2003, 2004) in collaborative activities. Observations, fieldnotes, video tapes as well as student interviews and journaling provided a rich basis to capture the multiple perspectives involved when complex and dynamic occupations emerge as meaningful social activities. Centered primarily on the interactions of 7 girls in the 5th grade, ages 10 and 11, fine-grained microanalysis of key events generate insights into how individuals negotiate times of uncertainty, make sense of their experiences, and shape their identities over time. Moral dilemmas reflect each individual's emotional vulnerability of struggles with fairness and responsibility toward others when pulled between personal desires and collective expectations. As powerful everyday encounters, moral dilemmas propel actions and present opportunities for students to find new ways to act through improvised occupations. When several girls organized a band to write and perform songs, meanings of membership and positions are negotiated at multiple levels of group engagement. Other girls created occupations of songwriting to voice resistance to frustrations with peer pressures, express reshaped identities (Holland, Lachicotte, Skinner, & Cain, 1998) and construct future possibilities for friendships. Changes occur within and between peer groups as the girls on the periphery of practice (Wenger, 1998) shift positions within and between these groups. These findings support occupations as dynamic endeavors with others. Building on the research in occupational science, this study contributes to what happens on the school playground and how occupations emerge as joint improvisations when students attempt to resolve moral dilemmas and transform identities in complex social interactions and relationships. N2 - Violence in America is an epidemic that service providers need to address with the growing statistics of youth violence and aggression. There are cost benefits to intervening early, when risk factors are becoming evident. Prevention works on a continuum and there are many types of programs that are successful in targeting violence. The National Institute of Mental Health (NIMH) and the Surgeon General have released reports that identify risk factors. Prevention research shows that secondary prevention is successful by targeting peer relations, social skills, and problem-solving skills. The Center for Disease Control and Prevention (CDC) identifies that social-cognitive problem-solving prevention programs are model programs. They identify, and developmental research supports, that middle childhood (ages 6-12) is an ideal time to target these risk factors with programs that teach social-cognitive problem-solving skills. Presently, Outdoor Behavioral Healthcare (OBH), which, through weak research, has shown benefits with a general population, have developed programs that seem effective in working with at-risk youth. The research is still minimal. The research exists, but only in the last five or ten years has the research begun to operationally define variables and utilize quantitative measures and research designs. Promoting Alternative Thinking Strategies (PATHS) is a curriculum that is empirically validated to successfully prevent violent behaviors by teaching emotional, social, and problem-solving skills in elementary school classrooms. It is also identified by violence prevention research as a model program. The curriculum has been replicated in other settings. The goal of this proposal is to provide an innovative approach to violence prevention with at-risk youth (ages 8-12) by combining the OBH programming and activities with PATHS curriculum lessons. The program will adopt the themed lessons from the PATHS curriculum and teach them while instructing campers on outdoor activities. By doing so, the outdoor activities will have specific aims in their lessons learned and the PATHS lessons will have immediate and real life applications. The program will be implemented and evaluated to add to the research in the areas of violence prevention, PATHS, and OBH. The eight-week outdoor program will incorporate a simple interrupted time series design utilizing screening questionnaire to aid in inclusion criteria, the Kusche Affective Interview-Revised (KAI-R), the Child Behavior Checklist (CBCL), the Youth Outcome Questionnaire (YO-Q), semi-structured interviews, and module evaluations. The participants will be 64 males between the ages of 8 and 12 years. The goal of the evaluation is to and to research in the field, but also ensure program quality. Through the research, the hypothesis is that results with this innovative approach, combining the OBH theory and programming with PATHS theory and curriculum, will demonstrate success in reducing the probability that the participants will develop violent behaviors in adolescence. N2 - Joint attention, the ability to selectively attend to an object of mutual interest, is a critical skill that develops early in life and consequentially affects future social-cognitive skills, social-emotional skills, and language development. It is widely known and accepted that children with autism have difficulties with joint attention. Children with autism need types of intervention that will systematically facilitate as much cooperative, negotiated and culturally relevant learning as possible. Interventions need to be deliberately monitored with attention to the learner's moment-to-moment motivational and interpersonal responses. Music therapy is one effective method for increasing interpersonal understanding, joint motivation, and cooperative skills. Music therapy interventions have been used with children diagnosed with autistic disorder for the past forty years. The present study examines the effectiveness of music therapy intervention on development of joint attention behaviors in children diagnosed with autistic spectrum disorder both within treatment and as reported by parents outside of treatment. Participants were 3 to 5 year old non-verbal males diagnosed with autism spectrum disorder. All participants fell in the Severely Autistic range of functioning as measured by the Childhood Autism Rating Scale (CARS) (Schopler, Reichler, and Renner, 1988). Participants received eight 30-minute individual music therapy sessions, twice weekly. Sessions consisted of five categories of musical experiences: greeting song, seated imitation activity, instrument playing, gross motor musical movement/imitation activity, and closing/goodbye song. Both live and recorded music was used. Musical improvisations were often created during sessions based upon the child's vocal and motor output with intent to musically join, reflect, and expand the child in his experience. Most parents noted improvements in responsivity to social cues and social approach behaviors as measured by the Parent Version of the Pervasive Developmental Disorder - Behavioral Inventory (PDDBI) (Cohen and Sudhalter, 1999). Parents noted improvement ranging between 8% and 40%. Positive changes were found in other areas measured on the PDDBI as well (e.g. decreased Ritualisms/Resistance to Change, Arousal Regulation Problems, and Specific Fears, and increased Phonological Skills). Video analysis of initial and final music therapy sessions showed that approximately 70% of participants had noticeable increases in joint attention behaviors. The range of improvement was between 36% and 200%. Results indicate that the addition of music therapy intervention to a child's treatment program can have positive outcomes and may be an effective method for increasing joint attention skills in some children with autism. N2 - The recent expansion of research guided by the metaphor of co-construction of family narratives has significantly contributed to the child and parent development literature (Bearison & Dorval, 2002; Wang, Leichtman, & Davies, 2000). Researchers have borrowed from various theories, including Vygotskian notions of how young children internalize thought and language, to capture the way parents scaffold their children's growing cognitive abilities (Rogoff, 1991; Wertsch, 1992). Similarly, potential also exists for using narratives to capture the manner in which parents help children develop an understanding of family dynamics and emotion (Oppenheim, Nir, Warren, & Emde, 1997). This report contributes to the field's knowledge base, by introducing a new method for assessing co-constructed narrative representations of family and emotion and toddlers' interactions with their parents. This approach builds upon two complementary premises: (1) parents are essential agents in socializing their children's knowledge of emotions (Denham, 1998; Hughes, & Dunn, 1997), and (2) parents can modify the impact of family process through the ways they portray relationships to their children through narratives (McHale, 1997). Eighty-seven families with 30-month old sons (n = 44) or daughters (n = 43) comprised the sample. In separate sessions, mothers and fathers joined their preschooler at a dollhouse with a family of dolls matching their own family structure, and were asked to narrate and enact three stories about a happy, a sad, and a mad family. The study evaluated the co-constructions by examining both (1) the process of the sessions, and (2) the content of the stories. Further, parents rated their child's behaviors on standardized surveys and teachers likewise rated the child's adaptive skills outside of the home. Additionally, the whole family took part in a semi-structured family play session, which was rated for overall levels of family warmth and conflict. Results documented several associations between both mother-child and father-child co-constructed narrative representations and process measures and observed family-level dynamics. Father-child, but not mother-child, co-constructed measures were also associated with children's socioemotional adjustment. Analyses established that father-child dyad representations in general did not mediate the relationship between family functioning and toddlers socioemotional behaviors, except in one instance. N2 - The purpose of this study was to investigate the effects of individualized video-modeled Social Story interventions on the social communication skills of three children with High Functioning Autism/Asperger's Syndrome (HFA/AS). Using a multiple-baseline across participants design, video-modeled Social Stories were implemented and direct observations of the participants' identified target behaviors were collected two times per week during unstructured school activities (e.g., recess). Overall, data demonstrated that video modeled Social Stories were effective for improving the rates of social communication for the participants, though modifications to allow access to social reinforcement was needed in two cases. In addition, all three participants demonstrated maintenance of skills at a two-week follow-up. However, generalization of skills was only observed for one participant. The present research provides no definitive claims of the effectiveness of a combined intervention for children with HFA/AS. Rather, it adds preliminary evidence that a combined intervention that teaches social communication skills and provides for a model of appropriate behavior may be a beneficial method of remediating social skill difficulties for many children and youth with HFA/AS. N2 - Educators face a considerable challenge in addressing youth at risk for serious problem behaviors. Particularly during the middle school years, the school environment may play a vital role in shaping pathways of risk or resilience for preadolescents. However, contextual factors within the school environment that influence student outcomes have not been adequately assessed via traditional methods (e.g., students' self-report questionnaires). Using a novel observational assessment of the school environment, the current study explored how school contextual factors are associated with a range of student outcomes. Participants in this study are 1076 preadolescent students from 8 middle schools in the Pacific Northwest (76% European-American; 54% female). Unobtrusive observational data was collected in each of the 8 local middle schools. Observed factors within the school environment included the physical environment (e.g., noise level, adequacy of lighting in the

hallways), management clarity (e.g., rules and expectations clearly posted), the emotional environment (e.g., student affect), and staff behaviors (e.g., quality of staff monitoring). Non-classroom settings were observed (e.g., hallways, outside corridors) during school transition times. One of the primary aims of this study was to examine the utility of the school observational measure, including the measure's reliability and validity. Using hierarchical linear modeling, both student report of school climate and observations of school context were examined as predictors of deviant peer affiliations and the student outcome variables (substance use, antisocial behavior, and positive engagement). There is initial support for the validity of the observational measure. The results suggest that student outcomes are associated with indicators of the school environment, particularly the school-level factors of a positive social-emotional environment and staff monitoring. There is limited evidence of a moderating effect of school context in the relations between deviant peer affiliations and the student outcomes. Sex differences emerged, in which the presence of certain school context factors was more protective for the female students. The observational assessment tool used in this study may provide future school-based research and intervention programs with a more cost- and time-effective data collection alternative. N2 - This study examined the effects of different recess timing regimens on preschoolers' classroom attention. Using cognitive immaturity theory, we predicted that attention to a classroom task would be greater after a recess break. We also examined the extent to which different recess timing regimens related to post-recess attention. Participants were 27 European American children (18 girls and nine boys; mean = 55.56 months, standard deviation = 4.01) from a northeastern US preschool. Observations were made in the classroom before and after recess and outdoors on the playground during recess. Findings revealed that post-recess attention was greater following sustained outdoor play periods. Gender differences emerged. Girls were more attentive to classroom tasks than boys were. Our findings support and parallel empirical findings with primary school children on the role of recess in children's cognitive performance. It seems reasonable that outdoor recess breaks rejuvenate young children and help them attend to classroom tasks. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) This chapter considers how observations of children's play can be undertaken at any time--indoors, outdoors and in more unusual situations, such as a visit to a theatre. It is often during situations that we are not expecting, that observations provide the richest moments in children's play. If practitioners are not tuning into the child, these moments are easily missed. Aims of the chapter are to develop an understanding of (1) ways of tuning into children; (2) ways of observing children's pauses and silences; and (3) ways of engaging with theatre and the arts. N2 - Interviews of 91 children living in a large high-rise, high-density planned neighborhood of 5277 families reveal that children find most of their psychologically valued settings within the neighborhood outdoor spaces such as designated play areas and developed parks. They are aware of differences in experience between such valued 'places' and other 'spaces'. They choose the places because such places offer some key environmental attributes--spatial, physical, and social--that support behaviors that children want to engage in. Due to these attributes, behaviors in places are different from behaviors in other spaces, with the former being more purposive, social, creative, and dependent on particular affordances of the setting. This can be confirmed in a follow-up behavioral analysis of three pairs of most popular places and their counterpart settings. This observational analysis shows that settings children mention to be important to them are utilized more often (about twice as much) than their counterparts, showing a variety of behaviors, incorporating more intentional activities (as opposed to transient, short-lived ones), encouraging group behaviors (as opposed to single-person activities), and providing children with a sense of their own territorial play area. The study demonstrates that in children's neighborhood environment, emergence of such important places is related to use pattern and there are

some key attributes and core behaviors greatly contributing to children's place experience. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Studies conducted in the US consistently demonstrate that parenting self-efficacy and construction of the parent role are critical elements associated with parents' involvement in their children's elementary school education. Less is known about the dynamics of parent involvement during the preschool period, or in nations outside the US. This study examined the relation of maternal beliefs and family socioeconomic status (SES) to three dimensions of parent involvement in Japan: preschool selection strategies, engagement in reading at home, and involvement in activities at the preschool. Interview and questionnaire data were obtained from 108 Japanese mothers, all of whom had a child in the last year of preschool. Consistent with theory and findings in the US, parenting self-efficacy and family role construction were associated with Japanese mothers' strategies for selecting preschools and frequency of engaging in home reading. Findings regarding family SES demonstrated a culturally specific pattern; mothers of higher SES background were more likely to access formal sources of information and to engage in daily home reading but less likely to participate at the school site. N2 - To identify appropriate free-time experiences, it is important to know what motivational factors predict physical activity decision making. In this study, I explore differences in free-time motivation scores between adolescents with visual impairments from a residential setting who are at criterion levels of body mass indexes (BMIs) and their fellow students who score outside the healthy zones. Participants in the study were 31 students (11 women and 20 men), 12 to 21 years old, who were involved in educational and after-school residential programs at a midwestern school for the blind. All participants had residual sight but were classified as visually impaired with vision deficits that affected their educational performance. None of the participants had any coexisting cognitive or physical disabilities. The resulting data revealed motivational differences among these participants. Physical activity continues to be a recommended course of action to alleviate obesity and improve physical functioning, and the data from this inquiry present interesting results that need further study.

VL - Teaching motor skills to children with cerebral palsy and similar movement disorders: A guide for parents and professionals. xviii, 237 pp. Bethesda, MD, US: Woodbine House; US.

N2 - (from the cover) While most families of young children with cerebral palsy and similar conditions work in conjunction with a physical therapist a few times a week, it takes daily intervention to help a child reach his motor potential and become more independent. Teaching Motor Skills is the resource that parents, therapists, and other caregivers can consult to help young children with gross motor delays learn and practice motor skills outside of therapy sessions. Written by an experienced physical therapist who is also the mother of a child with cerebral palsy, this comprehensive guide examines the physical characteristics of cerebral palsy and similar conditions--muscle tightness and weakness, increased or decreased flexibility, abnormal reflexes, impaired sensory perception--that affect a child's ability to sit, crawl, stand, and walk. Teaching Motor Skills offers dozens of easy-to-follow exercises with accompanying photos that parents may incorporate into many daily routines at home with the guidance and support of their child's physical therapist. Exercises address: head control; protective reactions; proper positioning; independent sitting with and without arm support; transitional movements; daily stretching; improving muscle strength and coordination; balance training; and gait training. Full of anecdotes and frequently-asked-questions, with a chapter on medical interventions and bracing, and an appendix of equipment and supplies, this user-friendly guide helps parents and professionals coordinate their efforts to achieve the best possible outcome for the child. N2 - Recent studies indicate that being intensely imitated for a brief period of time increases social interest among children with autism. The aim of this study was to replicate and extend these findings. Twenty children with an autism spectrum disorder (ASD) were randomly assigned to one of two interaction strategies: imitation (n = 10) or contingent (n = 10). The children had little or no functional speech, and their developmental age averaged 25 months (mean chronological age = 6:5 years). Both conditions were presented with repeated sessions of a modified version of Nadel's 'still-face' paradigm (still-face/intervention/ still-face/spontaneous play). The analysis revealed a significant increase of both proximal and distal social behaviours (touch and look at person) for the imitation condition, which confirms previous reports. In addition, an increase in elicited imitation, as measured with the PEP-R developmental assessment procedure, was also observed for children in the imitation condition, but not in the contingent condition. This finding extends earlier reports in that it suggests that the social expectancies unlocked by imitation also spread to tasks outside the experimental setting. N2 - Tessa is a 7-year-old girl with odd behaviors, worsening over the preceding year. She spends a significant amount of time alone in her room, talking to "Richard." Her father observed that Tessa is "in her own world." In school, she often glares at the teacher and refuses to work. She is alone at recess without any real friends. Her father reports that she eats little and only after he tastes the food. She is increasingly cruel to both real and toy animals. She tied a string around her cat's neck and swung it around, saying she wanted to punish it. She was heard to say to her stuffed cat, "Die, b....; die." Richard told her to do this and other "bad" things. Tessa has not had chronic health problems or developmental concerns. During the first 18 months of life, her height was between the 5th and 10th percentiles; it declined to below the 3rd percentile over the past 2 years. Weight has been consistently between the 3rd and 5th percentiles. Tessa's parents both have been diagnosed with schizophrenia. There are at least 7 first- and second-degree relatives with the same diagnosis. Both parents cared for Tessa for 4 years with a lot of support. Then, her father left the home, but he was in contact with her while managing his own illness. When the mother's illness and compliance worsened, Tessa was removed for neglect at 5 1/2 years old. Two foster homes preceded Dad's award of sole custody 13 months ago. Mother's weekly visitations are quite upsetting to Tessa. Tessa is a verbal, solemn, small, well-dressed girl with no physical abnormalities. She talks with advanced vocabulary and syntax, with normal prosody and good conversational skills. She says Richard is a bad boy who gets her into trouble at school. She equivocates when asked if he is real or imagined or if others can see him. She says that she misses her mother. In this article, several doctors offer their professional opinions on diagnosis and treatment of this challenging case. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The present study evaluates the trend of morbidity and growth of children and adolescents--the most vulnerable part of population. Negative trends in health of Slovak children and adolescents reflect probably increasing social differences, changes in life style and non-systematic preventive health care during certain periods of life--in school children, students, and working adolescents. A significant increase in chronic diseases and disorders in children and adolescents during the last decade are probably the results of many genetic, nutritional, environmental and also psychosocial factors related to changing life style patterns. Routine health statistics in Slovak Republic did not include some serious preventable diseases and disorders, which have an increasing trend in the young population and may have serious consequences in adulthood. Increase in chronic diseases prevalence is in contrast with trends of acceleration and shows the impact of present big social disparities. Prevention requires identification and elimination of known environmental risk factors in children and adolescents, and reinstatement of systematic intensive preventive health care. The health educational activities should become materialized in healthy life psychosocial conditions and environment of houses, schools, and playgrounds. Our results require further comprehensive analysis and international comparison. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study focused on the associations between individual variations in children's motor abilities and individual differences in social participation and play behavior. Indoor and outdoor play behavior patterns of 88 kindergarten children were observed, and a battery of standard assessments of basic motor functions was administered. The findings indicate significant associations between children's motor abilities and social and nonsocial forms of play. Results are discussed in relation to existing conceptual models of the underlying causes for nonsocial behavior. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) Teachers face more challenges today than during any other time. Students present with more challenges than ever before, particularly in the area of mental health needs. Clear evidence suggests that a variety of mental problems are increasing in frequency, and access to and availability of services for students with mental health needs have not improved for decades. In the face of such need, it is easy for educators to accept the responsibility of this burden borne by so many of today's students. But teachers should resist the propensity to shoulder a burden that is outside the purview of their professional training and focus. Educators should acknowledge, however, that they can have a positive impact on children's mental health. Teachers can play an incalculable role in fostering psychological resilience in children, which can serve to protect them from exposure to a variety of risk factors. The strategies suggested in this chapter are classroom techniques that can assist in the development of these protective factors. They are techniques that have been found to be effective, while actually tending to decrease, rather than increase, one's workload. In addition, the impact of protective factors seems to be cumulative so that the more of these strategies a teacher implements, the more protection a student may cultivate. Teachers are among the most involved adults in the lives of children. In our society, physicians maintain a high level of professional prestige, whereas teaching has lost credibility. Ironically, a child may go through life and rarely, if ever, see a physician. The same cannot be said of educators. If a child

begins to show symptoms of a mental health problem, teachers are likely to be the first professionals to see them. Thus, teachers can also play an indispensable role in recognition of problems, referral, participation in interdisciplinary planning, advocacy, and monitoring of their students and can do so without making a difficult job impossible. To assist in this, and to fill a void in most teacher training programs, this book is devoted to helping teachers recognize the most common mental health issues seen in children and adolescents and to offer strategies on how they can help encourage and support all their students. N2 - Play is the primary occupation of childhood and provides a potentially powerful means of assessing and treating children with autistic disorder. This study utilized a cross-sectional comparison design to investigate the nature of play engagement in children with AD (n = 24), relative to typically developing children (n = 34) matched for chronological age. Play behaviours were recorded in a clinical play environment. Videotapes comprising 15 minutes of the children's spontaneous play behaviour were analysed using time-interval analysis. The particular play behaviours observed and play objects used were coded. Differences in play behaviours ($p < 0.0001$) and play object preferences ($p < 0.0001$) were identified between the groups. Findings regarding play behaviour contribute to contention in the literature surrounding functional and symbolic play. Explanations for play object preferences are postulated. Recommendations are made regarding clinical application of findings in terms of enhancing assessment and intervention by augmenting motivation. N2 - To date, the empirical support for the use of social story interventions for children with Asperger syndrome (AS) is small. The purpose of this study was to examine the effects of individualized social story interventions on the social behavior of three children with AS. Using a multiple-baseline-across-participants design, social stories were implemented, and direct observations of the participants' identified target behaviors were conducted three times per week during unstructured school activities (e.g., recess). Data revealed an increase in the social behavior of two of the three participants when the treatment was implemented.

Unfortunately, maintenance of target behaviors was not observed. These data provide some initial support for the use of social stories to teach social skills to children diagnosed with AS. However, failure to demonstrate skill maintenance and poor results for one participant highlight possible limitations of the social story intervention and suggest a strong need for further research. Recommendations for future research endeavors and the potential benefits of social story interventions are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) A part of mathematics is learning how to work with numbers, but mathematical knowledge also includes knowing what the numbers represent; for example, understanding the amount off a price (discount); using patterns to explain natural phenomenon and business trends, etc. Mathematics reform stresses the contextualization of the mathematics. As teachers, we can bring real mathematics into the classroom; however, we cannot forget to include the mathematics outside of the classroom, such as a geometry nature hike to look at the patterns of the veins in leaves and a similar pattern in the branching out of tree limbs; being able to determine the area and perimeter of the layout of safety mats under the playground equipment; or comparing the angles of slides for different age groups. The 'School in the Park' (SITP) program, developed by the combined efforts of the staff at Balboa Park and Rosa Parks Elementary (under the direction of the City Heights Educational Pilot), provides the students multiple opportunities to study mathematics in the world

outside the classroom. Using the students' experiences in the SITP, I want to point out not only the obvious mathematics being used, but also the not--so--obvious mathematical experiences that teachers can tap into as they continue working with the students in the classroom across grade levels. IS - 2006

N2 - (from the chapter) We believe 'School in the Park' is a unique and bold educational endeavor implemented during a time of shrinking education budgets. Few schools and districts may have access to the resources necessary to operate a program on the scale of 'School in the Park'. However, the practical lessons learned are useful for understanding how community--based learning experiences can enhance educational outcomes for children. In addition, conditions can be created in which students will be motivated, focused, and excited about engaging in challenging learning tasks that most would consider out of their reach. Provided the right conditions exist, we would be thrilled if this book facilitated every school being able to offer multiple opportunities to apply the principles of 'School in the Park'. At the very least, understanding the principles and practices of 'School in the Park' will result in rethinking and reorganizing traditional field trip resources and moving instruction beyond: 1. Grade--level standards must drive the selection of environments, activities, materials, and assessments. 2. Grade--level standards can be taught and reinforced via hands--on, interdisciplinary, and experiential learning. 3. Formal (directed) and informal (constructive) learning need not be polar opposites. 4. Nontraditional classroom environments, when carefully selected, can provide motivation, purpose, and a depth of understanding for a standards--based curriculum. 5. If nontraditional classroom environments are to be effective in supporting a standards--based curriculum, then the instructional program must coordinate classroom and nonclassroom learning. The curriculum must be mapped and integrated into a year--long subject--specific pacing chart that identifies key standards that will be taught and assessed. 6. The number of nontraditional classroom environments accessible to most schools is limitless and can be inventoried via an environmental scan. Not all of these environments will require extensive logistical arrangements and costs. 7. Extending learning outside of traditional classroom settings creates an opportunity to expand instructors and create teaching teams. Time to engage all of the teaching adults in common planning is time well spent and can serve to support multiple classes and programs. 8. Extending learning outside of traditional classroom settings can increase the prior knowledge students bring to future learning environments and thereby increase their cultural capital. These principles and practices are described and exemplified throughout this book. We also hope that this book prompts new public and private interest in creating partnerships that continue to promote adding new environments and experiences to excite and enhance learning outcomes for students. Readers are challenged to begin to create their own asset maps of facilities and locations in their immediate community that are readily

available to provide educational opportunities that will extend and expand 'School in the Park'-type teaching and learning. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Quality improvement (QI) activities, designed to enhance program evaluation efforts and to improve quality of care, have become increasingly important in children's services research. QI activities examine outcomes and provide accountability data that can be very useful for telling the story of the development, implementation, and effectiveness of expanded school mental health (ESMH) programs. This article discusses the implementation and results of QI activities for two ESMH programs, one relatively new program, and one with 10 years of experience. When presenting each case example, the authors review key QI activities such as developing new measures and interventions, evaluating costs of care, and disseminating results to clinicians, program administrators, and funders. The article concludes with a discussion of the importance of QI in school-based mental health and reviews directions for future research and program development. N2 - This study explores the complicated social interactions related to gender that take place at school recess. Using grounded theory methodology and a social constructionist perspective, the researchers observed 67 recesses in New England and then examined the data to determine which themes emerged. Results demonstrate that there is great complexity in preadolescent gender relations and that their incidence and significance is influx during recess time. Among the results noted were ways in which children reinforce their gender identities; the wide intragender variability in choice of activities especially for girls; and clear evidence of borderwork that is, those interactions where boys and girls play together but there is something about the play that actually reinforces the gender divisions rather than diminishes them. Future research should examine ways adults can support children in developing relationships based on mutual collegiality and liking, thereby building their sense of competence and self-esteem. N2 - (from the chapter) Epidemiological works suggest that anxiety disorders (AD) are the most prevalent problem in infancy and childhood. The clinical picture varies according to the particular disorder, developmental stage and comorbidity. Moreover cross sectional and longitudinal studies point out AD as a malleable but more persistent disorder than once thought. Psychotherapy is quite widely used in the treatment of children with AD and research in this field has advanced considerably in the last few decades. A large body of studies found short-term efficacy of behavioral treatments. Some studies have shown long term effects over time, and several studies tend to support that outcomes are better for brief child psychotherapy where specific problems are targeted. Greater therapeutic precision and a careful sculpturing of treatments to children's clinical needs are also necessary for psychodynamic psychotherapy, which is widely used in mental services. After the description of a time-limited combined individual and parent-focused psychodynamic psychotherapy for

children in a clinical, naturalistic setting, a research project to evaluate its short and long term efficacy is presented. The treatment timing, phases and strategy are described as well as the role of intrapsychic conflicts and parental representations which are the focus of the treatment. Fifty-eight children meeting DSM-IV criteria for pure or mixed AD were assigned to either active treatment or community services; all subjects were measured at baseline, after six months and at a two-year follow-up, by C-GAS and CBCL. The benefits of treatment manifest both immediately and with delayed onset (sleeper effect): patients sought mental health services at a significantly lower rate than the compared condition. These findings permit to propose psychodynamic psychotherapy as a useful therapeutic tool in AD and illustrates the importance of developing empirical research on psychodynamic-oriented treatment widely applied in clinical practice but less frequently studied through careful long-term outcome evaluation. The role of the intensive involvement of the parents in our combined psychodynamic psychotherapy is proposed as an area of specific research for this type of treatment. N2 - Several studies show an association between the Hypomanic Personality scale (HPS; Eckblad & Chapman, 1986) and variables related to bipolar disorders. In theory, people with a hypomanic temperament are thought to be more active than others. The purpose of this study was to examine empirically which kinds of activities students with a hypomanic temperament typically pursue outside of the school context and especially how much time they engage in these activities. We hypothesized that students would report a high proportion of activities that are fun- and reward-related, also including problematic ones (e.g. alcohol abuse). Teenage students (n = 4045) completed several questionnaires, including the HPS, CES-D, questions about performance in school, future success, and leisure activities. Using the HPS, a high-risk group (n = 300) was denned and compared to a control group (n = 1709). As hypothesized, "hypomanic" adolescents spent most of their time outside of school socializing with friends and pursuing sports rather than attending to duties such as homework, smoked more often, drank alcohol more often, and were more often involved in physical fights. The results are discussed within the context of a model that regards dysregulation of the Behavioral Activation System as a vulnerability factor in bipolar disorders. N2 - The Webster-Stratton Classroom Dinosaur School Programme was developed as a therapeutic intervention to teach social and problem-solving skills and to reduce behavioural problems in young children. It has subsequently been developed as a classroom programme for use in schools (Webster-Stratton et al., 2001a). In 2001 Gwynedd Education Service in North West Wales undertook a pilot delivery of the classroom programme in the reception class of one primary school. This paper describes the programme and the detail that went into ensuring that the plan would be effective. It also reports on some outcomes from the first year of the programme in terms of pre- and post-intervention measures of child behaviour and use of social and problem solving skills. Interviews were also conducted with school staff and parents and their perceptions of the programme's effectiveness are reported. Results demonstrated positive effects on academic performance, social and emotional development and reductions in behavioural problems. There was evidence that improvements had generalised to other settings, playground and home, and to other children in the school. The success of the programme in the first year helped to ensure the continuation of the programme, which is now in fourteen schools. The paper concludes with discussion of why the programme has been successful and describes the way in which the plan has evolved since this first year. N2 - (from the chapter) There are numerous innovative bullying and aggression-prevention programs being used in schools across the country and worldwide. This chapter presents a review of the most commonly used sets of measures to identify aggressors and bullies and to determine the effectiveness of bullying and aggression prevention programs. The review will focus on the strengths and limitations of each set of measures. In addition, the chapter describes how our research team has collaborated with the adults who supervise students on the playground and in the lunchroom to develop and validate several innovative community-responsive questionnaires that can be used in conjunction with other methods to evaluate the effectiveness of bullying prevention and intervention efforts. The chapter concludes by discussing how to translate research to practice in the development outcome measures designed to evaluate the effectiveness of school-based bullying prevention programs. N2 - Investigated the usefulness of intensively training children with dyslexia with daily exercises based on the temporal processing theory of dyslexia. In the first study, 12 children, aged 10-12 yrs, received training for 1 hr a day, 5 days a week, over 5 weeks, and they were assessed on phonological tasks before, during and after

training. In a second study, 29 children with dyslexia, aged 5-12 yrs, received a similar training, but for only 15 min a day, 7 days a week, over 6 weeks, part at the speech therapist office, part in their own homes. The finding of comparable improvement in a more 'natural' environment and in children over a wider age range was found. However, this study also showed that 1 of 4 children did not improve as expected, prompting a third study where 23 children (mean age 9.5 yrs) underwent specific tasks presumably exploring various aspects of temporal processing in order to find predictors of training efficacy. A 'temporal order judgement' task was found to be best correlated with post-training improvement, suggesting that one could use this task for selecting the best candidates for temporo-phonological training. These studies provide further justification for a rational, indication-based temporo-phonological treatment of dyslexia. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Defiant behavior in two- and three-year-olds is a natural expression of a young child's growing autonomy, and, although frustrating to adults, is a natural phase of a child's socio-emotional growth. L.S. Vygotsky's socio-historical theory of the development included a discussion of "crisis" periods, one of which he felt occurred at age three. The crisis that Vygotsky asserted occurred at three is characterized by a group of seven "behaviors", all of which indicate a struggle with the child's position in relation to family social structures. This study examined the occurrences and characteristics of defiant behavior in two-and three-year-old children during outdoor play at a child development center, and the existence and context of defiant behaviors the modern childcare setting. Patterns in defiant behaviors during play in different age groups were apparent, and suggested an instrument to facilitate the documentation and analysis of defiant behavior in modern group-care settings. N2 - The author presents the analysis of a precocious traumatized little girl, which reveals the ways in which historical trauma is transmitted and intra-familial trauma is both disguised and represented. The play as it evolves is seen to simultaneously communicate what the child struggles with and to resolutely try to hide what has actually happened. Analyst and child together participate in play which utilizes displacement, enactment and interactive enactment, the latter play mode being the very hallmark of profound traumatic experience. Carlotta, the child, helps the analyst to follow her quest for meaning making even as the interaction between them adheres to and departs from the deepening pentimenti of traumatic experience, which needs to be unraveled and reconstructed in order that her own developmental progression can be rejoined. The analysis facilitates Carlotta's capacity to play in a more unfettered fashion and to assist her family's recovery as well. N2 - Bullying affects between fifteen and twenty percent of students in the United States (Batsche and Knoff, 1994) and up to eighty-eight percent of students witness bullying in school (Quiroz, 2002). A needs assessment was conducted to investigate the prevalence and patterns of bullying in a suburban elementary school. The Olweus Bully/Victim Questionnaire was used to survey 134 third through fifth grade students. This survey ascertained the percentage of bullies and victims as well as students' views about bullying. A bullying prevention program was designed to fit the needs of students and staff. Key staff members were interviewed to determine what character education programs the school already had in place and what resources would be available for a new bullying prevention program. Results of student surveys indicated that 49.3% of students were bullied and 10.4% of students reported bullying others. There was no significant difference in the prevalence of bullying by gender or grade. Students were most likely to be bullied on the playground and in the

lunchroom. The majority of victims reported that the bullying had lasted for at least a year. The majority of students reported feeling sorry for victims; however it was also reported that students rarely tried to stop bullying. Results from staff interviews revealed that the school has a variety of social programs in place at the primary, secondary and tertiary levels of prevention. A program was developed that consists of four components; a playground and lunchroom program, bullying lesson plans, a school-wide anti-bullying policy and a method for anonymous reporting. This program was designed to complement existing programs and utilize the limited resources available. Results are discussed and further areas of research are suggested.

N2 - Prior research in the field of video games has focused primarily on how violent content affects aggressive behavior. The current study was designed to show that game-users' ability to press a button and elicit an immediate and fixed response from the game will have an effect on impulsive reactions outside the gaming environment. Forty boys, age ten to fourteen, were given two questionnaires that gathered information regarding their video gaming habits (past and present) and their propensity for disinhibition or impulsivity in certain situations as measured by the Behavioral Activation System (BAS) Sensitivity Scale (Carver & White, 1994). Before and after engaging in a reward-based activity (playing video games vs. shooting baskets for a prize), participants were asked to perform a Time Perception Task as a measure of cognitive impulsivity. There were no significant differences between the experimental conditions. Participants who reported playing more video games per day, however, showed greater cognitive impulsivity following cessation of the reward-based activity regardless of which condition they were in. Results concerning the BAS Sensitivity Scale yielded findings in two of the three sub-scales of this measure. Participants who reported playing more video games per day reported a more impulsive, persistent pursuit of desired goals (Drive scale). Results also indicated that these same participants tended to respond more positively to the occurrence and anticipation of rewards (Reward Responsiveness scale). When viewed collectively, these findings indicate some support for the model proposed in this study, which attempted to link video game play with Patterson and Newman's (1993) theory of disinhibition. Also discussed are possible applications of the proposed model for future studies correlating high video game play and high BAS ratings with affect regulation, capacity for fantasy/imagination, clinical populations (ADHD, ODD, and Bi-polar), agency/locus of control, academics, and gender differences. N2 - Two experiments tested the effects of "peer-yoked contingencies" on the establishment of observational learning repertoires using a time-lagged multiple probe design across participants. The three participants in each experiment were preschoolers with mild developmental delays who did not have an observational learning repertoire prior to this study. Both experiments were conducted in a small tutorial room in a preschool for students with disabilities located outside of a major metropolitan area. In Experiment 1, a baseline probe for observational learning was first conducted in which a participant was seated next to a peer while the experimenter taught the peer to vocally identify a set of pictures. Once the peer mastered that set of pictures, the participant was probed for the same set of responses. This procedure was then repeated with the same participant and a different peer. The peer-yoked contingencies were then implemented in which a participant and one of the peers (the "game peer") played a game in which the participant was required to observe the peer's responses to a pre-set criterion in order to win the game for the team. Once the participant mastered the game, another probe for observational learning was conducted. The results of Experiment 1 showed that, following the peer-yoked contingencies, all of the participants showed an increase in the number of responses learned through observation. However, the degree of this increase varied across the three participants, and one participant showed only a very slight increase in observational learning. Experiment 2 was a direct replication of the previous experiment, with the major difference being that participants were exposed to additional sessions of the peer-yoked contingencies if they did not acquire observational learning after a single exposure. The results of Experiment 2 also showed that the peer-yoked contingencies were effective in teaching observational learning repertoires to these preschoolers and that the participants required different numbers of sessions of peer-yoked contingencies in order to establish this repertoire. VL - 66:

IS - 2-B

N2 - The effect of rewards on intrinsic motivation has been evaluated extensively over the last 30 years, and is still fervently debated. Some researchers claim that when extrinsic rewards are terminated while engaging in an activity that is intrinsically motivating and previously reinforced, the rates decrease below baseline levels (viz., the "Overjustification effect"). Other researchers claim rewards have no detrimental effect on intrinsic motivation; if reductions in behavior are reported, the behavior eventually returns to baseline levels. This investigation evaluated the effects of rewards on intrinsically motivating playground activities with three children. The participants were 2 girls and 1 boy, ranging from ages 8-11. The experiment utilized a multielement, multiple baseline design across participants, and provides data on percent of session engaged, as well as scores on an 8-item attitudinal self-report. Reinforcement was provided on fixed-ratio 4 and variable ratio 4 schedules. Discriminative stimuli are associated with each condition to facilitate discrimination. Other methodological advances include preference assessments on the intrinsically motivating playground activity and stimulus (reinforcer) preference-assessments to identify actual reinforcers rather than rewards. Moreover, a time-series design was utilized to allow for a comprehensive analysis of the data across conditions and a 2-week follow-up was also conducted. Results indicated reinforcement has no detrimental effect on intrinsic motivation for all 3 participants; conversely, increases in behavior in the postsession and 2-week follow-up data were observed. The 8-item self-report measure also showed no detrimental effects from the delivery of rewards. These results extend the behavioral literature on rewards and intrinsic motivation. N2 - The purpose of the present study was to explore relations among the forms and social dynamics of girls' playground aggression in comparison to boys' playground aggression. Physical, verbal, and social forms of aggression were assessed, as well as the extent to which the focal child was in a position of social power relative to peers, and the extent to which peers aligned with the focal child during the aggressive episode. Also, peer ratings of popularity and aggression were examined. The observational and survey data were drawn from a large, longitudinal study of bullying and victimisation among elementary school students (grades 1 through 6) attending two schools in metropolitan Toronto, Canada. The subsample of 39 girls and 39 boys were observed engaging in aggressive behaviour during episodes in which they were focal children (i.e., children who were the focus of the observations). The focal children were 5 to 12 years of age ($M = 8.77$, $SD = 1.76$). Naturalistic observations of playground interactions revealed that a larger proportion of girls than boys used indirect forms of aggression (i.e., social aggression), whereas a smaller proportion of girls than boys used direct forms of aggression (i.e., physical and verbal aggression). In addition, abstinence from physical aggression and reliance

on social aggression was associated with higher levels of social power among girls in comparison to boys. Theoretical implications and implications for research methodology, risk identification, and intervention are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

VL - 65:

IS - 11-B

N2 - Teacher-child relationships were examined as possible predictors of children's cortisol change in a preschool setting. Cortisol fluctuations across the day (daily change) for children ($n = 186$) in 17 full-day childcare classrooms were assessed in the morning and again in the afternoon on two days (one in Winter and one in Spring). In order to isolate the effects of the teacher-child relationships on cortisol, each child and his or her teacher took part in a one-on-one interaction episode outside of the classroom, and cortisol change was measured before and after the interaction episode (interaction change). Hierarchical Multivariate Linear Modeling (HMLM) was used to assess associations among teacher-child relationship qualities and cortisol change while taking into account or controlling for nested measurement (e.g., time since waking), child (e.g., sex and temperament), and classroom/teacher (e.g., group size and observed teacher negativity) effects. Morning to afternoon changes in cortisol replicated findings from previous research, with 51.2% and 45.8% of children showing increases in cortisol across the day, rather than the typical circadian pattern of decreases across the day. Modest stability was found for a.m. to p.m. cortisol change across the Winter and Spring assessments ($r = .20$, $p < .05$) with morning values showing the greatest consistency ($r = .30$, $p < .001$). Cortisol levels were associated with elapsed time since wake-up, but not with duration of sample collection. Teachers' reports of clingy relationships were associated with children's cortisol increases from morning to afternoon in the Winter classroom assessment. Teachers' reports of relationship conflict were associated with increases in cortisol across the teacher-child interaction task for boys but not girls. Child reports of relationship negativity were also marginally related to cortisol increases across the teacher-child interaction. Although the influence of teacher-child relationships on children's cortisol activity were not consistent across all measurement periods, the results provided a stringent test of the hypotheses and evidence that children's relationships with their teachers in the childcare setting may influence cortisol fluctuations, even after controlling for the effects of child, classroom, and measurement factors known to influence cortisol level. N2 - Recent literature has conceptualized teacher efficacy as context and task specific. Little is known, however, as to variables that predict such task specific teacher efficacy judgments, and there have been no investigations into the potential relationship between such efficacy judgments and student academic outcomes. The purpose of this study was to identify personal and organizational perceptual variables, as well as demographic variables predictive of teacher efficacy judgments in the areas of classroom management, student engagement, and instructional strategies. This study then assessed the relationships and predictive ability of the three task specific teacher efficacy judgments with student gain in the area of reading comprehension. Utilizing the recently developed Ohio State Teacher Efficacy Scale with 136 general education-upper elementary teachers (3rd through 6th grade), the current investigation revealed that both hardiness personality disposition and having a perceived high percentage of actively engaged students highly correlated with, and significantly contributed to, elevated teacher efficacy judgments in the three assessed tasks. Additional analyses revealed that supportive principal leadership accounted for significant variance in classroom management efficacy only. The reading performances of 2,011 general education students were deemed admissible for this study and included 699 third graders, 722 fourth graders, and 590 fifth graders. Analyses of the task specific teacher efficacy/student academic gain relationship revealed no significant correlations in the predicted direction. Subsequent regression analyses also revealed that none of the three efficacy judgments accounted for significant variance in student reading comprehension gain in the predicted direction. Recommendations for future research include the need for a case study approach of teachers who possess a hardy personality disposition, report a high number of actively engaged students, and supportive principal leadership to better understand how they differ from others in the way they process sources of efficacy information. Inclusion of both regular education and "at-risk" students when assessing educational outcomes in teacher efficacy research is also critical. The current study excluded students who received remedial reading support outside of the classroom setting, and previous research suggests that this "at risk" group may benefit the most from having highly efficacious instructors. Expanding the scope of assessed educational outcomes would also appear appropriate and include both academic and affective domains. Finally, the current study attempted to extend previous findings by utilizing a pre-post academic measure that was highly correlated with the students' actual curriculum. Recommendations for improvement include the use of pre-post measures that are curriculum based, standardized, and normed on the local population, along with use of cross-validation procedures that may include the use of nation ally-normed assessments, grades, or other curriculum based measures. N2 - This dissertation provides an analysis of how young people's everyday lives outside of school in Yorkville and East Harlem have changed from the 1940s until present time, and what factors contribute to consistencies or differences in young people's use and experience of their local environment. This research seeks to contribute to the limited academic literature on the historical geography of childhood in urban communities. The focus of this investigation is upon the period of middle childhood (roughly the period of childhood between ages 11 and 13), a time when most young people are able to actively and autonomously explore their communities. The emphasis of the research is on changes in children's geographies, or how children use, think about, and make sense of place in their everyday life. I compare children's geographies over three different time periods: (1) the 1940s, working with seniors in their 60s and 70s; (2) the 1970s, working with adults in their 30s; and (3) present time (2000s), working with young people aged 11-13. Topics explored in the research include young people's sense of place, their interactions with peers and adults in the community, their leisure time activities, their use of public space and their geographic territories. N2 - Participating in sports is one of people's favourite leisure time activities, but athletes are not a homogeneous group at any time, owing to obvious differences in gender and socio-demographic factors. Maximum participation in physical and sport activities occurs during a child's school years. On the other hand, participation in sports drops massively when children leave school, owing to a multitude of factors that depend on psychological and socio-personal factors. The objective of this article is to identify the athletic profile of people from the island of Majorca in accordance with sociodemographic variables and levels of participation. This paper is part of research conducted during 2001 that aimed to study and identify the athletic habits of the Majorcan population between 10 and 14 years of age. A sample of 2661 subjects was studied and a previously validated questionnaire based on authors' work was used for evaluation. The results obtained in this study demonstrate that taking part in sports has been consolidated as a life style in our society and that it is a favourite occupation for Majorcan pre-adolescents during free time. It is also significant to emphasize the obvious differences between males and females in the age groups studied in connection with taking part in sports outside physical education classes. VL - Achieving learning goals through play: Teaching young children with special needs :

IS - 2nd ed.

