Summary of general Global Burden of Disease study methods

The text in this section is a reproduction of text used in the supplementary appendices of other manuscripts based on GBD 2017 results. Subsequent sections are written to describe specifics of estimation of the burden of disease due to congenital heart disease. This publication complies with the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER). A GATHER checklist is in Table S1 below.

The Institute for Health Metrics and Evaluation, with a growing collaboration of scientists, produces annual updates of the Global Burden of Diseases, Injuries, and Risk Factors (GBD) study. Estimates span the period from 1990 to the most recent completed year. By the time of the release of GBD 2017 in November 2018, there were nearly 3,100 collaborators in 140 countries and two territories who contributed to this global public good. Annual updates allow incorporation of new data and method improvements to ensure that the most up-to-date information is available to policy makers in a timely fashion to help make resource allocation decisions.

The guiding principle of GBD is to assess health loss due to mortality and disability comprehensively, where we define disability as any departure from full health. In GBD 2017, estimates were made for 195 countries and territories, and 823 subnational locations, for 28 years starting from 1990, for 23 age groups and both sexes. Deaths were estimated for 282 diseases and injuries, while prevalence and incidence were estimated for 354 diseases and injuries, and exposure and attributable burden estimated for 84 risk factors and clusters of risks. In order to allow meaningful comparisons between deaths and non-fatal disease outcomes as well as between diseases, the data on deaths and prevalence are summarised in a single indicator, the disability-adjusted lifeyear (DALY). DALYs are the sum of years of life lost (YLLs) and years lived with disability (YLDs). YLLs are estimated as the multiplication of counts of death and a standard, "ideal," remaining life expectancy at the age of death. The standard life expectancy is derived from the lowest observed mortality rates in any population in the world greater than 5 million.¹ YLDs are estimated as the product of prevalence of individual consequences of disease (or "sequelae") times a disability weight that quantifies the relative severity of a sequela as a number between zero (representing "full health") and 1 (representing death). Disability weights have been estimated in nine population surveys and an open-access internet survey in which respondents are asked to choose the "healthier"² between random pairs of health states that are presented with a short description of the main features.

All-cause mortality rates are estimated from vital registration data in countries with complete coverage.¹ For other countries, the probabilities of death before age 5 and between ages 15 and 60 are estimated from censuses and surveys asking mothers to provide a history of children ever born and those still alive, and surveys asking adults about siblings who are alive or have passed away. Using model life tables, these probabilities of death are transformed into age-specific death rates by location, year, and sex. GBD has collated a large database of cause of death data from vital registrations and verbal autopsy surveys in which relatives are asked a standard set of questions to ascertain the likely cause of death, supplemented with police and mortuary data for injury deaths in countries with no other data. For countries with vital registration data, the completeness is assessed with demographic methods based on comparing recorded deaths with population counts between two successive censuses.

The cause of death information is provided in a large number of different classification systems based on versions of the International Classification of Diseases or bespoke classifications in some countries.³ All data are mapped into the disease and injury categories of GBD. All classification systems contain codes that are less informative because they lack a specific diagnosis (eg, unspecified cancer) or refer to codes that cannot be underlying cause of death (eg, low back pain or senility) or are intermediate causes (eg, heart failure or sepsis). Such deaths are redistributed to more precise underlying causes of death. After these redistributions and corrections for under-registration, the data are analyzed using cause of death ensemble modeling (CODEm), a highly systematised tool that runs many different models on the same data and chooses an ensemble of models that best reflects all the available input data. Models are chosen with variations in the statistical approach ("mixed effects" of spatiotemporal Gaussian process regression), in the unit of analysis (rates or cause fractions), and the choice of predictive covariates. The statistical performance of all models is tested by holding out 30% of the data and checking how well a model covers the data that were held out. To enforce consistency from CODEm, the sum of all cause-specific mortality rates is scaled to that of the all-cause mortality rates in each age, sex, location, and year category.