N2 - (from the cover) Play is more than fun; it's a powerful teaching tool that helps young children learn. The second edition of this practical guide gives early childhood educators creative, ready-to-use strategies for weaving individual learning goals into play activities throughout the school day. Developed for use with young

children who have special needs--but equally effective for typically developing children--Achieving Learning Goals through Play helps teachers (a) foster children's cognitive, communication, motor, social, and preliteracy skills during group activities and free play; (b) use existing classroom play centers and materials to create age-appropriate learning opportunities; (c) support individual and group learning goals during familiar types of play, such as outdoor activities and music and rhythm play; (d) work play activities into the classroom schedule with straightforward planning sheets; and (e) adapt activities for children with special needs. Helpful appendixes offer guidelines for developmentally appropriate practice, resources for including children with disabilities, and photocopiable planning matrices. With this strategy-filled handbook, early childhood educators will help all their students reach their individual learning goals in fun, creative ways. N2 - This study examined the effectiveness of the First Step to Success (FSS) early intervention program with four Native-American students, their teachers, and their parents on (a) targeted students' problem behaviors, (b) class-wide student behaviors, and (c) teacher behaviors. Participant teachers and parents were also interviewed to gather their perceptions of the FSS program. The results of direct observations of targeted students' play behaviors on the playground revealed that the FSS program had a significant positive affect on all participant students' social play behaviors. As soon as the intervention started, all participant students' social play behaviors significantly increased and their nonsocial behaviors decreased. All participant students showed higher levels of social play behaviors as soon as the intervention was initiated. Substantial decreases in problem behaviors were also reported by two teachers. Some positive changes in class-wide student behaviors and teacher behaviors were reported by the participant teachers. All but one parent reported significant changes in problem behaviors of targeted students. They all were highly satisfied with the program and rated it as easy to use. Limitations of the study and directions for future research are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Effective management of disruptive behaviors in schools is a national concern. While substantial resources are often allocated toward individual students who exhibit challenging behavior, less emphasis is placed on preventative interventions in common areas such as hallways, cafeterias and playgrounds. The purpose of this study was to determine whether a multi-component Positive Behavior Support (PBS) intervention consisting of positive practice, pre-correction, verbal praise, reinforcement, correction of inappropriate behavior, active supervision, discussion of behavior with students and on-time dismissal could improve middle school students' problematic hallway behaviors. The 5-week intervention phase resulted in a very large reduction between baseline and treatment phases of 42.36% across 950 students. This study provides evidence that readily available and cost-effective techniques can be used to make school common areas safer and more orderly. Implications for the use of school-based PBS practices are discussed. (PsycINFO Database Record (c) 2012

VL - A safe place to grow: A group treatment manual for children in conflicted, violent, and separating homes. ix, 220 pp. Binghamton, NY, US: Haworth Maltreatment and Trauma Press/The Haworth Press; US.

N2 - (from the introduction) This manual presents a unique, step-by-step model for treating children who have experienced chronic conflict or violence within their families. The first edition was developed specifically for children of highly conflicted separating and divorced families who were referred by family courts to the Judith Wallerstein Center for the Family in Transition, which has been one of the country's foremost centers for divorce research. The second edition includes changes that have been made to the model during the past seven years as it has been applied more broadly in multiethnic, multicultural neighborhoods, schools, and family agencies to help children who are living in a whole range of stressful situations related to family conflict and violence. Whereas the first edition focused solely on older school-age children, the second edition includes a section specifically designed for younger school-age children as well. Now the manual provides developmentally appropriate treatment curricula for children ranging from about five to fourteen years.

N2 - A phenomenological framework guided data collection and analysis of the prevalent influences on attitudes and behaviors of elementary, junior, and secondary school students towards their physically active leisure. Twenty-two students participated in individual in-depth interviews. Parental influence and outdoor play effected choice and level of physically active leisure for elementary students. Opportunities for organized and non-structured physically active leisure and friends were significant for junior students. Academic responsibilities and organized physically active leisure were influential for secondary students. Common threads were parental influence and the belief that the students were too old to start new activities. These findings highlight the importance of providing opportunities in safe environments for children and youth to participate in

a variety of structured and non-structured forms of physically active leisure. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - The general aim of this study was to examine the concurrent and longitudinal (6 month) associations between 8- to 9-year-old children's (N = 75) social activities and interactions during recess and their self-perceptions, and to test for gender differences in those associations. The underlying rationale was that recess provides an important, and hitherto unstudied, context in which children's experiences can impact on their views of themselves. Consistent with this proposition, several of the playground variables were significantly correlated concurrently with participants' self-perceptions regarding social acceptance, and, particularly, athletic competence. Even stronger evidence came from the longitudinal analyses which indicated that group size positively predicted changes in social acceptance and global self-worth scores; network positively predicted changes in physical appearance and global self-worth scores; rule games positively predicted changes in athletic competence, physical appearance and global self-worth scores; conversation negatively predicted changes in athletic competence, and alone negatively predicted changes in physical appearance and global self-worth scores. Several significant gender differences were obtained: the association between rule games and changes in social acceptance was negative for girls but positive for boys; a positive association between conversation and social acceptance was evident among girls but not boys; and a negative association between conversation and changes in athletic competence was evident among boys but not girls. The theoretical and practical implications of these results are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Two studies are used to illustrate the importance of context and length of time in the use of the Emotional Availability Scales (EAS) to predict aspects of child development. The purpose of the first study was to examine whether prediction of attachment by the EAS is better with increasing amounts of time. We scored emotional availability (EA) every 15 min for a total of 2 hr, with correlations showing an increasingly stronger relation with attachment with increasing time. In addition, difference scores were calculated between the first and the last 15 min for each EAS dimension. The difference score was significantly higher for the insecure group, suggesting that we need more observation time for the prediction of insecure attachments than is the case for the prediction of secure attachments. The second study investigated whether EA is differentially predictive based on context. We explored play contexts versus reunion contexts. We also explored the relations with other indices of child development. Results revealed that some dimensions of EA (e.g., maternal nonhostility) are difficult to detect outside of a stress context. Maternal nonhostility during the reunion (but not the play situation) was correlated with child aggression in the kindergarten classroom. In addition, most dimensions of EA assessed in the reunion context were better predictors of teacher reports of kindergarten adjustment than was EA assessed in the play situation. N2 - Access Nature (by Beth Gilbert Almeras and David Heath, 2001) is an inclusive curriculum created by the National Wildlife Federation. The main premise for designing this curriculum was to offer educators a tool that would aid in formulating quality environmental education programs that would reach and stimulate all participants with and without disabilities. This curriculum is designed around objectives in outdoor and environmental education with a main theme of habitat. Each of the activities in this sixty-hour curriculum is geared towards youth and teens ages 6-14. Specific adaptations are incorporated that address four categories of disabilities: hearing, learning/cognition, motor, and visual. Invaluable. This manual is a very useful resource for gaining awareness into the little things that can be done to create a safe and stimulating environment for all participants regardless of their abilities. The suggestions and guidelines for including participants with disabilities transcend the scope of the listed activities to programming in general. The Access Nature curriculum encourages facilitators to increase their comfort level working with inclusive audiences by offering all students the opportunity to explore nature. N2 - A developmental ecological model was used to identify child attributes, father characteristics, and familial factors associated with multidimensional father involvement with preschool children enrolled in Head Start. The relations between father involvement and children's school readiness were also investigated. Eighty-five African American fathers and father figures were surveyed about their involvement in child care, home-based educational and school-based educational activities. Children's school readiness competencies were evaluated via teacher report or direct assessment. Father involvement in child care and home-based educational activities were predicted by different contextual factors and child attributes. Fathers were more involved in child care activities when they lived in a child's home and when a child was highly emotional. Fathers who perceived the existence of a strong parenting alliance reported more involvement in home-based educational activities. Father involvement in child care and home-based educational activities was associated with higher levels of children's emotion regulation. Findings are consistent with a contextual, multidimensional perspective of African

American fathering and hold policy implications for fatherhood initiatives in the early childhood education field. Efforts to increase father involvement may be most effective when addressing the multitude of influences on fathering behavior and focusing on father-child activities that occur outside of the preschool setting. VL - Recess: Its role in education and development. xii, 202 pp. Mahwah, NJ, US: Lawrence Erlbaum Associates Publishers; US.

N2 - (from the preface) Writing a book about recess could be a very questionable endeavor for a serious academic psychologist. At first blush it seems to be a pretty trivial topic. It's the time during the school day when there's a break from what's typically considered the most serious work of the day--reading, writing, and arithmetic. Reflecting this trivial sort of tenor, it's also that time that kids will, perhaps only half-jokingly, say is their favorite part of the school day. There's even a cartoon TV show for kids called Recess! All of this reinforces the popular notion that recess is indeed trivial and certainly not worthy of serious academic and scientific attention. This perception has, I think, led to many schools questioning the role of recess in the school day. This orientation, I think, has done much more harm than good. If studying the role of recess during the school day seems questionable, so too, some people think, is the idea of taking recess away from kids in primary school. When people first hear of this state of affairs, a frequent initial reaction is disbelief--"You've got to be kidding!" This book attempts to broach these two views of recess; the perceived value of recess and the movement to eliminate or reduce the school recess period from the primary school day. Over the past 10 years, I have been contacted by a number of folk concerned with this trend. They know, in their hearts, that something is wrong here. When they speak with me, they ask for advice on how to counter the trend. I hope that this book helps them in this important job. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The majority of teens are having sex, however, we know little about sex that occurs outside the traditional dating context and the factors associated with these non-romantic sexual experiences. Prior work indicates that healthy sexual behaviors depend on the relationship context of sexual intercourse, but research on the characteristics of teens who engage in non-romantic sex is limited. We use two waves of the National Longitudinal Study of Adolescent Health to analyze adolescents' reports of non-romantic sexual intercourse, and whether key protective and risk factors as well as normative orientations distinguish the context within which sexual activity occurs. We find that the majority of sexually active teens have had some sexual experience outside of a romantic relationship. We conclude that teenagers' sexual experiences are not static over time, because 60% of sexually active teenagers have had sex in both romantic and non-romantic contexts. Our multivariate analyses indicate that the teen's normative beliefs have significant effects on teenage non-romantic sexual activity. The traditional risk and protective factors often are not related to teens' decisions about sexual partners. These results have implications for our understanding and encouragement of healthy adolescent sexual behaviors. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study investigated the relationship between the social and play behaviors of young children with pervasive developmental disorder (PDD) and without PDD. Videotaped observations of 21 preschool children (12 with PDD and 9 without PDD) were examined independently for (a) social complexity and (b) play complexity that was assessed on an individualized basis for each child. The researchers used log-linear analyses to analyze the data. The results supported an inverse relationship between play and social interaction: The children's play within a social interaction tended to be less complex than their play outside of the interaction. All children, regardless of diagnosis, demonstrated similar behavioral patterns, although the children without PDD engaged in social interaction to a greater extent. These results suggest that social interventions should be implemented in the context of play activities that the child has mastered, as opposed to those activities the child is in the process of learning. VL - Helping students fix problems and avoid crises: An easy-to-use intervention resource for grades 1-4. xv, 182 pp. Thousand Oaks, CA, US: Corwin Press; US.

N2 - (from the introduction) All children experience problems from time to time. These dilemmas go with the territory of being a child and are part of the developmental learning curve. In the long run, the vast majority of the predicaments prove inconsequential, and most children cannot even remember the previous day's dilemma. Having an argument with a friend, being kept in the classroom during recess for misbehavior, or getting a poor grade on a homework assignment are unlikely to leave a permanent imprint on a child's psyche, unless, of course, the scenarios are recurring and scripted. Of far greater concern are the more intractable problems that are often directly attributable to the student's attitudes and behavior. Children who chronically lie, tease, steal, bully, cheat, spread rumors, or act in socially inappropriate ways are transmitting a clear message that they are unhappy campers. Their actions are certain to generate undesirable repercussions that typically include peer rejection, alienation, and repeated admonitions and punishments from teachers and parents. Youngsters who are socially rejected, bullied, belittled, teased for looking or acting different, disparaged for having learning problems or other disabilities, or scorned for poor athletic skills are clearly at psychological risk. Their traumatic

experiences in the classroom and on the playground are all but certain to profoundly, and perhaps indelibly, warp their perceptions about themselves and their world. (from the cover) For the child who doesn't have friends, does poorly in sports, has difficulty learning, or who steals, lies, or bullies, Greene provides solid, proven methods to help these learners discover and practice better life skills. *Helping Students Fix Problems and Avoid Crises* includes: insightful stories for teachers and students illustrating each problem; practical activities and exercises illustrating techniques to help students address each problem; supplemental reproducible exercises; and encouraging follow-up and application exercises. The author divides each problematic issue into two sections: for educators, he looks at the dynamics and implications of each problem, and for students, he provides classroom scripts and exercises to bring their own awareness to each problem. This essential classroom resource also includes illuminating ten-minute read-aloud stories, strategic thinking questions, optional activities, and reproducible exercises! N2 - The current study deals with the development of system thinking skills at the junior high school level. The sample population included about 50 eighth-grade students from two different classes of an urban Israeli junior high school who studied an earth systems-based curriculum that focused on the hydro cycle. The study addressed the following research questions: (a) Could the students deal with complex systems?; (b) What has influenced the students' ability to deal with system perception?; and (c) What are the relationship among the cognitive components of system thinking? The research combined qualitative and quantitative methods and involved various research tools, which were implemented in order to collect the data concerning the students' knowledge and understanding before, during, and following the learning process. The findings indicated that the development of system thinking in the context of the earth systems consists of several sequential stages arranged in a hierarchical structure. The cognitive skills that are developed in each stage serve as the basis for the development of the next higher-order thinking skills. The research showed that in spite of the minimal initial system thinking abilities of the students most of them made some meaningful progress in their system thinking skills, and a third of them reached the highest level of system thinking in the context of the hydro cycle. Two main factors were found to be the source of the differential progress of the students: (a) the students' individual cognitive abilities, and (b) their level of involvement in the knowledge integration activities during their inquiry-based learning both indoors and outdoors. N2 - (from the chapter) Research has demonstrated that nonschool hours provide a powerful opportunity for community-based organizations to help children and schools reach their academic goals. For example, Reginald Clark says, "Youngsters who engage in constructive learning activities outside of school are more likely to excel in school and in life than those who do not. By participating in a well-rounded array of activities, they are able to practice and thoroughly learn skills required for academic success." Based on this knowledge, The Children's Aid Society (CAS) aims to integrate after-school and summer enrichment programs with classroom instruction through a model that both supports the school's academic mission and promotes healthy youth development. The vast majority of students in CAS's 10 community schools, which are located in New York City, struggle with basic skills; in addition, more than half are Spanish speakers grappling with English as a second language. Their parents, teachers, and principals look to after-school and summer programs to help address their needs. The challenge for CAS is to answer this call in a way that is fun and engaging for children and achievable for program staff. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study examined contextual factors associated with physical activity of urban African American preschoolers (N = 59). Qualitative research methodologies utilized data from home visits, caregiver and child interviews, field notes, and document collection. The primary finding suggested, "In underserved communities fundamental barriers exist that obstruct young children's ability to be physically active." Four themes were developed revealing that outside environments limited opportunities for physical activity, home environments resulted in sedentary behaviors, and communities had limited physical activity role models. Despite this, young children enjoyed being physically active. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Reviews the book *Fostering Adolescents* by E. Farmer et al (2004). This book is the published account of a Department of Health-funded research study that forms part of the Supporting Parents research series published by Jessica Kingsley. Its focus, therefore, includes the parenting skills required by the foster carers of adolescents and the support they and the young people require to ensure stable and successful placements. In this study two main outcome measures were used: placement disruption and placement quality in respect of 68 young people aged between 11 and 17 who were with foster carers from 14 local authorities and 2 independent fostering agencies. Results showed that fewer disruptions occurred when the young people were helped to talk about their past and present lives with their foster carers or where carers are supported and encouraged to communicate with a young person according to their emotional rather than actual age and understanding. Placements are more likely to be successful when foster carers were skilful at monitoring the activities of the young people outside their house or where they took a role in preparing them for life after placement. The book is timely as further government money and attention are currently being paid towards the development of treatment foster care across the country, for young people such as those in this study. Its findings are also of major importance and relevance to fostering managers of both local authorities and independent fostering providers who continue to grapple with the challenges of fostering teenagers in ways that are safe, secure and successful. N2 - Temperament is often regarded as biologically based psychological tendencies with intrinsic paths of development. The existing research findings reveal that the development of temperament plays a unique role in protesting and understanding children's personality and socialization in the future. With emphasis on the enhancement of people's quality in the 21st century, research on children's temperament will be of much value in developing developmental theories and promoting children's healthy personality development. Since the 1980s, developmental psychologists outside China have conducted a large quantity of research, both empirical and theoretical, in this area of children's temperament. This has made it one of the most active and important research areas in child psychology. In contrast, systematic research efforts have been rare in China's developmental psychology, and the general tendencies of the development of children's temperament in Chinese culture remain a big area to be explored. A comprehensive literature review is made with regard to the important empirical findings, major theoretical models as well as the research deficiency. The purpose of this study is to reveal the Structure of Chinese children's temperament aged 3 to 9, to develop indigenous instrument. Based on the open questionnaires that Chinese teachers provided on their students' characteristics, one temperament questionnaires for ages 3 to 9 was developed. Confirmatory Factor Analysis was conducted using AMOS and SPSS in attempt to testify the temperament structure of Chinese children. The major findings in the study are as follows: 1) The questionnaire of children's temperament has high reliability and validity so that it can be used by teachers and researchers to evaluate children's temperament. 2) The structure of Chinese children aged 3-9 is a multifactor, which involves five aspects; emotionality, activity, reaction, social inhibition and attention.

N2 - Part II of the monograph Mother-child conversations about gender: Understanding the acquisition of essentialist beliefs, by Gelman et al (see records 2004-18660-001, 2009-23551-001, 2009-23551-003, 2009-23551-004, 2009-23551-005, 2009-23551-006, and 2004-18660-002). Presents a description of the methods used in this study and preliminary findings. To examine gender talk in mother-child conversations, we videotaped mothers and their young children discussing a picture book that depicted stereotypical and counter-stereotypical gendered activities (e.g., a boy playing football; a boy sewing). These interactions were transcribed, coded, and analyzed in fine-grained detail. Mothers and children also completed tasks that measured gender stereotyping and/or gender constancy. Participants were 72 mother-child dyads, 24 at each of three child ages: 2 years (range 2.4-3.0; mean age 2.7), 4 years (range 4.0-5.0; mean age 4.7), and 6 years (range 6.1-7.0; mean age 6.7). Half the children at each age were girls, half were boys. The majority of the participants were white (94% of mothers, 92% of children); the remaining were ethnic or racial minorities (Asian, African-American, or other). Approximately one-third of the mothers indicated that they did not work outside the home (N57 at age 2 years, 10 at age 4 years, and 9 at age 6 years). Twenty university undergraduates provided ratings to help pre-select the activities that would be depicted in the picture book. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In contrast to the commonsense discourse of youth-as-unruly widely circulating in the West, the kind of discourse which has become part of the Singapore public and academic imagination is one that mobilizes constructions of youth as narrowly achievement-oriented, as "exam-smart muggers", who "lack an enquiring mind". This study attempts to complicate this picture of Singaporean adolescents, showing them to be sophisticated meaning-makers who employ texts of different modes to construct shifting subjectivities in their everyday lives. It draws on selected focus-group data my students and I have collected over the past two years from Singaporean 10- to 12-year-olds as they talk with their peers and us about the texts they like to read and watch in their spare time [Lim, L. E. (2002). Fast cars and magical cards: A study of gendered choices in cartoons. Singapore: Nanyang Technological University, Honours Academic Exercise; Seah, H. L. (2003).

Gender differences in the reading habits and attitudes of primary pupils in single-sex government-aided schools in Singapore. MA (applied linguistics) thesis: Nanyang Technological University]. Building on Moss' [Moss, G. (2000). Informal literacies and pedagogic discourse. *Linguistics and Education*, 11, 47-64; Moss, G. (2001). On literacy and the social organisation of knowledge inside and outside school. *Language and Education*", 15, 146-161] research on knowledge about informal literacies as a "horizontal discourse" (Bernstein), in the discussion of this data I argue that the youngsters whose voices we hear are not entirely trapped within monochrome schooled literacy practices, even though much of what goes on at home may reinforce these; rather, in the spaces they make for themselves, they can be seen engaged in an array of out-of-school activities around texts, displaying special competencies and taking up multiple reading strategies and positions as they navigate them. Having a better understanding of the kinds of "impr; oper" knowledge about literacy that is generated alongside the privileged pedagogized version in many Singapore homes can not only help complicate our current image of Singaporean youth but also help re-envision literacy education in schools in ways that the students' unsanctioned experiences and competencies with texts are recognized and built upon. N2 - The purpose of this study was two fold. First, to examine the changes in levels of aggression, delinquency and the three domains of resilience in middle school adolescents who participated in a relationship-focused intervention compared to those who did not participate. Second, to determine adolescents' perception of school safety, (how safe they felt at school and how much power they perceived they had to influence or change their school environment). A total of 164 middle school students met all study requirements which included completing both a pre-test and post-test. The relationship-focused intervention took place at two inner city middle schools located in a city enhanced enterprise zone. For a twelve-week period, students met with a program facilitator during one hour weekly classroom instruction sessions and two hours weekly outdoor/field activities. The relationship-focused intervention used a recently developed curriculum-based program for which the investigator served as lead writer. The study used a theoretical framework of resilience that links social learning and attachment theories. This framework illustrated that resilience can be strengthened in adolescents when they model the prosocial behaviors of an attached figure and are positively reinforced. The study used a quasi-experimental, pre-test/post-test comparison design with experimental and comparison groups. The resilience domains were measured using the Individual Protective Factor Index (IPFI): Social Bonding, (school, family, pro-social norms), Personal Competencies (self-concept, self-control, self-efficacy, and positive outlook) and Social Competencies (assertiveness, confidence and cooperation). Aggression and delinquency were measured using syndrome scales from the Youth Self Report (YSR). For hypotheses testing, repeated-

measures Multivariate Analysis (MANOVA/MANCOVA) procedures were conducted. Three qualitative questions were used to obtain adolescents' perceptions about their safety in school and their power to make a difference in their school environment. The results of the program found that mean scores were moving toward changes in levels of behavior for those who participated in the relationship-focused intervention. Qualitative data showed differences in adolescents' attitudes and intended behaviors after participating in the intervention. The investigator concludes that the relationship-focused intervention was promising but needed continuous rigorous evaluation including testing of a methodology of a post to pre-test comparison design with adolescents. N2 - This study focused on the potential contribution of individual variations in children's motor functions to individual differences in social participation and play behavior. The study further examined whether the interaction of social behavior with peers and children's motor abilities was related to the occurrence of behavior problems. Indoors and outdoors play behavior patterns of 88 kindergarten children (53 girls) were observed, and a battery of standard assessments of basic motor functions was administered. Maternal reports on children's behavior problems were collected. The findings indicate modest but significant associations between typically developed children's play behavior and various domains of motor functioning. High frequency of social play was associated with better motor planning and execution, posture control, and visual-motor coordination. In contrast, high frequencies of solitary behavior were associated with poor motor function. The combinations of high frequency of social play or low frequency of solitary behavior and high motor ability appear to serve as a protective factor that reduces child behavior problems. It is concluded that motor functions appear to play a significant role in children's social adaptation. Possible links between motor functions, their underlying brain's structures, and the extant neurobehavioral models of social withdrawal are discussed. VL - 64:

IS - 12-B

N2 - This study assessed the play performance of 37 boys with autism and 42 boys without disabilities, aged 3 to 5 years, in Taiwan. Play performance was determined from videotaped observation of boys playing in the naturalistic environment, and rated using the standardized instrument of the Revised Knox Preschool Play Scale (PPS). Results indicated that the autistic boys scored significantly lower than the normal boys on PPS and its four dimensions. Analyses demonstrated a significantly higher correlation between the PPS age scores and the chronological age in the normal boys than in the autistic boys. Discriminant analyses revealed that the age scores from PPS and its dimension of Space Management, Pretense/Symbolic, and Participation, each correctly classified the subjects into their actual groups with a high degree of precision (i.e., the classification rate ranged from .84 to .98). The score from Material Management dimension only correctly classified 67% of the subjects. The Chinese Version of Peabody Picture Vocabulary Test-Revised (PPVT-R) was administered to estimate subjects' cognitive capability. Of 37 subjects with autism, only 15 subjects completed the test independently with a score over 70. An additional statistic was applied to compare the performance of this subgroup of autistic boys with their normal peers. Analysis indicated that this subgroup of autistic boys scored significantly lower on PPS and three of its four dimensions (Material Management, Pretense/Symbolic, and Participation) than their normal peers did. However, caution should be given to the interpretation of these results since the cognitive functioning (as measured by PPVT-R) was significantly lower in this subgroup of autistic boys, as compared to the normal controls. This study broadened understanding of play performance in the Taiwanese population and was informative of the potential play deficiencies that may help explain a wide range of the impairments associated with autism. It also raised a number of concerns that demand future investigation. Some comments regarding the implication of the findings and the application of PPS in the Taiwanese population were directed to Taiwanese practitioners. N2 - The study examined the effects of caring adults, religiosity, and resiliency on African American middle school girls' self-concept, school attachment, and participation in out-of-school time programs. The study was conducted in two phases. In Phase I, African American girls (n = 130), grades 6-8, who resided in Columbus, Ohio, were asked to complete a survey to obtain data on the specific variables of interest. A sample of the girls reported on the survey that they participated in out-of-school time (OST) programs took part in a series of focus groups (Phase II). The focus groups were done to gather in-depth information regarding girls' perceptions of the role of OST activities on their development. Overall, the girls in this study had moderated to fairly high levels of self-concept, school attachment, and resiliency. They also perceived that there were caring adults (other than parents) in their lives. The overwhelming majority of girls reported involvement in at least two OST activities. A positive correlation emerged between girls' resiliency and religiosity. The girls' scores on the school attachment and self-concept measures were positively correlated. MANOVA analyses revealed that African American girls who had higher levels of caring adults in their lives (e.g., the degree of nurturing relationships with adults outside of their parents) and resiliency scores had significantly higher self-concept and school attachment scores than girls who had significantly lower caring adults and resiliency scores. Girls who reported higher levels of religiosity had significantly higher self-concept scores than girls who reported lower levels of religiosity. However, there was no difference for reported levels of religiosity on school-attachment scores. Regression analyses found that girls' levels of caring adults and religiosity accounted for a significant amount of the variance in their self-concept scores. Results also showed that girls' levels of caring adults and resiliency accounted for a significant amount of the variance in their school attachment scores. However, caring adults, resiliency, and religiosity did not account for a significant amount of the variance in the number of OST programs. The results from the qualitative portion of the study supplemented the findings from the Phase I examination. In particular, reports from the various focus groups indicated that the majority of the girls perceived that participation in OST activities has an influence on various aspects of their development (e.g., anger management and academic achievement). Participation in OST activities also provided the girls with a set of caring adults other than parents who provided guidance and support to them. N2 - This study utilized a mediation/moderation mixed model to examine the direct and indirect links between marital conflict and children's asocial and excluded behaviors as rated by teachers. The ecological validity of this study was enhanced by using independent raters of children's behavior and direct observations of parenting behavior. The participants (n = 72) in this study were a combination of families with substantiated cases of

physical abuse that were referred by a state human services agency and families recruited from the community. Participating children had a mean age of 7.3 years and ranged between 4 and 9 years old. To determine direct effects, marital conflict was assessed using a modified version of the Conflict Tactics Scales. Children's social behaviors were measured by two subscales on the Social Behavior Scale. To calculate indirect effects mediated through parenting behavior, parents and children participated in three 10-minute vignettes that were videotaped and coded. Overall, results supported a direct effects model in which marital conflict predicted 5% of the variance in children's asocial behavior. Asocial behaviors in the classroom were also significantly associated with peer rejection and low engagement on the playground. Although moderation of the relation between marital conflict and the three parenting behavior domains by parental anxiety, depression, and stress was not supported, substantial support was found for the negative impact of parent psychopathology and stress had on parenting behavior. Prevention/intervention efforts for children and parents using a family systems perspective were emphasized. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of this paper is to investigate current developments and controversies in the assessment of early childhood social skill, and to explore an alternative approach, focusing on the "practical utility" of assessment. The paper begins with an introduction to assessment of preschool social skill development; a review of the situational specificity debate in personality assessment and its implications for early childhood social skill assessment; a presentation of General Outcome Measurement (G.O.M.) as an alternative assessment approach; and a discussion of needed research to create a practical and useful general outcome measure of preschool social skill development. A standard of utility is emphasized as an important approach to developing an assessment tool. Three major issues are identified, facing the further development of social turns as a general outcome measure of early childhood social interaction: (1) The effect of situational variation in the data collection format on G.O.M. of social interaction skill; (2) The effect of situational variation on the validity of G.O.M.; and (3) The need to determine factors outside of the child that can account for variance in a G.O.M. Thirty-five children between the ages of 40 and 66 months participated in the study, 19 males and 16 females. Participants were predominantly from families with middle to high SES, and the ethnicity of participants was predominantly White, with 2 Asian-American and 2 African-American participants. Three children in the study were receiving special education services under an Individualized Education Plan (IEP), with social/behavior goals on their IEP. Participants played in dyadic play situations, with one of two specific toys and either a familiar or unfamiliar playmate. A repeated-measures design was used, in which all target children played in all four possible situations. Results indicate that setting has a significant effect on G.O.M. of preschooler's social skills, and must be accounted for in developing a practical measure. In addition, a significant portion of the measure's variance can be accounted for by the behavior of the peer, namely, the number of times the peer attempted to

initiate social interaction. Implications for implementing general outcome measurement of social interaction skill are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Clinical assessment of executive function in preschool-age children is challenging given limited availability of standardized tasks and preschoolers' variable ability to participate in lengthy formal evaluation procedures. Given the benefits of ecological validity of measuring behavior by rating scales, the Behavior Rating Inventory of Executive Function (Gioia, Isquith, Guy, & Kenworthy, 2000) was modified for use with children ages 2 through 5 years to assess executive functions in an everyday context. The scale development process, based on samples of 460 parents and 302 teachers, yielded a single 63-item measure with 5 related, but nonoverlapping, scales, with good internal consistency and temporal stability. Exploratory factor analyses identified 3 consistent factors: Emergent Metacognition, Flexibility, and Inhibitory Self-Control across parent and teacher samples. In a second study with a mixed sample of preschool children with various developmental disorders, parents and teachers rated these preschool children as having greater executive difficulties in most domains than matched controls. Such rating-scale methodology may be a useful complementary tool by which to reliably assess executive functions in preschool children via everyday behaviors in the natural environment. N2 - The influence of older peers on younger children's emerging symbolic play was examined for 24 young children in eight participating long-day child-care centres. Toddler participants (aged from 17 to 31 months) were observed and video-taped in three conditions in free play in the outdoor environment as follows: condition one, with their same-age peers; condition two, with their older, preschool-aged peers; and condition three, in a dyad situation with a familiar often 'self-chosen' preschool-aged peer. Fourteen of the participants were first-borns and 10 were later-borns. The toddlers' symbolic play was coded in the four dimensions of symbolic play ('decontextualization', 'thematic content', 'organization of themes', and 'self-other relationships') in accordance with Westby's (1991) 'Symbolic play scale'. First-born participants exhibited higher levels of symbolic play in all four dimensions as identified by Westby (1991) in mixed-age free play sessions. Additionally, in mixed-age free play, first-borns scored significantly higher in three dimensions in the most frequently occurring levels of symbolic play than did later-born participants. N2 - Surveys show that many young people do not engage in the recommended levels of physical activity, nor do they have diets meeting the US Dietary Guidelines. These health behaviors contribute to obesity, now at an

all-time high among adolescents. With this in mind, we developed "EatFit" to improve the dietary and physical activity behaviors of middle school students. The physical activity assessment has students examine their current fitness activity behaviors and guides them through goal setting and contracting. Each week, students track their eating and fitness goal progress. Many skill-building activities are included in the EatFit curriculum. Recipe preparation and tasting provide students with the opportunity to increase their self-efficacy for choosing and preparing foods that support their nutrition goal. Among the fitness lessons, activities are included that allow students to practice physical activity skills (eg, leg lunges, stretches). Practicing the skills in the classroom will increase students' self-efficacy so that they will be more likely to perform the physical activities outside the classroom. This education intervention was pilot tested with 34 middle school students who were Expanded Food and Nutrition Education Program (EFNEP) participants. Data from self-reported recall instruments indicated that students made positive changes in dietary behaviors (41%), dietary self-efficacy (29%), physical activity behaviors (56%), and physical activity self-efficacy (26%). Seventy-four percent and 79% of the students rated themselves as making one lasting improvement in their dietary and physical activity behaviors, respectively. N2 - To increase preschoolers' science and mathematics learning experiences both within and outside the classroom, we developed age-appropriate materials containing general questions and instructions that teachers and parents could use when interacting with their students and children. The questions and instructions were related to a specific science or mathematics skill (e.g., classifying), but were general enough so that they could be applied to a variety of situations. Observations of three classrooms and interviews with the classroom teachers and aides, and the parents of the children in the classrooms suggested that use of these materials was beneficial to the children, teachers, and parents, and resulted in increasing the amount of science and mathematics activities and discussions in two of the classrooms as well as outside the classrooms. N2 - Research suggests that the relationship between school bullying and its various risk factors should be clearer among girls than boys, and should become stronger with age, as roles within the peer group stabilise. This paper tests this theory by comparing sex, school type, and bully /victim status differences in friendships and playground social interactions, using data from nine surveys in seven countries: China, England, Ireland, Italy, Japan, Portugal, and Spain. A total of approximately 48,000 children completed various translations of the Olweus Bullying Questionnaire. Small but generally consistent main effects were found for sex and school type (boys and primary pupils enjoyed playtimes more and had more friends, but were also more likely to spend playtimes alone). Larger effects were consistently found for bully/victim status (victims were significantly worse off on all the measures in all the samples where a difference was found, while bullies and neutrals did not differ consistently), but the interactions between these factors varied widely between samples and there were few consistent patterns. It is concluded that bullying is a universal phenomenon with many negative correlates for victims and few (if any) for bullies, but that there are cultural variations in the... N2 - In this study we described development of boys' and girls' games on the school playground at recess as they progressed across the first year of primary school in London (UK) and Minneapolis (USA) in order to document age-related trends in games during this period and to examine the predictive role of games in children's adjustment to school and more general social adjustment. Consistent with expectations, games accounted for a significant portion of children's, but especially boys', behavior during recess. American children played games more frequently, especially simple games, relative to English children. Consistent with expectation, the complexity of games increased, especially for boys, across the school year for children in both countries. We also examined the extent to which facility with games forecasted adjustment to school and social adjustment. Games predicted both, but only in the USA sample. Results are discussed in terms of games being an important developmental task for children of this age. Implications for future research and educational policy are discussed. N2 - Given the prevalence of and growing concern about school violence perpetuated by bullies on school playgrounds, the need for progressive state-of-the-art interventions that promote the psychosocial development of children who are most susceptible to school violence during the school day must be acknowledged. The most vulnerable time for many children is during recess on the school playground. Programs during recess hold great potential for promoting positive playground and school experiences among children. The study discussed in this article builds on two studies that explored the effect of a social skills intervention on problem behaviors displayed by elementary school children during recess. Findings conclude that social skills intervention significantly decreased problem behaviors among school children at recess. Implications for behavioral management and healthy school environments are explored. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study examined the relationship between children's developing theory of mind and their ability to engage in two social behaviors which have, as their cognitive underpinning, the representation that what one knows may not be accessible to others. Children of 3, 4, and 5 years, in a quasi-naturalistic setting, played hide-and-seeK and also were required to keep a secret about a surprise. The ability to play hide-and-seeK was significantly related to children's ability to refrain from disclosing the secret, and there was a significant relationship between these behaviors and children's social cognition, as measured by theory of mind tasks. The relationship between these social behaviors and tasks measuring executive function was not significant once age was taken into account. With regard to the development of these social behaviors, few 3- year-olds, but most 4- year-olds, and almost all 5-year-olds could successfully play hide-and-seeK and keep a secret. This study demonstrates the importance of the conceptual understanding of mental states in the young child's social world. N2 - We investigated the influence of age, sex and familiarity on spatial performance assessed with a pointing task in 84 children: 21 kindergartners, 21 first-graders, 21 fifth-graders and 21 sixth-graders. Spatial performance was assessed in the children's natural environment, their respective school or kindergarten. The children had to indicate the direction of prominent landmarks on the school campus while sitting in their classroom, drawing an arrow on a sheet of paper. Since the children had spent different amounts of time at their respective schools, experience with the environment was regarded as a covariate. Data analysis revealed significant effects for age, sex and experience. Fifth-graders aged around 10 years outperformed the younger children. Sex differences revealed male superiority at all ages. Experience with the environment was also shown to play a vital role. Children who had spent a longer time at the school were able to demonstrate better spatial knowledge by pointing more accurately towards unseen landmarks. N2 - The purpose of this study was to examine parenting practices associated with adolescent free time use. Interviews (n = 17) were conducted with parents of adolescents (12-14 years) in two communities. Eight were from a university-based community in the northern U.S., and nine were recruited from rural communities outside a large metropolitan center in Eastern Canada. The parents in this study used a number of practices to structure, regulate and support their adolescents' behavior in the free time domain. These practices extended from: (a) parents' beliefs and expectations of the free time context, (b) the ways in which parents communicated and enforced these beliefs and expectations, (c) parents' actions to direct their adolescents' activity engagement, (d) strategies used to monitor the adolescents' activities, (e) the provision of resources to support preferred activity engagement, and (f) parents' efforts to support autonomous behavior in die free time context. The results are discussed in terms of extant literature on parental structuring and support of adolescents' free time behavior and leisure interests. N2 - The purpose of this study was to investigate the daily activities that young South African children perceived as health related activities. The sample included 117 children (33, ages 5-7 years; 44, ages 8-10 years; and 40, ages 11-12 years) chosen by two-stage cluster sampling in a rural community of the central region of the Northern Province. Results indicated that the most important health actions around healthy eating were, 'washing hands'; around dressing, 'wearing warm clothes'; around keeping clean, 'washing body and hair'; going to sleep, 'washing body'; activity at school, 'read and write'; recess and leisure time, 'playing football or netball'. Personal hygiene (washing, brushing teeth, etc.) was the most common health action of the children around healthy eating, keeping clean and going to sleep. Some health actions were insufficiently mentioned, brushing teeth for example and some wrongly mentioned such as eating porridge before going to sleep. This study showed that children have insufficient knowledge and understanding about health related activities. Results suggest that health professionals and teachers should consider providing more information about health related activities for young children. N2 - This study examined strategies teachers reported using to support friendships among young children in inclusive early childhood classrooms. The teachers included 25 general early childhood educators from 9 child care centers and 20 early childhood special educators from 9 specialized programs. The Playmates and Friends Questionnaire for Teachers documented the number and nature of children's friendships and teachers' reported use of 11 different strategies to support individual friendships. Overall, the friendship strategies that teachers reported using most frequently included providing sufficient free choice time, allowing children to form their own friendships, and commenting on the play between friends. The majority of teachers reported rarely using two strategies: arranging for children to play together outside of the classroom and allowing two friends to exclude other children from their play. Teachers reported using more active friendship strategies to support dyads in which one or both children had special needs. Implications of these findings to support friendship formation in inclusive early childhood settings and directions for future research are presented. N2 - The study explored the effects of ability (i.e., learning disabled [LD] versus nonlearning disabled [NLD]) and sex (i.e., male/female) on children's peer acceptance ratings and friendships when working in groups with cooperative learning goals. Methodological concerns in measuring peer acceptance and friendship were also explored. Finally, the correlation between students' peer acceptance/rejection ratings and their frequency of solitary lunchtime interactions and solitary outside play was investigated. Sixty fifth graders from two New York State school districts that used student work groups with cooperative goals for instruction participated in the study. Thirty LD (15 girls and 15 boys) and thirty NLD (15 girls and 15 boys) students assigned to typically achieving, inclusion classrooms were asked to list who they liked most and liked least in their classroom. On a scale of 1-5, students were also asked to rate how much they liked to play with their classmates on the playground. To assess the correlation between students' peer acceptance/rejection rates and their frequency of solitary behavior, children's unstructured social interaction time at lunch and recess was recorded. The results showed that contrary to expectations, there were no significant differences between LD and NLD children's peer acceptance/rejection scores. However, when LD girls and boys were directly compared, NLD children preferred LD boys to LD girls. Apart from ability, peer acceptance varied by sex. Moreover, regardless of sex, LD children engaged in significantly higher instances of solitary lunchtime and outside play behavior. No correlation between sociometric scales and frequency of solitary lunchtime interactions or solitary play was noted. These results are discussed in terms of their implications for future research and educational practice. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The present study investigated relations amongst parental emotion processes, family risk status, and emotion biases in children. Participants included 94 mothers, 39 fathers, and their children between 3-6 years of age (41 girls, 53 boys; M age = 4 years, 4 months) from diverse socio-economic backgrounds. Eighty-three families were followed up one year later. Parental appraisal styles were assessed via a naturalistic story-reading and explanation method, and maternal anger response and emotion regulation were measured by semi-structured interview and self-report questionnaire, respectively. Children's Time 1 and Time 2 emotion biases included teacher and mother ratings of emotion, peer ratings of emotion, as well as classroom and playground observations of emotion. Mothers using a disproportionate number of hostile appraisals over prosocial

appraisals when speaking with children was associated with children's sad/fearful biases at school. Responding angrily to their children's negative emotions was associated with both anger and sad/fearful biases at school. On bivariate correlation, paternal hostile appraisal styles were associated with children's sad/fearful biases at home. As predicted, mothers in high-risk families utilized fewer prosocial appraisals than low-risk mothers when explaining events to their children, and they tended to use a higher level of hostile appraisals than mothers in low-risk families. Similar patterns were found for fathers' hostile appraisals. Mothers in the high-risk group also demonstrated significantly more angry responses and less emotion regulation to their children's sadness than mothers in the low-risk group. Finally, longitudinal analyses showed a strong continuity of children emotion biases over a one year period, particularly with regard to anger biases. Maternal anger responses and emotion regulation at Time 1 had no predictive effect on a change in children's emotion biases over time; however, a hostile balance of maternal appraisals was found to predict change in children's anger biases in the home and school, with different effects in high- and low-risk families. These findings and future directions are discussed in the context of current theoretical, empirical, and clinical work. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Integration of children with disabilities into mainstream settings has become increasingly common in recent years. Research into interventions to enhance the success of such efforts have primarily focused on interventions after the child with a disability has been introduced. One area of intervention that has been relatively neglected in the literature is that of intervention before the child enters the classroom. In a computer analog study, Esteban and Romanczyk (2000) investigated the influence of various types of prior information on typical peers' willingness to interact with a novel peer. Their results showed that combining information about similarities with information about characteristics of disability was superior to simply providing information about the aspects of disability alone. In addition to the focus on intervention prior to meeting a novel peer, Esteban and Romanczyk (2000) used the pervasive developmental disorders (PDDs) as the model for the disability information, in contrast to most other studies of attitudes toward disability that have focused primarily on physical disabilities or mental retardation. The current study was conducted as an extension of that research to a quasi-naturalistic setting. Seventy-eight third- and fourth-grade boys participated. After being given information about one of four boys with PDD, each participant then interacted with that child for two 5 minute segments. One segment consisted of a structured puzzle activity, while the other was unstructured. After each segment, the participant completed a questionnaire regarding the segment, which included six behavioral intentions questions. At the end of the session, the participant was given the choice of playing with the other child or playing alone. Social behaviors displayed by both children were measured. The effect of information was not replicated for most outcome measures. A main effect of activity type was found for many measures such that the unstructured activity was superior to the structured activity, contrary to hypotheses. Possible explanations of these unexpected findings are discussed. In addition, exploratory analyses regarding the effects

of specific behaviors displayed by the children with PDD and the correspondence between self-report and actual behavior were conducted and are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Psychologists who have studied the development of racial attitudes have offered support for the sociocognitive theory of Aboud (1988). For example, children's reports of own-group preferences have been found to decline around age 7 (Doyle & Aboud, 1995), which has been associated with the attainment of conservation skills and increased cognitive flexibility in these children. The present study sought to explore how participants' racial attitudes were related to their attribution of traits to characters in a story. In addition, the relationship between racial attitudes and children's willingness to forgive an antagonist was explored. Forty-seven Caucasian participants between the ages of 7 and 10 years participated in this study. All were found to score predominately in the nonstereotyped category of the modified Preschool Racial Attitude Measure-II (PRAM-II) (Bigler & Liben, 1993). Children were asked to rate a narrative describing an interaction between two children, one an antagonist and the other a victim in a playground incident. Participants were systematically assigned to one of two experimental conditions. In one condition, the antagonist was Caucasian and the victim was African American. In the other, the antagonist was African American and the victim was Caucasian. Children then completed the vignette PRAM-II and the Enright Forgiveness Inventory for Children-Revised (EFIC-R). Results revealed no significant differences between the two experimental conditions on either measure. Based on the results of previous studies (Bigler & Liben, 1993; Doyle, Beaudet, & Aboud, 1988), greater variability was anticipated in the children's responses on the modified PRAM-II. Possible reasons (e.g., geographical differences, developmental age, transparency of the measure) are provided to account for the limited range of scores obtained in the present study. Accordingly, recommendations are given for future research on the development of racial attitudes in children. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Antisocial behavior is defined as "recurrent violations of socially prescribed patterns of behavior" (Simcha-Fagan, Langner, Gersten, & Eisenberg, 1975, p. 7). The purpose of the current study was to investigate the effects of home- and school-based interventions for students with an at-risk for antisocial patterns of behavior. Prospective participants were identified using a modified multiple-gating screening procedure (Walker & Severson, 1990), wherein three consenting Kindergarten and first grade teachers nominated students whose behavior pattern most closely matched an operationalized definition of antisocial behavior. Thereafter, students were screened for eligibility using parent- and teacher-rated social behaviors. Finally, students were required to demonstrate at least average intellectual ability. Three Kindergarten and two first grade students met criteria for inclusion in the study and received home and school-based interventions. Two intervention sequences were utilized based upon the First Steps to Intervention program designed by Walker and colleagues (Walker, Stiller, Golly, Kavanagh, Severson, & Feil, 1997) using a multiple baseline-multiple sequence design (Noell & Gresham, 2001). Pre- and post-test ratings were obtained on the Social Skills Rating System (SSRS; Gresham & Elliott, 1990) and Critical Events Index (CEI; Walker & Severson, 1990). Observations were conducted across four behaviors: total disruptive behavior, academic engaged time, negative social interaction, and solitary play during recess. Results showed that both home and school interventions resulted in high effect sizes and that larger decreases in disruptive behavior were demonstrated from baseline to phase one intervention than from phase one to phase two intervention. Collateral effects on academic engaged time were demonstrated for all participants across phases. Optimal treatment sequences were noted for disruptive behavior and academic engaged time but were confounded by order effects. Independent ratings conducted by two behavior analysts showed low-to-moderate interrater agreement. Moreover, ratings based on interocular inspection showed little correspondence to standardized difference effect sizes. Additional results regarding the interventions' effect on unstructured play behavior are presented and discussed, along with study strengths, weaknesses, and implications for future research. N2 - While research has confirmed a negative relationship between adult depression and physical activity, there is little evidence for children. This study examined the relationship of being classified as physically active or inactive by a parent or a teacher to depressive symptoms in children 8 to 12 years of age (N= 933). It also assessed the relationship of playing sports outside of school, and of meeting health related fitness standards, to symptoms of depression. Relative risk of depressive symptoms for inactive classification was 2.8 to 3.4 times higher than it was for active, 1.3 to 2.4 times higher for children not playing sports outside of school, and 1.5 to 4.0 times higher for those not meeting health related fitness goals. N2 - This short-term longitudinal study examined activities at recess and peer relations. We were interested in changes over the school year, and the sex and ethnic mix of groups. Data came from systematic observations of 129 pupils (61 boys and 68 girls) aged 7-8 years. Results showed that peer interaction dominated recess. Ball games increased over the year, and chasing games decreased. Aggression was most common during vigorous play and conversation, but not ball games. Cleavage in boys' and girls' play and activity was common but not inevitable. Mixed-sex play was not supported by particular game types. Boys' game networks were larger than those of girls but there were no sex differences in active networks. There was little ethnic group segregation on playgrounds, and games became more integrated with time. The results indicate that playground activities can have a positive role in social relations between different ethnic groups. N2 - The physical-spatial aspects of environments and their relation to subjectivity and human behavior have been increasingly studied by psychologists. Thus, this study investigated the relationship between playgrounds of two public preschools of Porto Alegre and the interaction of 50 5 to 6 year-old children who were enrolled in these schools. Children were observed at the playgrounds, which presented differences in terms of area (size), density and materials. The interaction states observed were related to types of play and toys used. Results drawn from quantitative analyses showed that children established more associative and parallel interaction states in the large playground, and unoccupied and solitary in the small playground. As for the type of toy, the association of this aspect with the interaction in the large playground was smaller than in the small one. A higher association between interactions and types of play in the small playground was found. The study shows that concerning environmental aspects the large playground favors a variety of interactions states. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study assessed the effects of Friendship Circles on the social interactions between students with mild disabilities and their nondisabled peers. A multiple probe design was used to analyze the social interactions during lunch. Data also were collected in the form of sociograms and anecdotal records. In addition, generalization was assessed during recess observations. Results indicated that the Friendship Circle intervention produced increases in appropriate interactions at lunch for all three students and for two there were increases in friendly play at recess. Anecdotal data suggested improved social interactions for two of the students throughout the day and improved social behaviors in the general education classroom such as cooperation during group activities. Implications for future research are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - This study examined connections between teacher-child interaction and children's perceptions of self and peers. 47 predominately white, middle-class preschoolers (27 boys, twenty girls; 40 European-American, 2 Hispanic, 2 African-American, 3 Asian) were observed during indoor and outdoor activity at their preschool over a period of four months. Children's time spent interacting with teachers, as well as children's cooperative behavior, emotional expressions, and aggression toward teachers was assessed. In addition, children participated in interviews designed to assess their self-perceptions and perceptions of peers. Results revealed that girls spent more time interacting with teachers than boys, and had more cooperative and positive interactions with teachers than did boys. Correlation analyses indicated that the quality of teacher-child interaction was differentially linked to boys' and girls' self-perceptions and perceptions of peers. The implications of interactions between teacher and child for children's cognitions about self and others are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study examined the effectiveness of social skills instruction for seven elementary-age students (aged 8.05 yrs-9.74 yrs) at risk for antisocial behavior who were unresponsive to a schoolwide primary intervention program. Students received instruction in social skills in a small-group setting over a 10-week period. A comprehensive list of acquisition deficits was generated for each student using an empirically validated assessment tool. These acquisition deficits became the core content of each intervention group. Results revealed lasting decreases in both disruptive behaviors in the classroom and negative social interactions on the playground. Students also experienced increases in percentage of academic engaged time. Findings from a social validity measure indicated that students viewed the intervention procedures as acceptable and reportedly used the newly acquired skills in multiple settings. Limitations are discussed, and directions for future research are provided. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study examined the psychosocial adjustment of preadolescents with spina bifida in relation to a comparison sample of able-bodied preadolescents (8- and 9-year-olds; n = 68 in each sample). The study also examined the potential clinical utility of a narrowband multimethod, multi-informant, and multidimensional perspective on the assessment of psychosocial functioning in children and adolescents with pediatric conditions. Findings revealed that children with spina bifida tended to be socially immature and passive, less likely to have social contacts outside of school, more dependent on adults for guidance, less competent scholastically, less physically active, less likely to make independent decisions, and more likely to exhibit attention and concentration difficulties. No group differences were found for externalizing symptoms, affective functioning, or global self-worth, suggesting resilience in these domains for the spina bifida sample. Findings also suggest that low socioeconomic status and the presence of a physical disability may be additive risk factors for certain psychosocial adjustment difficulties. N2 - (create) Studied how middle school students spend time during recess. Of specific interest was how adolescents interact, how much of the playground behavior can be considered physically active, to what extent recess behaviors can be considered "play," and how much negative behavior occurred. These questions were explored by systematically observing the play area during recess. A secondary interest emerged while conducting the observational research: Why do some students not go out for recess? How do students view recess, and what suggestions do they have for improving it? These questions were explored through a student survey. Findings suggest that recess provides valuable opportunities for students to interact with their peers, engage in physical activity, and play games. The observational coding system and the quick count used can be employed by other researchers, teachers, or parents to gather data on what behaviors occur during recess. This study suggests that recess is important to students and allows for play and other social behaviors that would not occur in structured physical education classes. Any school system considering the substitution of physical education for recess should learn what actually occurs during recess and consult with students before making a decision. N2 - Pauses and silence in family conversation has been investigated as a process implied in children's development and socialization. We grounded our study on the international literature about discourse's uses in natural settings. Nine hours of videotaped recordings of 6 dinners of 3 different families, consisting of father, mother, young child (3-4 years) and an older child, have been systematically observed in two different periods (8 months between the two measurements). Results have been analysed with log-linear and show that: 1) in the management of pauses there are shared rules and also a variability between families; 2) the person who speaks before the pause is usually the same one speaking after it (self-transition); however when the other-transition is taken into consideration, the patterns of association between familiar roles can be understood with a developmental explanation; 3) few differences and more similarities are identified among the two different periods. Overall results are discussed from the perspective of the role played by pause management within the family system at dinner table. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The objective of this research was to describe how a group of mothers of pre-school children spend their days in relation to the index pre-school child and in general. We examined time use by means of the Yesterday's interview for Mothers of Pre-schoolers (YIMP), a semi-structured interview, with 31 mothers recruited from mother and toddler groups. Detailed time budgets were obtained on three full days covering the content, duration and environmental context of mother-child joint activities. Reading was the most common joint activity. A substantial proportion of activities took place outside the home. Research implications in relation to the environmental context of joint activities are discussed. N2 - (from the chapter) Middle childhood is a time of considerable change in children's social competencies and interpersonal relationships. Descriptions of the salient features of this developmental period highlight an expansion of the social world as children spend increasing amounts of time outside their homes, away from their families, at school, with peers, and in extracurricular activities. Learning to interact effectively in these new and diverse social settings is at the core of social development in middle childhood. Building on conceptual models that emphasize adaptation to interpersonal and setting demands as fundamental to social behavior and social competence, in this chapter the authors describe the nature of and influences on social development between ages 6 and 12 yrs. N2 - The present study investigated physical activity trends among young children aged three, four, and five years old in Hong Kong preschools using pedometry. Subjects were 86 boys and 62 girls. The Digi-walker sw-200 electronic pedometers were utilized to collect activity data during daily regular physical activities in three preschools. School A was located in a rural area, whereas Schools B and C were in urban areas. An observation inventory. Children Activity Rating's Scale (CARS), was used to categorize the intensity level of the physical activities and to validate the pedometer counts. In line with overseas studies, significant age and gender differences in physical activity levels were also observed among the Hong Kong preschool children. A two (gender) x three (age groups) analysis of variance indicated that both main effects were statistically significant.

Older children in the school (School A) with a larger outdoor play space, in a rural district, were much more active than their counterparts in urban schools (Schools B and C) with limited indoor play space. The pedometer counts correlated significantly with the CARS scores, which suggested that pedometry can be a reliable tool to measure the intensity of physical activity level of preschool children. N2 - This study presents data collected from a nationally-representative sample of teachers of first through fifth graders. Teachers completed a time diary, recording exact beginning and ending times for all the target student's school activities for a randomly selected day. We examined students' total time in school and their activities while there. Students attending school for the longest day were significantly more likely to be White and have fewer special needs, and to have smaller classes with a larger percentage of White students and a smaller percentage of students of other races than students attending for less time daily. We grouped students' activities at school into four categories that accounted for all but 9 minutes of the school day: academic, enrichment, recess, and maintenance activities. We found variations in how students spent their time based on student, family, and classroom characteristics. Teachers of African American students reported spending more time on academic subjects, and less time on enrichment and recess activities than teachers of white students. The same pattern emerged for teachers of more advantaged students, and classrooms with a larger percentage of White students. Results are discussed in terms of school reform efforts and inequality issues. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Boston, like many other major cities, experienced a sudden increase in youth homicides during the late 1980s and early 1990s. Research evidence suggests that the epidemic of urban youth violence was intensely concentrated among criminally active young Black males residing in disadvantaged urban neighborhoods rather than all young Black males residing in disadvantaged Black neighborhoods. Other researchers, however, suggest that there was a diffusion of guns and gun violence from youth involved in street crack markets to youth outside the drug trade who armed themselves primarily for self-protection against the armed criminally active youth. In this paper, criminal history data are analyzed to determine whether the criminal profile of Boston arrested youth gun offenders (aged 12-24 yrs) changed over time and micro-level data on youth gun assault incidents in Boston are examined to unravel whether there were noteworthy changes in the nature of these violent events over time. The results of these analyses suggest that the youth violence epidemic in Boston was highly concentrated among serious youth gun offenders rather than a diffusion of guns away from the street drug trade, gangs, and criminally active youth. N2 - Background: Individuals with brain injury are prone to severe behavior problems related to various postinjury variables, including confusion, emotional distress, fear of challenging activity, and loss of skills to access desired outcomes. Objectives: This article proposes the use of a new model, errorless rehabilitation, to improve rehabilitation outcomes by systematically focusing on graduated and success-based exposure of clients with brain injury to increasingly demanding circumstances, to provide them with the ability to tolerate and manage the natural environment. Main Outcome Measures: Research on difficulties parents with brain injury experience with their children is subsequently reviewed and a new approach (based on the same principles as Errorless Rehabilitation) to treatment of parent-child relationship issues after brain injury is described.

Conclusions: A case study of a father with brain injury and his oppositional son is presented to demonstrate a specific application of this model for enhancing the quality of life of parents with such impairments. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) The author shows that children's design preferences for neighbourhoods are related to their degree of independent mobility and how they evaluate their environment. Analyses point to differences concerning the interaction with the physical environment and social aspects of the neighbourhood environment, in terms of affordances and individual evaluations. In the first study 732 children (8 and 11 years old) in 9 schools filled in questionnaires concerning, for example, how they had come to school on that particular day, how they used to travel to activities after school, if they were allowed to visit friends and go out and play without being followed by any adults. The children also made drawings showing their way to school. The aim of the second, qualitative study was to get a deeper understanding of differences that were found in the first study, but also the meaning of the neighbourhood's planning and characteristics related to children's independent mobility. Traffic-separated areas seem to be very positive for children's independent mobility, but they are not enough if you want the neighbourhood to be stimulating, developing and safe. There is more to it. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - What stories do young children's drawings contain? So often children's free drawings are not held in high regard but are seen as an activity which is undertaken outside lesson time or as an illustration to some prescribed task. However, the concentration and care with which some children undertake a drawing suggests that the content has real significance and has not been undertaken lightly. This small-scale study arose from observations in a school setting of young children talking to themselves as they drew pictures. Often it seemed that this talk was a rehearsal for the drawing and it was this link that the project set out to explore. Children aged from 3 to 7 years were studied in their classrooms where they were participating in a free choice of activities. This paper examines the drawings collected together with transcriptions of the children's descriptions of their drawings. It looks at the symbolism contained within the pictures and the stories woven within each one. The study is intended as a pilot for a longitudinal research project focusing not only on children's drawings and accompanying narrative but extending to an exploration of emergent writing. N2 - (from the introduction) This book is a collection of accounts of what children do after school, both outside and inside (especially inside) after-school centers. Centers are affiliated with communities, and because different communities have different values, different ways of doing things, centers differ. Readers will encounter centers in public schools, in libraries, and in labs. They'll find them in a small town, in small cities near large universities, and in big cities. They'll read about one cluster of centers that began in an urban setting but migrated to other communities, both in the United States and elsewhere. Readers will encounter academic and nonacademic centers, centers for young children and for older children, centers that provide activities for 5 children at a time and for 50. They'll see that some centers, like Baldwin's, are technology-oriented, whereas others emphasize reading, writing, or science activities. They'll note that some large multicenter programs have large multiyear grants, whereas some small operations just get by. In reading the accounts, readers will notice that the centers described by contributing authors, varied though they might be, have informality in common. Contributing authors have been invited to say something about how we should judge the work of an after-school center. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study examined the effectiveness of using a structured cooperative learning approach to increase appropriate behaviors of young boys who were identified as being at risk for the development of antisocial behavior patterns. Students received a six-week cooperative learning intervention using positive peer role models to teach interpersonal problem-solving skills through the combined use of cognitive and behavioral

techniques. Results show a significant increase in academic engaged time; however, the intervention failed to produce significantly lower rates of externalizing antisocial behaviors or negative playground interactions.

N2 - Describes therapeutic wilderness programming (TWP) as it is currently being used within the context of American Juvenile Justice. Based upon a review of the TWP literature and their personal familiarity with these programs, the authors developed a series of questions designed to provide additional insight regarding the structure, characteristics, and goals of TWP. The surveys were addressed to the chief administrative officer or executive director at each program. 35 of the original 106 surveys were returned for a 33.0 completion rate. Among other things, it was found that such programs are primarily intended to provide an alternative to punitive confinement, with the main goal of rehabilitating offenders. It was found that academic education, backpacking, and canoeing are the most popular means to achieve this goal. Findings are presented with regard to camp size, and camp staff/personnel issues are discussed. Finally, it is also noted that most of the literature regarding wilderness programs is found outside traditional criminal justice-, juvenile justice-, and criminology journals, despite the finding that states are heavily relying upon wilderness types of programs within their respective juvenile justice systems. N2 - Data from a sample of young adolescents between the ages of 10 and 12 years (N = 898) from the mother-child data set of the National Longitudinal Survey of Youth were analyzed in a study of influences that explain the relation between poverty and depressive symptoms measured 2 years later. Other variables that predicted youth depressive symptoms were also identified. Results indicated that neighborhood problems, nonparticipation in outside school and neighborhood activities, residing with mothers who exhibited depressive symptoms, and mother's use of physical punishment were partial mediators of the effect of poverty on depressive symptoms 2 years later. Youth health status, lower levels of school satisfaction, marital-partner conflict, and father's emotional support also predicted depressive symptoms. The findings indicate that youth depressive symptoms are multiply determined and that poverty can adversely affect young adolescents in many ways. N2 - Student outcomes are improved when ongoing intervention decisions are based upon formative assessment data. In the area of social competence, existing assessment instruments do not meet all criteria for optimal formative assessment tools. A brief, simple observation tool (ISC: Indicators of Social Competence) was designed around broad indicator behaviors that could reflect overall student performance. Research questions centered on reliability (stability and representativeness) and concurrent criterion-related validity of ISC data. ISC observations were conducted across days with 48 third-grade students during authentic school tasks (independent seatwork and unstructured free play on the playground). Parent and teacher ratings of student social competence served as criterion measures. Reliability. Most correlations reflecting stability of ISC data across days were statistically significant, but in the weak to moderate range. ISC data from the first half of a task period (i.e., seatwork or recess) adequately represented ISC data obtained from the entire task period. The stability and representativeness results suggest that collecting several brief samples will produce the highest quality data per investment of time. Validity. Three of four ISC behaviors correlated significantly with teacher judgments of social competence. None of the correlations between ISC data and parent judgments of social competence reached statistical significance. These results suggest that the ISC measure adequately reflects the social behaviors that are important for success in academic and free play tasks. Practitioners could consider using the ISC measure for formative assessment purposes, after reviewing its strengths and limitations, their data needs, and other available social assessment instruments. Researchers are encouraged to review the

challenges and outcomes of this project in their efforts to advance our assessment technology. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This qualitative study of an ethnically diverse urban third grade classroom asks how children used their peer structured talk and interactions during reading activities to negotiate peer identities and relationships. The study addresses the broad issue of how official literacy practices and children's unofficial social worlds are interwoven, drawing upon and mutually transforming one another. Theories of language socialization (Ochs, 1996), interactional sociolinguistics (Goffman, 1981), and interpretive approaches to child socialization (Gaskins, Miller, & Corsaro, 1992) frame the study; methods from ethnography of communication and ethnography (Erickson, 1992; Walcott, 1994, 1995) are used to create an analytic framework. Children's talk and interaction are analyzed as agentic social work during two reading activities that involved peer structured discussion of text: guided reading and self-selected reading. Data collected over a five month period include field notes, audio taped interviews with teacher and children, and video taped data. The findings suggest that reading activities provided opportunities to both maintain and to rework salient social categories of gender and popularity. The analysis of four children's talk during one guided reading activity shows how a less popular boy was able to reshape the official literacy activity so that it more closely resembled a unofficial peer interaction that had taken place earlier. He used the literacy activity to rework his social alignment to the girls at his table, and to ease gender and popularity divides. The analysis of self-selected reading activities shows that partner reading during self-selected reading was a girl gendered activity. Boys and girls could partner read together, but this was not easy to organize. There were, however, socially meaningful alternatives to partner reading during self-selected reading. Boys and less popular girls used talk during self-selected reading time outside of partner reads to affiliate with peers and to reshape the constraints of gender and popularity divides. The study suggests that peer structured reading talks may be a particularly rich arena in which children can work and rework constructions of peer identity, and that more research is needed to understand how to support children's efforts to use peer reading in this way. N2 - Kindergarten, first, and second grade children and their teachers were recruited from an elementary school in Oak Park, Illinois to examine social preferences and play behavior. Past research (e.g. Ladd, 1983; Pellegrini, Blatchford, & Kato, 2001) has found gender differences in children's behavior on the playground. These studies have also suggested that boys rejected by their classmates are often found to be playing with girls. At this age, where gender is a key factor in children's thoughts and actions, these findings led us to question what happens when children are rejected by their same-sex peers, but accepted by their opposite-sex peers. This study examined the differences in play behavior across gender and social status. To add to the existing literature, it explored the behavior profiles of children who are accepted by opposite-gender peers. Finally, it evaluated how teachers perceive the children who are accepted by opposite-gender peers. Findings indicated distinct behavior profiles for boys and girls at this young age: Boys played in cooperative, rule-governed activities, while girls engaged in associative, social conversation behaviors. Boys who were rejected by their same-gender peers ("Non-normal Boys"), but accepted by opposite gender peers did not show differences in play behavior when compared to the group of "Normal Boys." "Non-normal Girls" were found to have a distinct play profile compared to the other groups of children, marked by a significantly higher frequency of solitary play. No differences were found in teacher ratings across the groups of children. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - A great deal of changes occur in the lives of children between the ages of five to seven. Foremost in these changes is entry into a formal school environment and the shift from preoperational thought to concrete operational thought. During this time, a child also has the important task of negotiating social exchanges with same-aged peers, a relatively new task for many children. A child's social competence is closely related to a wide variety of factors that determine success in social and academic circles. Further understanding of how

children acquire their social status may be an instrumental first step in assisting children to have more social success and avoid the pitfalls associated with rejected peer status. The results of this study demonstrate the importance of cognitive developmental level when examining the social behavior of five to seven year old children. Results indicate that the social play behavior of children on playgrounds serves as a partial mediator in the relationship between cognitive developmental level and social status. N2 - This paper will establish classroom meetings as an effective problem-solving intervention in the reduction of recess problems. A multiple baseline across groups analysis was conducted of problems related to recess in three 4/5 th grade classrooms. Social problem-solving classroom meetings were introduced in each class and staggered every two weeks following two weeks of baseline for each class. This study was conducted over 9 weeks with daily data collection of recess reports and teacher surveys. Classroom meetings were effective in reducing the overall reports of recess problems. They were most effective in reducing problems of inclusion, playing alone and not joining others' play. Classroom meetings had a lesser effect on reports of Conflict problems, especially arguing. Implications of the study, including recommendations and suggestions for further study are addressed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Virtual reality (VR) technology applications targeting neuropsychological assessment and rehabilitation are now feasible and offer advantages that are not available using existing methods. The pilot study evaluated a VR Head-Mounted Display "classroom environment" designed for the assessment of Attention Deficit-Hyperactivity Disorder (ADHD). The Virtual Classroom scenario presents a standard classroom environment containing desks, plants, a teacher, blackboard, pictures on the walls, a large window looking out onto a street with vehicles and a playground, and a pair of doorways through which activity occurs. Within The Virtual Classroom, participants are presented with a traditional AX continuous performance test (CPT) on the blackboard and attention performance (RT) and other motor activity (head-turning, arm and leg-shaking) are recorded while a series of typical classroom distracters (i.e., activity and sounds) are systematically presented. Data were collected on 10 ADHD diagnosed children (aged 8 to 12) and 10 undiagnosed normal control children, comparing performance on the AX task and a basic listen-look-respond task, with and without distractions. VR exposure consisted of three conditions presented for 10 minutes each. Condition 1 measured performance on the AX task without distractions. Condition 2 was the same task with distractions included. Condition 3 consisted of a more realistic "ecologically valid" attention task requiring the integration of audio and visual attention processes. A battery of standard psychometric tests was administered to all participants for comparison with findings from the VR scenario. It was found that The Virtual Classroom scenario was able to differentiate between ADHD children and normal controls and in the expected direction. Within The Virtual Classroom, ADHD children responded with more omission and commission errors and greater levels of hyperactivity than normal controls among all conditions. ADHD children displayed more distractibility in their response to distractions than normal controls. Virtual Classroom measures were highly correlated with tests traditionally used to diagnose ADHD, the behavior checklist and CPT. The Virtual Classroom brings specific assets and improvements to the existing procedures and protocol for the assessment of ADHD. These assets and improvements strongly support the continued development and refinement of this virtual assessment tool. Suggestions for future research and clinical implications are discussed. N2 - The purpose of this study was to determine whether rough-and-tumble was a dimension of parent-child physical play and whether parent-child rough-and-tumble was related to preschool children's social competence. Participants were 157 married parents and 56 preschool teachers from the suburbs of a large northeastern metropolis. The core hypothesis was that father-son rough-and-tumble would be related to sons' social competence. It was predicated on the example of playground rough-and-tumble, a predominantly male activity that has been linked with the social competence of schoolboys. Both parents completed the Physical Play Questionnaire. The PPQ was a measure developed by the researcher to quantify frequencies of parent-child physical play. Fathers, mothers, and teachers rated preschool children with the Social Competence and Behavior Evaluation. Additionally, fathers and mothers filled out the Ray Directiveness Scale. Parental directive behavior was believed to be a mediating variable. Rough-and-tumble emerged as one of four principal factors of physical

play between parents and preschool children. Fathers and sons rough-and-tumbled approximately twice as much as mothers and daughters, respectively. Father-son rough-and-tumble was not associated with son's social competence, but father-son intimate physical play was. (Parental directiveness had no material effect on any relation). Additional analyses revealed that father-son rough-and-tumble behaviors that involved direct body contact were related moderately with sons' social competence and very strongly with 3-year-old sons' social competence. No kind of parental physical play was linked with daughters' social competence. The results of this study confirm that rough-and-tumble was both an intergenerational and domestic phenomenon. The quality of father-son rough-and-tumble was as critical to the contribution to sons' social competence as was the frequency. Because its benefits were both age- and gender-specific, rough-and-tumble emerged as an important factor for future research into the developmental course of parent-child play and parental gender-role socialization of children. N2 - The purpose of this study was to compare the effectiveness of an intervention consisting of an adventure education activity using a climbing wall (Treadwall) activity with no intervention as a means for enhancing children's general self-efficacy. A total of five fourth-grade and five fifth-grade classes were involved in the study, including 84 fourth-grade and 87 fifth-grade students. The researcher utilized Cowen's et al. (1991) Perceived Self-Efficacy Scale in assessing experimental and comparison group participants' general self-efficacy at a pretest and posttest, with one week between the tests. The 20-item Perceived Self-Efficacy Scale contains three subscales that consist of: Difficult Situations, New Experiences, and Problems with People. The data was analyzed using the t-test of independent means to compare pretest and posttest scores on the Perceived Self-efficacy Scale, Difficult Situations Subscale, New Experiences Subscale, and Problems with People Subscale across the experimental and comparison groups. ANCOVA (Analysis of Covariance) was used when initial differences in groups were determined to potentially influence the posttest results. Based upon data analysis, findings revealed that significant differences were found in the Problems with People Subscale between fourth- and fifth-graders who participated in the three-hour Treadwall activity, and those who were assigned to the comparison group. No significant differences were found between the experimental and comparison groups for the Perceived Self-efficacy Scale, Difficult Situations Subscale and New Experiences Subscale. N2 - Youth gangs are the subject of widespread fear and fascination in large part because of the high levels of violent and illegal behavior that gang members commit. Recent longitudinal studies have demonstrated that elevated levels of gang member offending are the consequence of group processes that facilitate such offending, rather than selection processes in which gangs recruit youth who are already high level offenders. Group cohesiveness and norms supporting aggression and antisocial behavior have been discussed as processes likely to play a role in facilitating offending. However, the importance and sophistication of youth gang organizational characteristics has been a topic of considerable debate among gang researchers and practitioners. Many experts view youth gangs as loosely affiliated groups with low levels of organization. But this view stands in contrast to evidence that many gangs possess characteristics suggestive of organization (e.g., leaders, identifiable symbols, regular meetings). In the current study, a conceptual framework is developed for considering the role of organizational features in facilitating gang member offending, and the relationship between these features and four categories of offending is tested using hierarchical multiple regression. Data are drawn from open ended interviews with 140 gang members in Denver, Colorado, Aurora, Colorado, and Broward County, Florida.

Results show that organizational features, including the presence of gang leadership, role differentiation, codes of conduct, initiation rituals, subgroups, and regular meetings, account for a significant amount of variance in gang member self-reported violent, property, and weapons offending, but not drug sales. Organizational features that appear to make the most important individual contributions are regular meetings and codes of conduct. The findings demonstrate that organizational features of youth gangs should not be dismissed in trying to understand gang member offending. Although youth gangs may not reflect high levels of organizational sophistication by outside or objective standards, the presence of organizational features is related to higher levels of offending among gang members. It is likely that organizational features serve to bring individual gang members into closer adherence with group norms that support aggressive and antisocial behavior. N2 - It has been assumed that children with autism have difficulty transitioning from one activity to another, but there has been little systematic investigation of the transitioning behavior of children with autism in their natural environments. The methods of ecological psychology were used in this study to explore how children with autism transition from one activity to another in their natural environments and how the transitions made by children with autism compare to those made by children with Down syndrome. A new construct, the behavioral transition unit (BTU), was developed for use in this study. Eight boys with autism and 8 boys with Down syndrome between the ages of 6 and 10 years were observed in their homes using the methods of ecological psychology. The structure of the transitions and the behavior of the children and others in their homes during transitions were examined. It was found that the boys with autism spent more time transitioning and had more frequent BTUs, which indicates a more immature pattern of behavior than that exhibited by the boys with Down syndrome. The boys with autism also took more time beginning activities and less time ending activities than did the boys with Down syndrome. This may reflect particular cognitive deficits seen in people with autism. Family members and caregivers were more likely to become involved in the activities of the autism group. In addition, the children with Down syndrome had the goal of getting attention or interacting with others more often than did the children with autism. There were some interesting similarities between the groups also. The relationship of these results to other research and theory in autism is discussed. N2 - The study investigated the development of verbal/physical and relational aggression in a community sample of five to seven year old children (n = 161). Playground behavioral observations and peer nominations were used to assess gender differences and continuity in levels of perpetrating and being victimized by verbal/physical and relational aggression across a 12-month period, as well as to examine the convergence between measures (i.e. self-report and behavioral observation). Results showed significant gender differences in displays of aggression. Males were more often perpetrators and victims of verbal/physical and relational aggression in comparison to same aged females. Males and females were found to engage in increasing amounts of verbal/physical aggression with age, with males showing a higher level of verbal/physical aggression at younger ages and continuing with this trend as they mature. In contrast, males and females did not demonstrate similar age-related change in relational aggression. As males matured, they engaged in increased displays of relational aggression, while females evidenced a decrease relational aggression. Modest levels of cross-time continuity were observed in the perpetration and being victimized by verbal/physical and relational aggression for both genders on the two measures. The covariation between verbal/physical and relational aggression for both genders was significant but greater for males. Convergence between measures was found for verbal/physical aggression, with the exception of females at the spring of kindergarten. In contrast, convergence between instruments was not found for relational aggression. For both genders, the covariation between perpetration and being victims of verbal/physical aggression was significant, with associations strengthening as children aged. The covariation between perpetration and being victims of relational aggression for both genders was less strong

than for verbal/physical aggression, and appeared to diminish with age. Results suggest that young males and females engage in verbal/physical aggression at increasing rates from age 5 to 7, with males showing rates of relational aggression that surpass those of females. Findings provide initial evidence for the importance of studying relational aggression in younger samples, as well as for the utility in incorporating observational methods in studies of aggression. N2 - Understanding and participating in the activities of young children, especially children with developmental disabilities such as autism, can be difficult for adults. In this qualitative study, the guiding question was "How do young children with developmental disabilities create and convey meaning through their daily activities?". The participants were a total of 5 three- and four-year-old children, with a diagnosis of autism, who did not consistently use language to communicate spontaneously. Participant-observation was used to collect data in the home and other natural settings in which the child engaged in daily activities. Interviews with key adults in the child's daily life provided supplemental information. Analysis of fieldnotes and transcripts was focused on the children's occupations, that is, meaningful, directed activities that occupied their time. Unique patterns and preferences were identified and described for each child and his or her activities. The meaning, from the child's perspective, was interpreted with close attention to how a child did the activity and its relationship to the child's needs, desires, and abilities. Findings were related to the following conceptual topics: defining occupation, framing an occupation, the nature of changes within an occupation over time, temporal links to past occupations, occupational structure, self-direction, and reframing of required activities into more satisfying occupations. Although they shared a diagnosis, through their engagement in activities, the children were seen as unique individuals with their own particular interests and abilities. Categories of the children's activities with others were identified as being equipped (accepting materials from another), guided (accepting assistance from another), mentored (incorporating another's suggestion), and shared (maintaining reciprocal interaction). The participants used their bodies, sensory perception, objects, and scripted action instead of words to mediate and focus their interaction on an activity with shared meaning. There was an implicit agreement about the shared meaning of the activity-what they were doing, why, and how. Through these shared activities, the children seemed to be connecting and building relationships with other people. Suggestions were made for balancing person-centered and family-centered services for children with developmental disabilities. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Children's attentional functioning impacts both their ability to perform everyday tasks and their potential for success in life. For example, children need a robust capacity to direct their attention for academic and social success. Can nature support children's directed attention? Attention Restoration Theory (Kaplan & Kaplan, 1989; Kaplan 1995) proposes that natural environments contain qualities that foster attentional restoration by allowing directed attention to rest. A growing body of evidence with adults indicates that nature does indeed support attention. We know little, however, about nature's potential for supporting children's attention. This dissertation examines whether nature in children's everyday environments is related to their attentional functioning. Two studies were conducted, each focusing on a distinct population of 7-12 year old children. One study examined 96 children with Attention Deficit Disorder living in predominately middle and upper-class neighborhoods with relatively high levels of nature. Data were collected through a written survey and follow-up focus group. The other study examined 169 children with normal attentional functioning, living in an inner city setting with relatively low levels of nature. In this study, data were collected through one-on-one interviews and objective performance measures. Is children's contact with everyday nature linked to their attentional functioning? This question was addressed through analyses involving both within and between-subjects comparisons, and multiple forms of everyday nature-activity setting, playspace, and residential nature. Numerous findings indicated that contact with everyday nature is related to better attentional functioning. In addition, some gender differences in the nature-attention relationship were discovered. The studies here are among the first to provide evidence for a systematic positive link between nature and attention in children. This work also contributes to Attention Restoration Theory, and the literature on the benefits of views of nature. Implications for design of children's spaces are discussed. N2 - Children growing up in the inner city are at risk of academic underachievement, juvenile delinquency, teenage pregnancy, and other important negative outcomes. Avoiding these outcomes requires self-discipline (SDP). SDP, in turn, may draw on directed attention, a limited resource that can be renewed through contact with nature. This study examined the relationship between near-home nature and 3 forms of SDP in 169 inner city girls and boys (aged 7-12 yrs) randomly assigned to 12 architecturally identical high-rise buildings with varying levels of nearby nature. Parent ratings of the naturalness of the view from home were used to predict children's performance on tests of concentration, impulse inhibition, and delay of gratification. Regressions indicate that, on average, the more natural a girls view from home, the better her performance at SDP. For girls, view accounted for 20% of the variance in scores on the combined SDP index. For boys, who typically spend less time playing in and around their homes, view from home showed no relationship to performance on any measure. These findings suggest that, for girls, green space immediately outside the home can help them lead more effective, self-disciplined lives. For boys, perhaps more distant green spaces are equally important. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In an effort to reduce problem behavior, it is recommended that schools develop a continuum of positive behavior support (PBS) that focuses on prevention/early intervention as well as individualized student support systems for those students who display chronic problem behaviors. While there is a large database to support the use of PBS practices at the individual student level, the knowledge base supporting prevention/early intervention strategies is characterized as emerging. The purpose of this study was to investigate the efficacy of PBS prevention/early intervention strategies on the rate of problem behavior displayed by 450 elementary school students during recess. Specifically, this study examined the effects of directly teaching playground-related behaviors and the use of a group contingency to reinforce mastery in an elementary school. Results indicated that the intervention reduced the frequency of problem behavior across three recess periods. Results

are discussed with respect to support of an emerging empirical database and implications for practice.

N2 - Examined aggressive behaviors of preschool children according to the context in which they occur and examined subtypes of aggressive behavior in relation to gender, peer group status, and numbers of aggressive children. Four- and 5-yr-old preschoolers (16 boys and 18 girls) were observed in a natural setting for 1 yr. A total of 160 aggressive behaviors were observed and classified into 3 categories: Proactive/overt aggression, instrumental/bullying, and relational aggression. Results show that boys show more proactive/overt aggression and instrumental/bullying aggression than girls, while girls show more relational aggressive behaviors than boys. In addition, children were aggressive according to their peer group status. Children who were classified as "nuclear" in their peer group had higher frequencies of relational aggressive behavior than children who were otherwise classified. Children who were classified as "isolated" suffered more than others from relational aggression. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Research describing peer relationships of students with disabilities has focused on younger children and students attending inclusive schools. The following study incorporated multiple measures that included: peer nominations, peer interviews, and direct observations in the playground, as a means of describing the peer relationships of 7 middle-school students (aged 5-18 yrs) who attend a separate school for students with disabilities. Results were compared to those obtained using the same measures in a nearby inclusive school, for one child who attended both schools, and for typical middle-school students. Results reveal that students with disabilities who attend a separate school experience a variety of peer relationships that included reciprocal positive nominations as preferred peers as well as low social status, lack of social interaction during recess and engagement in age-inappropriate activities. Results suggest that strategies to facilitate peer relationships that include students with disabilities are needed to foster the development of positive interactions between peers during unstructured periods at school. N2 - Documents the linguistic and nonverbal resources through which girls practice forms of social exclusion and ridicule in their spontaneous play, focusing on an age group (10-12 yr olds). The role of dispute and exclusion in children's groups are considered. The author discusses 3 groups of 10-12 yr olds that have been studied ethnographically. Psychological studies of aggressive behavior are reviewed that differentiate female forms of 'relational aggression' from other forms. Play patterns of different gender groups are discussed. How social class is made relevant in girls' everyday conversations is explored by discussing forms of comparisons that girls make. The article also deals with forms of exclusion within a girls' group, both among status equals as well as with respect to a 'tagalong' girl, a person defined by her marginal status. Through attention to language practices, the author demonstrates how girls articulate for each other their concern or disdain for one another, and position themselves relative to other girls. N2 - 385 children (aged 9-12 yrs) in Singapore rated the degree of usefulness of the activities for fostering creativity on a 5-Likert scale (1=not very useful, 5=very useful). They comprised Grade 4 (29.9%), Grade 5 (31.9%), and Grade 6 (38.2%) students of Singapore schools. Three clusters (C) were elicited from their responses. Cluster 1 (C1) was featured by 15 "student-centered participatory activities." Children belonging to this cluster (26%) seemed to hold relatively similar conceptions of creativity with the experts. They seemed to understand that creativity challenges an individual's multiple competencies. Cluster 2 (C2) was nearly characterized by all items, except verbal presentation, recess, listening to jokes, and video show with a final cluster center "3." Cluster 3 (C3) focuses on teacher guidance, recitation, and independent learning. 40% of the children belonged to a cluster (C3) resembling learning activities of the Singaporean everyday classroom of the upper elementary level. Singaporean children sit for 2 streaming examinations at the age of 10 yrs (Grade 4) and at the age of 12 yrs (Grade 6). Half of the 4th graders (n=58, 50.4%) belonged to this cluster, indicating possible influences of the national streaming examination on their responses. (PsycINFO Database Record (c) 2012

N2 - Reports on the social skills and social status of 22 students (aged 7.5-11.3 yrs) with mainly moderate intellectual disabilities who had received an inclusive preschool intervention and were subsequently followed up from 18 months to more than 5 years later in their mainstream classrooms. Measures included direct assessment of social interaction in the playground, social status obtained by interviewing classmates, and the ratings of classroom teachers, parents and school principals. Large differences were found between the students with disabilities and their typical peers for amount of time spent interacting with peers and amount of time spent in isolation, with a moderate difference found for interactions with teachers. However, no difference was found between the social status of the 2 groups, and the students with disabilities were still spending more than half their time in the playground interacting with typically developing peers. Parents generally rated their children as having better social skills than did principals or teachers. A moderate relationship was found between the direct measures of peer interactions and teachers' perceptions of peer interaction skills. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The relationship between maternal socialization strategies and children's safety practices was examined in a sample of 80 low-income Mexican American mothers (mean age 31.8 yrs) and their 4- to 8-yr-old children. Mothers were interviewed about the socialization strategies they used to influence their child's safety practices and about their children's safety behaviors in the home. Observations of the home environment yielded a measure of the family's use of proactive safety strategies. Children's safety knowledge was assessed in a structured play situation conducted in a simulated home environment. Results show that although mothers uniformly set safety rules regarding child behavior inside and outside the home, a significant number of mothers engaged in relatively few proactive practices to ensure child safety. Children who showed the greatest degree of safety knowledge and/or behavior tended to have mothers who used proactive safety strategies and who relied on consequence explanations versus commands or unelaborated explanations to teach child safety. N2 - (from the chapter) This chapter reports on 3 research studies, each using separate and independent measures of behavior to monitor young children's behavior across the availability of broadcast television on the island of St. Helena. Study 1 involved cohorts of nursery class children (aged 3-5 yrs) and incorporated teachers' ratings of children's behavior around school. Study 2 investigated 3- to 8-yr-olds' freeplay behavior in 2 school playgrounds in 1994 (before the availability of broadcast TV), and on two post-TV occasions in 1997, and 1998. Study 3 centered on a focus group discussion with 16- to 18-yr-old students from a secondary school on the island. The students' discussion threw light on potentially mitigating environmental factors. Findings on the whole showed little change in children's social behavior following the introduction of broadcast TV on the island. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (create) Investigated the effect of the introduction of television to the leisure activities of children (aged 9-12 yrs) on St. Helena. The project team conducted a series of surveys based on children's diary entries that attempted to record children's "leisure" behavior and other activities undertaken outside school including "work" in or outside the home and daily tasks such as washing and eating. The first survey took place in October 1994 (before television), the second in 1995 after the introduction of the Cable News Network, the third in 1997 and the fourth in 1998, both following the addition of other cable networks. Results indicate that the arrival of television had a considerable impact on the leisure activities of these children, however television has not (for the great majority) dominated their lives, even when interest was at its height in 1997. The children have continued to engage in a wide range of out-of-home and in-home activities and have not dramatically shifted their behaviors. Although changes are taking place in the pattern of leisure activities of these children and the arrival of television has clearly been an important influence, the authors attribute these changes to the process of growing up, of which television has been another aspect of this experience. N2 - Examines from a macroscopic perspective the preschool education available in Spain for children younger than 6 yrs. In contrast to most other countries, Spain offers few choices for preschool education; almost 98% of public preschool programs are provided by the Ministry of Education or autonomous communities, and serve four- or five-year-olds, while over 94% of private programs (mostly for those under four) are provided by private sources or the Catholic church. Almost 65% of early childhood educators work in the public sector, and over two-thirds are trained for that age level. Finally, 52% of pupils rely on school transportation; 89% of programs operate from 9 AM to 5 PM; 52% of children attend from 4 to 5 hours a day; 47% of programs are housed in school buildings; 4% lack outside playgrounds; and 95% offer an educational program. N2 - 12 boys and 12 girls provided home dreams and waking fantasies (WFs) at 3 age levels: 9-11, 11-13, and 13-15 yrs. A total of 299 dreams and 286 WFs were coded by 2 independent raters using C. S. Hall and R. Van de Castle (1966) content categories. There were few changes in dreams or WFs of either boys or girls, but dream reports were longer at ages 13-15 yrs, aggression/friendliness percent increased over time, joint-sex peer groups became more frequent, and girls showed a decline in animal percent. The tendency for men to dream mostly about other men and for women to dream equally of women and men was found in both dreams and WFs. Dreams and WFs differed markedly, with dreams containing more outdoor and unfamiliar settings and more bizarreness. In dreams, Ss tended to portray themselves as victims of aggression and recipients of friendliness, but in WFs they took a more active role as aggressors and befrienders. N2 - 71 children (aged 23-68 mo) entering infant day care at varying times and receiving varying amounts of care were compared on their reunion-with-parent behavior, teacher and parent ratings of their behavior, and playground play interactions. Age of entry into day care (<6 mo vs >6 mo) had no significant effect on attachment to mother as measured by reunion behaviors or on play and socialization skills as measured by observation and behavior rating scales in a full-time day-care setting. Ss with more hours and months of day care engaged in less watching, solitary play, and teacher comfort-seeking behavior and they showed more cooperative play, positive affect, peer interaction, and positive verbal interaction. N2 - 12 toddlers' (aged 22-32 mo) interpersonal spacing patterns were studied in preschool environments of different density and design. Results show that an apparently spacious open classroom may produce behavioral changes reminiscent of crowding in young children. When more space was available on an outdoor playground children (1) increased interpersonal distances overall and (2) aggregated more with classmates and teachers,

fragmenting into subgroups that were separated from the class overall. With visual dividers added to the classroom to facilitate subgrouping, toddlers formed larger subgroups with teachers. Parent/child behavior during separation also affected distances: longer hand-holding and verbalization were found in children who stayed further from others. N2 - Investigated the reactions of 251 elementary school children (aged 6-13 yrs) 1 yr subsequent to a sniper attack on their school playground in which a 10-yr-old was killed and 14 others were wounded. A childhood grief reaction inventory was developed to collect data. Scores increased with degree of acquaintance with the deceased schoolmate and with degree of exposure to the violence. Results show that children responded similarly to adults (as previously reported in a number of studies), both in the nature and frequency of grief reactions and in that normal grieving was still ongoing after 1 yr. There is also evidence that while at times there was an interplay between grief and posttraumatic stress reactions in children, at other times the 2 reactions occurred independently. N2 - Examined the percentage time estimates of momentary time sampling (MTS) against the real time obtained with handheld computers among 16 1st-4th graders in a natural setting. Concurrent observations were conducted by 1 observer who used 15-sec MTS and a 2nd who used a handheld computer. Results for 6 behaviors (school work, looking, other activity, child interaction, teacher interaction, and out of seat) show a close correspondence between the MTS percentage observation intervals and the real-time percentage observation time. However, 15-sec MTS tended not to sample low-frequency short-duration behaviors. Short-interval MTS estimated percentage time accurately for a wide range of behavior frequencies and durations, and observers using MTS in a natural setting are able to obtain accurate data. N2 - Examined the importance of family and social risk factors for injuries at school in Athens, Greece. During study on 80 nonconsecutive days, 101 injuries occurred, 49 on the playground, 39 in classrooms or corridors, 10 during sporting activities, and 3 during transportation to or from school. Results indicated that low SES increases the risk for injuries, not only by creating adverse environmental conditions, but through mechanisms related to behavior and education that can operate even in the school environment. Children from single parent families were 5 times more likely to sustain a school injury. (PsycINFO Database Record (c) 2013 APA, all rights reserved)