Non-fatal estimates are based on systematic reviews of published papers and unpublished documents, survey microdata, administrative records of health encounters, registries, and disease surveillance systems.⁴ These are cataloged in the Global Health Data Exchange (GHDx, http://ghdx.healthdata.org/), the largest repository of health data globally. We first set a reference case definition and/or study method that best quantifies each disease or injury or consequence thereof. If there is evidence of a systematic bias in data that used different case definitions or methods compared to reference data, we adjust those data points to reflect what their value would have been if measured as the reference. This is a necessary step if one wants to use all data pertaining to a particular quantity of interest rather than choosing a small subset of data of the highest quality only. DisMod-MR 2.1, a Bayesian meta-regression tool, is our main method of analysing non-fatal data. It is designed as a geographical cascade where a first model is run on all the world's data, which produces an initial global fit and estimates coefficients for predictor variables and the adjustments for alternative study characteristics. The global fit adjusted by the values of random effects for each of seven GBD super-regions, the coefficients on sex and country predictors, are passed down as data to a model for each super-region together with the input data for that geography. The same steps are repeated going from super-region to 21 region fits and then to 195 fits by country and, where applicable, a further level down to subnational units. Below the global fit, all models are run separately by sex and for six time periods: 1990, 1995, 2000, 2005, 2010, and 2017. During each fit, all data on prevalence, incidence, remission (ie, cure rate), and mortality are forced to be internally consistent. For most diseases, the bulk of data on prevalence or incidence is at the disease level, with fewer studies providing data on the proportions of cases of disease in each of the sequelae defined for the disease. The proportions in each sequela are pooled using DisMod-MR 2.1 or meta-analysis, or derived from analyses of patient-level datasets. The multiplication of prevalent cases for each disease sequela and the appropriate disability weight produces YLD estimates that do not yet take into account comorbidity. To correct for comorbidity, these data are used in a simulation to create hypothetical individuals in each age, sex, location, and year combination who experience no, one, or multiple sequelae simultaneously. We assume that disability weights are multiplicative rather than additive as this avoids assigning a combined disability weight value in any individual to exceed 1, (ie, be worse than a "year lost due to death"). This comorbidity adjustment leads to an average scaling down of diseasespecific YLDs ranging from about 2% in young children up to 17% in oldest ages.

All our estimates of causes of death are categorical: each death is assigned to a single underlying cause. This has the attractive property that all estimates add to 100%. For risks, we use a different, "counterfactual" approach,

answering the question: "what would the burden have been if the population had been exposed to a theoretical minimum level of exposure to a risk?" Thus, we need to define what level of exposure to a risk factor leads to the lowest amount of disease. We then analyse data on the prevalence of exposure to a risk and derive relative risks for any risk-outcome pair for which we find sufficient evidence of a causal relationship.⁵ Prevalence of exposure is estimated in DisMod-MR 2.1, using spatiotemporal Gaussian process regression, or from satellite imagery in the case of ambient air pollution. Relative risk data are pooled using meta-analysis of cohort, case-control and/or intervention studies. For each risk and outcome pair, we evaluate the evidence and judge if the evidence falls into the categories of "convincing" or "probable" as defined by the World Cancer Research Fund.⁶ From the prevalence and relative risk results, population attributable fractions are estimated relative to the theoretical minimum risk exposure level (TMREL). When we aggregate estimates for clusters of risks (eg, metabolic or behavioural risks), we use a multiplicative function rather than simple addition and take into account how much of each risk is mediated through another risk. For instance, some of the risk of high body-mass index is directly onto stroke as an outcome, but much of its impact is mediated through high blood pressure, high cholesterol, or high fasting plasma glucose, and we would not want to double count the mediated effects when we estimate aggregates across risk factors.