N2 - Examined the social processes used by 74 African American children (aged 49-62 mo) to choose peer affiliates in a natural classroom setting. Preference ratings for each classmate were collected individually from each S, and the amount of time each S spent with peers during free play periods in the classroom was observed and coded. Results indicate that Ss were selective in their affiliation with peers; they spent substantial social time with a small number of peers and little time with remaining peers. Ss' initial affiliation with each of an array of same- and opposite-gender Ss and temporal changes in those affiliations were strongly related to the relative proportion of positive consequences the Ss experienced during social interaction with those peers. Strong mutual affiliations or friendships were established between Ss who provided each other with the highest levels of positive social consequences available from peers in the classroom. N2 - This study used a single-subject reversal research design to examine the effectiveness of using a computer to improve attention to visual analysis activities in five preschool children with disabilities in a special education programme. Baseline levels of attention to task behaviours were measured during the performance of fine motor tabletop visual analysis activities of matching, requiring shape recognition, counting, free drawing, and size and colour discrimination. During the intervention phase, computer-based visual analysis activities were introduced. Results suggest that each child's attention to task performance improved during the computer-based activities, when measured by the number of distractions, although sitting tolerance and visual attention to the task did not change. The findings of this study, although limited to five participants with developmental disabilities, suggest that the students were interested and motivated to engage in computer-based activities. More research is needed to examine a longer intervention phase and the effectiveness of computer-based intervention in natural settings such as a classroom. N2 - The nearby natural environment plays a far more significant role in the well-being of children residing in poor urban environments than has previously been recognized. Using a premove/postmove longitudinal design, this research explores the linkage between the naturalness or restorativeness of the home environment and the cognitive functioning of 17 low-income urban children (aged 7-12 yrs). Both before and after relocation, objective measures of naturalness were used along with a standardized instrument (the Attention Deficit Disorders Evaluation Scale) measuring the children's cognitive functioning. Results show that children whose homes improved the most in terms of greenness following relocation also tended to have the highest levels of cognitive functioning following the move. The implications with respect to policy and design are also discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Taking recent ethnomethodological insights into gender as an ongoing interactional accomplishment as a starting point, a research group conducted an ethnographic exploration of the practices of gender differentiation among nine- to twelve-year-old schoolchildren in Germany. From 1993-1997, the two researchers observed two classes of 20 children each at the Laborschule in Bielefeld in their school years 4, 5, and 6. This article deals with a small segment of these gender differentiation practices: spontaneous territorial games, characterized by a high degree of physical activity in which the children split up into gender-homogeneous teams. Based on the detailed analysis of two recess situations, the article explores how gender-defined territories are achieved interactionally and how gender polarity is thus staged. The concluding play-theoretical reflections in particular show that territorial games simplify, alienate, and aestheticize gender arrangements. N2 - Presents the case study of Robert to demonstrate an interaction collaboration model for family therapists and school counselors. When family therapy originates outside the school setting, the school is likely to be ignored, but communication is often poor between school and therapists even in cases where therapy originates through school referral. Robert (aged 9 yrs), repeatedly demonstrated acting-out school behavior. To assist him in gaining control of his emotions, implemented procedures and activities included Robert's unconditionally sanctioned attendance at social events, setting up a routine contact schedule with his distant father, minor classroom changes, and school group counseling sessions. All family members set aside quality time. The school counselor coordinated classroom arrangements with Robert's teachers. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 50 German schoolboys (aged 10-13 yrs) demonstrate a new procedure for gathering physiological, psychological, and behavioral data on TV viewing in the home environment on a normal school day, using a special ambulatory monitoring device. The mean time spent watching TV was 123 min per day, during which the

Ss watched mostly entertainment and action shows. Results indicate that different types of TV programs had differing physiological effects and more specifically, heart rate (HR) as compared to other programs was low for entertainment and high for action shows. Compared to school and leisure time, additional HR during TV viewing was much higher. Boys with high TV consumption read fewer books, showed diminished activities outside home, a tendency for reduced school-related homework, and reduced interest in hobbies. Findings show that psychophysiological effects of TV viewing can be monitored in the home environment. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the school/nonschool ecology of early adolescent friendship activity using data from 115 female and 95 male White students and 39 male and 33 female Black students. Principal components analysis of friendship measures revealed distinct dimensions for activities that occur during and outside school with the best school friend. Social skill and environment-related obstacles to seeing school friends outside school were also identified, particularly among Black Ss. Activity with the best school friend was more frequent during school and environmental obstacles interfered to a greater extent with seeing school friends outside school than did social skill problems. Activity with the best school friends during and outside school was related to self-esteem among boys but not among girls. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The School Function Assessment (SFA) was developed to provide information on students' abilities to meet functional demands of the elementary school program. This judgment-based, criterion-referenced assessment supports a comprehensive, detailed examination of the extent to which students with a variety of disabilities are performing important school-related functional tasks and activities such as moving around the school, using classroom materials, interacting with peers, and caring for personal needs. The factor structure underlying the SFA Activity Performance scales was investigated using data from two heterogeneous national samples of students with disabilities (266 and 341 Ss aged 5-14 yrs). Analysis with the principal axis technique and oblique rotation identified two factors, a Cognitive/Behavioral Function dimension and a Physical Function dimension. These factors were moderately correlated, which is congruent with definitions of the function construct that emphasize the integration of physical, cognitive, and social abilities in the performance of daily activities in the natural environment. N2 - Examined the interactive effects of criminogenic factors on delinquency among youth in China and Hong Kong. Ss in the retrospective study comprised 63 male youth (aged 12-18 yrs) residing in Hong Kong and Guangzhou, China, 32 of whom were convicted delinquents. Ss completed interviews concerning parental closeness and supervision, reaction to parental supervision, academic performance, relationships with

classmates and teachers, reactions to teaching practices, and time spent in sports activities, youth clubs, and religious activities. Results show that 65% of Hong Kong delinquent Ss, and 40% of Guangzhou delinquent Ss came from broken homes. Nearly all delinquent Ss reported that they were ignored by their parents and seldom felt understood. Delinquent Ss exhibited higher school drop-out rates, which they attributed to their own behavioral problems, academic difficulties, or poor teacher-student relationships. Non-delinquent Ss associated with friends from school; in contrast, delinquent Ss met their peers in video arcades, street corners, or playgrounds and had close ties to neighborhood gangs. N2 - Every year thousands of Brazilian children die or get injured from traffic accidents. To know the inherent factors to the dangerous behavior at the moment accidents happen, we studied twenty non-lethal cases involving children from 5 to 10 years old. The study included not only the interview of the victims, their parents, witness and drivers but also the use of psychological tests, questionnaires and drawings which aimed the reconstruction of the accident scene and the better understanding of the behavior of the subjects. Secondary factors, such as the type of road, climatic conditions, day and time of accident, and the reason for the subject's presence at the scene, were also evaluated. The results indicated that 1) lower-income boys, due to their precarious living conditions were more exposed to high-risk traffic conditions. The following aspects were characteristic of accident causality: a) they were busy with some outdoor activity, b) were distracted, c) had poor schooling, and d) seemed unaware of traffic-related dangers. 2) With reference to their psychological profiles, the boys did not differ significantly from peer controls, which led to the conclusion that available psychological test are not predictive of accident proneness. In conclusion, there is an urgent need for restructuring the Brazilian transit system. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Analyses were made of the location and quality of free play of 244 3- to 5-year-olds from 6 different preschool and day-care centers. Although SES and ethnicity were confounded with amount of space and the range of choices available, 13 play sites/activities could account for at least half the children's time in every center. There was no simple relation between the amount of space allocated to a setting and the proportion of time that the children used it. Patterns of use varied as a function of weather-related accessibility in spacious facilities. Differences across samples drawn from the same SES/ethnic pool indicated that the particular make-up of a group (the "cohort") in the same physical context can affect specific patterns of usage. Among children drawn from all 6 centers, there were sex differences in time spent in 5 of 9 common play sites. Moreover, across centers and a broader spectrum of areas, certain play sites consistently yielded different patterns of social exchanges with peers and adults. N2 - Naturalistic observations were made of 17 aggressive and 22 nonaggressive children in Grades 1 to 6, filmed with video cameras and remote microphones on school playgrounds. Observers coded interactive behaviors, affective valence, and play states. Aggressive children displayed more verbal and physical aggression, more prosocial behaviors, and higher rates of interaction than did nonaggressive children. The 2 groups spent similar time in solitary and group activities. Sequential analyses indicated that peers made similar initiations to aggressive and nonaggressive children, but aggressive children were more likely to respond

antisocially. Aggressive children initiated more mixed behaviors (prosocial and antisocial) than did nonaggressive children. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Observed 33 hearing and 29 deaf 3-5 yr olds during outdoor play at their schools over 7 mo. Three types of peer relationships were examined: nonfriends, temporary friends, and long-term friends. Both deaf and hearing Ss typically had 1 temporary friend and 1 long-term friend at a given time. The 2 types of friends differed from the nonfriends in the affective tone of their interactions. Compared to nonfriends, friends were less likely to behave negatively and were more likely to be of the same sex and ethnicity. Long-term friends engaged in more social than parallel play and were more similar in age and ethnicity. Except for differences in stability, the pattern of friendship was similar for deaf and hearing preschoolers. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Evaluated integration in school of 14 disabled children (aged 7.6-13.11 yrs) during the experience of a stage for memory improvement that was carried out during class time. Ss were divided into 3 working groups; all Ss attended primary school, except one child who attended Italian middle school. All Ss willingly accepted the stage and actively took part in the proposed work; at the end of the stage (3 mo; a total of 60 hrs) Ss' visual memory and verbal memory were improved ($p < 0.005$ and < 0.001 respectively). The children's behavior after integration in school was studied using the Social Emotional Dimension Scale (J. B. Hutton and G. T. Roberts, 1986); similar values were obtained before and after the stage. Results suggest that selected Ss may be able to work outside general class during some hours a week without detriment to their capacity to socialize and to integrate in school. An Italian translation of this article precedes the English version abstracted here. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In order to enable teachers to detect social anxiety in preschoolers the authors developed a scale. The TRSA-"junior" (Teacher Rating Scale of Social Anxiety-"junior") is a brief Likert-type questionnaire for the identification of social anxiety in 5-to 6-year-old children. Reliability (internal consistency plus test-retest correlation) collected in 2 samples (N=173, N=285) was high. Convergent and divergent validity of this newly developed rating-scale were also studied. A high level of social anxiety correlated with a low level of social participation, as observed on the playground. The TRSA-"junior" score correlated with "internalizing" as measured by the Behavior Questionnaire for Toddlers and Preschoolers (BQTP) and the Child Behavior Check List (CBCL), and with the subscales "anxious-depressed," "thought problems," "social problems" and "withdrawn behavior" of the CBCL. In the second study a high score on social anxiety appeared to be related to less positive sociometric judgments by peers. The authors conclude that the TRSA-"junior" may aid in the identification and prevention of social anxiety at an early age. In addition, the scale would appear to be a useful instrument in research, given its sound psychometric qualities. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the effects of outdoor environmental education activities involving school children. 36 students (aged 11-12 yrs) residing in Finland were categorized as experiencing high, moderate, or low levels of outdoor education, which included field trips, hiking, camps, canoeing, and sailing. Collected data included questionnaire responses, interviews, drawings, landscape photographs, and S observations during outdoor activities. Results show that nature experiences developed Ss' self-confidence and feelings of safety, which in turn increased their willingness to participate in future outdoor activities. In comparison to Ss experienced with outdoor activities, those who were inexperienced were more uncertain and anxious about trying new things, were quicker to express their inability, and had more difficulties in working as a group. Experienced Ss showed a strongly empathic relationship to nature, better social behavior, and higher moral judgements. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Presents an overview of boys' and girls' musical learning inside and outside school. Ss were 877 pupils (414 boys and 463 girls) in 9 Chinese secondary schools. Most of the Ss were aged 12-16 yrs. The paper argues that patterns of gender stereotyping associated with music among Hong Kong students have some similarities with those in the Western world. The impact of gender beliefs was most evident in types of instrumental learning, types of music activities, and listening and singing preferences. The Ss' attitudes toward the promotion of popular and Western classical music in school emerged as statistically significant, while their attitude toward Chinese classical music was nonsignificant. N2 - Evaluated the effectiveness of 8 behavioral intervention programs directed at modifying aggressive behavior in children. These interventions were designed based on those factors that research in the field has identified as being directly linked to the development and maintenance of childhood aggression. They were offered to the three groups of change agents that have been shown to be related to these patterns of behavior: the child itself, it's parents and teachers. 84 children participated in this study and were exposed to one of several to the following intervention programs: Parent Training for young children (6-9 yrs), Parent Training older children (10-13 yrs); Classroom Behavior management; Playground Behavior management; Self-control training in anger management for young children (6-9 yrs); Self-control training in anger management for older children (10-13 yrs), Problem Solving training with peers, and Social Skills training. For each of the intervention programs, a series of measures were obtained before and after completing the training, which indicate an important level of effectiveness in the reduction of aggressive behavior, suggesting the viability of its application and their pertinence in the development of multimodal intervention strategies for this population. N2 - Examined psychosensory and static load and physical activity among Slovak school children. 2,108 1st-9th grade Slovak schoolchildren reported daily regimen activities in 1982; 2,339 1st-9th grade Slovak schoolchildren did so in 1998. Data were compared concerning: (1) psycho-sensory and static load; (2) leisure time sports activities; (3) sleep; and (4) outdoor activities. Results show that significantly more younger subjects (Ss) attended optional and private lessons and other educational activities in 1998, compared to 1982. New daily sedentary and psycho-sensory activities with personal computers were reported by 36% of Ss. Watching television significantly increased in all Ss, and was correlated with a significant shortening of sleep. Regular sports activity increased in younger Ss. Physical and sport activity was lower in females than in males. 84% of younger Ss relaxed outdoors <3 hrs daily. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (create) This reprinted chapter originally appeared in Journal of Emotional & Behavioral Disorders, 2000(Fal), Vol 8(3), 165-176. (The following abstract of the original article appeared in record 2000-02433-004). Describes Linking the Interests of Families and Teachers (LIFT), a prevention program designed for delivery to children and parents within the elementary school setting. The LIFT targets for change those child and parent behaviors thought to be most relevant to the development of adolescent delinquent and violent behaviors, namely child oppositional, defiant, and socially inept behavior and parent discipline and monitoring. The 3 major components of the LIFT are (1) classroom-based child social and problem skills training, (2) playground-based behavior modification, and (3) group-delivered parent training. The results of a randomized controlled evaluation of the LIFT, using 1st and 5th graders and parents from high juvenile crime neighborhoods, are reviewed. To date, the program has positively impacted the targeted antecedents. Most importantly, during the 3 yrs following the program, the LIFT delayed the time that participants first became involved with antisocial peers during middle school, as well as the time to first patterned alcohol use, to first marijuana use... VL - 62:

IS - 5-B

N2 - This research concerns biological understanding of inheritance. Among other things, biological understanding entails knowing that biological processes operate outside the forces of mechanical and intentional causes. A question that has been the center of much debate is: When do children possess such understanding? One view is that before the age of approximately 7 years, children interpret biological phenomena in terms of psychological forces such as beliefs and intentions and that between 7- and 10-years of age, they undergo something akin to paradigm shift. The other view is that children possess an autonomous theoretical framework related to biology at a much earlier age. Of particular interest in the current study is the types of explanations individuals endorse or generate when thinking about biological inheritance. In this study, students in Grades 2, 4, 6, and university were systematically and intensively interviewed on the topic of inheritance. They were presented with three tasks. In the Generation Task, participants were presented with a variety of items intended to elicit explanations about how physical traits are inherited across one or two generations. In the Endorsement Task, participants were asked to render an opinion concerning seven explanations for the color of an animal, a plant, and an artifact. Finally, in the Background Knowledge Task, participants were asked questions that were designed to determine their knowledge about genes and the role they play in transmission of traits, their knowledge about the environment and how it influences the expression of traits, and their intuitive statistical knowledge regarding natural variability and homogeneity. In the Generation Task, participants in all age groups generated approximately six types of explanations, suggesting that participants have at hand a variety of explanations from which to choose. Adults tended to generate explanations that were congruous with biological theories of inheritance but included a clear causal mechanism in their explanations. Children's explanations were also mostly congruous with biological theories of inheritance, but frequently lacked a clear causal mechanism. Implications of evaluating biological understanding and its development from the perspective of multiple,

overlapping explanations are discussed. (Abstract shortened by UMI.) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Asperger's Syndrome is a cluster of cognitive, social and affective deficits that falls in the continuum of Pervasive Developmental Disorders. Current methods of intervention have met with limited success and have not been replicated outside of the treatment setting. In this study, an Interplay based brief group treatment, utilized a metaphor of acting skills to teach social skills to a group of six latency aged boys with Asperger's Syndrome. A measurement instrument, designed for this study, assessed play skills, social skills, Theory of Minds Skills, and verbal and non-verbal communication skills. Pre- and post-intervention results were measured using separate single case research designs. Only minor gains in skills were noted, although qualitative report of group members and parents were positive. Recommendations for future treatment and research include small group size, increased parent involvement, and a high child to facilitator ratio that permits both participation and reflection on the group process. N2 - Understanding the process of social exclusion is necessary to develop effective intervention programs. The effects of peer relationship problems are far reaching, and include academic difficulties, problems with parental relationships, and even a variety of mental disorders. Researchers have a good understanding of the antecedents

of social exclusion and its deleterious effects on the outcast child; however, much less is known about the process of social exclusion in the context of peer group entry. It has been determined that peer group entry attempts is one of the most difficult social situations for young children, and a child's performance, or lack thereof, in this domain is significantly correlated with the peers' behavior toward that child. Of the studies which have focused on peer group entry, most have been conducted in laboratory settings. The present study examines naturally-occurring group entry attempts of rejected and neglected children, focusing on the types of group entry attempts made, how the group responds to these children, and whether these two findings are a function of subgroup differences. Participants for this study came from a larger study examining the effects of a social exclusion intervention on the social and emotional experiences of kindergarten children in the classroom: The sample for this study was 41 kindergarten-aged children who were identified from the original study at risk of peer group exclusion based on sociometric status. These children were observed during freeplay in the classroom and on the playground for 12, 5-minute observations across at least 5 different days. Observations were conducted during the first half of the school year, and again during the second half. Behaviors were coded on the basis of group entry attempts made and responses of the group. The different patterns observed help explain the strategies used, processes, and outcomes of peer group entry for socially excluded children, and, therefore, provide knowledge that can be applied for use by teachers, and also to increase the effectiveness of interventions focusing on childhood social exclusion. N2 - A case study design was used to determine if a cognitive approach, based on socio-constructivist theory, could facilitate gross motor skill acquisition in preschool aged children with Down Syndrome (Ds). After a pre-assessment, seven children, ranging in age from 2 years 10 months, to 5 years 9 months, participated in six trials each for sliding and jumping activities. Two intervention formats were used with each child. The command and practice (C&P) format focused primarily on the physical aspects of motor skill acquisition while the graduated prompt (GP) format was designed to influence the cognitive domain. After each intervention session, tasks measuring children's declarative knowledge of the motor skills were presented. Procedural knowledge was measured by observing the child in gross motor play at a large playground one day and one week after the intervention session. Information about each child's sliding and jumping related behaviours was collected using video observations, floor plan/maps, anecdotal notes, parent interviews, and journaling. Qualitative and quantitative information was reported in a case by case approach and compared using cross-case analysis. Patterns of improved and more independent psychomotor behaviours emerged during the intervention session, were observed later in free play sessions, and confirmed by parents. For the most part, current theories of motor learning and control were unable to explain the changed motor behaviours of the children. Therefore, a hypothetical description which blends motor learning with Vygotsky's socio-historical theory, is presented as the explanation for why and how psychomotor skill improvements were made. This project determined that the psychomotor domain is modifiable. Implications are that the GP format is a useful assessment model for the

psychomotor domain, and therefore, when teaching children with Ds gross motor skills, people should use verbal, visual, gestural/kinesthetic prompts, demonstrations of skills displayed with dolls and models, and explanations aimed at influencing cognitive understandings of motor skills. Future research options include motor theory development with Vygotsky's proposals, finding new ways to assess psychomotor knowledge, and using declarative and procedural knowledge when teaching motor skills to children with movement disorders/motor delays. IS - 10-A

N2 - The goal of this study was to investigate children's everyday play in a working class Taiwanese preschool. Because Taiwan is currently rethinking the direction of early childhood education, it is timely to look closely at play in a preschool setting. Since recent debates in the U.S. have led some American schools to sacrifice free-play time in order to increase time for teaching academic subjects, investigation of children's play in this academic-oriented cultural case will be illuminating to American educators as well. This study was ethnographic in approach, involving thorough observation and investigation of children's play at regular intervals over a period of three years. The researcher was able to establish a special role in the preschool to access the children's peer groups that were not often accessible to adults. The findings indicate that children constantly engaged in play, and their play fitted well into the daily routine; in their L year (equivalent to the kindergarten year in the U.S.) the children earned more official play time by behaving well and concentrating on assigned tasks than they were in the M year (equivalent to the final preschool year in the U.S.); the children displayed a complex way of exploring male/female relationships both inside and outside of play. These findings suggest a strong cultural influence of Confucian ideas to the children's preschool life and their play environment. Children's hard work was rewarded by more official play time when they were in the L year. The issue of gender was crucial to the understanding of children's friendships and daily interaction with peers. Overall, this study provides a basic understanding of the Taiwanese preschool children's life, which is essential for educational reform in Taiwan. The fact that the children were flexible to fit play into their daily routine, and their way of earning more play time by good conduct, challenges to American educators that increasing academic time does not necessarily equal decreasing play time. N2 - The purpose of this pilot investigation was to examine playground interactions of eight children (aged 6-10 years) with learning impairments (LI) and their typical peers in order to clarify further the social behaviors of these children. The participants were videotaped during the morning and lunch recesses. Their behavior was coded into one of the 37 subcategories and the subcategories were grouped into 6 general categories. Children with LI demonstrated significantly more withdrawn behaviors than did their peers. Typical children spent considerably more time interacting with peers than did children with LI. No other significant differences were observed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the chapter) In the child-centered group play therapy (GPT) process, children experience an environment that is marked by warmth and acceptance and promotes safety and growth. This environment allows children the opportunity to discover that their peers may be struggling too, which helps to deconstruct the barriers that children have of feeling along in their pain. A sense of belonging develops, and children appropriate ways to relate within and outside the playroom. In the child-centered GPT process, children experience a consistent and accepting response from the therapist, regardless of their presenting problems, degree of normality, or extent of personal adjustment. The group experience allows children to communicate about these issues on both an intrapersonal and interpersonal level. The child-centered therapy process takes the focus off the therapist and allows the children to experience self-exploration, self-discovery, and self-realization. It is the actualization of empowerment. This chapter discusses issues related to diagnosis and treatment planning, therapeutic limiting setting, the rationale for utilizing group play therapy, and group structure and logistics. A case example is presented of child-centered GPT involving 3 children (7 and 8 yrs old). (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Both ethnography and experience-sampling methods (ESMs) are effective for assessing children's home activities. The authors combined them to examine home activities that were school-like, complementary to school, or unrelated to school. The activities were then related to children's school achievement in a sample of 8 low-income Latino immigrant families and their 10-11 yr old children at risk for low school achievement. Children reported a wide variety of types of activities in their evening routines. Children with higher school achievement were engaged in chores; homework; monitored outside activities; family social activities and hobbies; and self-directed, goal-oriented activities. Children with lower levels of school achievement tended to be engaged in more television, video games, peer and solitary play, and resting. ESMs are a valuable and effective complement to ethnographic and school achievement data in the study of home activities and home-school relationships. N2 - Discusses an approach to helping children see and discover meaning in their science learning beyond the classroom. Two 5th grade teachers, their students, a science teacher, a technology coordinator, and a bilingual instructor participated in a student-identified problem of pollution along a nearby river as an interdisciplinary anchor for teaching science, math, language arts, and civics. The resources, knowledge, and experience of students, parents, and teachers were combined to clean up a riverbank site and transform it into a community green space. Explored areas included the kinds of activities students were engaged in, how they evolved over time, and the kinds of supporting knowledge and experience that were brought together. The real-world problems were interdisciplinary in nature, were relevant to both the curriculum and students' lives, and were highly visible and accessible. N2 - The goal of the present investigation was to examine whether early coordination impairments were related to later football participation in the school playground. The participants were 64 boys (aged 6-10 yrs), 32 in a movement impaired group and 32 in a non-impaired group, who were divided into groups of those who were often alone and those who were not. The not-alone group was further subdivided into those who played football for considerable periods and those who did not. There were 10 boys with poor scores on the Movement Assessment Battery for Children (Movement ABC) who were not often alone and who played football for considerable amounts of time. Analyses of the subscales of the ABC indicated that the balance subscale was significantly related to participation in football, but that some boys with relatively poor balance scores did play football. Only extremely poor performance on the balance tasks of the Movement ABC was related to non-participation in football. Some of the key differences between groups of children with movement impairments in terms of their inclusion in social and physical games like football may not relate to hand/eye coordination and manual control, but to the ability to maintain posture while carrying out other movements, particularly when balance skills are extremely poor. N2 - Examines children's procedures for dealing with simultaneous bilingual speech as it arises in multiparty play episodes. Sequential analyses of more than 10 hr of videorecorded recess activities at an English school in Sweden revealed that Swedish-English bilingual children in grades 2 and 4 use code-switching and an array of methods to minimize the overlapping passage. Exceptions to this may be found in exchanges that are demonstrably competitive with regard to turn taking, in which participants' actions strive to gain exclusive rights to the floor, often resulting in stretched overlaps. Moreover, the sequential location of bilingual overlap onset proved relevant for its resolution: Whereas in interjacent onset participants would use different methods to deal with simultaneity, resulting in various outcomes of overlap negotiation, instances of overlapping turn beginnings occasioned by multiple self-selection were always resolved the same way, with the speaker diverging from the language of previous turn(s) keeping the floor. It is therefore suggested that the linguistic contrast arising with the code-switch may enhance second speakers' chances to acquire the floor and that the effectiveness of this "turn security device" is strongly dependent on its sequential placement. N2 - Students in 4 inner-city middle schools serving mostly (90.9%) economically disadvantaged, minority youth were asked how they spend their time after school and on weekends. Analysis of responses from 1,583 students revealed that the vast majority did not participate in after-school programs (77.2%) or lessons of any kind (86.5%). Students reported extensive time spent watching television or hanging out with friends. Weekends presented a similar pattern of unstructured social activity with even more television viewing and considerably less homework. Implications for designing after school programs are discussed in light of the students' highly unproductive use of time outside school. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In Scandinavia it has become popular for kindergartners to spend more time outdoors in the natural environment. Some kindergartens are organized as outdoor schools, where the children, aged 3-6 yrs, spend all or most of the day outdoors in a natural environment. Playing in a natural environment seems to have positive effects on children; they become more creative in their play, and play activities and play forms are increasing. It is also indicated that absence due to sicknesses is lower among children in outdoor kindergartens than in the traditional ones. At the very least it is evident that children's motor fitness is improved in such an environment. They move easily around in a rugged terrain and cope with physical challenges, which improve their motor ability. Although few in number, these studies indicate that the natural environment is a stimulating arena for learning in general, and for motor fitness training in particular. The present research corroborates the main findings. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Evaluated a 10-wk educational home-based program for feeding wild birds, intended to increase elementary school age children's knowledge about birds, especially those wild birds commonly encountered at outdoor home feeders. The authors measured changes from pre- to post-program in 65 7-12-yr-old children's knowledge about wild birds, as well as in environmental attitudes. The goal was not only to increase bird knowledge in the target child but also to involve other family members in home-based nature education activities. After the program, 7-9-yr-old boys and girls showed significant gains in bird knowledge, but older children (10-12 yrs) did not significantly improve. Children's increased knowledge was positively associated with parental education. There was no systematic change in environmental attitudes. Parents identified family involvement as a particularly beneficial aspect of the program, and 90% of contacted families were still feeding birds one year after program termination. N2 - Evaluated factors influencing compliance with a home therapeutic program for children with disabilities in Jewish and Bedouin Israeli populations. Members of 83 Bedouin and 110 Jewish families with disabled children (mean ages 6.8 and 9.54 mo) completed questionnaires concerning compliance with suggested home exercise, disability status and medical diagnoses, belief in outcome, satisfaction with service, and economic burden. Results show that Bedouin Ss had more severe disabilities than did Jewish Ss. Bedouin families had lower levels of education, more mothers working outside the home, more children, and stronger feeling of burden from caring for Ss. Compliance was significantly lower among Bedouin families. Families with higher levels of intensity of destiny-questioning were less compliant with therapeutic regimes. A trial intervention program for Bedouin families, involving telephone contact, translation facilities, and detailed explanations during visits to the center, increased the compliance rate of the Bedouin to 76%, compared to 81% for Jewish families. It is concluded that increased attention through strengthened communication can greatly improve compliance with home therapeutic programs. N2 - Studied the relation of spontaneous sonorous productions during play time and environmental factors in play areas at 8 nursery schools and 12 primary schools in France. Ss included 50-100 children (aged 3-6 yrs) per nursery school play area and 60-200 children (aged 6-12 yrs) per primary school play area. Children's sounds and environmental sounds were tape-recorded during 30 min intervals and scored using the Repertoire of Sound Effects method (J. -F. Augoyard, 1987). Musical and other sound productions of children were evaluated according to timbre, scale changes, audibility, rhythm, and melodic elements; environmental factors were evaluated according to background sounds, sound uniformity, number and spatial arrangement of children, movement of children, and tension. The results show that children's spontaneous productions tend to be school-specific. The results also suggest that disturbing demographic and acoustic conditions at some playgrounds may increase tension via sound overload. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - There is an increasing prevalence of overweight in preschool children among the U.S. low-income population. Although research indicates that important correlates of physical activity in preschoolers are time spent outdoors and prompts to be active by adults, there are few educational materials available for parents that build on this research. Nutrition educators with the University Extension Service developed materials to increase physical activity and improve eating habits of low-income families with preschool-aged children in a mid-state cluster of counties. To learn more about the physical activity and eating habits of families, focus group interviews were held with three groups of Hispanic and Anglo mothers attending WIC clinics. Information was obtained about needs, barriers, and motivators for physical activity and reactions to ideas about proposed types of educational materials. Results indicated that barriers to being active with preschoolers were lack of time and energy and limited resources. Educational materials were developed based on needs suggested by focus group participants. Materials included an activity calendar, reminder refrigerator magnet, poster, motivational videotape, and brochures. Most women responded favorably when asked if they used the calendar; and more than half indicated that it helped them be more active with their preschooler by serving as a reminder and a source of ideas for activities. The materials are currently being used by county staff, with future plans to make them available statewide. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated parent (PA) and sibling (SI) perspectives on the educational and community inclusion of students (aged 3-20 yrs) with moderate or severe disabilities. Interviews with PAs from 21 families identified the type and extent of inclusive educational and community settings in which the student and his/her PAs and SIs were involved. Eight of these target SIs were also interviewed to provide insight on their experience of inclusion. Mothers reported involvement in an average of almost 4 community activities, with fathers averaging 3 activities, siblings averaging 1.33 activities each, and the student usually engaged in only one activity outside of school. Themes that emerged included: 1) the belief that the child with a disability can function and achieve in the real world; 2) the desire to have the child with a disability around typical children as much as possible in order to serve as models of skill and behavior; 3) the PAs' view that regular education teachers are unwilling or untrained to accommodate children with disabilities; 4) the general satisfaction with the amount and type of inclusion both at school and in the community; and 5) the view that the student with disabilities models the typical sibling. SIs' perceptions tended to mirror those of the PAs. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined preschool children's play interactions and beliefs in inclusive preschool settings in order to better understand the experience of inclusive classrooms for children with and without disabilities. Individual interviews of 21 typically developing children and observations of 29 children with and without disabilities in the classroom and on the playground provided data for the study. Summaries of children's play patterns showed a tendency for children without disabilities to engage in more cooperative play and less solitary play and onlooking behavior than did their peers with disabilities. Descriptive comparisons of activity choice showed a high level of similarity between the types of activities that children with and without disabilities selected during free play. Typically developing children spent less time interacting with their peers with disabilities than was expected, and children with disabilities interacted less with their typically developing peers than was expected. An understanding of disability was predictive of stated preference to play with hypothetical peers with disabilities. Actual interactions with peers with disabilities were predicted by children's age and teacher presence, but not by an understanding of disability or stated playmate preference. N2 - Two experiments developed a physical activity scale for elementary school children, and examined the relationship between their daily physical activity and stress responses. In Exp 1, 234 pupils in grades 4-6 completed a battery of questionnaires in the classroom. Factor analysis revealed that the physical activity scale had a single-factor structure that consisted of 5 factors: physical education class, recess, lunch, after school, and the evening. 306 Ss in grades 4-6 participated in Exp 2, where results of a correlation analysis of the relationship between daily physical activities and stress responses indicated that the amount of daily physical activity was consistently correlated with the stress response subscales: physical states, depressive-anxious feeling, irritated-angry feeling, and helplessness. It was concluded that the increase of physical activity improves children's mental health. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The present study examined the relationship between peer social behaviours in naturalistic settings and lab-based measures of social understanding. A sample of 120 3- and 4-year-old children were presented with tasks assessing theory of mind, future-oriented self-control and sharing, peer-rated likability and empathic concern. They were also given a standard measure of general language ability. Children were also videotaped during a 10-minute naturalistic peer play session. Parents and teachers completed questionnaires rating children's global social skills, problem behaviours, and mental state concepts. It was hypothesized that older children would perform more successfully on lab-based measures and that their peer social behaviours would be more sophisticated. Results indicated that most of the lab measures, questionnaires, and naturalistic observations discriminated between the 3- and 4-year-olds in the expected direction. Compared to the 3-year-olds, the 4-year-olds achieved higher scores on lab-based measures of social understanding and these abilities enabled them to interact in meaningfully different ways with others. Four-year-olds interactive abilities were also seen as more sophisticated than 3-year-olds by peers, parents, and teachers. Three-year-olds used their restricted abilities in an indiscriminate fashion and were periodically successful in their interactions. In contrast, 4-year-olds showed more purposeful social behaviour. The patterns of data provide evidence of clear developmental differences between age-groups. These findings are discussed in terms of their implications for children's social development. N2 - The purpose of this research was to determine whether a challenge/initiative program conducted in an existing recreation setting that was not in an outdoor wilderness could be used as a treatment technique in enhancing a positive self-concept of low-income inner-city children. Data were collected using a pre-test-post-test control group design with the Piers-Harris Children's Self-Concept Scale (1996), (the standard and the modified scale version) administered from mid-April to late May of 1999. The dependent variables for this study were the post-test and the pre-test self concept scores as measured by the Piers-Harris Children's Self-Concept Scale (Piers & Harris, 1996). The independent variables were the types of treatment program experimental or control/ or challenge/initiative games or traditional games. Also sex, age, and ethnic background were considered independent variables. A total of 96 three-, four- and five-year old inner-city pre-schoolers were randomly assigned to experimental and control groups. The treatment group received challenge/initiative game treatment; the control group received traditional playground type competitive games for a duration of six weeks. Analysis of Variance (ANOVA) was used to determine whether there was a significant difference in overall self-concept as measured by the Piers-Harris Children's Self-Concept Scale (Piers and Harris, 1996) of post-test scores of low-income children who participated in the challenge/initiative games (experimental group) when compared with the low-income children who were involved in traditional recreational games (control group). Multivariate analysis of variance (MANOVA) was also used to test for differences in self-concept scores, pre-test scores (dependent variables), and the independent variables of sex, age and ethnic background. Results showed that there were significant and practical differences between the treatment and control groups when measured with the modified scale. The results of this study indicated that there is a need to address the development of children's self-concept within the pre-school setting of the inner city. Future investigations are needed, however, to identify other recreation programs to be included in the school curriculum to allow the children opportunities to explore their feelings and perform tasks successfully, thereby increasing their sense of competence, causing significant increases in their self-concept. Happy, cooperative, well-behaved children are more likely to make the pre-school environment a better work setting for the adults, and pre-school environments that promote the widespread use of cooperative games may have a positive impact on future social behavior. N2 - The effects of empathy training on the peer approval of students who had the most least-liked votes on a class sociogram and were considered the least empathic by their classmates was investigated. Peer approval was assessed through the administration of a pre, post, and follow-up classroom sociogram, Structured playground observations were utilized to determine if the empathy training resulted in an increase in positive peer interactions and a decrease in negative peer interactions. Peer perceptions of classmates' empathy were determined through the use of a sociometric format Students were asked to name the classmates they would like to be with if they felt sad and which they would not like to be with when they felt sad. Acquisition of empathy skills was measured by the pre, post, and follow-up administration of Bryant's Index of Empathy for Children, and Adolescents (1982). A multiple baseline across subjects design was utilized, to determine if empathy training increased the three participants' playground peer approval. Study results indicated that teaching children empathic responses increased peer approval as reflected by playground observations. These observations indicated that peers positively approached participants more and that the approaches of the participants were accepted more frequently. Participants also displayed a decrease in aggressive behavior. A six month follow-up of participants' playground behavior demonstrated that behavioral improvements had been maintained. Peer approval, as measured by a classroom sociogram administered immediately after the intervention's, completion, revealed minimal improvement in the participant's peer status. The minimal gains made by the participants on the classroom's pre- and post-intervention sociogram and empathy measure were not maintained six months later. These findings are consistent with previous results which indicate that empathy training contributes to an increase in prosocial skills and a decrease in aggressive behavior. N2 - The purpose of this study was to explore how, in the culture of an elementary school, children gain knowledge about moving, sitting still, and using their bodies in response to the daily demands of schooling. It describes the body use of a class of typically developing first graders (while viewing their learning as a step in

the larger enculturation process that prepares them for adult work roles in our society). Using qualitative research methods, the children and their teachers were observed and interviewed over an entire school year. The children also drew pictures and told stories about their perceptions and understanding of classroom and playground environment. Their skills in the areas of body concept and body use, and their physical size were assessed using quantitative research methods. After examining the school culture, four factors (program structure, the physical environment, and the behaviors of the children and their teachers) were found to have both overt and covert influences on body use. Two contradictory movement agendas (one expansive, the other limiting) were observed to operate simultaneously in the school setting. Body use factors identified as important in the school environment included sensory and perceptual processing, movement, neuromuscular integrity, cognition, and psychosocial skills. The children's performance on a repeated measure of body concept did not change significantly over the school year as had been anticipated. Their body use and physical size did increase significantly between pre and posttesting. Detailed descriptions of posture and movement (gross motor, upper extremity, and fine motor), based on observational data, were developed. From the children's stories, six themes relative to the body use enculturation process were identified. They included teaching and learning, work and play, understanding rules and routines, pleasing adults, and pleasing yourself. Recommendations for school personnel include advocating for more space, greater variability in classroom environments, and enriched playground environments. The development of teacher training materials in the areas of body use learning and classroom management of movement is also suggested. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purposes of this study are: (1) observe ways in which prekindergarten children initiate social interactions among peers to gain group entry and (2) examine the equivalent interactions from the children already in the group and (3) examine whether boys and girls use different social strategies and behaviors in their play. The research was conducted in a prekindergarten center located in a public elementary school located in a large urban community. The school served predominantly black middle class children. The center had four to five year to five year old children attending the extended day prekindergarten program five days a week. The children's uninhibited group play with their peers in centers and on the playground was examined through time sampling. Written descriptive observations of the children's activities during 10-15-minute-time observations were recorded on social interaction checklists and through field notes. Each child was observed according to a prearranged list, over a period of 15 weeks yielding to a total of 200 minutes of observations per child. The researcher served as an on-site participant observer three to four hours per day, four days a week. The methodology of participant observation consists of principles, strategies, procedures, methods, and techniques of research. Through participant observations, it is possible to describe what goes on, who goes on, who or what is involved, when and whether things happen, how they occur, and why-at-least from the standpoint of participants-things happen as they do in particular situations. The findings revealed: (1) prekindergarten children are accepted into social context by their peers more often than they are rejected. (2) When prekindergarten

children use verbal statements or commands when entering a social context, they are usually accepted by the peers than when attempting to enter non verbally. (3) Peers we more likely to non verbally accept or reject children who attempt to enter a social context and (4) Prekindergarten children rarely engage in solitary activities or avoid making bids for entrance into social contexts. The results from this study indicate that prekindergarten children who acquire social skills and verbal communication strategies are more likely to be accepted by their peers when attempting entrance into social context. N2 - The first relationships a child establishes are within the family context. As children grow older, their social interactions outside the family environment increase, and peers become more influential in their socialization. A very important research question in social development is how the family and the peer systems are related. Do children's interactions within the family influence children's interactions with peers? Although it is frequently argued that family interactions serve as a base for the establishment of interactions with peers, the nature of the processes and mechanisms by which the family and peer systems are linked have not been elucidated. More specifically, evidence of the role of family members other than the mother in children's peer interactions has been limited. The main purpose of the present research was to extend the studies of family-peer linkages to one of these neglected family members: the father. Thirty-five 7-year-old children (18 girls and 17 boys) were videotaped behind a one-way mirror in two 24-minute play sessions, one with their father, and one with an unfamiliar same-sex peer. Videotapes were scored using rating scales that assessed father individual behaviors with children, father-child dyadic interactions and children individual behaviors with peers. The results showed that some father individual behaviors were correlated with children individual social behaviors with peers. Similarly, dyadic synchrony was found to be significantly related to children's social behaviors with peers. However, the two types of measures (individual vs. dyadic) did not correlate with the same children's behaviors. Further statistical analyses showed that dyadic synchrony contributed to the prediction of children's social behavior with peers above and beyond father individual behaviors. These results suggest that both individual and dyadic measures of father-child interaction are necessary for an understanding and prediction of children's social interactions out of the family context. N2 - The matching law (Herrnstein, 1961) is a mathematical expression that predicts how individuals distribute their behavior between alternative sources of reinforcement. In general, the law states that the proportion of behavior given to a source will match the proportion of reinforcement received from that source. Tests of the matching law in experimental and natural settings have suggested applications to educational settings. The present study asked how well the matching law can predict from a teacher's allocation of attention to children's engagement with toys how the children will allocate their time to engagement or nonengagement. The participants were three very young, typically developing girls (ages 19, 21, and 24 months) who attended a university-based infant and toddler full-daycare program; and three teachers, who at the time were undergraduate students enrolled in a practicum in early-childhood education. After an analysis of how the teachers and the children allocated their time during a baseline condition, four subsequent experimental conditions were programmed in an ABC1DC2 design for two of the children, and three subsequent experimental conditions were programmed in an A 1BCA2 design for the third child. In each condition, different ratios of teacher attention (sometimes combinations of talk, laughs, and touches; and sometimes only talk) were prescribed for the children's engagement and nonengagement. When the relative values of teacher attention for engagement were compared to the relative values of child engagement, the results overall suggested that the matching law was predictive: Across conditions, the proportion of teacher attention to the children's engagement predicted a roughly matching proportion of the children's engagement, relative to their nonengagement. All three participants, however, showed some degree of undermatching and bias. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of this research was to examine the peer processes that occur during episodes of bullying on the school playground. These processes were examined within a social learning theory perspective, while also drawing on emotional contagion theory, an ethological approach to studying dominance hierarchies, and dynamic systems theory. Fifty-three segments of videotape that contained a peer group viewing bullying on the school playground were examined. Peers were coded for actively supporting the bully, passively watching the bullying, and for actively supporting the victim. Also coded were the levels of affect, aggression, and distress of bullies, victims, and peers, throughout each episode. On average, four peers viewed the schoolyard bullying, with a range from two to 14 peers. Averaged across all episodes, peers spent 53% of their time passively viewing bullying, 25% of their time actively supporting victims, and 22% of their time actively supporting bullies. Older boys were more likely to spend time helping the bully, and less likely to spend time helping the victim, than were younger boys, or girls of either grade level. Sequential analyses were used to examine, over time, peer influence on bully affect and aggression ratings. Peer active support for the bully was related to subsequent decreases in bully negative affect ratings, and increases in aggression ratings. Other types of peer interaction with the bully or victim (i.e., passively watching the bullying, intervening to help the victim) were not associated with changes in bully affect or aggression ratings. Chi-square analyses indicated few relationships between the number of peers present and intervention on the victim's behalf. Regression analyses of peer social status indicated a relationship to intervention on the victim's behalf: overall, the trend was for less disliked children to intervene more, while more disliked children were less likely to intervene. Taken together, the data suggest that peers are often aware of playground bullying, but may feel powerless to effectively intervene. The viability of a dynamic systems framework for examining peer influences on playground bullying is considered, and the results of the study are discussed with regard to possible intervention strategies.

N2 - To date, a small number of researchers have identified cultural factors that appear to explain the high academic achievement of Asian American students. In their explanations for achievement, some have acknowledged motivation by citing related constructs such as high achievement standards, effort attributions, and perseverance. This study was undertaken to determine if the motivational patterns of Korean and Caucasian American students vary significantly, assuming differences in cultural values and socialization practices at home. Additionally, in light of the intensive focus on the math success of Asians, patterns of motivation were

assessed with respect to both social studies and math. Questionnaires were administered to fifth and sixth graders ($n = 275$) attending schools in predominantly upper-middle SES neighborhoods. Students answered questions tapping various motivational constructs such as goal orientations and achievement standards. Their parents were asked questions designed to capture thoughts about child-rearing and academic expectations. Data were subjected to race by sex analyses of variance and regression analyses. Students tended to take the same approach to learning math and social studies. Moreover, with respect to patterns of motivation, little distinguished Korean American students from Caucasians. However, as reported in existing literature, Korean students tended to hold higher academic standards for themselves than their Caucasian peers and in fact felt subject to higher parental expectations. They believed themselves to be more able in math than social studies, but did not significantly differ from Caucasians with respect to achievement measures. A greater percent of Korean students than Caucasian participated in activities outside of school. As for parents, the Koreans expected their children to maintain set grades. Caucasian parents were not so inclined. Finally, Korean parents, like their children, appeared to view math and social studies differently. Not only did they believe their children to be better at math, they tended to feel that their children work harder at it than social studies. To better understand patterns of motivation and achievement as well as differing views toward various school subjects, future studies should examine more diverse groups of students, socioeconomic and otherwise. N2 - The purpose of this study was to compare the effects of Leonard Gordon Institute developmentally-oriented, low-organized games and free play recess on the self-esteem of young children ($N = 20$). The subjects were 5 to 8 year old patients in a psychiatric partial hospital. All 20 of the young children had been diagnosed with some type of psychiatric disorder according to the Diagnostic and Statistical Manual (DSM IV). Most of the young children also suffered from Attention Deficit/Hyperactive Disorder, with accompanying cognitive developmental delays. The intervention was a program of 25, 30-min sessions of Leonard Gordon Institute developmentally-oriented, low-organized games. The young children were evaluated four times, over a period of 15 weeks, using the Behavior Rating Scale of Presented Self-Esteem in Young Children. The intervention took place during the 6th and 10th weeks. A within-subjects design was used to allow for the maximum number of young children to participate in the intervention. The data were examined with a one-way analysis of variance for repeated measures with four levels. Based upon the findings of this analysis, young children did not increase their self-esteem, at the $p < .05$ level of significance. In an effort to elicit qualitative feedback about the participants' experience in the game program, the young children were interviewed, individually, following their participation in the intervention. Questions and participant responses are included and discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Utilized qualitative and quantitative measures to explore the abilities of 11 young children (36-49 mo old) nominated by their parents as gifted. A part-time preschool enrichment program provided a naturalistic setting in which to investigate measures that might reflect potential giftedness, predict later achievement, and reveal individual profiles of development. The curriculum invited children to display any differences from typical preschoolers. Characteristics nominated by parents as indicators of their child's giftedness were consistent with indicators in the research literature and were generally supported by norm-referenced test results and teacher observations. In spite of test limitations, both quantitative and qualitative measures played a valuable role in revealing advanced abilities amidst diverse profiles of abilities, skills, and interests. Longitudinal data would help to confirm the potential apparent in some of these children as giftedness. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Employed naturalistic observations to compare 185 school children's bullying and victimization in the playground and in the classroom. The results indicated that there were more opportunities to observe aggression and receive and initiate aggression in the playground than in the classroom. The frequency of bullying was higher in the playground (4.5 episodes per hour) than in the classroom (2.4 episodes per hour). The nature of bullying reflected the constraints of the context (i.e., direct bullying was more prevalent in the playground and indirect bullying was more prevalent in the classroom). Being at the receiving end of aggression was more likely to occur in the playground as compared to the classroom. Nonaggressive children were more likely to bully in the playground, whereas aggressive children were more likely to bully in the classroom. There was no difference across context in the proportion of episodes of reinforcement with peers present or in the rate of peer and teacher intervention. The results highlight the necessity of a systemic intervention program that addresses not only the individual characteristics of bullies and victims, but also the roles of the peer group, teachers and the school. N2 - Presents 3 interlinked studies aimed at (1) developing a curricular frame for physics education; (2) assessing student interest in the contents, contexts, and activities that are suggested by that frame; and (3) developing a curriculum in line with that frame and measuring its cognitive and emotional effects on students. The curricular frame was developed by drawing on the expertise of 73 persons from the fields of physics and other sciences as well as education. Data of some 8,000 11-16 yr old students and information of the presently taught physics curriculum were sampled longitudinally and cross-sectionally. The 3rd study comprised 23 experimental and 7 control classes. As a result of the comparison between the features of the curricular frame, the interest structure of students, and the current physics curriculum, there was a remarkable congruency between students' interest in physics and the kind of physics education identified by the science and education professionals as being relevant. The data suggest physics be taught so that students have a chance to develop a positive physics-related self-concept and to link physics with situations they encounter outside the classroom. A curriculum based on these principles proved superior compared to a traditional curriculum. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the purpose and patterns of Internet usage among 384 junior-high and high school students (aged 12-18 yrs) in Israel, with a focus on the linkage between Internet usage and school activities. The findings show that the Internet was being used by about half of the students, with the main use being for communication. Search for information was the second reason. A low degree of connection was found between Internet usage and school practice. The results show significant sex differences. In general, more boys were using the Internet more extensively than girls. Only a few differences among age groups were found. The findings are discussed in terms of the range of Internet use among youngsters and its emerging role as an alternative knowledge resource outside school. N2 - Private speech (PS)-or speech for the self-was studied in 25 preschool-age children to determine how widely and with what characteristics it occurs when examined in the familiar home setting. Activities were selected that required several steps and that were intended to engage working memory or longer term recall. Both quantitative (numbers of words and utterances produced) and qualitative (utterance type) analyses were conducted on the children's PS. Across the age range from 4.5 to 6 yrs, younger children had higher frequencies of PS than older children. Increased information loads resulted in more PS, indicating a relation between PS and task difficulty; however, total quantities of PS were not correlated with degree of task success. Self-regulatory utterances accounted for 89% of the PS produced; the majority of these utterances involved repetitions of the instructions that appeared to enhance recall, to help pace the children's activity, or to enable deliberation with respect to making choices. There was a strong age trend in which the amount of audible PS decreased with age. Qualitative differences across tasks are presented and considered in relation to how PS functions for different activities and possibly achieves adaptive significance. N2 - Examined everyday interactions with peers of children observed in natural settings of a school. Ss were 122 grade school children (aged 10 yrs) in Germany. Ss were observed engaging in a poetry writing task and playground activities to determine which kind of activity caused the most frustration and conflict. This article discusses the diverse functions of violence in children's interactions, such as affirmation of reciprocity and justice, experience of agency and control, preservation of territories against intruders, clear messages, compensations of lacking capacities, and self-defense. Results show that quiet activities, such as reading and writing, yields higher frustration levels, but lower incidences of physical violence; whereas, rough-and-tumble play yields more physical confrontations. VL - Childhood social development: The essential readings. xi, 375 pp. Malden: Blackwell Publishing.

N2 - (from the preface) Introduces students to the field of childhood social development and is intended for readers who are newcomers to the field of social development research and are interested in reading current and original articles by developmental theorists and researchers on various aspects of social development. This book also is designed as a supplementary text for undergraduate and graduate courses in developmental psychology and social development. The selection of articles is based on several criteria. (1) The articles should represent the current state of research into social development: thus, 11 of the 13 articles have been published in the 1990s. (2) The articles should be representative of current theoretical and methodological approaches in social development, as well as illustrating elegant empirical research. (3) The articles should be accessible, in the sense of being understandable to students with limited backgrounds in psychology. (4) Finally, because this book is one of a series, the authors have tried to avoid repeating the same article in different readers. (create) The chapters are journal reprints that were covered by PsycINFO at the time of their original publication and can be found in the PsycLIT journal database. N2 - Examined the relationships between levels of the diachronic approach in children and their ability to imagine solutions to a conflict between children. 60 children (aged 8-12 yrs) were presented 1st with tasks assessing their level of diachronic tendency (propensity to evoke past or future stages of a present situation), of dissociation of 2 temporal sequences (absence of covariation of a cause and its delayed effect) and of dynamic synthesis (ability to describe a set of pictures representing the successive steps of an event by a single noun phrase). During a 2nd session, the participants were presented with a drawing representing 2 boys fighting in the playground and they were asked to explain the reasons for the fight. Participants then had to imagine several solutions to prevent the 2 boys fighting. Results showed a development in the ability to imagine solutions to a conflict and a significant correlation between the levels of this development and the levels of 2 aspects of the diachronic approach, temporal dissociation and dynamic synthesis. N2 - Examined the physical and social play of children, with a focus on types of motor play and whether children played alone or in groups. The playground activity of 110 children (aged 6-10 yrs) was observed for 10

5-min periods. 55 children were assigned to a developmental coordination disorder (DCD) group and 55 to a control group, on the basis of their scores on the Movement Assessment Battery for Children. Results indicate that Ss in the DCD group spent more time alone, were onlookers more often, and played formal games in large groups less often if they were boys and informal games in large groups less often if they were girls. It was found that social fantasy play did not differentiate between the 2 groups but social physical play did, particularly in the older age groups. Play performance in the DCD group was more variable overall with some boys taking an active part in team games while others never took part in them. It is suggested that as social non-physical play decreases with age, some children with impaired coordination may not become involved in social physical play and that children with impaired coordination can become isolated and solitary in the school playground. Various routes to social exclusion for these children are proposed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Changes in intergenerational attitudes in 32 children (aged 8-11 yrs) and 20 elderly adults (mean age 71.7 yrs) were investigated using activity groups. Applying the theory of realistic intergroup conflict, the authors varied the amount of joint activity between groups. In the experimental group, joint activities (e.g., writing stories, making glove puppets, performing a puppet show) were organized by the researcher. In the control group, although there was visual contact among them, the children and elderly participants worked alone. The elderly adults' ratings of the participating children became more positive only in the experimental group. However, children's ratings of the elderly participants improved regardless of the experimental condition. Seven wks after the end of the intervention, only the children's changes in attitudes toward the elderly participants remained significant. Improvements in intergenerational attitudes during group activities were associated with increased frequency of intergenerational contact outside the group. N2 - Investigated the decision to outsource child care among 103 families involved in family-owned businesses who had at least 1 child under 5 yrs of age. A management framework is used to examine the impact of inputs to the decision (i.e., goals, resources) and level of management activity (i.e., planning, implementing) in these families as predictors of the choice to outsource child care. Data are from a subsample of the data from a project by M. Winter et al (1998) undertaken in 1997. Household managers who worked in the family business were less likely to outsource child care than were those who worked outside the family business. More educated household managers purchased more and managers in larger families purchased fewer hours of child care. Female household managers purchased significantly fewer hours of child care than did their male counterparts. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Considers the commercialization of playgrounds and its significance to the commodification of childhood. J. McNeal's (1992) theory of the social group of children as a market is introduced as a framework through which commercial playgrounds may be understood. An introduction to commercial playgrounds and the project from which the article is derived sets the context for an analysis of how parents and children perceive and experience these environments, how they are marketed to them and how they consume them. Data was collected as part of a project in which research was conducted in 10 field sites, 872 families were surveyed, of which 30 Ss (adults and 5-12 yr olds) were interviewed, and, in turn, 7 participated in a family day-visit/postvisit video-based interview. It was found that it is overly simplistic to suggest that these developments are testimony to the new-found consumer power of children. Children play a marginal role in the production of these play environments; in contributing to parents' information field prior to decision-making; and in the visit decision-making process. Some groups of children were found to be more active consumers of these spaces. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The main purpose of this study was to determine the stability across time and social setting of children's social participation and social withdrawal. The authors followed a sample of 98 Canadian children, aged 5 yrs at the beginning of the study, for 2 yrs. Data were collected through home visits, interviews with parents, and direct observation of Ss. Children from lower-SES homes were less involved than those from the higher-SES in group play after school and during outdoor recess. Across the full sample, social withdrawal was not very stable. There was, however, considerable stability across setting and time among extreme groups of withdrawn participants. Social withdrawal was largely unrelated to parents' initiation of peer contacts for their children.

N2 - The role of the community environment in shaping dietary and physical activity (PA) behaviors has received increasing attention in recent years. Although schools are a key part of the community environment, interventions that promote PA and healthy eating among students through changes in the school environment have received relatively little attention. After reviewing the role of environmental factors in shaping health behavior, this paper describes the various aspects of the school environment that influence PA and nutrition behaviors. Relevant research is described and new directions are proposed for 5 key environmental influences: recess periods, intramural sports and PA programs, PA facilities, foods and beverages available outside of the school meals program, and psychosocial support for PA and healthy eating. Recess, intramural programs, and access to school PA facilities outside of school hours can provide opportunities for health-enhancing PA. States, school districts, and schools can establish strong policies and implement creative interventions to promote healthy eating through the foods and beverages offered at school. Schools can offer psychosocial support for PA and healthy eating through school policies, role modeling by staff, and the use of cues and incentives. N2 - Increasing a school's capacity to effectively deal with challenging behavior on a systemwide basis has increasingly been advocated as a promising practice. However, there is limited empirical support for large scale interventions focusing on specific school settings. The purpose of this study was to examine the effectiveness of implementing a pre-correction and active supervision strategy on the rate of problem behavior observed during recess on an elementary school playground. Participants were 475 students and 42 staff in an elementary school serving kindergarten through 5th grade. Using a multiple baseline across groups design, results indicate that the intervention reduced rates of problem behavior exhibited by elementary students, but was not effective in increasing rates of active supervision on the part of playground monitors. N2 - Investigated the ways in which alternative and authentic assessments would result in students of varying learning abilities increasing their self-expectations and performance levels. During the 1995-96 school year, 25 6th-grade students engaged in authentic and alternative learning experiences, reflection, goal setting, and self-assessment. A portfolio design was used that would allow Ss to give evidence of their growth as learners to an outside audience. Four Ss were targeted and their work collected. Presented are a synopsis of findings including the goals they set for the different quarters and reflections or writing products of selected units of instruction. Evidence was collected demonstrating that when given the opportunity to engage in performance-based activities and assessments, students with learning disabilities can begin to clarify their strengths and weaknesses as learners in order to set goals for improvement. N2 - The purpose of this study was to develop, implement, and evaluate an after-school program aimed at preventing unhealthy dieting and excessive weight preoccupation. This study targeted preadolescents (ages 10-12) and took the prevention program outside of the classroom, incorporating the curriculum into the Girl Scout program. This program used a nonacademic approach to teaching concepts similar to those in programs that have previously been targeted at older adolescents within school setting. The primary objectives of the program were to develop healthful attitudes toward eating, physical activity, body image, and weight control in order to prevent unhealthy behaviors. The program in this study consisted of six weekly, 90-minute sessions that focused on three health messages: "Enjoy a variety of foods," "Physical activity is fun," and "Be proud of yourself-everyone is different". Results showed that changes in eating attitudes and behaviors were minimal. The parents completed written evaluation and focus group questions. They reported that they enjoyed the program but found that they had little time to read the parent tip sheets. The minimal impact of the intervention on eating attitudes and behaviors has led to the conclusion that programs of this nature (i.e., short duration, low intensity) may need to take a more focused approach. N2 - Based on survey responses from 230 students enrolled in a summer gifted program at a university, this study gives a description of gifted students' participation in extracurricular activities in and outside of school. Findings show that gifted students were more involved in competitions, clubs, or other extracurricular activities in mathematics than in other subject areas and were the least involved in computer science activities. Sports were the most frequent extracurricular and outside-of-school activities, as well as playing and working with computers. The data reveal some gender-stereotypical tendencies regarding participation in and outside-of-school activities and gender-typical patterns of support from parents. Grade and course differences were also found. Contributions this study makes to the existing literature are to assess the consonance of children's participation in outside-of-school and extracurricular activities with their talent area and to document

empirically parental involvement and independent home study for gifted adolescents. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - (from the chapter) The epidemics of pregnancy and sexually transmitted diseases (including HIV) that currently affect so many youth must be addressed. Despite adequate knowledge about how pregnancy and HIV transmission may occur and how to prevent them, many youth put themselves at risk through sexual behavior. When questioned, youth will often comment that sex "just happened." Interventions must take into account the cultural, social, and contextual aspects of sexual behavior. A curriculum is presented that was developed to assist 6th, 7th, and 8th grade students in postponing sexual activity and using protection if they are sexually active. Focus groups and practice sessions were used extensively in development. Evaluation of the curriculum involves a 36-mo longitudinal randomized trial following 2,892 middle school students. The curriculum has many characteristics that are shared by successful HIV prevention and sex education curricula: theoretical foundation, focus on social pressures of sexual behaviors, and modeling and practicing communication and negotiation skills. Specific activities from the 20-lesson curriculum and activities of the educators outside the classroom (during office hours) are discussed. N2 - During recent years there has been an increase in the use of challenge course programs as a method of building teams (Springett, 1987). Although participation in these activities is growing, research in this area remains limited (Johnson, 1992). There is a need for studies to further investigate the use of challenge course programs and examine possible outcomes of their implementation. One of the key factors in the development of a group is the idea of cohesiveness (Griffin & Pennscott, 1991). A setting in which group cohesion is desired is with challenge courses (Davis, Ray, & Sayles, 1995). The use of outdoor activities as a team-building technique has become increasingly popular (Springett, 1987). Generally, participants who have been removed from their normal social context engage in a number of physical activities that often are not directly related to the group's primary purpose, with the aim of attaining new goals, both as individuals and as a group (Martin & Davids, 1995). The label "challenge course" has been used to encompass a wide array of programs used with diverse populations. For the purposes of this study, the term was used to describe a low-element (close to the ground) experiential program designed for groups rather than individuals. These group exercises require participants to share responsibility and to solve problems as a team. Successful solutions to these problems depend upon the extent to which group members cooperate, trust and communicate with one another. In addition, these group exercises impart "lessons," which participants will later apply to problems in their personal lives (Harris, Mealy, Matthews, Lucas, & Moczygemba, 1993). A review of related literature provided no study that investigated whether one-day low-element challenge course programs increased the perception of group cohesion among adolescents ages 11 to 14. This research was designed to measure the perception of group cohesion among adolescents in this age range who participated in a low-element challenge course experience. The variables of gender, race, age, and being labeled "at risk" were included to determine their effect on the outcome of the study. With limited amounts of previous research in this field, this study sought to broaden the knowledge about the impact of challenge course programs, and add credibility to activities which have long claimed to produce favorable results. This study revealed that participating in a low-element challenge course program did increase perceptions of group cohesion among adolescents 11-14 years old. Furthermore the study showed that the variables of gender, race, age and being labeled "at risk" had no significant effect on the results. In addition, this research provided an instrument created specifically for use in measuring perceptions of group cohesion among adolescents. N2 - The present research attempted to address how metacommunication of young children relates to the products in a collaborative problem solving, along with the three main purposes: first, to investigate the relationship between metacommunicative talk in a dyad and the proper movement of the robot; second, to compare metacommunicative output by the two roles in the robot game, which are Operator and Witness; and last, to examine the increase of metacommunicative talk over the course of the games. To answer the question above, using a small battery-operated robot, 10 kindergartners and 12 first-second graders were asked to play games, which were a collaborative task that requires two children; Operator and Witness. Each dyad participated in three sessions, playing both roles during one session. After quantitative analysis of the data administered to address the three purposes, qualitative analysis was done to detect the in-depth processes between metacommunication and the collaborative problem solving. The relationships between metacommunicative talk in a dyad and the proper movement of the robot were complicated, indicating the relationships are more task-specific. It was found that there is a fair amount of role-dependent variability. Frequencies of metacommunicative output vary from the subcategories of metacommunication. Usage of the subcategories is related to the role that a child plays in the robot games. Adversely to prediction about the last purpose, the metacommunicative usage decreased as the sessions continue. The plausible accounts were addressed about the findings. Qualitative analysis revealed that the children utilized metacommunication for various reasons. They are to clarify statements, to retell previous statements, to prompt the games, to expatiate insufficient instructions voluntarily or with input from the outside, to be aware of linguistic references, to repeat other's statement, to regulate other person's statement in order to stop partner's talk or to start own talking, and finally to integrate a previous statement to the present communication. In coda, the benefits of using metacommunication were acquisition of a correct concept on the instruction given and advancement of communication skills as the game proceeded. N2 - Depression in children has been associated with social skills deficits and limited and negative social interactions with others. The purpose of this study was to apply the interpersonal model of depression to depressed and nondepressed children and to examine their temporal interaction sequences. This study compared the behavior of 21 depressed and 25 nondepressed children, from third to sixth grade classes, in a local elementary school within structured gym class and unstructured free play contexts. A real time direct observation method was utilized to code the children's behaviors within a time-sampled interval coding system. Children were observed for six ten-minute intervals, for a total of 60 minutes, distributed equally and randomly across both settings. Children's behaviors were coded into positive, depressive, aggressive, noncompliant and solitary behavior categories by trained observers. Within each 20 second interval, the observers first coded the target child's behavior (A), followed by reciprocal responses (B) from his/her partner, peer or teacher, and finally the consequent behavior displayed by the target child (C). Results indicated that the depressed group exhibited a lower propensity to display positive behaviors than the nondepressed group. This group also spent

more time engaged in solitary activity: (a) alone in isolation from others; (b) alone displaying depressive affect; and (c) alone but in proximity of others. Although they were not able to maintain them, depressed children initiated as many interactions with partners as nondepressed children. Their interactions, whether positive or negative, were significantly shorter in duration compared to those of nondepressed children. Negative behaviors for both groups occurred with significantly greater frequency in the playground than the classroom. Gender differences indicate that boys displayed significantly more aggressive initiations and exchanges than girls, whereas girls exhibited a higher frequency of isolative behaviors with depressive affect than boys. Results support an interpersonal model of depression for children. Depressed children demonstrated difficulty in maintaining their interactions despite their efforts to initiate contact with others. N2 - This study was designed to obtain a comprehensive assessment of social competence and social functioning problems of elementary school children with Attention Deficit/Hyperactivity Disorder (ADHD) using multirater rating scales and social cognitive measures. The sample consisted of 83 children, both boys and girls, between the ages of 8 to 12. There were 41 children in the ADHD group and 42 in the comparison group, which consisted of typically developing children. Social competence was measured using the Social Skills Rating Scales (SSRS). The scale was administered to parents, teachers, and children. The social cognitive measures consisted of six stories depicting children in three conditions (intentional, non-intentional, and ambiguous) and in two contexts (classroom and playground). The children listened to the stories and identified the intent of the story characters, generated behavioral responses for both self and the story character, and assigned a punishment level. The findings indicated that teachers and parents rated ADHD children lower than the typically developing children on social skills, and higher on the problem behaviors domains, whereas the ADHD children rated themselves to be comparable to the typically developing children in the self-control and empathy subscales. However, when standard scores were utilized for comparison, both the groups were comparable in social skills, problem behaviors and academic competence. In social cognitive measures, the girls in the ADHD group assigned higher levels of punishment in the intentional-playground context than did those in the comparison group. This suggests that the ADHD girls may be at risk for negative social consequences since they were more punitive than the typically developing girls. Although the relationship between social competence and social cognition was not established for all variables, nevertheless, the findings do show that the ADHD children may not have serious deficits in overall social skills functioning, social knowledge or social competence. N2 - Research on resilience to urban stress has focused on family factors, social support outside the family, and personality factors as important determinants of adjustment. The current study examined optimism as a personality factor that promotes positive adjustment in inner-city middle-school students exposed to high levels of community violence. In phase one, optimism and comparative optimism were investigated, with particular attention to optimism about controllable and uncontrollable events. Three models were examined, testing a mediating, additive, and moderating relationship among exposure to community violence, optimism, and emotional adjustment. In phase two, two mediating models of the relationship between optimism and adjustment were tested. The first of these was based on Sroufe's (1990) organizational model of self, with self-system functioning as a mediator. Self-system functioning comprises a set of expectations about self, others, and interactions with others. The second model was based on Scheier and Carver's (1982) work in which behavioral self-regulation is a mediator. Behavioral self-regulation involves use of active coping strategies, rather than withdrawal tactics. Participants were 250 (133 boys, 117 girls) 11-16-year-olds recruited from two public middle schools in primarily African-American and Latino/a, low-income communities. In phase one, consistent with the adult literature, adolescents evidenced comparative optimism, believing that they were less likely to experience negative events than was the average person their age. Participants believed they were more likely to experience uncontrollable events (e.g., being shot or killed) than controllable events (e.g., drinking alcohol). Adolescents exposed to higher levels of community violence experienced more emotional distress and were less optimistic, particularly about uncontrollable events, than were those exposed to lower levels. Support was found for an additive model, in which exposure to community violence and optimism both contribute independently to emotional distress. Phase two data indicated that optimism influences both the development of self-system functioning and positive adjustment. Behavioral self-regulation appeared to mediate the relationship between optimism and adjustment for students who were doing well in school, but not for students referred for counseling groups due to referred students' use of behavioral withdrawal as a coping strategy. Longitudinal research is needed to verify the directionality of the current findings. Interventions that target optimistic beliefs by encouraging mastery of challenging situations may provide a means to improve adjustment and self-system functioning in adolescents. N2 - The purpose of this study was to explore and describe the role of play in the development of social competence of at-risk preschoolers. The study was guided by four research questions: What is the role of play? How does play advance the development of social competence in at-risk preschoolers? What are the components of play? How does the classroom influence play? Initially there were 19 preschool children in the study. Their ages ranged from 48 months to 66 months. The group was comprised of eleven girls and eight boys. The girls ranged in age from four years to five years and three months, having a mean age of four years and nine months. The boys ranged in age from four years to four years and eleven months, having a mean age of four years and seven months. Thirteen of the children were African-American, five were white, and one was Latino. Three of the children were classified as having speech and language problems, and seven of the children were enrolled in the program for other unspecified circumstances. By the end of the school year, there were 20 children in the study. All of the children were from low income families, all had been recruited from the county's Head Start waiting list, and all had been enrolled in the Head Start program on a full-time basis. All of the children were considered to be at risk of failure. Observation, interview, documents, and artifacts were used to address the four research questions. The children's social behaviors were observed as they interacted in the course of indoor and outdoor play. Social problem solving skills were assessed in an interview with each child. Hypothetical play situations were presented to the children in photographic representations and discussion. The children were questioned as to their interpretations of each play situation and what ideas they had to resolve the problem. The collected data were examined using domain analysis procedures. Vygotsky's theory of play provided the framework for interpreting the findings. The study's findings indicated that, for at-risk preschoolers, social information processing is fundamental to social competence; aggressive strategies lead to non-compliance and conflict situations; mixed-age collaborative play enhance problem solving strategies and prosocial skills; components of play advance total development, the social context of play influence peer interaction; making choices promotes self control and an acceptance of responsibility for one's actions; and caring and supportive adults in the play environment promote positive peer interaction and enhance social competence. N2 - The purpose of this study was to examine the peer interactions of children with Down syndrome during recess. Twenty-nine children aged 6 to 11 years were observed during recess in two different educational placements, a special education placement (N = 14) and an included placement (N = 15). Two behavior measures were employed in this study. One was used to directly assess peer interactions on the playground (Howes, 1980). The other was used by teachers to assess the social competence of their students (Guralnick, 1990a). Each child was observed two times during their recess for a total of 30 minutes of observation time. Play categories that were coded included entry behavior, response to entry behavior, agonistic behavior, agonistic response, involvement, play behavior, affect and interactions with adults. There were group differences (special education versus included) in the categories of involvement (onlooker behavior), and positive adult interactions. Children with Down syndrome in the general education placement spent less time in onlooker behavior during recess than children in the special education placement. Children in the special education placement had adults managing their behavior at recess in a positive manner approximately three times as often as children in the included placement. There were also gender differences in the categories of unoccupied behavior, neutral affect and negative adult interactions. Girls were engaged in unoccupied behavior nearly three times as often as boys. Boys displayed neutral affect twice as frequently as girls and were observed in negative adult interactions while girls had no observations of negative adult interactions during recess. In spite of differences in observed playground behaviors of children with Down syndrome, teachers rated the social abilities of the children similarly. Overall the results suggest educational context had little effect on the peer interactions of children with Down syndrome. Gender influences and particular child characteristics (etiology specific) may be important contributors to peer interactions for school-aged children. N2 - The purpose of this study was to compare the effectiveness of two approaches to conflict resolution instruction on the knowledge and behavior of elementary school children. One approach, the modified peer mediation program, employed a class meeting procedure for addressing student conflicts. The second approach, the curriculum based program, utilized the Second Step Violence Prevention Curriculum. Two fourth grade classes and one third grade class were randomly assigned to treatment groups. A remaining third grade class served as the control group and received no treatment. Classroom teachers led instructional sessions in conflict resolution strategies for the course of a semester. An analysis of covariance (ANCOVA) was conducted on

Matson's Evaluation of Social Skills with Youngsters (MESSY), Teacher and Student versions and "How I Solve Problems" test. A repeated measures analysis of variance was used to analyze scores on the Conflict Report Forms, Self Report. A Chi Square analysis was conducted on the number of office referrals. The playground observation provided a naturalistic component to the study and results were described nonstatistically. Initial examination of the results indicated grade level differences. For this reason, results were analyzed separately along grade levels. The results of the MESSY, Teacher Version, indicated teacher perception of growth was significantly greater for the curricular group of third graders and the class meeting group of fourth graders. The results of the MESSY, Student Version, indicated a treatment by gender interaction. The third grade boys in the class meeting group scored significantly better than the girls in the same group, and the third grade girls in the curriculum group scored significantly better than the boys in the same group. None of the other analyses indicated significant differences between the groups. This study represented the first attempt to compare conflict resolution programs for elementary school children. The results suggest that a combination program, which relies primarily on teacher directed lessons for younger children with increased student responsibilities for children over third grade, may provide the type of eclectic approach necessary to benefit all children. N2 - This case study involves a change in the method of interaction between an elementary school principal (participant-observer) and students (informants) who have been involved in playground misbehavior incidents. The site is a suburban school in a primarily white, middle socioeconomic community. The grade levels of the school span nursery to grade three. Prior to the beginning of this study, the school had lost its playing fields and much of its playground structure due to district building and safety initiatives. The purpose of the study is to describe, explain, and evaluate the "Guided Interactive Story Telling" (GISStT) process. This method of interaction was developed to enable young school children, ages 5-10, to recount playground misbehavior events to the school principal. The study evaluated the influence of GISStT on the understandings, emotions, and subsequent actions of its participants. The study compared the effectiveness of GISStT with the more traditional approach formerly used at the school. The latter was an interview-type of interaction based on due process and assertive discipline (DuAD). The results of the study followed the "effect" pattern: z-scores of the cognitive and emotional quality of the scripts were above the critical value; and the time-series graph for repeated misbehaviors showed a decline after GISStT was introduced. The problem-finding character of the interaction was noted to be an essential element in predicting the students' success. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of this case study was to portray the literate behavior of a Taiwanese young child in naturalistic settings at home and the preschool. A further purpose was to explore the socio-cultural characteristics embedded in the literacy environment the young child experienced. A qualitative case study method was implemented to systematically gather descriptive data in the naturalistic field and to inductively derive common features grounded in one young child's literate behavior and the literacy environment the child experienced. The field work conducted for this study lasted about ten months, during which time the child aged from four years seven months to five years five months. The findings of this study suggest that the participant constructed her emergent literacy knowledge through consistent social and functional engagement in literacy activities at home and the preschool. The literate behavior patterns demonstrated by the participant are illustrated in the aspects of knowledge about print, use of print, story reenactment, and the attitudinal behavior toward literacy. In addition, a varied range of adult attitudes toward literacy learning, literacy activities held at home and school, literacy props, as well as literacy facilitation are identified in this study. Concluding remarks in the perspective of the investigator and the directions for further research are provided. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated the relations among cooperative interactions of 70 children with or without special needs (aged 3.2-5.6 yrs) in groups of typically developing peers, peers having special needs, and in inclusive groups, as well as the complexity of the activities in which they were engaged in. Complex activities were those involving fine motor skills as well as higher levels of cognitive, social, and language abilities. The associations among child and program level factors and the children's involvement in different cooperative activities also were examined. Findings indicated that children with or without special needs were likely to engage in cooperative play only with other typically developing children during complex activities (e.g., playing with small toys in the sand or talking). Results also indicated that children with or without special needs tended to engage in cooperative play in inclusive groups (composed of children with and without special needs) during less complex or low-demand activities involving predominantly gross motor skills (e.g., sliding or running). Interventions are needed to facilitate involvement of children with special needs in complex activities on the playground. This is an important area for future research and educational practice efforts. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Studied the effect of the elementary school playground on the social and solitary activities of students with mental retardation who learn in regular classrooms, special classrooms in a regular school, or a special school. 26 moderately mentally retarded elementary school students (mean age 9 yrs) who attended regular classes (10 Ss), a special class in a regular school (8 Ss), or a special school (8 Ss) in Canada were observed during at least 1 recreational period lasting at least 15 min. One O was present in about 85% of cases, and 2 Os were present in about 15% of cases. Compared with Ss from special classrooms or a special school, Ss from regular classrooms had more opportunities to interact with normal peers during recess (although their school playground offered less play-related materials than playgrounds designed for mentally retarded students), were more involved in group play, and demonstrated less rough play and less solitary play. However, Ss in all 3 environments often were alone and unoccupied during recess. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Used a multilevel universal intervention program for at-risk students and those identified as having emotional and behavioral problems in urban schools. The program addressed classroom management, social skills, and peer tutoring. Students at risk or with emotional and behavioral disorders (EBD) were selected based on the Systematic Screening for Behaviors Disorder test. This sample included 21 boys and 3 girls in K-7th grade, with 16 African American and 8 Caucasian students. An experimental-control, posttest design was used to analyze data from a target group and a control group. Direct observations revealed differences in on-task, positive recess interaction and play, aggression and, out-of-seat behaviors. Teacher reports indicated significant differences for appropriately requesting attention, following directions, and reducing disruptive behaviors for the target group. Implications for early prevention and behavioral support systems for students with or at risk for EBD are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Urban African American fathers' involvement with their children born outside of marriage is assessed through maternal reports. Multivariable composites of paternal involvement indicate that about half of unmarried fathers are highly involved at the time of birth and when children are preschool age, and half are uninvolved. However, nearly 40% of fathers move into or out of active parenting during this time. Multinomial logit analyses indicate that paternal education and employment increase the likelihood that fathers will be highly involved as children age and decrease the odds of a loss of paternal involvement. Strong or harmonious mother-father relations (romantic or not) increase the odds of fathers' being highly involved and mediate the impact of fathers' residential and marital status. Finally, neither new maternal partners nor highly involved grandmothers deter paternal involvement. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Conducted a 7-session, cooperative games program with a 2nd grade class of 24 students who had demonstrated trouble with working together cooperatively. The session goals were to have fun, provide 30 min of activity, and to learn about cooperation and teamwork. The classroom teacher used this intervention as a springboard for a unit on cooperation in the classroom. The program was evaluated following each session by a question and answer period with the children and by evaluatory comments by the classroom teacher. Direct observation of the games and the students by the counselor provided further opportunity for evaluation. following the intervention, some of the formerly excluded children said that they were now being included in activities during recess and outside of school activities. A shift in attitudes from the first to the last session was observed, with more helping behaviors noticed towards the end. The class had to learn to incorporate everyone to reach individual and group goals. Over the course of the sessions, cooperation and group cohesion when participating in these games increased. The teacher was also able to translate the cooperative game rules and philosophy to reading groups and other in-class activities. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This article discusses an elementary guidance counselor's plan to help students understand the physical and social consequences of smoking as well as what it means to be addicted. The counselor implemented his plan on November 21, the Great American Smokeout Day, to 4th-grade classes. Every 30 minutes the students would have to go outside for 5 minutes, to represent how often a "two pack a day" smoker needs to smoke. Each student was given a Chinese Finger Trap to keep his or her hands occupied during these periods. Teacher's evaluation sheets were filled out immediately after the experiment and student surveys were conducted 4 mo later. Student surveys consisted of questions about nicotine and addiction as well as if they planned to smoke when they were old enough. All students said they would never smoke. It is concluded that counselors need to give students as much information as possible so that they are better equipped to make good choices.

N2 - (from the chapter) Investigates children's perceptions of advertising on the World Wide Web (WWW) and examines the potential for displacement of media and of nonmedia-related activities by the WWW. The study assesses children's perceptions of the persuasive intent of favorite Web sites and identifies their preferences for WWW surfing vs other favorite media-related and nonmedia-related after-school activities. Based on previous research, the following questions are addressed: 1. does the WWW have the potential to displace other advertising media, 2. does the WWW have the potential to displace other non-media related activities, and 3. do children ages 9-11 yrs demonstrate the ability to identify the persuasive intent of advertising on the WWW? Fourth graders visited the authors' university to 'surf the Net' and completed pretest and posttest questionnaires and an introductory hands-on Internet session. 39% of Ss said they would prefer to surf the Net than to engage in their favorite after-school activity. Ss were most willing to give up playing with friends or siblings, inside (79%) or outside (89%). 67% of Ss naming TV viewing as a favorite activity would prefer to surf the Net than to watch TV. Only 13% of Ss thought the purpose of their favorite site was to advertise. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated the effect of school size (number of students and classrooms, class size, perceived crowdedness) on various educational and environmental factors in Saudi Arabia, based on a 1990 survey of 1,031 boys' schools. The survey included site observations, personal interviews, and a questionnaire for school principals. Factors investigated included school level (elementary, intermediate, secondary), ownership, spatial elements (library, cafeteria, laboratories, lecture hall, art room, playground), availability of educational technology, building attributes (room sizes, climate control, etc.), school maintenance, principals' authority in running schools, and educational goal achievement. Results show that large schools were more satisfying and had higher levels of achievement. However, large schools were associated with problems of maintenance, daily supervision, and less authority available to principals as school administrators. N2 - Children in two age groups (88 first- and second graders and 76 fifth- and sixth graders) were observed in a study of elementary school playground interactions. A time-sampling procedure was used to record the gender, race, and group size of all interactive play in seven playground areas during each age group's recess period. Older children played in same-gender, larger groups more than the younger children did. Girls and boys were equally likely to play in same- and mixed-race groupings. While both same- and mixed-gender interaction was more likely to be mixed- rather than same-race, mixed-gender interaction was much more likely to include more than one race than all girls' or all boys' interactions. Mixed-race interactions also included more children than same-race interactions. Other analyses examined variations in playground area by age, gender, race, and group size. N2 - Analyzed energetic costs (expressed in terms of caloric expenditure) associated with physical play in 4 field experiments of play in 30 5.3-11.5 yr old primary school children. Exp 1 established the concurrent validity of an observational checklist to estimate caloric expenditure of children's physical play. Exp 2 compared caloric expenditure of the play (defined as all behavior exhibited during play time) for 2 age groups of children

(7.0-7.7 vs 9.1-9.9 yr olds) during playtime outdoors and during indoor sedentary activity. Results show that caloric expenditure of outdoor activity was greater and was significantly correlated with ambient temperature. In Exp 3, children were observed during indoor play to control for the influence of ambient temperature. Outdoor physical play was more energetically costly than indoor physical play. In Exp 4, children's behavior was observed outdoors and caloric expenditure for play, games and other activities was compared. Physical play was more costly than other forms of behavior and games. Estimates of total energetic costs of play ranged from 6 to 15%. Results are discussed in terms of the relatively low caloric costs of play. VL - 59:

IS - 5-B

N2 - Little is known about children with autism in their natural environment, and children with autism who have more limited cognitive and verbal abilities. This study is the first to apply methods from ecological psychology to increase the understanding of autism. A better understanding of behavior that occurs in the natural habitat will aid diagnostic and assessment efforts and the identification of ecologically-relevant treatment variables. The ecological approach described by Scott (1980) was applied to study the in-depth structure of the behavior stream. Participants included 8 boys with autism and 8 boys with Down syndrome between the ages of 6 and 10 of similar adaptive communication levels. Narrative records were collected and analyzed based on duration and frequency of behaviors. Each record was analyzed by marking the behavior stream into activity units, which are naturally occurring chunks of behavior from the perspective of the child and occurring along a constant psychological direction. Each activity unit was then coded. Findings based on the structure of the activity units revealed that children with autism exhibited activity units of shorter duration and with less overlap. No differences in features related to the setting or in qualitative aspects of activity units were found. Partners of children with Down syndrome were more likely to be rated as being involved with high duration. Children with autism were more likely to use physical mechanism (e.g., physical contact, physical assistance); children with Down syndrome used more gestures (e.g., pointing, nodding). Both groups of children spent most of their time playing and watching TV. Analysis of the duration of intention of activity units revealed that children spent similar amounts of time participating in all but two types of activities. Children with autism spent more time readying their environment; children with Down syndrome spent more time eating and drinking. Subcategory analysis revealed that children with autism were four times more likely to fail to respond. In summary, findings that children with autism behaved in a more sequential manner, engaged in one activity at a time, shifted frequently from one activity to another, and persisted in a given activity for a relatively short time suggest behavior of more immature children than expected based on mental age. N2 - School personnel search for ways to help behavior-disordered students maximize their potential in the classroom. One school district administration took primary responsibility for student success by developing and funding a specially-designed program for children at risk in the elementary school. This study examined: the effectiveness of the CARES program in increasing reading, mathematics, and spelling skills, as well as, increasing appropriate social skills; and how any increase in skills compared to increases in social and academic skills of similar students on a waiting list for the CARES program who stayed in their regular classroom without further intervention. The CARES program contained seven components designed to: (a) elicit voluntary cooperation, (b) intervene early, (c) teach positive social skills, (d) meet individual academic needs, (e) offer personal counseling, (f) encourage regular parental participation, and (g) network as active partners with parents and outside social service agencies. The experimental group consisted of 18 third through fifth grade students and the control group totalled 13. The differences between the two groups' pre and post-test scores on the Burks' Behavior Rating Scale and the Behavior Assessment System for Children, as measured by the Mann Whitney U test on the small sample, determined if the students' social skills showed a significant gain. Pre and post-tests of students' academic growth were assessed using the Wide Range Achievement Test-Revised and the Wechsler Individual Achievement Test. Statistically significant improvement was seen after 3 months for the experimental subjects compared to control group participants in increasing reading, mathematics, and spelling skills, as well as, increasing appropriate social skills. From the results of this study, the data appear to support a relationship between increased academic and social skill levels of the experimental subjects and the CARES program. Previous studies included one or more of its seven components, but none with all seven combined in one program like CARES. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of the study was to explore thought processes and strategies of three 8-, three 11-, and three 14-year-old students that occurred while composing with technology. In this descriptive study, the following data were analyzed: (1) students' thoughts, responses, and behaviors that occurred during three composing sessions; (2) students' verbal responses to questions, given after each composing session, about their composing activities; and (3) students' verbal responses to questions, given before and after all composing sessions, about composing in general. The findings from the above three analyses were examined to discern what developmental patterns, if any, emerged across ages. Nine students were involved in seven 1-hour sessions. In two age-specific information sessions, students were introduced to a software program. In the third session, each student met individually to review what was covered during the information sessions and was asked questions about composing in general. In sessions four, five, and six, each student was asked to compose, think aloud while composing, and respond to questions via an unstructured interview technique. Each session ended with the student responding to questions about the composing activities. In the seventh session, the students presented their compositions to each other. Analysis of data for research question 1 revealed nine themes: elements of music, concepts, expressive gestures, composing processes, incorporation of known material, non-composing processes, technological problems, outlier verbal reports, and outside influences. Analysis of data for research question 2 generated five categories: awareness of activities, ability to recall activities, occurrence of mental activities between sessions, ability to recall interaction with musical elements, and range of evaluative comments. For research question 3, data were organized around: changes in content of specific responses, relationships between descriptions and experiences, descriptions of beginning composing activities, movement from third to first person, and perceptions about composing and listening. Developmentally, patterns emerged in the composing behaviors and in the treatment of timbre, beat, melody, and harmony. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of this research was to identify specific entry behaviors used by preschoolers ranging in age from 4 3 to 5.2 as attempts are made into play groups in the natural setting of the classroom and play yard.