Uncertainty is propagated throughout all these calculations by creating 1,000 values for each prevalence, death, YLL, YLD, or DALY estimate and performing aggregations across causes and locations at the level of each of the 1,000 values for all intermediate steps in the calculation. The lower and upper bounds of the 95% uncertainty interval are the 25th and 975th values of the ordered 1,000 values. For all age-standardised rates, GBD uses a standard population calculated as the non-weighted average across all countries of the percentage of the population in each five-year age group.⁷

GBD uses a composite indicator of sociodemographic development to evaluate trends by development status and epidemiological transition. The composite indicator is termed the Socio-demographic Index (SDI) and reflects the principal components analysis (PCA) of normalised values of a location's income per capita, the average years of schooling in the population 15 and over, and the total fertility rate under 25 years. Countries and territories are grouped into five quintiles of high, high-middle, middle, low-middle, and low SDI based on their 2017 values.¹ A map of each GBD location according to its SDI quintile is shown in Figure S1. Figure S1. Socio-demographic Index quintiles by GBD administrative Level 1 geography, 2017 All locations are color-coded according to their Socio-demographic Index (SDI) quintile in the year 2017. Subnational locations that are estimated separately for GBD 2017 can belong to different SDI quintiles. SDI is a composite metric of total fertility under 25 years, years of education, and per capita income. SDI=Socio-demographic Index.

Congenital heart disease: overview, definitions, and cause classification

Cause-specific mortality overview

No significant changes were made to the cause-specific mortality estimation process for congenital heart disease in GBD 2017. Each death in GBD is assigned to a single underlying cause. Mortality was limited to the age range from birth up to 70 years for all types of congenital birth defects. We started by estimating total congenital birth defects mortality using CODEm (described above). Nine subtypes of congenital birth defects were then estimated separately using CODEm, with the sum of deaths from each scaled to match the total for all congenital birth defects and total congenital birth defects summed with all other specific causes of death to equal all-cause mortality for each age group, sex, location, and year. Subcauses of congenital birth defects included 1) neural tube defects, 2) *congenital heart anomalies*, 3) orofacial clefts, 4) Down syndrome, 5) other chromosomal anomalies, 6) congenital musculoskeletal anomalies, 7) urogenital congenital anomalies, 8) digestive congenital anomalies, and 9) other congenital birth defects. Two additional types of congenital birth defects – Klinefelter syndrome and Turner syndrome – were estimated as causing non-fatal disease burden only.

Non-fatal health outcomes overview

We substantially revised the estimation strategy for non-fatal health outcomes across all types of congenital birth defects, with important ramifications for the assessment of non-fatal CHD burden in particular.

First, in GBD 2010, GBD 2013, and GBD 2015, only *isolated* birth defects were included in the case definition of each model, so all those individuals with coexistent chromosomal or genetic disorders were not captured, which may have substantially underestimated the number of prevalent cases of CHD in particular. This was revised starting in GBD 2016 so that the reference case definition includes all persons with each defect.

Second, prior to GBD 2016, CHD were all subdivided into one of three broad categories – critical, severe, and less-severe – and prevalence was estimated based solely on congenital birth registry data. Long-term CHD prevalence was assumed to vary as a function of access to three tiers of medical facilities: "no" care, "supportive" care, or "modern" care. Survival probabilities in each group were derived from expert opinion (no care group) or via global application of standardised mortality ratio (SMR) observations from high-income locations,⁸⁻¹¹ with the added assumption that treatment availability (and therefore survival) for CHD tracks linearly with overall neonatal mortality ratio. While this mechanistic modelling approach produced consistent results that were easily interpretable, they lacked a true empirical basis. Starting with GBD 2016, in consultation with GBD experts and paediatric cardiology experts, we have reorganised cause categories for non-fatal estimates to be more anatomically similar, clinically relevant, and structured in a way to facilitate incorporation of literature, registry, and administrative data to inform levels and trends. It was also developed with two additional constraints, namely to minimise how many 4-digit and 5-digit ICD-9 and ICD-10 codes were split between different groups and to also maximise the matching with reporting groups in major congenital birth defect registry systems (eg, EUROCAT). These five CHD categories are named descriptively as the following, and ICD-9 and ICD-10 codes mapped to each are shown in Table S2:

- 1. Single ventricle and single ventricle pathway defects
- 2. Complex congenital heart defects excluding single ventricle and single ventricle pathway defects
- 3. Malformations of great vessels, congenital valvular heart disease, and patent ductus arteriosus
- 4. Ventricular septal defect and atrial septal defect
- 5. Other congenital cardiovascular anomalies

Third, disabling sequelae for CHD prior to GBD 2016 were limited to heart failure and a generic health state referred to as "congenital heart disease" that was derived from analysis of survey responses to the Medical Expenditure Panel Survey in the United States as described previously. We completed systematic literature reviews as described below for GBD 2016 to facilitate quantification of additional common outcomes that occur as a result of CHD, most notably developmental intellectual disability.