When successful entry behaviors are displayed by preschoolers and are identified by researchers or teachers, those behaviors can possibly be taught to preschoolers who exhibit a need for more control over their entry strategies. Potentially successful entry bid strategies might be hovering near the group while observing their activities, making statements and displaying body language relevant to the group's activities. The design of this research is sociological and ethnographic in terms of the researcher having observed patterns of behaviors as they emerged during play in the natural setting. The basis of this observation, analysis, and evaluation is predicated on related research and literature in the fields of educational psychology, sociology, and educational studies. N2 - The purpose of this study was to examine children's play and language when a variety of unfamiliar multicultural pretend foods and cooking utensils not typically found in dramatic play centers were introduced. The study was conducted in a laboratory preschool setting with three multiage heterogeneous groups of children over a period of 7 weeks. Three methods of data collection were employed: (a) videotapes of children in the dramatic play center, (b) a notebook of observations made by the teachers when the researcher was not present, and (c) interviews with 18 children. The children who chose to play in the dramatic play center were videotaped daily during indoor play time for 1 week prior to the introduction of new materials. The new multicultural pretend foods and cooking utensils were introduced during the second week of the study. The children were then videotaped daily for 2 more weeks and then once each week for the next 4 weeks. The data collected from the videotapes and teacher notes were used to develop coding categories. Categories of children's play were: (a) time spent playing with unfamiliar materials, (b) conventional use of materials, and (c) unconventional use of materials. Categories of children's language were: (a) labeling, (b) other conversation in dramatic play, (c) questions, and (d) conversation about the materials outside of the dramatic play center. The data were interpreted to discover how children interacted with and talked about the multicultural pretend foods and cooking utensils. It was concluded that children interacted with the unfamiliar multicultural pretend foods and cooking utensils in much the same manner as familiar materials. Labeling items or being able to put words with the foods and cooking utensils appeared to be important to the children. Children used unfamiliar materials unconventionally more often than they used familiar materials unconventionally. Furthermore, children did not see a relationship between the items in the dramatic play center and materials in other parts of the preschool. N2 - Previous play research has focused on social or representational processes occurring within make believe. This study examined young children's metaplay-the process of suspending actual role playing to think or communicate about pretend themes from outside of the play frame. 12 preschool Ss were videotaped during 8 separate half-hour sessions, as they engaged in spontaneous free play with a same-aged peer. Videotapes were transcribed and analyzed using the constant comparative method-a naturalistic data processing procedure. The primary researcher and a 2nd observer unitized all metaplay behaviors, categorized these units, named the resulting categories, and wrote rules for inclusion. The outcome was a typology of metaplay behaviors, comprised of 3 broad categories-initiations, responses, and constructions-and 38 subcategories. Each specific metaplay behavior was described and working hypotheses were formulated regarding its cognitive, metacognitive, and social significance. It is concluded that a rich array of developmentally useful interactions-which increase in frequency and complexity with age-transpire outside of actual role playing. N2 - Explored leisure preferences and open space needs of 12-60 yr old Chinese Americans of Chicago's Chinatown. 203 face-to-face interviews and focus group discussions were used to identify outdoor leisure patterns and preferences, in general, and with respect to new park development being planned for the community. Findings show that although some popular activities were no different from what might be expected for the mainstream Anglo American population, the meaning and significance of these activities had clear and unique ties to Chinese culture. Preferences for the new Chinatown park development mirrored activity preferences, emphasizing facilities that enhance the natural environment for passive activities. Notable differences in activity preferences were found within the sample of respondents according to age, generational status, and other factors. N2 - Examined the health actions young children say they take in contexts that structure their day including eating, dressing, keeping clean, going to sleep, schoolwork, recess, leisure time, and going places. Structured interviews were conducted with 1,674 5-12 yr old children. Children mentioned actions related to eating (food choices, eating behaviors), engaging in physical activity, avoiding illness or injury, being clean, getting fresh air and mental health (fostering interpersonal relationships, helping others, and making oneself feel good or relaxed). The authors conclude that the report of these these actions by large numbers of children, and across different contexts, supports their inclusion as key topics in developmentally appropriate health promotion. N2 - (from the chapter) This reprinted article originally appeared in (Social Problems, 1976, Vol 23[4], 478-487). The following abstract of the original article appeared in record 1977-08033-001.) Studied the role of the world of play and games in childhood socialization. Data from observations of school-yards, interviews, questionnaires, and playtime activity analysis provided information about 181 5th graders, half of whom were from suburban and half from city schools. Sex differences were observed in "real" play activities: (a) Boys played outdoors more than girls; (b) Although boys and girls played alone about the same proportion of the time, when they were in social play, boys more often played in larger groups; (c) Boys' play occurred in more heterogeneous groups; (d) Girls more often played in predominantly male games than boys played in girls' games; (e) Boys played competitive games more often than girls; (f) Girls played more than boys and boys "gamed" more than girls. It is suggested that play and games contribute to the preservation of traditional sex-role divisions in society by equipping boys with the social skills needed for occupational careers while equipping girls with the social skills better suited for family careers. N2 - Differences in the quality of play in thematic and housekeeping organizational patterns of the sociodramatic play center in preschool classrooms were documented by biweekly videotaping children's play during free choice time in 18 classrooms of an early childhood program in a moderately sized Midwest city. Videotapes for each classroom group were divided into the 4 quarters of the academic year. Of these, 68 were randomly selected and evaluated for play quality. The thematic organization resulted in higher quality sociodramatic play in which the children enacted more roles outside the home, utilized more aspects of their roles, demonstrated higher levels of symbolic prop use, and played longer. Early childhood educators wishing to utilize the thematic organization of the sociodramatic play center will find the practice supported, leading to longer play episodes, increased symbolic prop use, and higher quality make-believe. N2 - A multiple probe across skills single-S research design was used to evaluate the effectiveness of a simultaneous prompting procedure with a physical guidance controlling prompt to teach 3 dressing skills each to 2 preschoolers (aged 28 and 25 mo) with disabilities. The format was activity-based in that both probe and instructional trials were embedded within activities that occurred throughout the day when dressing would be a natural activity (e.g., putting on a jacket to go outside to play) in the preschool setting. Both students maintained the skills with 90% accuracy up to 6 wks following acquisition. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The BeSafe (Behavioural Safety) Method, has been developed by International Mining Consultants Ltd for assessing and reducing risk in industrial contexts. BeSafe is an ergonomic method of risk analysis and reduction, targeted at prevention of accidents due to human errors and violations, and emphasizing management strategies for action. Using the BeSafe Method, it may be possible to structure safety assessments of the use of

products and target improvement measures. The authors tested the relevant parts of the method on children's play equipment in 24 playgrounds, and questionnaires were also administered to 348 7-11 yr olds and 15 adults. Useful results were obtained, suggesting that BeSafe could be adapted for other consumer products in a similar way. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Studied the outcome of psychodynamic treatment in young children lacking language and relational play. Human Ss: Nine Italian preschool children (aged 2-5 yrs) (autism). The Italian translation of the Peabody Picture Vocabulary Test (PPVT) was administered to 2 Ss. Treatment efficacy was measured periodically in all Ss. Results are discussed in relation to the important role of the natural environment (the family and school settings) in the treatment of autistic children. Treatments: Game therapy and psychoanalytic family therapy were used, and educational support was provided. Treatment lasted from 6 mo to 4 yrs. N2 - This is an evaluation of the Partnership, a school-based mental health service program for children labelled "Seriously Emotionally Disturbed (SED)." Two characteristics emerge as priorities in the literature

regarding the needs of emotionally disturbed children. One is the development of models of care that offer services that can be adapted to the needs of each child or family. The other vital component is collaborative interaction among adult caregivers. To date, neither education nor mental health services have shown consistent success in meeting the complex needs of SED children. The Partnership is a school-based mental health service program that strives to incorporate recommendations for flexible care and collaborative relationships. Forty-three children, first through fifth graders, from five SED special day classrooms located in three San Francisco public schools were included in the study. Also included were their adult providers and caregivers. Process and outcome evaluations were undertaken. Outcomes were assessed based on student academic and social functioning ratings which were collected from a variety of sources. Program components were assessed using the Partnership Survey which was developed for the purpose of this evaluation. This was a single measure that captured the unique perceptions of professionals, parents, and caregivers alike. Findings indicated that the different adult collaborator groups (parents/caregivers, teaching staff, outside providers) rated the program very highly. Some exceptions were thought to be related to phases of development in collaborative relationships. The consistently high ratings of the program by parents and caregivers in this study are noteworthy, in that the literature has shown that this group is typically dissatisfied with mental health services to their SED children. A striking finding related to the characteristics of the population of SED students was the large number of stressful or traumatic events in their lives. These included frequent home placement changes coupled with a very high number of school placement changes. Although correlations were not found between the stressful events and the students' school functioning, dramatic increases in school stability were found among Partnership students. Relationships found between collaborators' ratings of the Partnership and the students' social functioning suggest that adult collaborators play a key role in students' success. N2 - The relationship among different settings for young children's play behaviors and peer interactions was examined. The participants were forty-one children from 2 to 5 years of age (21 2- and 3-year-olds and 20 4- and 5-year-olds) enrolled in three child care programs. The children were videotaped for 5 minutes each on 4 different days both indoors and outdoors. Program measures described the quality of the child care program (the Assessment Profile for Early Childhood Programs) and additional measures described the playground setting. Children's play behaviors were categorized using the Parten-Smilansky Scale, which combines social play categories and cognitive play categories (Rubin, Watson, & Jambor, 1978) using 16 categories of play behavior. Children's peer interactions were categorized using the Peer Play Scale (Howes & Matheson, 1992). Results indicated that all six classrooms and their related playgrounds were mediocre child care programs. Children were more likely to engage in parallel functional play and the highest form of peer play (i.e., social pretend play) and play behavior (i.e., interactive dramatic play) outdoors than indoors. The younger age group was more

likely to be engaged in playing alone or interacting with adults, whereas the older age group was more likely to interact with peers. These findings reinforce the importance of both the indoor and the outdoor environment for promoting more complementary play behaviors and peer interactions. Finally, additional findings of relationships between the Parten-Smilansky Scale and the Peer Play Scale showed that the combination of the two scales provide a more valid and comprehensive assessment of children's social interactions with peers in naturally occurring contexts. N2 - Social-cognitive perspective taking of elementary school students was examined in the context of a schoolwide conflict resolution program. The study compared perspective taking of children trained as mediators with untrained participants over the course of an academic year. Dependent variables were perspective taking and interpersonal problem-solving strategy choice. Independent variables were mediation training/practice and gender. Dependent variables included cognitive, affective and projective aspects of perspective taking. One hundred twelve students in 4th through 8th grades in a bicultural school community participated. Sixty-two students were selected and trained to mediate the disputes of their peers on the playground. Another 50 students served as a comparison group for purposes of evaluation. The 50 nonmediators were aware of the program and sometimes participated as disputants in mediations on the playground. Training was assisted by the Arizona State Attorney General's Office of Community Relations. The interval between pre and post intervention assessment was six months. Results of repeated measures of analyses of variance showed that perspective taking scores on the cognitive and affective perspective taking scales of the Davis Interpersonal Reactivity Index increased over time for all participants, with the students trained as mediators showing greater increases than the untrained students. Pre-to-post increases in perspective taking indicate that the cognitive and affective perspective taking of mediators may be enhanced by mediation training and playground mediation practice. Further, the finding that perspective taking scores of untrained participants increased substantially suggests that observational learning and participation in mediation as disputants may also have a favorable influence on perspective taking. Females scored slightly higher than males on perspective taking measures, although not significantly so. Boys and girls showed different (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study compared the peer interaction patterns, peer social networks, and interactions patterns with adults of young children with and without physical disabilities. Three pairs of classmates ranging in age from five to eight years participated. Each pair consisted of one child with a physical disability and normal cognition and a typically developing classmate who were matched for demographic variables. Momentary time sampling techniques were used to record children's interactions with peers on the playground during recess. Semi-structured behavioral observations were used to record qualitative aspects of children's interactions with peers and teachers. Teacher interviews provided additional information regarding children's educational programs, social adjustment, and peer relationships. Analysis of quantitative data revealed that children with physical disabilities had cooperative play episodes of shorter duration, spent less time in interactive behaviors of any kind, had more interruptions in cooperative play episodes, and had less intensity of interaction than their peers. Analysis of qualitative data revealed that children with physical disabilities had a strong desire to engage in social interactions, but difficulty initiating and sustaining interactions. Teachers often interrupted the work and play interactions of children with physical disabilities, limiting the amount of peer interaction time available. Children with physical disabilities actively initiated peer interactions, but had more unsuccessful interaction attempts than their peers, and approached adults for social interactions much more frequently than their typically developing peers. Children with physical disabilities demonstrated a strong desire to be helpful and involved in classroom activities, but were marginalized as classroom contributors both as a result of physical limitations and because of poor social initiation skills. N2 - Rough and tumble (R&T) play is widely researched in relationship to social affiliation and the cognitive benefits associated with participation in this type of play. One less researched aspect of R&T play is the affective dimension, more specifically, the way in which boys care for one another through R&T play. The first part of this research examines the various ways in which boys participate in R&T play, how the R&T scenario is set up, who plays, what the rules are and how they are enforced. Boys were video taped while engaging in R&T play and during a game called Smear the Queer (Smear). Data gathered from observing the video taped segments of R&T play clearly suggests that R&T play is a way in which boys express care for one another, that Smear is a camouflage for intimacy, and that R&T play is more like a dance among the players than a helter-skelter mix of running, chasing, and tackling. The second part of this study involved interviewing the players while they watched selected video segments of R&T play and expressions of care exhibited during R&T play. Analysis of the interview transcripts established that the boys were able to clearly delineate the difference between R&T play and aggression. Furthermore, the participants were able to validate the game of Smear as a way in which boys are able to express care for one another. Finally, the participants described R&T play as the vehicle in which they are able to experience physical intimacy with one another. It is concluded that R&T play is clearly misunderstood by the uninformed observer. The players are keenly aware that engagement in R&T play is a time that it is acceptable to hug, hold hands, and otherwise experience bodily contact not permitted outside the play arena. N2 - This study addressed sibling roles in families where one child has diabetes. Subjects consisted of 48 families who had second-borns with diabetes and 48 families who had second-borns without diabetes. Parents and first-borns were interviewed about how many hours per week first- and second-borns spent performing household chores and outside of home activities. The amount of time spent doing chores and activities was examined based on respondent (parent or child), health status of the second-born, and the child's age, birth status, and gender. Children engaged in approximately 10.3 hours of work per week. Respondents had similar perceptions of how much work was performed by first-borns. However, parents felt that second-borns performed more work than was reported by first-borns. Older siblings' performance of chores was not affected by having a younger sibling with diabetes. Children with diabetes performed more chores than healthy peers and appeared to be "super" capable. Excluding diabetes care, age was positively associated with the amount of chores children performed. One exception was that parents perceived adolescent and preadolescent first-borns who had a younger sibling with diabetes to have equal responsibilities. Controlling for age, sibling care was the only type of work that was associated with birth order. Gender was not as predictive of household work as in previous studies. The amount of outside of home activities engaged in by first-borns was not affected by their

sibling's health status. Male second-borns who had diabetes performed more outside of home activities than female second-borns with diabetes. The amount of activities a child performed was affected by their own health status but not their sibling's health status. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The purpose of the study, conducted in a Midwestern, suburban intermediate school with a diverse student population, was to evaluate the effectiveness of a peer mediation training program on the skill acquisition, maintenance, and generalization of trained students. Co-mediator skill proficiency was assessed for 10 pairs of students in the training group and 7 pairs in the control group. A mixed method, pretest-posttest control group design was employed. Analogue role-play tests, naturalistic observation, self-report data, and parental observations were utilized to evaluate skill acquisition, treatment integrity, social acceptability, and generalization of student skills. Statistically significant results ($p <$) indicated that trained students demonstrated appropriate skills across mediation steps during analogue assessment and within the natural setting. Further, treatment integrity measures demonstrated proper implementation of mediation skills during actual mediation sessions. Social acceptability data, although inconclusive, revealed that the program was positively perceived. Finally, parental observations showed that active mediators successfully demonstrated learned skills in the home. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Describes the development 2 structured interview procedures: The Community and Home Activities Related to Technology and Science for parents of Preschool Children (CHARTS/PS) and for School-Age Children (CHARTS/SA). These interviews can be used to construct profiles of children's exposure to science activities outside of school, such as watching TV, reading, attending exhibits or events at community facilities, participating in experiments or demonstrations at home, and asking questions of parents. The CHARTS/PS interview was conducted with the mothers of 29 kindergarten children, while the CHARTS/SA interview was conducted with 35 5th and 6th graders. Focusing primarily on the CHARTS/PS interview, the article describes how these interviews were developed, what kinds of information this type of research enabled the authors to obtain, and what lessons they have learned in the process. The level of extracurricular participation reported in a wide range of science-related activities was very high. Structured interviews can help teachers gain information about students' exposure to science-related learning activities in their home and community. This information can be used as a platform on which classroom instruction can be built. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the cover) The contributors in this book on teaching and learning mathematics all hold the view that mathematics is a form of intelligent problem solving which plays an important part in children's lives outside the classroom as well as in it. One theme of the chapters is that an important part of teaching mathematics at school is to make explicit for children mathematical ideas which they have already picked up and used in more informal settings. The authors also stress the social construction of children's mathematical knowledge at school through the acquisition of new modes of representation which increases the power of their mathematical understanding. Two major contributions of the book are to seek an integration of social and cognitive aspects of learning and to bring together for the first time in English a comprehensive description of teaching methods based on the idea of social construction which have been developed in Holland, France and Switzerland.

N2 - Examined the effects of cooperative learning on the social skills of students and their behavior both in and out of the classroom. The 1st author implemented a 10-wk cooperative learning program in a class of 10-12 yr olds, to develop social and academic skills. Classroom activities provided specific training in, and required Ss to use and monitor the use of, identified social skills. Task-oriented skills included sharing, persuading and managing time. Person-oriented skills covered being positive, valuing others and conflict resolution. Ss worked in pairs and larger groups, with each S responsible for a specific academic or social task. Findings show evidence of social growth even though the study lasted only 10 wks. Social interactions became noticeably more varied and students agreed to work in groups, including members they did not like. These changes carried over into playground activities. The interpersonal relationships of previously isolated Ss improved and there were also improvements in student behavior. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Using a 4-yr cross-sectional study, the reading attainments of a sample of 834 Year 2 children who had one of 3 types of preschool experiences (nursery school attendance, playgroup attendance, or no preschool provision outside the home) were examined. Ss' scores on the Primary Reading Test (PRT) were compared over the 4 yrs, as were the reading Standardised Assessment Task (SAT) scores of the last 2 cohorts. Results are not clear cut. For 3 out of the 4 yrs, the group with no-preschool experience performed significantly less well on the PRT than did at least 1 of the other 2 groups. The SAT levels of Ss who attended nursery school were higher than those of the other 2 groups. It appears that preschool provision had an effect on children's reading attainments and that this effect was still significant in Year 2. The validity of the SAT is considered as a factor in the relative reading attainments of the 3 groups. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Social and affective processes connected to children's relationships inside and outside the school setting are important factors in children's successful adaptation to school. This study examines the relationships of 1,226 low-risk elementary and middle school children across a variety of relationship partners. Descriptive data on the profile of these school-aged children's patterns of relatedness with others are presented. Developmental trends are explored as well. There is a shift in the self-reported quality of children's relationships with adults (mothers and teachers) and peers (best friends and classmates) from elementary school to middle school. In middle school, children report more positive perceptions of their relationships with peers and less positive perceptions of their relationships with adults than do elementary school children. These findings are discussed in terms of the implications that children's interpersonal relationships have for facilitating readiness to learn and active engagement in school. Limitations of the present study and methodological issues connected to the assessment of relationships are discussed as well. N2 - Presents a rationale for the importance of recess in primary school curriculum. The authors propose that children's immature cognitions are well adapted for their particular phases of development and that children can get the most out of school when educators take advantage of children's immaturity to foster attention to classroom work. Because young children are not able to focus their attention for extended periods of time as well as older children, their cognitive performance will be hindered if they persist at tasks requiring focused attention for prolonged periods. The authors argue that by giving them frequent breaks during and between highly focused cognitive and academic tasks, their performance on later tasks should be enhanced relative to children who are not given such breaks. Also, performance on repeated tasks requiring focused attention decreases over time and trials, until rest periods are given. Rest periods in the form of recess enhances subsequent performance, although the nature of the recess activity may affect the extent of the subsequent benefits. N2 - An individualized, classroom-based social skills training program, which used a combination of coaching and social problem-solving approaches, was developed and evaluated with a sample of 45 children, 9 to 12 years old, with learning disabilities, in self-contained special education classes. Thirteen children received a 6-week intervention (Intervention 1), 7 received a 12-week intervention (Intervention 2), and 25 were in a no-treatment control group. We found modest gains in social skills and decreases in problem behaviors in the Intervention 1 group compared to the control group as measured by self-report, teacher rating scales, peer nominations, and classroom and playground observations. The peer acceptance of the Intervention 1 children remained stable over the school year, whereas the peer acceptance of the children in the control group deteriorated. Equivalent changes were not observed in the Intervention 2 group, largely due to dynamics specific to that classroom. (PsycINFO Database Record (c) 2012 APA, all rights reserved) (journal abstract)

N2 - Data from time diaries kept by parents in 2-parent, 2-child families in 4 states in 1977 and 1978 were used to examine time shared by parents and children, as well as parent solitary times, in a number of household activities. The analysis focused on how the mother's employment time affected shared parent-child time and whether the time was sex-typed. In addition, a weak test for whether parent-child shared time stimulated children's human capital development was devised and the hypothesis confirmed. Mothers who spent more time in market work shared less traditionally defined child-care time, but only with the older child. In contrast, as a

mother's time in market work increased, parent-child shared housework and shared leisure time increased. Household activities shared by the parent and the child were sex-typed. Mothers tended to share more time with daughters in meal preparation and family-care activities, and fathers tended to share more time with their sons in activities involving the home, yard, car, and pet maintenance and in shopping activities. N2 - Observed and compared the behavior of 2 groups of Black South African children who had been identified as either popular or rejected by their peers. 631 children (aged 8 yrs to 12 yrs 3 mo) nominated classmates they liked most and least. 29 rejected (RCs) and 29 popular children (PCs) were identified, and were observed in their school playground during recess and in their classroom. Findings indicate that social rejection was related to aggression, disruptiveness, and rule violations; popularity was associated with prosocial behavior among peers. Characteristics of PCs were that they were seldom aggressive, they reminded others of the rules of the group, they provided guidance in difficult circumstances, they were caring and affectionate, and they were the instigators and recipients of positive behaviors. RCs initiated more negative interactions with others, and were also the recipients of more negative and aversive interactions. Additionally, RCs were more frequently observed in interactive activities on the playground, but PCs engaged in these for longer periods. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - For children at school, playtime occupies more time than that recommended to be allocated to any formal curriculum area. Educational psychologists (EPs) can have a role in encouraging schools to consider ways of structuring playtime to increase the quality of children's social experiences and preventing troubling behavior. To inform such a role better, this study sets out to gain an impression of the Scottish playground from the perspective of 290 preschool and primary school students through the use of a questionnaire. N2 - This project explored the effects of a cooperative learning program implemented in integrated kindergarten classrooms. Academic performance, cooperative interactions during lessons, and prosocial behaviors during play activities were examined. Scores on curriculum-based mathematics probes and direct observations of cooperative interactions during the intervention served as the primary dependent measures. Additionally, direct observations during a play period following the cooperative learning lesson and weekly observations in a free play setting outside the classroom served to assess generalization of prosocial behaviors in natural settings. A multiple probe design across classrooms combined with a quasi-experimental group design was employed. Pretest and posttest measures on standardized basic readiness scales and student sociometric nominations/ratings were statistically compared at the conclusion of the study. Social validity measures, procedural integrity, and one-month maintenance data also were collected. Results indicated that the cooperative learning procedures lead to improved academic growth as measured by both the curriculum-based mathematics probes and the mathematics section of the standardized group readiness test. Levels of cooperative behaviors increased substantially for all participants during the instructional period when cooperative learning was in effect. Furthermore, prosocial skills learned and practiced during the intervention generalized to the free play settings in and outside of the classroom environments. An increase in interactive play behaviors also was observed for all participants during these time periods. However, for cooperative behaviors, the generality of effects with respect to maintenance over time was not supported. No statistically significant differences were

noted between experimental and control groups on the sociometric nomination measure, but an improvement was seen for both work and play measures on the rating scales. S (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This research was a year-long longitudinal study examining the friend making activity of kindergarten children. The subjects were a diverse sample of 38 children, attending two kindergarten classes in a suburban public school in North Carolina. The sample included 15 girls (mean age 65 months), and 23 boys (mean age 67.6 months). Median income of subjects' families was \$40,000. Spot observational methods were used to record children's social interactions. Observational data were aggregated by seven coding periods to identify frequent playmates. Teacher and child nominations of individual's common playmates were recorded at the end of each coding period. The three methods of playmate identification were compared to determine the concordance between them. It was hypothesized that concordance between all methods would exist. Individual children were identified as friends by the frequency, stability, and quality of their interactions, and the concordance between at least two identification methods. It was hypothesized that the individuals who became stable friends with classmates would engage in more interactions outside of the proximity of teachers, and during free activity times. It was also hypothesized that boys would be more likely than girls to be identified as stable friends. By using observational data, three stability-change types of individuals were identified. Marginals were relative social isolates. Changers were children who changed play partners. Consistents had one or more frequent and lasting play partners. Data signifying the level of joint activity and positive reciprocal interactions by types were compared. Graphs were constructed showing the variability of these interactions by types across the year under varying conditions of the proximal setting variables, teacher presence and classroom structure. Results showed a lack of concordance between assessment methods during the first semester (average agreement level 48.8%). N2 - Depression is a major public health concern, with a robust continuity from childhood through adulthood. This study had six objectives: first and second, to examine the relationship of being classified as physically inactive by a parent or a teacher to depressive symptoms in 8 to 12 year old children (n = 933); third, to assess the relationship of playing sports outside of school, to depressive symptoms; fourth and fifth, to determine whether meeting Fitnessgram health-related fitness standards for body composition and cardiovascular endurance were related to depressive symptoms, and; sixth, to examine the prevalence of depressive symptoms in this population. Using the "Dimensions of Depression Profile" and applying DSM-IV criteria, symptoms of major depression were identified in 48 to 65% of children, while symptoms of minor depression were noted in 8.4% of girls and 6.3% of boys. Chi squares revealed significant ($p <$) differences for girls classified as inactive by a teacher and for boys classified as inactive by a parent ($p <$). Differences were also noted for boys not playing sports outside of school ($p <$) and for those not meeting body composition standards ($p <$), as well as for girls not meeting cardiovascular standards ($p <$). Relative risk of depressive symptoms for inactive classification was 2.8 to 3.4 times higher than for active, 1.3 to 2.4 times higher for children not playing sports, and 1.5 to 4.0 times higher for those not meeting health goals. N2 - This research investigates the impact of maternal employment and mother/child involvement on children's adaptive functioning in school. Data were collected from mothers (n = 97) on a daily basis over a period of 37 days to assess their level of involvement in leisure activities with their children. The mothers were categorized on the basis of their self-reported employment status: unemployed outside the home, employed part-time, or employed full-time. Teacher reports of child functioning at school were collected on 89 of the children whose

mothers completed home reports of involvement. Analyses revealed no statistically significant relationship between shared mother/child leisure activities and school performance as a function of mothers' level of employment. In general, the mother's level of employment had no impact on the level of involvement in daily activities between mother and child as reported by the mother. However, increased involvement on the part of a mother employed full-time had a modest negative statistical association with the child's adaptive functioning at school. Future studies might collect data from the child as a corroborative reporter on involvement in parent/child activities in the home. It is recommended that the involvement of the father be examined to learn something more of the changing roles of mothers and fathers in the nuclear family. The evolution of more equally shared parenting responsibilities warrants further study of how differing family environments impact children's social and cognitive functioning at school. N2 - Despite their efficacy in skill acquisition, externally managed behavioral interventions have been criticized widely for poor generalization and maintenance effects. In the past two decades, various self-management strategies have been developed to involve students in their own behavior change process and to increase the generalization and maintenance of behavior changes. Among self-management strategies, self-recording, self-evaluation, and self-graphing are considered useful, especially when they are combined systematically. Because findings of self-management studies to date have been inconsistent, additional self-management research must be conducted to support claims about achieving generalization and maintenance. This study examined the relative effects of a combination of self-management strategies to a combination of externally managed treatments on the generalization and maintenance of playground social behavior changes. A multiple baseline across subjects design was used. All seven subjects in this study were taught specific playground social skills. During the generalization intervention phase, subjects in the external treatment condition spent extra time practicing their newly learned social skills through role-playing. Immediately after each morning recess, the subjects received positive feedback from the investigator for their behavioral performance on the playgrounds. In contrast, subjects in the self-management intervention were asked to monitor their own behaviors by using a golf-counter during morning recess to count the frequency with which they used learned social skills. At the end of recess, they self-evaluated and self-graphed their performance according to pre-established criteria on a self-management observation sheet developed for this study. A partial interval time sampling method was used to collect daily observation data for each subject during morning recess and after-lunch-free time on the playgrounds. The results indicated that neither (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Described the place of TV violence in one type of social exchange, children's interactions with social workers. 21 social workers who worked primarily with children in schools, in community mental health agencies, and in private practice were interviewed, using grounded theory methodology. Social workers were asked to recount a time when they believed that a child between 6-12 yrs old had drawn, played, or talked about themes or characters related to violence witnessed on TV. Results confirm the assumptions that children recreate what they see on TV and share their experience of TV with others. In addition, social workers do observe TV-related themes and characters in offices and on the playground and are aware that children use TV violence specifically and thematically in interaction with others. TV violence appears to be a largely unacknowledged presence in social work practice with children. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Since 1953, Norwegian national standards regulate ratios of children to staff, training requirements, group sizes, leadership and subsidies. Both national and local subsidies support the management and quality level of day care centers. In Norway a current viewpoint on quality in day care is to stimulate innovation in day care activities by rewarding local initiative and creativity. Outdoor activities and giving the children freedom to learn are highly valued. Preschool teacher education, which is three years at college, shares a common frame of a governmental curricular guideline as well as a nationwide curriculum for day care. A responsive and warm interaction between staff, children and parents is a definite moral value of the preschool teacher profession. Current issues of quality are related to the shortage of highly qualified directors and leaders in public day care as well as the expansion of private centers with questionable quality. Quality control of day care centers is now discussed as a necessary surveillance system of the quality of contexts and interactions in children's daily life.

N2 - Originally published in Contemporary Psychology: APA Review of Books, 1995, Vol 40(11), 1067-1068. This is a review of the book, "Behind the Playground Walls: Sexual Abuse in Preschools" (see record 1993-97375-000). The authors of "Behind the Playground Walls" detail their research into the circumstances and clinical aftermath of several preschool sexual abuse cases, including the nation's most prominent case of alleged ritualistic child abuse, the McMartin Daycare case in Manhattan Beach, California. Three groups of children are compared: (a) alleged victims from highly publicized and legally unsubstantiated ritualistic abuse cases in southern California; (b) nonritualistic sexual abuse victims from a less controversial, legally confirmed day-care case in Nevada; and (c) nonabused control children attending day care. The authors are to be commended for their longitudinal design, for testing theory in a field sometimes lacking it, for conducting the research in spite of many pragmatic difficulties, and for producing a book that is readable by laypersons but that includes enough detail about method and analysis to be useful for serious researchers. The book has enough merit to transcend the controversy inherent in its topic. Child abuse researchers and therapists and families of children involved in sexual abuse cases will benefit from the findings of this research. N2 - Creative thinking involves both emotion and personality, including enough confidence and courage to consider new approaches to problems, rather than hiding in the security of familiar and accepted ways of thinking. There is a conflict in education between the need for emotional control for academic excellence and the need for a more free and open minded approach. Students who were extremely successful academically are often found to be creatively inhibited because of the narrow focus and pressure of their school education. The problem for teachers is to enable intellectually gifted pupils, who have the ability for high academic achievement, to keep a playful, creative approach to their work and general outlook. An environment in which the exceptionally able child can prosper all round must be balanced. This implies enough time with other people to make good social relationships and develop interests outside study areas. Topics discussed include: where creativity starts, the creative cost of high academic achievement, and education for creativity (imaginative play). N2 - Conducted an observational study to identify different kinds of relationships among preschool children in natural settings. Human Ss: 17 normal Italian preschool children (aged 27-46 mo) (Ss from 1 day care center) (Group 1). 28 normal Italian preschool children (aged 33-41 mo) (Ss from 2 different day care centers) (Group 2). Group 1 Ss were observed in their day care center upon arrival, during mealtime, and during free play. Group 2 Ss were observed twice, about 1 mo apart, during mealtime and free play. Ss' individual behavior, proximity to other Ss, degree of intimacy with other Ss, sharing, conflicts, and prosocial behavior were assessed using a checklist. N2 - Assessed the degree to which performance on continuous performance tests (CPT) and a solid-state actigraph could be used clinically to distinguish between attention deficit hyperactivity disorder (ADHD) and other psychiatric symptoms in 97 patients (aged 6.5-13 yrs) from a child psychiatry outpatient clinic (40 with ADHD symptoms and 57 without ADHD symptoms) and in 18 normal controls. Discriminant function analyses correctly classified 72.4% of Ss in the ADHD vs normal control comparison, and 66.2% in the ADHD vs non-ADHD comparison. Poor performance on objective measures was generally indicative of ADHD relative to normal controls, but "average" performance could not be used to rule out ADHD. Diagnostic classification indices were much lower in the ADHD vs non-ADHD patient discrimination. CPT inattention scores had moderate sensitivity, but low specificity; CPT impulsivity and actigraph scores had low sensitivity but high specificity. Results suggest that examination of CPT performance and objectively assessed activity level are not diagnostic in and of themselves, and should not be used outside the context of a full clinical examination. N2 - Examined the relationship between gratification of needs, self-esteem, and computer games. 120 children (aged 11-17 yrs) from North London were given a questionnaire concerning computer game use, companionship, and solitude/escape. Results show that 92.5% of Ss played regularly. Playing computer games was equally popular with males and females, but males spent more time on it. Positive correlations between playing and items on the needs scales were obtained. Males who were heavy players scored highly on the preference to friends' need, but interestingly they were also likely to see their friends more often outside school, thus providing no support for the theory that computer games are taking the place of normal social interaction. For females there was evidence of a negative relationship between self-esteem and need gratification through playing computer games. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the effects of different recess timing regimens on elementary school students' classroom and recess behaviors. In Exp 1, recess timing for 34 boys and 28 girls in grades K, 2, and 4 was varied by 30 min. An analysis of pre- and postrecess behavior and of outdoor recess behavior showed that prerecess inattention varied as a function of deprivation duration. Boys in particular were more socially interactive on the playground following a long deprivation compared to a short deprivation. Recess behaviors did not relate significantly to postrecess inattention. However, inattention rates were higher before recess than after. Exp 2 utilized a similar paradigm with a sample of 2nd and 4th graders. In general, results from Exp 1 were replicated. In Exp 3, Ss' recess was manipulated, but the recess period was indoors. Results of the 2 samples replicated each other and the preceding experiments. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Studied the prevalence, general trends and nature of bully/victim problems in elementary school students, and determined whether bullies and victims endorsed certain aggression-supporting beliefs to other peers. 379 4th-6th graders (aged 8-22 yrs) in Canada were assessed on the Bully/Victim Questionnaire (D. Olweus, 1989) and Belief Measures (R. G. Slaby & N. G. Guerra, 1988). Results show that 21.3% of the Ss were bullied and 11.6% bullied others. Victims tended to be the youngest Ss and were at risk for being bullied by both age mates and older Ss. Verbal abuse was the most common form of bullying, and the playground was the most common location. There was no significant association between gender and direct or indirect bullying. Bullies tended to be in the older grades and were mainly boys. They were more likely than victims, and students who were neither bullies nor victims, to endorse aggression-supporting beliefs. N2 - To explore changes in the residential outdoor play landscape, this study surveyed 40 adults on their memories of middle-childhood experiences and interviewed 14 children (aged 6-11 yrs). The physical landscape as well as personal meanings attached to childhood places were studied for both adults and children. Though both groups showed an unquestionable preference for the outdoors, it appeared as though the amount of imaginary, creative, and non-equipment game play was reduced. Probably the largest changes occurred in the extended home yard environments, where fields, woods, and orchards were replaced by formal city parks and busy streets. These landscape changes, as well as personal meanings of place, address important interdisciplinary issues. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Sought to identify the critical factors that differentiated 56 1st grade boys, at-risk for developing antisocial behavior patterns, from a randomly chosen comparison group. Through the use of a multi-method approach (consisting of teacher nominations, teacher ratings, and direct observation of behavior) 3 areas of significance emerged. Boys nominated as at-risk for developing antisocial behavior patterns were found to have higher teacher ratings of aggression, more negative peer interactions on the playground, and lower levels of academic engaged time than their comparison peers. These findings have implications for designing interventions to prevent the escalation of antisocial behavior patterns as well as to increase the pace and complexity of classroom instructional delivery. N2 - Examined playcare provision, defined as providing care for children aged 5-12 yrs in communal settings which explicitly offer creative play opportunities. The role of children in determining the sort of playcare environment they spend time in after school and during school holidays was assessed. Data were obtained from 229 interviews with children. Results suggest that children are increasingly excluded from the independent use of public space which has important implications for the kinds of play opportunities available to them. The paper shows 1 possible way of enabling children to exercise their right to play through the use of playcare centers. The research was designed to provide a public forum for the voices of children, to allow them to

express their own views and opinions about what happens to them outside school hours. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the jacket) Children's temperaments make a substantial contribution to their environments and their interactions with them. Certain of these largely inborn behavioral style differences, which are not abnormal in themselves, may lead to clinical problems by predisposing children to abrasive, incompatible relationships with caregivers. [The authors] present a . . . summary of the recent clinical research on temperament, in particular from the last 10 yrs, coupled with practical suggestions on how to use this information in a variety of clinical and educational settings. . . . They take the professional-psychologist, physician, nurse, teacher, day care worker, and social worker-through all the stages of a child's life to show how the effects of temperament play out in infancy, the preschool years, middle childhood, and adolescence. [The] book brings theory and practice to life and shows how all those who work with children can improve their care by understanding these important differences. N2 - Relations between patterns of attachment with mother and subsequent behaviour with peers and perceptions of self were examined in a sample of 39 five year-old children (22 girls, 17 boys). Attachment classifications and ratings had been determined when the children were 4 1/2 years old, using procedures and coding systems originally developed for infants by Ainsworth (Ainsworth, Blehar, Waters, & Wall, 1978) and modified for 3-4 year-old children by Cassidy and Marvin (1988). When each child was five years old, behaviour with peers was assessed through direct observation on the school playground. A continuous commentary of interactions was made into a hand-held microphone, while a radio microphone concealed on the child picked up the child's speech and speech directed toward him/her. Tapes were transcribed using a coding system based on that used by Hinde, Easton, Meller and Tamplin (1983). Perceptions concerning perceived competence and social acceptance (Harter & Pike, 1984), self-efficacy (Wheeler & Ladd, 1982), perceived popularity with and liking of peers and interpersonal problem-solving ability (Shure & Spivack, 1974) were assessed in a series of interview sessions. Analyses revealed meaningful relations between patterns of attachment and behaviour and perceptions. Insecure-ambivalent children exhibited more negative behaviour toward peers and sought the attention of peers more than did secure and insecure-avoidant children, and they complied to control attempts by peers less than did secure children. Insecure-avoidant children tended to engage in more neutral, less involved behaviour with peers. In addition, insecure-avoidant children generally reported negative self-perceptions while insecure-ambivalent children reported very positive perceptions concerning competence, social acceptance and peer relationships. Analyses indicated different patterns of relations for girls and boys. The results provide support for the predictive validity of the modified attac (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - This study identified differences in play activities engaged in by children varying in sex, age and socioeconomic status. Frequency of parent-child play was correlated with parental acceptance and child's self-concept. Sex, age and socioeconomic differences in parent-child play activities were described. Lastly, differences in play and other social behaviors of children varying in popularity and self-concept were identified.

Four hundred thirty-seven first and fourth graders from two public and two private coeducational schools completed a Home Play Survey, a sociometric instrument, the Child Parental-Acceptance Rejection Questionnaire and the Pasao Self-Concept Scale. Based on the results of the sociometric measure, 32 selected children were observed during recess. Results of the Home Play Survey showed that there were age, sex and socioeconomic differences in play activities at home. These differences could be accounted for by social and lifestyle variations among families and by cognitive and social development of children. Among the fourth graders, more frequent parent-child play was associated with more parental acceptance indicating that parent-child play could be a cause or an indication of positive parent-child relations. Among the first graders, more frequent parent-child play was associated with more parental rejection and higher self-concept. The latter indicates that this interaction can enhance competencies and relationships. The PARQ scores could have a different interpretation for younger children and that moderate parental acceptance is associated with more frequent parent-child play. Different models for predicting self-concept, with parent-child play and parental rejection as predictors were separately presented for Grade One and Grade Four children. Sex-typing was observed in parent-child play activities. There were fewer play activities among the lower class older children than among the middle class and the lower class younger children. N2 - The purpose of this study was to explore the connection between emotional expression in the child's family environment and children's social competence with peers at school. Previous research was extended in two ways: by direct observation and quantification of affective dimensions characterizing family expressiveness, and by extending prior laboratory-based work to the naturalistic environment. Fifty families of kindergarten girls and boys, varying by sociometric status, were videotaped in spontaneous dinner-table interactions. The parents completed questionnaires concerning emotional expressiveness of self and spouse, rating the frequency, intensity, and clarity of expressive behaviors. Videotapes were coded for frequency, intensity, clarity, and type of affect exchanged between parent-parent and parent-child dyads. Results indicated that family affective interactions previously observed in structured parent-child play interactions are generalizable to the unstructured home environment. Both parental expressiveness and observed parental affect were found to be meaningful predictors of children's sociometric ratings. Specific observed affect measurement validated the concept of positive expressiveness and clarified questions regarding negative expressiveness. The predictiveness of expressiveness ratings to children's social status and social competence with peers was improved by the addition of intensity and clarity ratings. Differences were found in parental sensitivity to negative expressiveness and in the effects of negative affect on boys and girls. The results of this study have implications for understanding the role of emotion as a mediator linking the child's family and peer systems, and for developing and implementing family-based interventions aimed at remediating children's social competence deficits and related problems. N2 - The objective of this research was to describe and examine the bullying on the school playground. The subjects were children observed either bullying or being victimized on videotapes of playground interaction gathered in a previous study on peer relations. Data were derived from two sources, questionnaires and observations of bullying interactions. The questionnaire measures collected were: Marsh Self Description Questionnaire (Marsh & Smith, 1982), Social Intentional Problem Solving Inventory (Bream, Hymel, & Rubin, 1986), Teacher's Report Form of the Child Behavior Checklist (Achenbach & Edelbrock, 1986), Teacher Version of the Marsh Self Concept Questionnaire (Marsh, Smith & Barnes, 1986), Revised Class Play (Masten, Morison, & Pellegrini, 1985), and a measure of sociometric status (Coie & Dodge, 1983). A total of 52 hours of video and remote audio recordings of playground behaviour were collected at two schools, in the winter and spring. The results indicated that bullying occurs regularly on the playground, approximately once every seven minutes and is of short duration, 37 seconds. Three percent of the episodes were racist. Bullies used weapons in 4% of the episodes, while only one victim used a weapon to defend himself. The majority of bullying episodes (68%) occurred within 120 feet of the school building. Adults intervened in 4% of the episodes, while peers intervened in 11% of the episodes. Adults, however, were more likely to intervene than peers if they were present. While some peers intervened in bullying, others participated in a variety of capacities that may have contributed to the continuation of these episodes, either by observing, or participating. Peers were involved in some capacity in 85% of the episodes. Bullies and victims were equally likely to be involved in bullying and victimization from the winter to the spring. Contrary to expectations, males and females were equally likely to be involved in bullying. Males were more likely than female (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In two studies I address the question of how an understanding of the origins of species is achieved. Study One is an investigation of when and how children come to adopt natural-evolutionary explanations for biological origins, as opposed to psychological-creationist explanations. Forty-nine elementary school children (6- to 12-years old) were asked about their natural history knowledge and about the origins of biological entities. A coherent pattern was demonstrated, with systematic age-related shifts from a primitive natural explanation, spontaneous generationism, to an intentional explanation, creationism, and from there, for some, to a more sophisticated natural explanation, evolutionism. The presence of evolutionism was positively related to subjects' natural history knowledge, independently of age. In Study Two, both creationist and evolutionist beliefs were investigated in more detail. Subjects were 175 children and their parents, from fundamentalist and non-fundamentalist elementary schools. In the non-fundamentalist community, a replication of the pattern of results found in Study One, was achieved. For the fundamentalist community, creationist explanations dominated at all ages, and all natural explanations, including knowledge of natural-history, were suppressed. Additional measures across the two communities revealed comparable parent educational levels, and comparable child interests in neutral areas, such as outdoor activities and reading, but divergent interests and knowledge in religious activities, fossils and adaptation. It was not until early adolescence (10- to 12-years) that the children's pattern of responses converged on the pattern found in the adults of their respective communities. It is argued that the divergent developmental pattern across the two communities can be optimally explained with a model of constructive interactionism: Children generate both natural and intentional beliefs about origins, while the communities privilege certain (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Using an African Psychology paradigm, this study examined whether African-American children's academic achievement and psychosocial functioning are related to the closeness they feel with their biological fathers and with other male parenting figures in their lives. The sample included 95 African-American, inner-city, fourth through sixth grade children. Fifty-one percent of the children (n = 48) had a father or father-figure living in the home. The Inventory of Family Feelings (IFF) was used to measure closeness between children and

their fathers, and between children and other male parenting figures living in the home. The IFF demonstrated outstanding internal consistency reliability with this sample. The Comprehensive Test of Basic Skills was used as a standardized measure of achievement. The Child Behavior Checklist was used to assess children's School Competence (grades), Total Competence, Internalizing Behavior Problems, Externalizing Behavior Problems, and Total Behavior Problems. In addition, qualitative interviews were conducted with five of the children and their primary caregivers to explore the children's significant relationships with male parenting figures (other than biological fathers) outside of the home. This expanded definition of significant male parenting figures was consistent with an African Psychology perspective. Results of the quantitative analyses showed: (1) School grades correlate significantly with children's closeness to their biological fathers; (2) achievement test scores in math correlate significantly with children's closeness to male parenting figures living in the home (regardless of whether those male parenting figures are biological fathers or other father-figures); and (3) children's aggressive and delinquent behavior problems correlate with less closeness to their biological fathers. The qualitative interviews revealed that a wide variety of men in the extended family and in the community were playing significant father (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - A cross-sectional, correlational study of 30 children (aged 3-5 yrs) investigated relations between their theory of mind development and social interaction, controlling for age and general language ability; the effect of sex was examined as well. All Ss were native English speakers, although for 10, it was a second language. Ss's overall performance on 4 standard false belief tasks was associated with their production of joint proposals and explicit role assignments during a 10-min session of pretend play. False belief task performance was not associated with the child's total amount of pretend play or with a measure of empathic concern. The significance of an association is discussed between a laboratory measure of theory of mind development and children's behavior observed in a naturalistic setting. N2 - Assessed the utility of a peer-pairing procedure for enhancing the sociometric status and positive social interaction of peer-neglected children. Sociometric nominations for 229 1st and 2nd graders (mean age 7.6 yrs) were obtained and used to identify 24 peer-neglected, 24 popular, and 24 average children. Peer-neglected and popular Ss were randomly assigned to peer-pairing or to control conditions. Each neglected S in the pairing condition was paired with a popular S from her or his own classroom, and the pairs participated in 12 15-min play sessions over 4 wks. Behavioral observations of social interaction were conducted for Ss during recess. Sociometric nominations and behavioral observations were reconducted after intervention and 1 mo after treatment. The paired group experienced significant improvement in both sociometric status and positive interaction rate compared with controls, and improvement was maintained at 1-mo follow-up. N2 - Investigated the effects of a self-evaluation procedure on the recess behavior of 3 7-yr-olds with behavior problems, and determined whether the use of 3 age-matched peers in the procedure would facilitate the generalization of behavioral gains. Following the baseline, a peer-mediated self-evaluation procedure was introduced in the morning recess period according to the time-lagged procedures required by a multiple baseline across Ss design. The procedure produced clear improvements in the recess behavior of the target students. These improvements were maintained throughout all experimental conditions as the self-evaluation procedure was systematically faded. In addition, the treatment effects generalized to an afternoon recess period. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - (from the cover) Designed to enhance educators' understanding of the nature, origins, and causes of antisocial behavior, this book offers interventions and model programs that can be used in preventing or remediating this growing problem. Inside you'll find: a comprehensive approach to intervention involving teachers, peers, and parents of students with antisocial behavior patterns; methods for early identification of students at risk for antisocial behavior patterns; ways of designing an optimally effective classroom environment; case studies that illustrate the application of intervention procedures; [and] steps you can take to prevent and remediate antisocial behavior patterns. (from the preface) This book is written for the educator-practitioner who must cope with students who either already have or are at high risk for developing antisocial behavior patterns. This book is based upon principles of social learning that govern how diverse forms of behavior are acquired, maintained, and reduced or eliminated. N2 - (from the cover) The recess period represents a unique part of the school day. It is one of the few times
when children can interact with their peers on their own terms with minimal adult intervention. Consequently, it
represents one of the few places in primary and middle schools to observe spontaneous peer interaction. "School
Recess and Playground Behavior" offers a programmatic examination of a neglected aspect of children's
behavior and informs related literatures such as the educational, social-developmental, and cognitive-
developmental literatures. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The aim of this study is to investigate young children in primary schools not having had any breakfast; and
without being provided with a snack for the morning break. To collect the data, researchers went into
classrooms, usually between the beginning of morning school and break time, while the children could still
remember what they had eaten before school. One of the researchers would address the whole class and explain

that they wanted to collect very special and secret information. They asked the children to take the piece of paper which would be given to them, put their name and class on it, divide it into four, and draw all the things they did before going to school. The findings suggest that out of the entire study sample, 15 out of each 100 children had a snack on the way to school or in the playground before school started, but this often consisted only of sweets. Only eight out of 100 had a drink. We found that more girls (six in 100) went without breakfast than boys. Worryingly, the rate was highest in four- and five-year-olds; among eight-year-olds, the rate was four in 100. It is known that going without breakfast is even more common among older adolescents-but they may be able to compensate more easily during the rest of the day by buying or bringing snacks or food of their own choice. N2 - Used multiple measures in 4 integrated classes of disabled and nondisabled young children to assess social relationships. Nine 10-min observational recordings during indoor and outdoor free play activities, peer nominations, and teacher and peer interviews provided information about social status and strength of association between children with disabilities and their classmates. Results revealed that reciprocal, positive relationships were found between children with disabilities and classmates in all classes. Individual differences in social status and profile of children with disabilities indicate that varied patterns of social relationships are found in integrated classrooms. Brief interviews with the children and teaching staff provided valuable information about relationships based on helping or pity, shared interest in activities, and friendship. N2 - A peer-mediation training program was conducted in 4 multi-age classrooms in an American, suburban, middle-class elementary school. 92 students in the 1st-6th grades received 30 min of training per day for 6 wks, focusing on negotiation and mediation procedures and skills. Prior to the training program, frequent conflicts involving physical aggression, playground activities, access to or possession of objects, turn taking, put-downs and teasing, and academic work were reported. Ss were able to transfer the procedures and skills and apply them in real conflicts among classmates. Careful observation of hallways, the lunchroom, the playground, and the gymnasium revealed that 4 mo after training, Ss seriously and carefully used these procedures to resolve highly emotional and prolonged conflicts with fellow students. Discipline problems were eliminated as Ss became more autonomous in managing their conflicts constructively. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Assessed the nature and environment of children's (aged 5-12 yrs) activities in telephone surveys of 1,000 households in 6 states. Children's behavior was sampled on both weekdays and weekends over all 4 seasons of the year using a retrospective time diary to allocate time to activities during the previous 24 hrs. Information was obtained on the kinds and locations of activities, the nature of the microenvironments of the locations, and the time spent in the different environments. Measures of variability in addition to mean hours per day are reported. Results of this study closely match those of J. A. Wiley (1991) on California children's activities, particularly TV viewing, sleeping, eating, and school attendance. Also, the present Ss spent most of their time indoors at home, indicating that risk assessments should focus on indoor, on-site hazards. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Motor development, mental development, and 15 environmental components were the independent variables and social maturity (SCM) was the dependent variable in a study of 89 infants assessed at 3, 6, 9, 12, 18, 24, and 30 mo of age. Ss' total sleep hours, toys, interactions, and type of activities were repeatedly recorded. Independent variables were studied for their contribution in the variance of social maturity. The components were grouped under development, child's life at home, parental characteristics, family characteristics, and physical environment. The highest contributing component under each group was used to develop a descriptive picture of congenial environment for development of SCM during infancy. A child having educated parents, an elderly mother with commitment for outside work, and a father occupied in work related to learning or skills with managerial freedom was in an environment contributing positively to development of SCM. N2 - Examined longitudinal changes in boys' and girls' school peer networks in Grades 6 and 7 and determined the extent to which network measures in the 1st yr of middle school predicted school adjustment in the 2nd yr. 56 White Ss were observed on the playground for 22 mo, and Ss and their teachers completed measures of Ss'

popularity, physical attractiveness, ability, achievement, and behavior. While certain personality and behavioral measures were stable across the 1st 2 yrs of middle school, networks became more gender integrated across the period. Sixth-grade network measures were predictors of 7th-grade adjustment, and Ss' adjustment could be explained in terms of learning and exhibiting gender-stereotyped behavior. N2 - Reinterviewed 126 Australian and 117 New Zealand children 1 yr after exposure to sexual abuse prevention programs. These included Protective Behaviors in Australia, aimed at developing assertiveness skills and empowering the children, and Keeping Ourselves Safe, developed by New Zealand educational and police experts to meet the unique needs of the Maori, European, and Pacific Islander populations. The survey used problem-solving methods to assess whether Ss could suggest safe strategies for dealing with situations such as becoming separated from parents, facing a babysitter who wants to play undressing games, being approached by a strange woman who meets them outside of school, and being touched inappropriately by an adult. There was no marked improvement in the quality of the Australian Ss' responses. However, all the New Zealand Ss showed some gains in safety skills; significant predictors of success were teacher commitment and socioeconomic class. N2 - Used a sample of 16 preschoolers (10 boys and 6 girls; aged 27-62 mo) to determine if children accurately report their best friends, know their best friends' physical characteristics, and understand the function of friends. Data were collected through classroom and playground free time sociogram observations, teacher responses, and interviews with the children. Ss' self-report of best friends corresponded with teachers' reports, however Ss were not accurate in reporting with whom they had played that day. Ss were accurate in reporting friends' age, hair color, and height, but often forgot their eye color and last name. Preschoolers cited playing with each other and liking each other most frequently as the reason why they liked their best friend. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the impact of job preparation, short-term outdoor adventure, and family relationships programming on juvenile probationers' self-concepts, loci of control (LOC), and perceptions of juvenile justice (PJJ). 45 probationers (aged 12-17 yrs), of whom 15 had been placed on intensive probation, participated in the study. Seven Ss from intensive and 15 Ss from moderate probation were put in the experimental-moderate group, and 8 Ss from intensive and 15 Ss from moderate probation were put in the control-moderate group. The experimental intervention proved to be no more effective than the standard probation services offered in reducing Ss' offense activities or in modifying their self-concepts, LOC, and PJJ. Although the PJJ displayed by all groups improved somewhat in the pre- to posttest interval, the PJJ measured at posttesting were moderate and did not significantly differ between groups. N2 - Argues that since difficulties experienced by children are traceable to problems in underachievement that begin during the first years of early schooling, a thorough understanding of the transition-to-school process is needed. Two principle assumptions in examining this process are suggested. First, multiple risk factors associated with certain child, family, and child care characteristics are expected to predict early school experience both in and out of the classroom, and, thereby, social and academic success and failure in the early school years. Secondly, it is expected that day-to-day experiences in the classroom and on the playground will

exacerbate or mitigate risk, resulting in some children performing better than would otherwise be expected and others functioning worse than anticipated. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the relation between ratings and observations of 34 hyperactive children (aged 5-13 yrs) in public schools in placebo-controlled, double-blind stimulant drug evaluations. The Ss received either 2 or 3 doses of methylphenidate and placebo for 2 wks. Findings indicate that rating scale scores were significantly correlated with classroom, lunchroom, and playground observations of negativistic (e.g., aggression, noncompliance, interference) but not hyperactive (inattention, motor movement) behaviors. However, when the data were analyzed controlling for the variance accounted for by the other dimension (partial correlations), there was evidence supporting the differential validity of hyperactivity and negativistic behavior scales of the IOWA Conners Teacher's Rating Scale and the Abbreviated Teacher Rating Scales across settings and as measures of drug response. N2 - Focuses on the importance of task situation definition in naturalistic settings where adults and children interact together, and the children play a more active role and contribute actively to the flow of discourse. Naturalistic data taken from 1 9-yr-old girl's activities and discourse during an entire day in the home, at school, and in other social settings are presented and analyzed. These data provide evidence for the heterogeneity of speech events and for the use of cultural tools in order to change the authoritative structure of the discourse. An expanded interpretation of the sociocultural approach requires that authority and value should be assumed as essential properties of both intermental and intramental functioning. N2 - Analyzed the relationship between playground skill (measured on the Playground Skills Test) and several socialization variables, including opportunities for practice and parental involvement with playground play. Data were collected for 64 children (aged 7-9 yrs). Descriptive statistics are presented for availability of playground equipment, frequency of playground play outside of school hours, and amount of parental involvement. Playground proficiency was not related to frequency of playground play or to direct parental support (attendance and assistance while child was at a playground). Parental perceptions of a child's skill and attempts at risk-taking were significantly correlated with playground proficiency. A regression analysis of all socialization variables showed that the only significant predictor of playground proficiency was a child's risk-taking attempts. N2 - Examined similarities among 45 sibling pairs in Grades 2-5 in their social and academic adaptation to the school setting. Measures included teacher ratings and ranking of academic skills, social behavior, and peer acceptance; peer sociometric ratings; and direct observations on the playground with peers and in the classroom with teachers and peers. Comparisons were made with randomly selected, unrelated S pairs matched on sex, grade, and classroom. Significant correlations were found only among sibling pairs on peer ratings of social preference, teachers' judgments of academic competence, popularity, social behavior and school adjustment, positive behavior with peers on the playground, and teachers' disapproving behavior in the classroom. Results underscore the need for more multiagent and multimethod research on sibling concordant-discordant adjustment regardless of theoretical orientation. N2 - Children (aged 4-5 yrs) were recorded in everyday classroom interaction at the beginning and the end of their 1st year at school. Groups of 8-20 children were invited to come into the classroom during the lunch playground break and 12 recordings were made. The children's use of language in pretend play was analyzed from transcriptions of the video record. Although girls directed a greater proportion of their speech to controlling others, there were no consistent differences between girls and boys in the use of directives or instructions to pretend. On their entry to school these children displayed few distinct gender-related patterns in their spontaneous speech. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined relations between aspects of 42 male 5th graders' rough-and-tumble play (RTP) and social competence. Ss were observed on the school playground for 20 wks and were asked to nominate peers whom they liked most and least, rank-order peers in terms of dominance, and solve hypothetical social problems. Teachers completed a temperament questionnaire for each S. Neither relative frequency of RTP nor the vigor dimension of RTP accounted for significant variance in Ss' popularity beyond other forms of reciprocal social interactions. Further, relative frequency of RTP was negatively, but not significantly, related to popularity. The flexibility dimension of RTP did account for significant variance in social problem solving. Both aspects (i.e., activity and flexibility) of temperament measured correlated significantly with the vigor level of RTP.

N2 - (from the jacket) [This book offers] an in-depth examination of the varied and intense emotional life of children from ages one to three. Drawing on her lifelong research, [the author] addresses commonly asked questions and issues [raised by the parents of these children]. [The author] gives new insights on how best to handle common toddler problems, such as sleep disturbances, sibling rivalry, and temper tantrums. She also provides invaluable information on the normal anxieties of this age and how to recognize when anxiety is excessive, needing special attention. Finally, she gives us a fresh, insightful picture of how toddlers typically handle the stress of their parents' divorce and outside child care, and provides sensitive practical advice on

easing the toddler through these transitions. [This book] is an invaluable resource for parents, clinicians, researchers, and child-care workers alike. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

VL - Behind the playground walls: Sexual abuse in preschools. xii, 308 pp. New York, NY, US: Guilford Press; US.

N2 - (from the jacket) Representing over 6 years of research with children reporting nonritualistic and ritualistic sexual abuse in preschool settings, "Behind the Playground Walls" is a clear, comprehensive examination of the effects of reported molestation on young children and their families. Based on data gathered from the children, parents, and therapists in a comparison study, the book covers the effects on children's behavior, fears, PTSD [posttraumatic stress disorder] symptoms, sexuality, achievement, school performance, and self-concept. Moreover, the ways in which the children and their families coped with reports of abuse and the factors associated with positive short- and long-term outcome are detailed. "Behind the Playground Walls" is valuable reading for psychologists, psychiatrists, social workers, pediatricians, teachers, and day care center personnel. Written in an accessible style, it also serves as a text for graduate and advanced undergraduate courses on child abuse, child psychopathology and intervention, children and the law, and family problems. N2 - In Study 1, the time when aggressive fighting involving 86 8- and 11-yr-old children took place was examined by direct playground observations during recess. There was a tendency, significant in the younger group, for more fights in the last quarter of recess. In Study 2, the causes of fights, the sex of the participants, the proportion of fights that were escalated by other children joining in in a nonconciliatory way, and the proportion in which children intervened to stop the fights were investigated. The most common causes of fights were disputes over some aspect of a rule-governed game, teasing, retaliations to accidental hurt/injury, and disputes over space. Most of the fights involved boys only, were not escalated by other children, and did not involve attempts to stop them by other children. In Study 3, many children expressed generally negative attitudes toward fighting. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Explores the effects of child-level variables (e.g., gender, age, and temperament) and school-level variables (e.g., recess timing and duration) on children's recess behavior. The implications of recess are discussed in terms of impact on classroom behavior and on measures of social and cognitive competence. Recess has important educational and developmental implications. Timing and duration of recess relate to playground activity, and possibly to classroom behavior, in ways that interact with age, gender, and temperament. N2 - Investigated styles of interaction and gender cleavage in children's (N = 64) play groups at the pre-school level. About a third of play groups observed in a part-time and full-time early childhood center were of mixed gender and two-thirds were same gender. Mixed groups were larger than same gender groups and kindergarten (part-time) groups were larger than childcare (full-time) center groups. In the kindergarten, outdoor play was much more common and there was a significant difference in boys preferring to play outdoors, followed by mixed groups, and then girls. In both centers boisterous play was more likely in boys' groups than girls' groups, with mixed groups more similar to boys' groups in the predominance of boisterous play. While there were examples of successful cross-gender co-operative play, there were also examples of the breakdown of reciprocity due to contrasting styles of play. N2 - To explore relationships among parent's self-reported disciplinary strategies, preschoolers' outcome expectations, and playground behavior, 136 mothers of preschool-aged children (aged 39-71 mo) participated in

home disciplinary style interviews. Measures of preschoolers' outcome expectations and observations of children's prosocial, antisocial/disruptive, and nonsocial/withdrawn playground behavior in preschool settings were also obtained. Results indicate that power-assertive mothers had preschoolers who engaged in more antisocial/disruptive behavior and who expected successful instrumental outcomes for hostile methods of resolving peer conflict. Preschoolers with such outcome expectations also participated in more antisocial playground behavior. Older preschoolers of inductive mothers engaged in more prosocial behavior and expected prosocial behavior to lead to both instrumental gains and enhanced relations with peers. Preschoolers who were more prosocial envisioned friendly-assertive strategies as leading to instrumental gains and, in the case of less nonsocial behavior, to enhanced relations with peers. Children's outcome expectations were also found to be different for older vs younger preschoolers. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In order to assess the magnitude and types of child abuse among 6-16 yrs children, four slums and two red light areas of Calcutta were purposively selected. 165 slum and 100 red light area households participated in this study. One third of the house holds were below poverty line and half of the head of the households were illiterate. Only 50.2 % of 6-16 yrs children were found attending school. The majority of the children were involved in non-economic activities both inside and outside the house. Children in the red light areas were very often used to entertain their mother's customers by bringing cigarettes and alcoholic drinks. Significantly higher numbers of children in the slums were involved in economic activities than the children in the red light areas. Slum children had to work for 6-10 hrs a day for a meagre earning of Rs. 4-10 per day. Child abuse in terms of deprivation from the right to an education and involvement in various deviant activities was more common in the slums than in the red light areas where girls were more vulnerable of commercialized vice. N2 - Examined the extent to which social-cognitive aspects of children's kindergarten experience predict success in 1st grade. Success was defined in terms of achievement, a personality measure, and behavior with peers. 24 5-yr-olds under adult supervision were observed on their school playground during recess for 2 yrs. 75% of the variance in their 1st-grade achievement was predicted with measures of kindergarten achievement, object play, and peer interaction. Peer interaction was positively related to achievement, whereas adult-directed behaviors were negatively related to achievement. Aspects of 1st-grade children's personality disorders and aggressive behavior were predicted by kindergarten popularity. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated the relation between length of play period and the frequency of reported conflicts (RCs) by preschool children. 23 children (aged 2.5-5 yrs) participated in the study, which encompassed 64 days of data collection and was conducted in the natural setting of a day care center. The rate of RCs for the class during 30 min of a 60-min play period was compared to the rate during a 30-min period broken into 2 15-min play periods. When the 30-min play periods were scheduled, the mean numbers of RCs were 4.0 and 6.9, respectively. When 2 15-min play periods were scheduled, the mean numbers of RCs decreased to 1.8 and 1.37, respectively. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the impact of context and repeated observations on mother-child interactions with 36 mothers and their preschool children (aged 3-5 yrs). Families were videotaped during both dinner and a structured block play sequence on 2 occasions. A within-Ss repeated measures design examined the impact of context (dinner and blocks) and time (1st and 2nd videotapings) on the observed interactions. Findings indicate that change in context consistently had a stronger impact on the dyad's controlling and supportive behaviors and their reciprocity than did repeated observations. Significant time x context x marital status (divorced vs married) effects were observed for mothers' supportive behaviors. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the participation of 43 8-yr-old and 43 11-yr-old children (39 girls and 47 boys) in playground activities in Study 1. At both ages, the 2 most common categories of behavior engaged in were sociable activities and rule games. The older Ss spent significantly more time in rule games and significantly less time alone than the younger Ss. Girls spent significantly more time in sociable activities and significantly less time alone than boys. Middle school children's feelings at being excluded by other groups were examined by interview in Study 2. It appeared that the older boys were largely responsible for the lack of mixed age and

mixed sex play on the playground. Molar categories of behavior coded in the study are appended. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Food intake measured over the course of a year, duration of schooling, and family SES were related to playground behaviors in a sample of 111 Kenyan school-age children. Better nourished children were more active, happy, and showed more leadership behavior, whereas poorly nourished children appeared more anxious on the school playground. Children who had attended less school were more solitary and inactive than children with more school experience. Aggression on the playground was related only to family background. The relations between food intake and activity level persisted even when family education, SES, and school participation were considered. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 90 parents whose children attended preschool/day care programs completed a 50-item checklist to assess the frequency, content, and context of parent-child communication about school. Parents and children communicated most frequently on weekdays (particularly when the parent picked the child up from school), at meal times, and when the other parent returned home from work. Topics of conversation focused on the child and his/her friends, outside play, learning activities, and special events. Children, particularly girls, often communicated by describing, asking questions, and performing. Mothers initiated conversations most frequently, particularly with younger children, though fathers and children did so quite often. Conversations were most often triggered by daily routines and parental observations of children at school. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated the relationship between boys' temperament and rough-and-tumble (R&T) play and determined the group composition of R&T, games, and other forms of reciprocal social interaction. The extent to which the vigor and flexibility components of R&T are related to social affiliation and social problem solving flexibility was explored. 13 sociometrically defined popular boys (aged 107-138 mo) were observed on their school playground during recess for 20 sessions. They nominated peers they liked most and least, ordered peers in terms of dominance, and solved hypothetical social problems. Teachers completed temperament questionnaires. R&T groups were similar to other social groupings in terms of number and dominance symmetry. The flexibility dimension of R&T was related to affiliation and social problem solving. Temperament was minimally associated with measures of behavior. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined descriptions of children's injury types within specific environments, with level of supervision considered explicitly. 61 mothers recorded each injury occurrence and reported bi-weekly on their 8-9 yr old children's minor injuries. Children had relatively few injuries in environments usually thought to involve risk (e.g., bathrooms, stairs); instead, children were injured in environments in which they spent the most time (e.g., their own yard, living room, bedroom). Two exceptions were playgrounds and roadways, which constituted the 2 largest injury categories and which also resulted in the highest proportion of potentially serious injuries. Level of supervision was found to vary by location, with vigilant supervision present in the majority of injuries in the kitchen, playing field, car, and bodies of water. N2 - Studied the effect of a daily program of physical activity on mental performance. Ss were 50 Russian school-age children (deafness) (1st and 5th graders). Control Ss followed the traditional school day.

Experimental Ss participated in a program consisting of the following: 10-22 min of morning gymnastics (8-22 exercises), a 15-20-min morning walk outside before classes, and 5-7 min of gymnastics before each class. The diagnostic part of the study was conducted in October, the experimental regimen was conducted throughout the year, and the results were veried in April-May. N2 - Examined differences in the play activities of preschool children under conditions of relatively high and low program structure. The Ss were 259 girls and 286 boys (aged 4-5 yrs) from 26 Australian preschools and 72 of their teachers. Results indicate that (1) children in high-structure programs spend more time on what teachers would perceive as "educational" activities; (2) children in high-structure programs are slightly more oriented to adult organized and led activities, while children in low-structure programs are more oriented to self-initiated activities and peer interactions; and (3) children (especially boys) in low-structure programs are more involved in outdoor play, much of a gross-motor kind. N2 - Used time-sampling data to evaluate experiences of boredom of students in Grades 5-9, both as a state (i.e., related to specific school and nonschool activities) and as a trait (i.e., related to individual dispositions) that students bring to school. 392 Ss carried pagers and reported on their activities and emotions at random times over 1 wk when signaled. While boredom was reported frequently during schoolwork, it was also prevalent outside school, and the same persons report boredom across these contexts. High rates of boredom were correlated with high ability and, when ability was controlled, with oppositional behavior, but not with the onset of adolescence. Data suggest that individual dispositions are an important contributor to boredom. Nonetheless, variations in rates of boredom across classroom situations indicate that schools should be structured to reduce student boredom. N2 - Observations of 86 middle school children (younger Ss with a mean age of 8.5 yrs and older Ss with a mean age of 11.5 yrs) participating in rough-and-tumble play (r/t) were related to sociometric data for liking and strength. Partners in r/t liked each other more than chance predicted, and tended to be closely matched for strength. Neither initiators of r/t episodes nor recipients were consistently perceived to be the strongest partner. Ss were also found to like their partners in a wide range of non-r/t activities significantly more than chance would predict. Thus children could simply choose to spend time with peers that they like, rather than r/t representing a special case. This view is supported by the finding that Ss had the same partners in a range of playground activities as they had for r/t. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Compared features of rough-and-tumble of play (RTP) and aggressive fighting (AF) based on direct playground observations of 2 classes each of 8- and 11-yr-old children. Most bouts of RTP and AF were dyadic, but significantly more bouts of the former involved 3 or more participants. RTP contained more individual action patterns than AF, but the latter was more varied in form. Both wrestling and chasing were seen more in RTP than AF, but restraint in bouts of chasing was not more common in playful than aggressive chasing. Positive and neutral facial expressions were more characteristic of RTP, and negative facial expressions were more characteristic of AF. RTP initiations were more likely to receive an RTP response and less likely to receive an aggressive response than were aggressive initiations. VL - 1:

IS - 1

N2 - Conducted 2 studies on the school behavior adjustment status of 2 groups of boys: an antisocial group (n = 39) and an at-risk control group (n = 41). In Study 1, the authors compared the groups on a series of behavioral measures across Grades 5, 6, and 7 that included (1) teacher ratings of social skills, (2) classroom observations, (3) playground observations, and (4) school archival records. Results indicate extremely problematic behavioral profiles for the antisocial Ss and much more favorable profiles for the at-risk controls. The behavior profiles for the groups appeared to be quite consistent and stable across the middle school years. In Study 2, the authors used a series of selected 5th-grade variables, derived from the 4 major clusters of study measures, as predictors in regression analyses of Ss' status of 7th grade criterion measures of school success or failure. The criterion measures predicted were (1) reading and math achievement, (2) school discipline contacts, (3) attendance, and (4) time spent within a nonregular classroom. There were multiple Rs for reading achievement and time spent in a nonregular classroom. Multiple Rs for math achievement, school discipline contacts, and attendance were moderate to moderately high. N2 - Described differential treatment (DT) of minority students by 2 middle school science teachers (Teacher 1 [White] and Teacher 2 [Black]) and explained patterns of DT within the framework of cultural perspective. Four classes taught by the teachers were examined. Two major aspects of DT were discussed for each teacher: how science content was presented in daily instructional activities and how school policies and classroom practices on citizenship grades operated concerning students' participation in outdoor science activities. Teacher 1 provided learning environments for enriched students (mostly White), but used nonverbal gestures and verbal expressions that led to disengagement in science learning in his regular class (mostly non-White). Teacher 2

treated her 2 classes equitably. Findings suggest significant implications for classroom practices, policy-making, and further research. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 18 boys and 17 girls in kindergarten, 16 boys and 14 girls in 2nd grade, and 14 boys and 15 girls in 4th grade were observed for 8 mo during their recess periods on the school's playground. The observers used scan-sampling techniques and the children were administered measures of socio-cognitive status. Data indicate that behavior varied by location on the playground and by gender. Further, boys and girls self-selected themselves into different environments to engage in preferred forms of play. Only boys' behavior appear strongly related to measures of both adaptation and maladaptation. Results are discussed in terms of boys' propensity for active, outdoor play, and the usefulness of such behavioral data for gauging children's social-cognitive status. N2 - Examined the amount of time 196 6-yr-olds in inner London engage in educational activities at home, and linked these results with earlier research (e.g., B. Tizard et al, 1988) on the association between parental help with reading and children's reading progress. The median child in this sample read aloud at home about 20 min per week, and received about 40 min per week total teaching in reading, writing, and mathematics outside school. Consistent with the results of Tizard et al, Black parents heard their children read more than White parents and girls spent more time with books than boys. The more educational qualifications the mother had, the more time the children spent on all the measured educational activities. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Determined the effectiveness of a friendship awareness activity as an unstructured intervention strategy for affecting the frequency and type of social interactions between the students with mental retardation and their nonhandicapped peers. Four 8-20 yr old students with disabilities were investigated using a modified multiple baseline research design. Observational data were collected using a time sampling technique during recess and lunch periods. The friendship awareness activity alone was not enough to produce changes in social interaction between students with and without disabilities. When interactions between disabled and nondisabled peers did occur, they were brief. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Explored the impact of a sniper attack on elementary school children: 19 Ss who were on the playground during the attack, 21 Ss who were in school but not on the playground, 28 Ss absent from school that day, and 32 Ss who were on a 3-wk vacation from the year-round school. A children's grief inventory was used to examine the relation between Ss grief reactions and their posttraumatic stress reaction. 14 mo after the attack, level of exposure to that event remained the primary predictor of ongoing posttraumatic stress disorder (PTSD) in the Ss. Guilt feelings and knowing the child who was killed were associated with a greater number of symptoms. Grief reactions occurred independent of degree of exposure to the event. N2 - Response to peers' distress for which they were (target-caused) or were not (bystander) the cause were coded for 11 abused and nonabused preschoolers between the ages of 35 and 67 months. Each child was observed on a playground for an average of 115 min. Consistent with results of research with toddlers, abused preschoolers exhibited more inappropriate responses (aggression and withdrawal) toward distressed peers (bystander incidents) than did nonabused preschoolers. Also, abused children were more likely to cause distress of peers. These findings suggest that even among abused children who have had opportunities to interact with nonabusive caregivers and peers (i.e., regularly attended day care), differences in responses to peers' distress are obtained. VL - 43 1989, pp. 77-99.

N2 - This review researches on pre-school playgrounds in the UK. For this review, we located some 60 references providing research findings or statistical information on playgrounds in the UK. The research areas covered in this paper include: geographical distribution of playgrounds; the family background; concept and practices of parental involvement; and the experiences of children in playgrounds. In conclusion, playgrounds provide for more children than any other form of pre-school service: most children who use playgrounds attend for 2 or 3 half-day sessions a week. Registered playgrounds are varied in many respects. A majority involve parents in management, although many do not conform to the model of a "parent run" service. Also, there are large variations in the geographical distribution of playgrounds. Provision is highest in the South and in rural and suburban areas. There is however a strong inverse relationship between levels of playgrounds and nursery education provision. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Studied the structural features of classroom scripts of elementary and secondary school students. Human subjects: 64 male and female schoolage children and adults (4th- and 6th-grade primary school students and 2nd- and 5th-level secondary school students). Ss were interviewed individually and asked to relate how they would explain what happens in a classroom setting to a child who has never been to school. Transcripts of the conversations were analyzed using the grill technique of G. H. Bower et al (1979). The numbers and types of goals, activities/events inside and outside the classroom, student and teacher roles, and school accessories

identified by the Ss were evaluated according to sex and class level. Scripts for entering a classroom, working in a classroom, and leaving a classroom; and scripts for recess were also determined. Statistical tests were used.

N2 - Observed 27 female and 12 male 4th and 5th graders who regularly played the game Foursquare (a ball-bouncing game) at recess over 2 yrs. A subsample of 10 female players was interviewed. Analysis focused on (1) differential use of and appeal to rules at different junctures in the game and(2) the relationship between stated rules and observed action in the game. Four interlocking criteria consistently arose in Ss' discussions of similarities and differences among rules: (1) what kinds of actions rules governed, (2) how rules governed those actions, (3) whether rules were supposed to be changed, and (4) the primary purpose of the actions rules governed. A taxonomy of the Ss' rules is elaborated. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Explored 401 5th-9th graders' experiences of the basic daily tasks of personal care (e.g., grooming, eating) and household maintenance (e.g., chores, errands), using the experience sampling method (M. Csikszentmihalyi and R. Larson; see record 1988-03173-001). Quantity of time, companionship, and subjective states in these activities were examined during 1 week. These tasks were particularly subject to sex typing. Girls engaged in grooming more often than boys; time spent grooming increased with age for girls but not for boys. Boys did more outside chores, while girls did more indoor chores. Girls were also more likely to carry out household tasks with family, while boys did more chores alone. Older girls reported a greater sense of motivation and choice than younger girls. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 26 open interviews were conducted with about 250 kindergarten children (aged 6-12 yrs) who were asked about their pet animals, experiences with wild animals, and activities in natural environments. Results are described in light of the way in which children try to form a consistent concept of their world, using a syncretic way of thinking. The development of child-animal relationships is discussed as following a pattern in which the child moves from a somewhat fearful initial contact to a trusting relationship in which a fusion of horizons occurs. Letting children play freely with animals is strongly recommended if environmental education is to transfer awareness and knowledge. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 585 4th and 5th graders completed a questionnaire on attitudes toward play (ATP) in 3 contexts (neighborhood play, recess at school, and organized youth sports). The relationship between the amount of experience in organized sports and ATP was also examined. Results are consistent with the conclusion that treating ATP as a generalized disposition may be a questionable practice with regard to developing an understanding of attitudinal transformations in response to childhood play experiences. Ss reported more professionalized ATP in some social contexts than in others, and many Ss reported that winning was more important in organized sports than in neighborhood play. N2 - Four observers rated 48 male and 46 female kindergartners', 2nd graders', and 4th graders' rough-and-tumble play (RTP) with respect to aggression over an 8-mo period. Ss were observed during playground school recess periods. Ss' sociometric status, social problem solving, antisocial behavior, and ability to discriminate between RTP and aggression were measured. The incidence of RTP varied according to sex and playground location; RTP accounted for 11% of play behaviors. Boys engaged in significantly more RTP than did girls. Aggression rarely occurred and did not vary by age, sex, or playground location. RTP led to games with rules and was positively correlated, for boys, with social competence. Girls' RTP was positively related to antisocial behavior. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

VL - Children's social networks and social supports. x, 373 pp. Oxford, England: John Wiley & Sons; England.

N2 - (from the preface) The book attempts to synthesize this new knowledge [current theorizing and research on children's networks and sources of support], to suggest implications from this research for supportive interventions for children, and to raise new questions and provide new tools for further study. The volume takes an inclusive view of childhood, with some chapters focusing on a particular developmental period and others spanning the entire age range from infancy to adolescence. The book also takes an inclusive view of social networks, including under this heading individuals both inside and outside the child's household, institutional connections, and even pets. The book is meant for researchers, clinicians, and those with public-policy concerns about the well-being of children, as well as for students of these topics. N2 - The Open Middle Interview (OMI) and the Children's Assertive Behavior Scale-Self-Report were compared for their ability to discriminate among 56 4th-grade boys known to differ in social competence, to predict behavior in a naturalistic setting, and to correlate with peer ratings of likability. Although both procedures measure similar constructs, significant differences were found. Each scale differentiated between socially rejected and popular boys. Only the OMI, however, consistently correlated with observed playground behavior. Neither measure was consistently related to peer ratings. N2 - Extended previous research by examining the relation between children's entry behavior and sociometric status under more naturalistic conditions. First, 3rd, and 5th graders (N = 72) of high, low, and average status were observed during recess. Observers coded Ss' entry and noninteractive behaviors, peers' responses, and the size of groups with whom Ss interacted. Low-status Ss engaged in more passive entry attempts and less sustained group interaction than high-status Ss, and were accepted less and ignored more. Compared with 5th graders, 1st graders attempted entry proportionately more, were alone more, joined smaller groups, and sustained interaction with groups a smaller proportion of time. Group size influenced both the choice of entry bids and the group's response to an entering peer. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - A synthesis of 8 statewide reading assessments and a secondary analysis of the 1984 National Assessment of Educational Progress, which included measures of scholastic achievement, out-of-school activities, and reported TV viewing exposure, were used to analyze 4 theories of how TV viewing displaces other activities in school-age children. Results indicate that differences in reading scores for Ss watching 2-4 hrs/day were small beyond 4 hrs of viewing, the effects were negative and increasingly deleterious. Analysis of outside activities suggested that TV viewing was tied to a different set of needs and gratifications than leisure reading, sports, or spending time with friends. For most Ss, however, time spent on TV viewing was tempered by the increasing

demands of schooling and the onset of social activities. (French, Spanish & German abstracts) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - As they worked on two academic tasks, pairs of friends and pairs of other classmates were observed to determine the effects of existing social relationships on interactions during cooperative learning. A total of 130 third graders and seventh graders were paired either with a close friend or with another classmate who was not a close friend. Each pair of students was videotaped, first, as they discussed topics from social studies texts and, second, as they took turns asking each other questions about the topics. Measures of the content of the students' conversations and of interactional processes (e.g., agreements and disagreements) showed no significant differences between friends' and other classmates' interactions. On a posttask questionnaire, however, the pairs of friends said that they engaged in more academic and nonacademic activities outside the experimental setting than did the pairs of other classmates. The implications of the results for the assignment of students to cooperative learning groups are discussed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - The intent of this study was to describe relations between elementary-school children's rough-and-tumble play and their social competence. Elementary-school children (Grades K, 2, and 4) were observed on the school playground during their recess periods. Results suggested that rough-and-tumble play for popular children led to games-with-rules, whereas it led to aggression for rejected children. Furthermore, popular children's rough-and-tumble was positively correlated with measures of social competence. These results are discussed in terms of the possible effects of the sociometric composition of rough-and-tumble play groups. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the relationship of daycare quality to the activities of 55 4-yr-olds during free play and their knowledge of social problem solving. Indicators of daycare quality included quality of interaction with teachers, arrangement of the physical space, spaciousness of the environment, appropriateness and variety of the materials provided for play, quality of the outdoor area, group size, and child-teacher ratio. Relationships were found between these dimensions and Ss' absorption in solitary play and knowledge of social problem solving. Most relationships held up after the effects of social class were statistically removed. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated the relation between preschoolers' peer behavior and status over a school year by exploring whether early behaviors predicted changes in peer status or vice versa. 28 White preschoolers' playground behaviors and peer status were assessed at 3 times during the school year (fall, winter, and spring). Analysis of the behavioral antecedents of status produced some findings that were consistent with those reported for grade school samples (e.g., J. D. Coie and J. Kupersmidt; see record 1984-11902-001). Higher levels of cooperative play at the outset of the school year predicted gains in peer acceptance by the end of the year. Arguing forecasted increases in peer rejection at both the middle and end of the school year. In contrast, early peer status was not predictive of changes in preschoolers' later social or nonsocial behavior. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In a study of the development of the differentiation of fantasy from reality, it was hypothesized that preschool children would progress through a stepwise sequence of developing ever clearer boundaries between fantasy and reality. Evidence for this development was based on children's reactions to various kinds of interruptions to their fantasy play that were initiated by an experimenter as she engaged in role playing with each of 39 children. The children were 2 1/2 to 6 1/2 years of age. The results indicated that as age increased, children showed higher steps in the sequence, until at 5 and 6 years they could incorporate an interruption into the fantasy scenario without stepping outside the fantasy and without having the interruption upset them. N2 - Focuses on a theoretical position of elective mutism (EM) derived from clinical experience with a 5-yr-old girl and a 6-yr-old girl whose EM was present for 3 yrs. In both cases, individual play psychotherapy was the chosen intervention. Different theories of EM focus on passive-aggressive behavior, fear/anxiety reduction, controlling/withholding aspects, and family dynamics. EM is viewed as a distortion, at a point of crisis, of a basic process of psychic development. Therapeutic approaches must adjust to particularities, since each case

will reveal its own special pattern of interconnection that links the child's experience of self, family, and outside world. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Interviewed 59 middle-class public-school suburban children (aged 8-18 yrs) about their use of places inside the house and outside on household property. Ss also photographed all places important to them. Bedrooms were particularly salient in the Ss' daily lives and evaluations. Female Ss evaluated their homes more positively, and the sexes differed in terms of which places were important and how places in the home were used for personal activities and social interactions. It is concluded that these different patterns of home use were related to gender differences in attachment. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the amount of time spent by 1,045 rural children (aged 6-17 yrs) in household activities and several demographic factors related to their time use, using data from a survey of family use of time in which home interviews were conducted with families from rural areas of 10 states. Findings indicate that Ss averaged 65 min/day in household tasks. Ss spent the most time in shopping and in maintenance of home, yard, car, and pets. Age and sex of the child, education and employment of the mother, state of residence, and season of the

year significantly affected time spent on tasks. Results are interpreted in terms of E. H. Erikson's (1968) stages of development. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Studied the effect of behavior modification techniques on 191 2nd- and 5th-grade students' playground behavior and cognitive knowledge of friendship. An event recorder instrument was developed, and misbehavior on the playground was recorded. Ss were identified as being more and less disruptive from the baseline measures, and the knowledge of friendship was determined. Two behavioral treatments were administered with continuous recording of misbehaviors. Baseline measures were continued when treatments were withdrawn. At the conclusion of the study, the knowledge of friendship was measured again. Results indicate that for 5th graders, both treatments were equally effective in reducing disruptive playground behaviors. For 2nd graders, behavior games were not effective when used as the 1st treatment, but individual behavior contracts were very effective. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Interviewed 103 children (aged 2-6 yrs) and surveyed 73 of their parents and 60 preschool teachers about their perceptions of play. Most parents defined play as something for fun or amusement, while teachers saw it both as fun and as an opportunity for cognitive and social development. The majority of teachers did not view play as an integral part of the curriculum, but instead described a learn-play dichotomy. Parents did not support having their children spend a large amount of time in play during preschool. Children's favorite play activities according to children and their parents and teachers were outdoor play, dramatic play, blocks, and art activities. N2 - Identified 13 rejected and 13 popular 3rd- and 4th-grade boys using sociometric nomination measures. Playground observations and interview assessments of social problem solving were administered during the winter and spring. Rejected Ss both exhibited and received more aversive behavior than popular Ss. Although no status differences in the overall rate of interaction were found, rejected Ss exhibited more onlooker behavior and solitary play than the popular ones. No differences in the frequency of alternative solutions to hypothetical social problems were found between status groups. The solutions of rejected Ss were, however, less effective and more aggressive than those of populars. Chosen solutions of rejected Ss were also more likely to be ineffective and aggressive than those of populars. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Measured 65 teachers' and 123 children's facial, verbal, and physical affectionate behaviors in 7 daycare centers during a variety of daily routines. Affectionate behavior occurred much less frequently than other social interaction, and smiling occurred more frequently than verbal or physical affection. Children almost never expressed affection verbally, although their teachers did. Physical affection occurred most frequently during unstructured indoor and outdoor freeplay periods; verbal affection occurred most frequently during structured small group activities. Analyses of behavioral patterns across centers indicated that centers that ranked high on the expression of some types of affectionate behaviors during particular daily routines did not necessarily rank high on all affectionate behaviors. N2 - Evaluated the activities and social contacts of a group of 5 severely mentally handicapped people (aged 10-18 yrs) who left a hospital to live in a residential setting. Results show that the Ss experienced increased contact with their families and spent more time in a wider variety of activities outside the house. The degree of handicap had little effect on results. Activities depended almost entirely on the staff. The nature of the Ss' social contacts is examined, and conclusions are drawn about staff selection and training and attention to the maintenance as well as the provision of social contact. N2 - The effects of methylphenidate on the social behaviors of hyperactive children between the ages of 6 and 11 were examined during relatively unstructured activities in outdoor settings. The 12 younger (mean age = 7-8 years) and 12 older (mean age = 9-21 years) children received placebo, a low (0.3 mg/kg), and a moderate (0.6 mg/kg) dose of methylphenidate. During recess, lunch, and exercise sessions, trained observers coded the children's actions as either appropriate social, negative social, or nonsocial behavior. Both age groups showed decrements in negative social behaviors when placebo was compared with the low dose of methylphenidate. Only the younger group showed incremental improvement between the low and moderate doses. There were no significant age or dosage effects on the rates of nonsocial behaviors, which remained low throughout the study. Several implications for the treatment of hyperactive children are discussed, including (a) the finding that disruptive behaviors can be reduced successfully without decreasing overall sociability, (b) the importance of interpersonal heterogeneity and the distinction between group and individual patterns of response, and (c) the

need to study relationships and friendships as well as social actions. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 25 2nd graders' (12 males, 13 females) and 24 5th graders' (10 males, 14 females) playground activities during school recess were studied with a 1-yr follow-up. At the 2nd time of assessment, measures were also taken of logical reasoning, interpersonal understanding, and understanding game rules. Both grade and gender differences were found in the complexity of Ss' activities. Generally, older Ss participated in more complex activities than younger Ss, and boys participated in more complex activities than girls. The complexity of children's activities increased over the 1-yr period, especially for boys. The correlates of game complexity differed for boys and girls. For boys, game complexity was negatively related to interpersonal understanding and positively related to understanding game rules. For girls, game complexity was positively related to interpersonal understanding. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Observations were made of mother-child, father-child, and mother-father-child groups in an urban park playground. Results show great similarity between father-child dyads and mother-father-child triads, with mother-child dyads being consistently different. It is suggested that the similarities between triads and father-child dyads may occur because fathers and children rarely spend time alone together. Their dyadic rates of interaction and activity thus resemble those found in the triadic setting they usually experience. Group size and roles and relationships appear to exert a complex interactive effect on family-interaction patterns. The degree to which results might be situation-specific is considered, and implications for our understanding of family-interaction processes are discussed. N2 - Examined play-fighting and chasing activity among 7-, 9-, and 11-yr-olds (n = 29, 29, 36, respectively) in their school playground, where it took up some 10% of their time. Judging by characteristics of initiations and terminations, it tended to occur in a friendly, nonaggressive context. Sociometric information supported this interpretation. Observed rough-and-tumble partners liked each other better at all ages than chance predicted. With increasing age, the importance of strength relations in partner choice increased. 11-yr-olds tended to choose partners who were similar in strength to, but weaker than, themselves, while neither factor influenced 7- and 9-yr-olds' choices significantly. Findings suggest that rough-and-tumble activity performs an affiliative function in young children, becoming important for dominance and fighting-skill development in older children, although immediate motivation remains nonaggressive. N2 - The present investigation evaluated the effects of cognitive-behavioral problem-solving skills training (PSST) and nondirective relationship therapy (RT) for the treatment of antisocial child behavior. Psychiatric inpatient children (N = 56, ages 7-13) were assigned randomly either to PSST, RT, or to a treatment-contact control condition (in which children met individually with a therapist but did not engage in specific activities designed to alter antisocial behavior). Children were hospitalized during the period in which treatment was administered and discharged thereafter. The PSST condition led to significantly greater decreases in externalizing and aggressive behaviors and in overall behavioral problems at home and at school and to increases in prosocial behaviors and in overall adjustment than the RT and contact-control conditions. These effects were evident immediately after treatment and at a 1-year follow-up. The RT and control children did not consistently improve over the treatment and follow-up periods. Comparisons with nonclinical (normative) levels of functioning revealed that a significantly higher proportion of PSST children, compared with those in other conditions, fell within the normative range for prosocial behavior at posttreatment and at follow-up. Even so, the majority of PSST children and almost all RT and control children remained outside the normative range of deviant behavior. The implications of the results for further research for antisocial youth are highlighted. (31 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Describes 4 of 38 grid games that were used to determine if total body movement would help improve the reading ability of 26 6-14 yr olds in elementary school who were experiencing reading problems. The Ss had been diagnosed as having learning disabilities on the basis of reading levels that were below grade levels and the Ss' inability to perform at a passing level in a regular classroom. For 16 wks an experimental and a control group were taught with the same instructional materials, content sequences, and time allotments. The experimental group was also given the total body movement exercises for 20 min each day, while the control group was given a placebo treatment that consisted of small group reading with assignments outside the regular classroom. Comparison of pre- and posttreatment scores on the Wide Range Achievement Tests indicate that the experimental group demonstrated a higher reading level than the control group at the end of the testing period. Results suggest that the total body movement treatment did enhance the reading ability of the students beyond the increase evident when traditional classroom methods are used. N2 - Observed the free play of 109 working- and middle-class 3-4 yr olds to examine the effects of social class and the educational orientation of the center on the children's play. Data indicate that both social class and the type of preschool center affected aspects of the Ss' play. There was no support for the belief that the presence of trained teachers improved the quality of the play. Working class Ss were more than twice as likely as middle-class Ss to play outside, particularly with wheeled vehicles, while middle-class Ss more often chose paints an pattern-making. Results also show that the working-class Ss were less often involved in symbolic play than their middle-class counterparts, and more often made only partial use of play materials, both characteristic of the play of younger children. N2 - 26 mentally handicapped 6-12 yr olds participated in a study of a social skills training (SST) procedure. Ss were randomly assigned to 1 of 3 groups: SST plus contingency management procedures (Group 1), SST only (Group 2), and control. Ss in Group 1 were exposed to an SST curriculum that taught critical classroom behaviors facilitative of classroom adjustment and peer-to-peer social skills. For this group, behavior management procedures were applied in the classroom and on the playground to strengthen specific skills taught by the curriculum. Training required 4-7 wks and was conducted using small-group teaching formats. Teacher ratings, a criterion role-play test (CRPT), and behavioral observation data recorded in classroom and playground were used to assess changes in Ss' behavior. Results favored the 2 experimental groups over the control on all dependent measures. However, significant differences were obtained only on the CRPT and classroom observation data. One of 3 interactive measures derived from playground observation data approached significance. Group 1 was favored on ratings of classroom and peer-to-peer skills as well as playground observations. Results are discussed in terms of study limitations, ways of improving intervention procedures, and needed research in the social skills area vis-a-vis mainstreaming. VL - :

IS - 1973

N2 - (create) This reprinted article originally appeared in (Journal of Speech and Hearing Disorders, 1970, Vol 35, pp. 256-276). The case of Teddy illustrates the strategy of the experimental analysis of behavior in treating

the communication deficits of a child with autistic behaviors. The speech clinician coordinated the efforts of parents, teacher, and psychologist to generate and maintain appropriate behavior of the child in various settings. Consistently applying the same procedures to the child's behavior at school, at home, and in the clinic is of critical importance in maintaining and generalizing newly acquired vocal responses and nonvocal behavior to all areas in the child's environment (Lovaas, 1968). Teddy was born after a full-term pregnancy and his birth history was essentially normal. His acquisition of gross motor skills followed a somewhat delayed pattern, and medical reports, when Teddy was six, listed several "soft" signs of neurological dysfunction. Multidisciplinary evaluations between ages four and five indicated a poor prognosis with diagnoses of mental retardation, infantile autism, organic brain damage, emotional disturbance, and arrested hydrocephalus. later it was discovered that he had a bilateral conductive hearing loss. Teddy was six years, five months old at the beginning of the program. Three overall, long-range goals for Teddy's treatment were formulated: (1) deceleration of certain undesired vocal and nonvocal behaviors; (2) acquisition of the language and social skills required for success in school; and (3) generalization of these skills to Teddy's environment away from the clinic. After five months of language and behavior training, both in the clinic and when extended to the home, the initial behavioral objectives of treatment were achieved. Steps were taken to find an appropriate school placement for Teddy. After the treatments were extended to the school environment the effects of the training procedures were beginning to show in his ability to learn appropriate responses quickly and in the spontaneous generalization of his responses. During the early treatment there had been several unsuccessful attempts to teach Teddy some play skills and appropriate social behavior. Although Teddy would try out his responses on peers in these situations, his repertoire was not sufficient for him to maintain communication. Reports indicate during his first two years of school he still preferred to play alone at recess. During the last year, however, he began to acquire social skills appropriate for his age and routinely played with other children in school and in his neighborhood. Teddy's language repertoire was greatly expanded and he was able to routinely converse in sentences in an essentially normal manner. His general articulation was what one would expect from a child his age. The only reported difficulty was that he occasionally spoke too fast when excited, but this is not uncommon for children his age. The question of which of the procedures in force was related to changes in Teddy's behavior cannot be answered with the data available on Teddy. However, the intent of this study was pragmatic: to demonstrate how procedures, whose effects on behavior have already been rigorously demonstrated (for example, Girardeau and Spradlin, 1970), can be applied clinically without sacrificing scientific rigor. N2 - Three learning-disabled (LD) males between the ages of 8 yrs 2 mo and 10 yrs 10 mo, selected on the basis of peer sociometric ratings and teacher referral, received social-skills training. A group training procedure consisting of coaching, modeling, behavior rehearsal, and feedback was used to teach Ss the target behaviors of eye contact and appropriate verbal responses. The following measures were obtained during baseline, posttreatment, and 1-mo follow-up for the experimental Ss and 3 control Ss: (a) performance on role-play scenes not trained during treatment sessions, (b) behavioral observations in a free play setting, and (c)

sociometric ratings. In addition, the trained and untrained role-play scenes were administered by novel experimenters following treatment. Results indicate that socially unskilled, LD children can be taught to respond appropriately to role-play situations. However, improved performance did not generalize to the natural school setting, and treatment did not affect ratings of peer acceptance. N2 - Interviewed parents of 24 5-12 yr old physically disabled children attending primary schools who had been referred to child guidance for various reasons. Data were collected to determine their characteristics and the external and educational support they received. Results show that Ss received medical, social work, and education attention. Most parents regarded their initial contact with professionals as poor or very poor; the majority believed they needed more help from outside agencies. Most parents expressed satisfaction with the response of teachers to the needs of their children. Most parents felt that they had played an important part in the decision to place their child in a regular school, and they were satisfied with that placement. Data show that measured IQ for spina bifida Ss was of questionable value and that there was a lack of interest in measures of social integration and adjustment for these Ss on the part of psychologists. N2 - Used a 10-item attitudinal survey to assess 57 involved and 44 uninvolved 6th graders' perceptions of teachers, school, and self in 3 settings: (1) the regular classroom situation 2 wks before an outdoor education experience, (2) immediately following a 2-day outdoor education experience, and (3) 2 wks after the outing in the regular classroom. The activities for the outing were designed to encourage a high degree of physical, mental, and at times, emotional involvement. The outdoor experience was rated as significantly more positive than the regular classroom experience by involved and uninvolved Ss as well as the total population of 213 6th graders. During the outing the uninvolved Ss' perception of teacher trust improved significantly more than the involved Ss' perception. Ss had significantly more positive perception of the regular classroom 2 wks after the outing than 2 wks before. Findings indicate that outdoor education is a highly appropriate mode of instruction for improving uninvolved and involved students' perceptions of school, teachers, and self. N2 - Examined the effects of 2 methods of selecting and exchanging back-up reinforcers with 2 mentally retarded 6- and 7-yr-old boys participating in a token economy in a special education class. In separate experiments, each S received tokens contingent upon attentive behavior. Methods of selecting and exchanging back-up reinforcers (i.e., free time, a recess, selection of a small toy, playing with a valued toy) consisted of preselecting back-up events that were to be purchased in advance of earning the tokens vs selecting back-up events only after tokens had been earned. The 2 methods were compared in separate simultaneous-treatment designs for each child. In each experiment, preselecting back-up reinforcers led to higher levels of attentive behavior than selecting back-up events after the tokens had been earned. The possible influence of making back-up events less remote in relation to the token-earning behaviors and the prompting function of the preselected procedure are discussed. N2 - Ss were 28-50 yr old White parents of nonstuttering (NS; 14 mother and 13 fathers) and stuttering (ST; 14 mothers and 13 fathers) children-12 male and 2 female 4-13 yr old stutterers. Parents of NSs were matched with the ST group by virtue (a) of having a child of the same sex and age as the stuttering child and (b) the same number of children in the family. All parents completed the Parent Attitude Research Instrument and a measure

of attitudes toward the freedom of children; STs completed the Family Relations Test. Results indicate that the fathers of STs were more rigid and conventional concerning children's natural expressions than fathers of NSs. Mothers of STs were more accepting of the parent role, exercised more democratic principles within the family, and were more protective of their children with regard to outside influences. Although it was not determined whether parental attitudes of the mother and father directly caused the child to stutter, it is suggested that the stern, intolerant position of the father could create a stressful environment conducive to an impediment of speech development. N2 - Studied age and sex differences in the aggressive behavior of a total of 84 2-5 yr olds from different schools during 63 hrs of observation in a 3-phase investigation. Eight categories of aggressive behavior (5 inspired by the work of M. Manning [1972] and 3 used for the first time in studies with children), were defined and tested. Behavior was observed by direct techniques on the school playground during free play. Aggression as defined by Manning was reassessed in Phase 1, different types of aggression were categorized and tested in Phase 2, and the frequency of these types of aggression and the relationship between incidence, sex, and age were studied in Phase 3. Boys and younger children, independent of sex, had the highest frequencies of aggressive behavior. Most aggression involved 2 children. Ss were classified as initiators, receivers, and intermediaries and into high, middle, and low aggression subgroups. The implications of the findings for preschool education are discussed. N2 - Evidence from studies conducted in classrooms and analogue settings suggests that popular and unpopular children form their own unique subsystems and that their interactions with peers differ in quality. The present study assessed the behaviors and peer networks of popular, average, and rejected children in a larger and more diverse social setting. Based on sociometric measures administered in each classroom at 2 elementary schools, 48 3rd and 4th graders were selected to represent each sociometric membership group and then observed during mixed-grade recess periods. Analysis of children's behaviors indicated that rejected Ss spend less time in prosocial interactions and more time in agonistic and unoccupied behaviors than did popular or average Ss and paralleled average Ss in time spent watching others play. Analyses of various network measures revealed that a larger proportion of rejected Ss' interactions, as compared to those of popular and average Ss, was conducted in small groups and distributed among younger and/or unpopular companions. Popular and average Ss were also named as friends by a greater proportion of their frequent playground companions; they also tended to have networks that were more cliquish or comprised of mutual friends. N2 - Sociometric nominations were used to select groups of popular, average, rejected, and neglected 3rd- and 5th-grade children (N = 320) in 2 studies. Ss' peer-interactive behaviors were naturalistically observed in their classrooms and on the playground. In contrast to popular Ss, rejected Ss displayed fewer task-appropriate behaviors and more task-inappropriate and aggressive behaviors. Whereas rejected Ss prosocially approached peers as frequently as did popular ones, peer responses to the approaches of rejected Ss were more likely to be negative. Neglected Ss, on the other hand, displayed relatively few task-inappropriate and aggressive behaviors, and socially approached peers infrequently. Their approaches also met with frequent rebuff by peers. Findings are discussed in terms of the behavioral bases of sociometric status. Suggestions for clinical researchers interested in behavioral change with rejected and neglected children are included. (28 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Analyzed essays by 75 Israeli 7-11 yr olds on their experiences when suddenly left at home without parental supervision. Ss generally described the experience of being left home alone as forced on them and fearful. Younger Ss perceived the environment as an active entity and attributed their fears to outside sources. Older Ss, with a more rational approach to their environment, viewed their fears as inconvenient feelings derived from inside and stimulated by the situation of loneliness. Younger Ss felt more challenged by the circumstances than older Ss. Findings emphasize the importance of the social component of the home environment in determining children's emotional states. N2 - Studied the effect of traditional playgrounds (TPs) and contemporary playgrounds (CPs) on play behaviors (PBs) of 40 preschool children in 2 age groups (aged 2-3 yrs and 4-5 yrs), videotaped during their 30-min outdoor play period at a nursery school. Each videotaped PB category was coded. Chi-square analyses and a repeated measures analysis of variance (ANOVA) were done. No significant differences were found between the 2 playgrounds concerning the cognitive play categories. More unoccupied behavior occurred on the CP. Less solitary play occurred on the TP. Findings concerning locomotion, verbal interaction, balance-posture, receipt propulsion, fine motor, and body image categories showed marginally more sitting behavior on the CP. More passive physical activity occurred in the CP setting. The decrease in these behaviors appeared to be supported by an increase in active climbing on the TP. The CP reduced physical play activity slightly. (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Discusses the mastering of feelings of aggression and excitement by the preschool child. The problem of TV-influenced aggressive play has persisted for generations. Conflicting forces act outside the child and shape the future adult. The forces inside the child vary with age. With repeated experience, children learn that it is possible to be angry without endangering themselves or loved ones. A young child is very vulnerable to the example of magic people on TV who indulge their urges but fight off danger. Excitement and aggression, not created by TV, are stimulated and given a false measure of reality and adult sanction. If TV is limited, children invent their own monsters and aggressive play, but these feelings are easier to master without outside stimulation. Self-control results in inner safety and self-esteem, which is suggested as the best approach to monsters and superhuman beings in the classroom. N2 - Investigated the prosocial behavior of 76 4th-graders by observing their sharing, caring, and helping actions on the playground and by obtaining sociometric measures (peer nomination) of a variety of prosocial actions. Personal characteristics such as assertiveness, empathy, self-concept, value orientation, and moral-motivational reasoning based on role taking were also assessed. Prosocial responding was moderately coherent for girls, but caring, sharing, and helping were relatively independent domains for boys. Associations between prosocial behavior and personal characteristics were observed. Sex differences in these relationships suggest that females' predominant prosocial responses reflect expressiveness and caring, whereas males' most salient prosocial responses are more active and instrumental. N2 - Compared the effects of different levels of cooperation on cross-handicap interaction in 2 studies. In Study 1, 27 handicapped (i.e., with severe learning and behavioral problems) and 45 nonhandicapped 6th graders were randomly assigned to 3 conditions (cooperative controversy, cooperative debate, and individualistic) stratifying

for sex, ability level, and handicap. Ss participated in the study for 55 min/day for 11 instructional days. In Study 2, 15 handicapped (i.e., learning disabled and emotionally disturbed) and 36 nonhandicapped 4th graders were randomly assigned to 2 conditions (intergroup cooperation and intergroup competition) stratifying for sex, ability, and handicap. Ss participated in the study for 55 min/day for 10 instructional days. An activity report scale was given to Ss to determine who they interacted with in structured class activities, unstructured class activities, school activities outside of class, and activities in the home. Results indicate that both cooperative conditions promoted more constructive cross-handicap interaction than the individualistic condition; pure cooperation promoted more frequent cross-handicap interaction than did a mixture of cooperation and competition. The interaction patterns formed within cooperative learning situations generalized into unstructured class and school activities. (6 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 86 3rd-grade boys were given measures of cognitive style, social reasoning, and IQ, along with nonsocial tasks. Teachers completed measures of the Ss' motivation and behavior; each S was also rated by 3 female and 3 male peers. Results indicate that impulsive Ss (n = 45) chose assertive responses to conflicts less often than reflective Ss (n = 41). However, no style group differences were found for other types of self-rated responses or for teacher and male peer ratings of social behavior. Impulsives were rated by their female peers as more physically aggressive on the playground and as more verbally aggressive, likely to leave social conflicts, and assertive in the classroom. Highly reliable group differences were found for the teacher, peer, and experimenter ratings of motivation, with impulsives being rated as less motivated than reflectives. Impulsives demonstrated maladaptive social behavior and inadequate motivation, in spite of their adequate social reasoning. Findings suggest that the traditional social cognitive skill deficit model of maladaptive behavior is inadequate and that control deficits (e.g., impulsivity) and production deficits (e.g., low motivation) merit consideration in the treatment of maladaptive behavior in general and impulsivity in particular. N2 - Observed the behaviors of 16 children (aged 6 mo to 2 yrs 5 mo at 1st observation) while viewing TV in their own homes for a period of 6-8 mo at a time when Ss were actively involved in the language acquisition process. At the last observation, Ss ranged in age from 1 yr 2 mo to 3 yrs. Findings reveal an overwhelming and consistent occurrence of language-related behaviors among Ss and their parents in the viewing situation. Four main categories of Ss' verbalizations were identified, including designating objects, characters, animals, and other things on the screen; questioning about TV content; repetition of TV dialog; and description of TV content. Four main categories of parental verbal behavior paralleled the kinds of child behavior and included designation, questions, responses to child comments, and description. Within each category of child or parent behavior there were identifiable subtypes, and examples are presented. The categories are compared with those reported for parent-child interactions outside the viewing experience, particularly joint book-reading. A model of TV as a talking picture book is proposed. It is argued that TV has the potential to serve as a facilitator of children's language acquisition. Transcripts of observations of 2 Ss are appended. N2 - Examined the notion that individuals uncertain about the appropriateness of their behavior may imitate to reduce their uncertainty by observing 24 preschool boys and girls (aged 3-5 yrs) in their regular classroom. 12 Ss in the experimental condition were observed for 48 min/day (during free play) for 1 wk. Subsequently, they were moved into a different classroom and observed for another week. The teacher, peers, and surroundings were unfamiliar to the Ss, and it was predicted that this manipulation would create a sense of response uncertainty and, hence, increase imitative behavior. 12 control Ss were observed in their original classrooms for both 1-wk periods. Imitation was scored by frequency of occurrence. Additionally, the type of social interaction

engaged in by the S was recorded using the scan-sampling technique at 30-sec intervals. Results indicate that mode of social interaction did not change for Ss in either condition from Week 1 to Week 2. The experimental Ss, however, imitated significantly more in Week 2 than in Week 1 and more in Week 2 than did the control Ss in Week 1 or Week 2. N2 - Investigated the relationship between classroom organization and the experiences of 9 preschool handicapped (HC) children (aged 2.8-6 yrs) and 9 non-HC children (aged 2.1-5.3 yrs) in mainstreamed settings. Six HC Ss were developmentally delayed, 1 had Down's syndrome, 1 was cognitively and hearing impaired, and 1 was autistic. Ss were observed in 3 settings that differed in grouping, supervision, and teacher direction: center time, rug time, and outdoor play. Findings indicate, as predicted, that HC Ss differed from non-HC Ss in their classroom experiences. HC Ss spent less time on-task, interacted more frequently with adults and less frequently with peers than did non-HC Ss. Furthermore, HC and non-HC Ss' experiences were differentially affected by the setting. HC Ss spent less time on-task in rug time than in center time while HC Ss' time on-task was similar in each setting. HC Ss' interaction with peers was similar in all settings while non-HC Ss interacted most frequently with peers in outdoor play. (23 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Conducted a 7-wk study to evaluate toy preference and associated gross and fine motor movements of 15 preschool orthopedically handicapped children (aged 3-6 yrs) in a free-play situation. Observation sessions were scheduled 2 times/wk, each lasting 1 hr. 20 toys were evaluated using a modified version of the procedure developed by H. R. Quilitch et al (1972, 1977). Measurement of movement behavior associated with toy play involved application of a movement glossary developed by the experimenter. A Wilcoxon 2-sample rank test revealed no significant differences for either gender, age, or ambulation in relation to toy preference or nature of movement demonstrated. Analysis revealed that Ss spent considerable time using toys in a manner that did not correspond to their design. The observation that Ss more often sat either in, on, or next to a toy and made fewer attempts to move that toy in a purposeful manner suggests that, in a natural setting, the actual vs expected outcomes of organized, informal toy play may be less than desirable. It was recommended that orthopedically handicapped children might benefit from learning how to play under the direction of a parent, teacher, or similar individual. N2 - Synthesized selected research results of studies focusing on imaginativeness, creative behaviors, and single parent families. The finding of T. D. Yawkey and M. C. Yawkey (in press) that children in single-parent families display higher imaginative scores, have more imaginative companions and more imaginative talk with these companions, play more imaginative games when alone, and engage in more imaginative outdoor games than those in dual-parent families is discussed along with similar results from other studies that show significant correlates between high degrees of imaginativeness and single-parent families. Suggestions for single parents to use to develop their children's imaginativeness are presented with regard to the following parental roles: present but unengaged, attentive but uninvolved, engaged and responsive, and facilitator/modeler. N2 - Assessed the relationship of 2 approaches (teacher's ratings and observation of behaviors in a naturalistic setting) used to measure children's social behavior that are frequently used to select children for social-skill training. 26 preschool children (aged 31-71 mo) were observed during free-play activity times. Behaviors were coded for the most prominent type of play for each 15-sec time unit. The Ss' playmates were also coded to obtain 2 popularity measures. Ss were observed randomly for 2 min each day on consecutive school days until 12 min of observational data were obtained for each S. The 2 classroom teachers rated each S on a form

measuring the S's social behavior and nominated the 5 most popular and 5 most isolated children in the classroom. Correlations among the behavior categories indicated that group positive behavior was negatively related to solitary, parallel, and teacher-directed behaviors. Furthermore, group positive behavior was positively related to group positive popularity and group negative behavior was positively related to group negative popularity. Group positive popularity was also positively related to group negative popularity. The 6 items on the teacher rating form tended to be correlated more with group negative behaviors than isolate or group positive behaviors. Also there was little relationship between the teacher-nominated Ss and the ranking of those Ss according to their behavior in a naturalistic setting. N2 - Defines the dual-career (DC) concept in terms of a relationship in which both the woman and the man work outside the home and are actively involved in developing a professional lifestyle, which demands intense involvement, long hours, and much psychic energy. Views regarding maternal employment prior to the 1960's and during the 1960's and 1970's are presented. The literature on the effects of maternal employment on preschoolers is summarized in terms of attachment, sex roles, IQ, academic achievement, and psychosocial

adjustment. Several issues pertaining to the adjustment of school-aged children of DC couples are addressed; these include time spent with children, role models, academic achievement and IQ, adequacy of substitute care, psychosocial adjustment, child's perceived rejection, and career aspirations. It is acknowledged that some factors are specific to SES levels. The characteristics of DC couples are delineated, and some factors that tend to decrease the negative effects of a DC lifestyle are discussed. (28 ref) (PsycINFO Database Record (c) 2012

N2 - Observed 8 5-7 yr old spina bifida children of average academic ability attending regular primary schools in Australia and 8 matched controls in the playground during 2 recess and 2 lunch breaks. Analysis showed that disabled Ss, 5 of whom were in wheelchairs or on crutches and 3 with no need of aid for mobility, had significantly fewer interactions overall, interacted with fewer people, and spent more time alone or in dyads. Peers initiated significantly fewer interactions with disabled Ss, suggesting lower levels of acceptance. Underlying patterns of interaction differed, especially in terms of setting and length. The disabled also interacted less with opposite-sex peers. Findings raise doubts about the presumed benefits of integration. (6 ref)

N2 - Hypothesized that the effects of cooperative experiences on cross-ethnic and cross-sex relationships would be strongest for structured class activities, next strongest for unstructured class activities in the broader school environment, and least strong for activities in students' homes. In Study 1, 74 6th graders were randomly assigned to 3 conditions (cooperative controversy, cooperative debate, and individualistic) stratifying for sex, ability level, and ethnic membership. Ss participated in the study for 55 min/day for 11 instructional days. In Study 2, 51 4th graders were randomly assigned to 2 conditions (intergroup cooperation and intergroup competition) stratifying for sex, ability, and ethnic membership. Ss participated in the study for 55 min/day for 10 instructional days. An activity report scale was administered to Ss to determine with whom they interacted in structured class activities, unstructured class activities, school activities outside of class, and activities in the home. Results show that in Study 1, both the cooperative controversy and cooperative debate conditions promoted more positive cross-sex and cross-ethnic relationships than did individualistic learning. In Study 2, intergroup cooperation promoted more positive cross-sex and cross-ethnic relationships than intergroup competition. Relationships formed within cooperative learning situations did not generalize into unstructured class, school, and home activities. N2 - Investigated the causes of mental overload in 126 schoolchildren in Grades 5-8. Questionnaires completed by teachers, graphs demonstrating weekly fatigue patterns, and students' class schedules were analyzed. The number of hours devoted to schoolwork, extracurricular activities, and free time was calculated. It was found that the weekly school workload ranged from 48 hrs 54 min for 5th graders to 57 hrs for 8th graders. The excess burden was attributed mainly to extracurricular activities. Several proposals for preventing mental overload of schoolchildren are provided, including reducing the frequency and duration of extracurricular activities and scheduling them right after the end of regular morning classes. Recommendations are made to help teachers prevent mental overload of their students. (English abstract) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Studied the interactive behavior of 35 preschoolers (most ages 4 yrs 4 mo to 5 yrs 5 mo) in the classroom during free play and lunch recess over a period of 39.22 hrs. Observational data were collected using the categorical running commentary technique. The behavioral events identified with prosocial behavior were categorized and coded. 946 episodes of prosocial behavior were identified. Boys were responsible for a significantly greater number of categories relating to objects, place, privileges, and cooperation. There were no

sex differences with regard to the categories "help" and "empathy." 68% of the episodes occurred during the lunch break, without any inducement. Most events following episodes of prosocial behavior were positive. The acquisition and development of prosocial behavior are discussed. VL - 40:

IS - 1

N2 - Discusses the advantages of building with blocks for young children and how they can learn about space and spatial relationships from positioning blocks. Developmental changes in the symbolic representation of space with blocks are reviewed: As children mature, they make use of a wider range of spatial forms to represent spatial configurations. Basic spatial representations (e.g., on, by, in) with blocks are generally mastered before 4 yrs of age, after which further spatial elaborations (e.g., enclosure) begin to emerge. Also emergent at this time are the differentiation of objects within a construction, clarification of indoor and outdoor space, and coordination of landmarks. Suggested activities for increasing children's awareness of spatial concepts are presented, and implications for classroom teachers are noted. To promote spatial representation by children with blocks, teachers should provide a sufficient number of blocks and ample space, help children notice and explore spatial features of their world, and pay attention to the configurations in children's block

constructions and how they relate to their development of spatial concepts. (17 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined the effects of a reinforcement program on social behaviors of 3 preschool children (aged 3.5-4 yrs) who displayed inappropriate behaviors during peer interactions. A multiple-baseline design across the 3 Ss and 2 settings (morning and afternoon classrooms) was employed to determine the effects of reinforcement on

each S's rate of cooperative play and on intervals spent in time-out due to aggression. For 15 min each session, Ss were rewarded a token for each minute that they engaged in cooperative play. Tokens were exchanged for outside time. Once cooperative play exceeded an 80% criterion, tokens were faded out but verbal praise continued. The program was effective in increasing cooperative play among these Ss by at least 50% over baseline, and the behavior changes were maintained when tokens were withdrawn. N2 - Argues that childcare programs for school-age children promote commitment to care essential for their best physical, social, emotional, and cognitive development. There is a gap between need and availability of adequate care. Single-parent families require institutions outside the home, and the acceptable expression of parent priorities for work increases the need for accommodations. Childcare by the school can focus on social and emotional development and can complement, support, and extend the school's educational purposes. Recreation departments, libraries, museums, scouts, boys' and girls' clubs, and 4-H have provided childcare in the past, and they continue to play an important role in supplementing both family and school opportunities for a child's healthy growth and development. A quality childcare program is flexible with appropriate activities to meet developmental needs. The child needs peer group interaction, with appropriate limits set by adults. The child needs opportunities to experience success, a sense of industry, and a sense of competence at physical and intellectual levels. Awareness of needs is basic in planning. N2 - Investigated the changes in frequency of language used by 6 Down's syndrome children as they interacted with nonretarded peers within a normal school playground setting. Two Ss were 3.5-4 yrs of age, 4 Ss were 6-7 yrs old. Each S was observed once a week over a 9-wk period. Recordings were made of the percentage of the observation period engaged in interaction, frequency of initiation of an interaction, and frequency of responding to peers' verbal directions. As a group, the Down's syndrome Ss demonstrated a positive relationship between percentage of time engaged in interaction and the increasing frequency of language use in interaction. However, a less consistent relationship emerged when scores were examined on an individual basis. Implications are drawn regarding the benefits that may accrue to a retarded child from interaction with his/her nonretarded peers. N2 - Interviewed 56 families who had a hospitalized 5-12 yr old and 1 or more children (n = 104) living at home who were under 18 yrs old. Results show that most siblings maintained regular, direct contact with the hospitalized child. Almost half the siblings participated actively in accommodating family life to the hospitalization by assuming additional responsibilities during this time. Parents reported negative responses to the hospitalization in only 16% of the siblings. Negative responses clustered in those siblings cared for outside their own home during the hospitalization and in the 4-21 yr age range. It is suggested that visits to the hospital do not harm and may be beneficial to siblings. (8 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Hypothesized that a highly structured adult-directed preschool program that used discussions, role playing, and social modeling would, in contrast to control-group comparisons, positively increase listening skills and perspective-taking competencies. 36 3-5 yr olds were assigned to experimental and control groups; Ss in the experimental group were placed in the 10-wk university preschool program. Ss were administered measures of affective and perceptual perspective taking and the Pre-Primary Auditory Screening Test pre- and postprogram. Comparison of scores indicated that affective perspective taking and listening skills increased with time. Perceptual perspective taking failed to demonstrate significant gains for either experimentals or controls. However, listening skills and affective perspective taking showed significant increases between pre- and posttest measures for the experimental group, while affective perspective taking showed significant increases for controls. It is suggested that either maturation or a common experience outside of the preschool education accounted for intraindividual changes. N2 - 38 Black and 25 White kindergartners were observed during classroom instruction and during recess on school playgrounds in both the fall and spring. As compared with a random model of selecting same-color peers for social interaction, both Blacks and Whites showed same-color preferences in their social behavior. This tendency was greater during recess than during classroom instruction and was greater in spring (after the 1st 7-9 mo of schooling) than in the fall. Although neither Blacks nor Whites behaved differently toward other-color as compared with same-color peers, Whites talked relatively more than Blacks, and Blacks emitted relatively more negative behavior and commands than Whites. It is concluded that Black and White children indicated a preference for same-color peers at the beginning of kindergarten, that this preference increased over the school year, and that differences in behavioral style between Blacks and Whites may play a role in same-color preferences. N2 - Surveyed 160 10-yr-olds from 2 geographic locations (rural, urban), 2 types of residences (single family homes, apartments), and 3 socioeconomic levels (blue collar, white collar, managerial). Data were gathered on 10 activity categories: daily activities (e.g., meals), family tasks, scholarly activities, indoor leisure, sports, outdoor play, walks, TV viewing, exceptional activities, and social center activities. Geographic location

differentiated time-budgets on several dimensions: Time spent outdoors was more important in rural locations, as were outdoor play and walks. No differences were apparent among the other categories; TV viewing was equal across categories. Type of residence and socioeconomic level appeared to have little influence on the manner in which 10-yr-olds budgeted their time. JF - Pratt Institute Creative Arts Therapy Review

VL - 3 1982, pp. 33-40.

N2 - Outlines the use of creative arts therapy with a boy (age 5 yrs 10 mo; IQ 52) who attended a school for the developmentally disabled. Movement therapy was inaugurated to help him reach the level of psychic organization that would allow him to make eye contact and relate his verbalizations to reality. The therapist began by mirroring the self-stimulation of S and introducing structured activities (e.g., play with hoop and balanced eye contact in a "hello-goodbye" game). Increasing mastery of movements initiated by the therapist helped S explore passivity and/or activity. S needed reassurance at this time that his body integration was being maintained; tracing lines of his body reinforced body part connections. When S began to introduce various prohibitions into the sessions, the 3rd and final level of organization of polarities had been reached. A "superhero" sequence of strength was used in the termination process; some regression occurred but outside of sessions S progressed in most activities, especially in his concentration and attention span. It is suggested that for polarities to be balanced, both opposing elements must be developed so that they present an appropriate pull for each other. N2 - Administered a questionnaire to parents of 54 preschool children attending a laboratory nursery school during the period 1975-1978; parents completed the questionnaire at the time of their children's admission. Results show that 88.8% of the children had one sibling or were only children. Almost all were full-term babies and had been immunized against disease. Most were right-handed and most had habits of nail-biting, thumb sucking, and nose picking. Their most common fears were of darkness and loud sounds. Milk, cereals, and pulses were liked by most children. Mothers selected toys for their children who liked to play indoors and outdoors; most preferred to play with siblings and friends. Interests in music, dance, clothes, and pets were commonly reported. The mother was the primary disciplinary agent. It is suggested that parent education programs are needed to help parents understand the needs of their children. (5 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Examined sex differences in the preferred play activities of 11 boys and 11 girls (aged 4-5 yrs) who attended an urban kindergarten and the influence of teacher participation and location of activities on such differences. Ss were observed during 9 play sessions, and play activity was recorded using a time-sampling method. Sex differences in play generally conformed to previous research. Boys had a high preference for sandpit play and other energetic outdoor activities, while girls preferred quieter, indoor activities. However, there were more similarities between the activities chosen and avoided by each sex than has previously been reported. Also, boys showed a relatively low frequency of aggression and rough play. While girls tended to choose activities in which their teachers were involved, their most-preferred activity was climbing. Although the presence of female teachers seemed to maintain many of the girls' stereotyped choices of activity, this same presence appeared to extend the range of boys' choices beyond activities that were stereotypically male. N2 - Describes the research context in which the question of the relationship between cognition and behavior has arisen within the field of social-cognitive development. A selective review of some of the studies emanating from this author's research program concerning the specific issue of the relations between the level of social cognition in the child and the adequacy of the child's social interactions in a naturalistic setting are presented. Studies included (1) the identification of the influence of children's level of social cognitive skills on the frequency and adequacy of their dyadic verbal communications during free play, (2) the examination of the relationships between preschooler's performance on laboratory measures of role playing and communication skills, and (3) measures of their request performance incorporating criteria similar to those in social-cognitive tasks. The potential flaws and limits of the original ways of measuring and conceptualizing these relations are

examined. Finally, a sketch of the conditions that need to be considered for specific types of social behavior to be regulated by particular aspects of cognition is presented. (French abstract) (46 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - 16 preschool children were identified as having an internal or external locus of control based on the Stephens-Delys Reinforcement Contingency Interview and were observed interacting with peers, teachers, and classroom materials. It was predicted that internal Ss would show greater task persistence by spending more time in physical-motor, cognitive, and social activities, while external Ss would spend more time in non-task-involved behaviors, such as watching others and moving around. Results do not confirm this hypothesis.

Findings are discussed in terms of a distinction between experimental and natural settings. (10 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - In Study 1, immediate imitation of peers was observed during free play in 4 groups of preschoolers (N = 67) ranging in age from 23 mo to 5 yrs. Amount of imitation decreased with age. A majority of imitations were followed by positive consequences in the form of maintained or increased social interaction, including counterimitation. Ss whose imitations were successful in this sense imitated more, while those who responded positively to being imitated were imitated more. Generally, there was a positive relationship between dominance and being imitated. There were no sex differences in imitating or being imitated. In Study 2, immediate imitation of both peers and adults was observed in 6 groups of preschoolers (N = 64) ranging in age from 27 mo to 5 yrs. The results for peer imitation replicated those of the 1st study. In addition, most of the Ss' imitations of adults were followed by positive consequences, although the content of peer and adult imitation differed. N2 - The sex-typed play behavior of 48 preschoolers (37-60 mo old) was assessed using (a) a behavioral sampling procedure within the laboratory, (b) the Toy Preference Test, and (c) observation within a classroom. All 3 measures proved to be internally consistent and/or stable over time, although the responses of males showed less consistency than those of females. Correlations for data from all Ss found that both laboratory measures correlated significantly with rates of "masculine" play in the classroom. When within-sex correlations were examined, however, neither laboratory measure consistently predicted Ss' classroom behavior. Results suggest that normal sex-typed play behavior in a naturalistic setting cannot be accurately predicted relative to their same-sex peers by means of the laboratory-based procedures typically employed in the literature. N2 - Measured distances between closest playmates during free play in 50 mentally retarded and 48 normal children. Ss in both groups were in either Grades 1-3 or 4-6. Unobtrusive observation techniques minimized interference and a spacious playground environment was chosen to avoid effects of confining walls on spatial behavior. Younger Ss (Grades 1-3) kept closer distances than older Ss (Grades 4-6), independent of clinical history or sex. Parallels are drawn with findings of previous observational studies in adults and nonhuman primates. Two hypotheses, based on cognitive development and social disturbance, are proposed to explain the findings. One hypothesis proposes that closer distances and increased touching occur under conditions of social disturbance; the other suggests that younger children may stay closer to a single playmate because their cognitive development does not facilitate simultaneous interaction with many members in a group. N2 - Evaluated the relative efficacy of the components of a treatment package for aggressive behavior. 25 males (6-9 yrs old) were selected on the basis of observation and teacher and peer ratings of aggressive behavior. Five Ss were assigned to each of 5 groups: waiting list control, attention placebo, contingent reward, modeling, and modeling plus rehearsal. Five-day baseline and posttreatment phases consisted of daily participation in a verbal taunting game. Then, for 10 days, each treatment group participated in a verbal taunting game receiving token reinforcement for coping. The modeling group viewed a 3-min videotape of a coping model before participation, and the modeling plus rehearsal group viewed the videotape and verbally rehearsed coping statements before participation. Generalization measures on the school playground were conducted throughout the study. Results indicate the effectiveness of contingent reward, modeling, and modeling plus rehearsal procedures, and further indicate that the addition of modeling and rehearsal components to the contingent reward procedure may not be necessary. Suggestions for systematic replication are discussed. (11 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Observed 408 kindergartners and 1st graders in outdoor free play, 40 min each day, for 3 continuous wks. Social interactions and social organization were recorded using a modified version of M. B. Parten's (1932) system of categorization. Findings show that Ss engaged mainly in positive-active behaviors. Solitary play and onlooker behavior accounted for 30% of Ss' social behavior. Parallel play occurred less frequently than reported earlier for younger children, although no age differences were observed between kindergartners and 1st graders. Boys were significantly more active than girls and exhibited negative social interaction more frequently. Social organization was balanced. Ss were observed 57% in dyads, 27% in groups of 3 and 4, and 14% in groups with more than 5 Ss. Kindergartners participated in significantly smaller groups than 1st graders. N2 - 16 minimally handicapped and 18 nonhandicapped children (CA 2.5-4 yrs, handicapped Ss were on the average 10 mo younger developmentally) were observed playing as separate classes and as a combined group on

their preschool playground. Play behaviors directed toward self, toys, teachers, and peers were recorded using a time sampling procedure. Repeated measures analyses revealed that handicapped Ss engaged in less peer-directed and more teacher-directed behaviors than the similar CA but developmentally more advanced normal Ss. During the combined group play situation, normal Ss directed more behaviors to their own classmates, while handicapped Ss directed approximately equal amounts of behavior to their own classmates and to their normal peers. These and other results suggest that normal Ss were not negatively affected and the handicapped Ss were positively affected by the integrated play situation. N2 - Assessed the effects of a cooperatively structured games program on sharing and on happiness when playing games among 71 5-yr-olds. Ss consisted of 4 intact, half-day kindergarten classes from 2 schools. Each school had 1 experimental group and 1 control group, both of which were taught by the same classroom teacher. Experimental groups were exposed to an 18-wk cooperative games program, and control groups were exposed to a traditional games program of equal duration. Pre- and postmeasures on a candy-sharing task revealed that Ss in the cooperative games program increased their sharing significantly more than did those in the traditional games program. Overall happiness when playing games outside of school increased for all groups. (12 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Data are presented for 5 Ss from a larger investigation that included 20 21/2-3 yr olds from 3 daycare centers. 15-min filmed observations were made during 4 types of activities characteristic of the centers: meals, indoor and outdoor free play, seat work, and directed play. Four categories of behaviors were coded: imitation, coaction, initiation, and response. Ss' behaviors can generally be described as socialized. Imitation, which appeared as a positive social behavior, was used to establish contact. Response behaviors were more numerous than initiation behaviors. N2 - Observed the incidence of exercise play outdoors in nursery school children aged 2.10-4.9 yrs after a short or long period of confinement indoors. For both boys (18 Ss) and girls (18 Ss) there was a greater incidence of exercise play after the long period of confinement, the levels decreasing with time. No sex differences were obtained. Results are considered in relation to theories of the functional significance of exercise play. (26 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Investigated in 3 studies the active vs reactive dimension of development as a personality variable called engagement style. Ss were 51 male undergraduates, who completed Rotter's Internal-External Locus of Control Scale, and 403 2nd-12th graders. The dimension of development refers to the perception one has of oneself either as doing (agent) or being done to (patient). The dimension is distinguished from similar constructs, such as locus of control and locus of causality. A semi-projective measure of engagement style was developed and was demonstrated to yield high reliability coefficients. In studies using the Test of Engagement Style, the following hypotheses were confirmed. Boys from large families had more extreme scores (i.e., more agent or more patient) than those from small families. Agency scores declined significantly with age from childhood to adolescence. Boys from entrepreneurial family settings had higher agency scores than those from bureaucratic settings, while girls whose mothers work outside the home were more agent than those whose mothers are not so employed. Just as the active-reactive dimension is currently a focal point in developmental theorizing, engagement style is seen as an important analogous personal construct. VL - 327 1979, pp. 101-113.

N2 - Investigated the hypothesis that children of both sexes initially learn the mother's language, but that boys shift to the use of male dialect with contact outside the home. 12 males and 12 females (aged 4-12 yrs) were observed playing in same-sex and mixed-sex dyads. Of the 45 language features investigated, only 8 showed sex differences that held across both age and type of dyad. Two of these features showed an increase in sex-typing with age. Three other features were typical of boys or girls at the youngest age but practically dropped out at the older ages. Five additional features varied with the sex of the play partner, but in all cases the variation occurred in the girls' speech. In general, the patterns of development were similar for boys and girls. However, those features that emerged as sex-associated fit traditional sex stereotypes. Perhaps more important is the variability in girls' speech as a function of the sex of the listener. Results indicate that the concept of "genderlect" must be broadened to include variation across contexts and conversational partners. (15 ref) (PsycINFO Database

N2 - Observed play behavior of 9 male and 9 female preschool children in their natural environment. The study focused on the general demographics of free-play behavior, sex differences in the uses of various play areas, the effect of different play areas on the incidence of make-believe vs exploratory play, and the differential influence of play area on social interaction. Results indicate that both boys and girls used areas that had traditionally been thought of as sex-typed. For example, both sexes appeared with equal frequencies in the household area and the block and truck area. Within these areas, the sexes apportioned their time equally in terms of play activities.

Overall, the household area elicited more make-believe play and social interaction than did the other play areas. (40 ref) (PsycINFO Database Record (c) 2012 APA, all rights reserved)

N2 - Children's abilities to search for missing objects in real-life environments were investigated in 2 studies with a total of 70 2 yr 7 mo-6 yr 2 mo old Ss. Exp I involved searches of 8 locations on a school playground; Exp II involved searches of 8 large cupboards. In each study, Ss performed a free search followed by a logical search. In free search, the S was instructed to search the 8 locations to find a missing item. In logical search a critical search area within the 8 locations was defined for the Ss on the basis of (a) where the item was last seen and (b) where it was first discovered missing. In free search, more older than younger Ss searched each location at least once and searched all locations sequentially. Detailed comparisons of search patterns under the free and logical conditions revealed that older Ss understood the critical search area. In contrast, younger Ss' searches under the logical condition depended on one salient association of a location with the missing item. The developmental trends indicated that several memory and logical processes determine search procedures. The development and integration of these processes are discussed. N2 - Analyzed similarities and discrepancies in the cognitive structures and attitudes of parents and children using a questionnaire and interviews. Ss were the members and parents of 5 classes of 2nd-yr students (75 boys and 65 girls) at a public middle school in Japan. The questionnaire used was constructed from H. Kojima's version of the Parental Behavior Inventory (PBI). From the 192 categories of the PBI, 16 categories weighted to measure psychological control/autonomy and 10 categories weighted for acceptance/rejection were selected. Items relating to acceptance, child-centeredness, positive involvement, and acceptive individuation were used to assess emotional support; and items relating to control, enforcement, control through guilt, hostile control, instilling persistent anxiety, extreme autonomy, and intrusiveness were used to assess the control/autonomy relationship. The children were interviewed during a morality class at school, and the parents were each sent a questionnaire. The 4 dyadic relationships-father/son, father/daughter, mother/son, and mother/daughter-were separately analyzed. Results show several areas of discrepancy. Fathers rated questioning their sons about outside activities as showing a personal interest in their son's behavior and thereby offering emotional support; the sons viewed this questioning as a control mechanism. A complex qualitative difference was noted in the cognitive perceptions of girls in relating to both of their parents. N2 - Administered the Junior Eysenck Personality Inventory to 334 children ages 11-13 yrs. Ss' familiarity with the area's traditional outdoor games had previously been tested by multiple-choice questions and by asking them to list games from memory. A "home orientation" rating was also obtained from their reported attachment to indoor activities, including reading, hobbies, and TV. No relationships were found between extraversion, rejection of indoor activities, and familiarity with outdoor games. Daily exposure to school playgrounds was the most important factor in Ss' knowledge of traditional games, rather than personality or out-of-school habits. N2 - Previous research has indicated that interpersonal touch is more likely for female than for male children, more likely for same-gender dyads, and more likely for Black than for White children. The effects of race and social class on touch have not been observed separately. In the present study, a total of 274 3-5 yr old children were observed at play in Black low-income, Black middle-income, White low-income, and White middle-income preschools. Rates of touch were higher for low-income children in inside play areas and higher for same-gender pairs. In outside play areas, touch was higher for Black same-gender pairs, but there was no race difference in touch for different-gender pairs. In general, rates of touch were higher than those previously reported for older American children and adults, but lower than those for both children and adults from some other cultures.