Overview of data availability for congenital heart disease

The subsequent sections describe the sources and processing of data sources for estimation of CHD burden. Availability of data on fatal and non-fatal cases of CHD varied widely across countries and regions as can be seen in Figure S2. Temporal coverage of data by GBD region for each of mortality and non-fatal analyses are shown in Figure S3. Cause-specific mortality data were identified from the majority of countries globally, but from few countries in Africa, southeast Asia, or Oceania. Non-fatal data were identified from a few additional lower SDI countries, although the temporal coverage of non-fatal data was categorically lower than that of mortality data.

Figure S2: Classification of countries according to the availability of data on mortality and non-fatal cases of congenital heart disease, 1990–2017

This map shows availability of data at the country level according to presence of data for cause-specific mortality only (purple), non-fatal prevalence data only (orange), or both (green). Countries with no mortality data or non-fatal data from 1990 to 2017, inclusive, are coloured in yellow.

Figure S3: Data representativeness by region and year, 1980–2017, mortality and non-fatal data Marker size corresponds to the number of site-years of data available in a given year for cause-specific mortality (top panel) and non-fatal models (bottom panel) from 1980 through 2017. Site-years of data for mortality and non-fatal modelling are shown. Marker size corresponds to the number of site-years of data available. GBD 2017 used the term "site-year" to refer to an individual geographical dataset (ie, community-based, subnational, or nationally representative datasets) in a given year. Marker size may differ from legend because data are continuous. *Non-fatal models contain data representative of the Latin America and Caribbean super-region, but site-years are not shown in this figure.

Supplemental methods: Cause-specific mortality of congenital heart disease

A flowchart illustrating the estimation process is shown in Figure S4

Figure S4: Estimation flowchart for cause-specific mortality due to congenital heart disease The flowchart indicates the input data, databases, results, and processes used to estimate cause-specific mortality due to congenital heart disease. Colour-coding indicates the domain of GBD estimation in which each item is classified.

Input data

Deaths due to CHD were estimated using a common cause-specific mortality framework developed for GBD 2017. Each death was assigned to a single underlying cause. All data were centrally extracted, mapped to specific GBD causes, processed, and stored in causes of death (CoD) database. Those CoD data sources that specified the sub-cause of birth defect were included in estimation of both the parent congenital anomalies model as well as in sub-type-specific models. Vital registration (VR) was the dominant data type, followed by verbal autopsy (VA) and surveillance systems. Deaths assigned to ill-defined or nonspecific causes (eg, "heart disease, unspecified" [ICD-10 code I51.9]) or intermediate causes (eg, "heart failure" [ICD-10 code I50]) were reassigned to likely causes of death, including CHD, with the use of statistical redistribution algorithms. Illustrations of redistribution for ICD-9 and ICD-10 in the United States are shown in Figure S5.

Figure S5: ICD-9 (left) and ICD-10 (right) redistribution of ill-defined deaths to congenital heart disease for USA, all years, all ages, both sexes (original on left, final after redistribution on right)

The Sankey diagram illustrates the quantitative effects of redistribution of ill-defined deaths in the GBD cause of death data processing algorithms. The left panel shows ICD-9 and the right panel shows ICD-10 for all years in the USA. The left side of each panel shows the original cause of death as coded, while the right shows the final GBD cause to which those deaths were assigned. The relative size of each band corresponds to the number of deaths. (D=disease. S&S=signs and symptoms. HF=heart failure. RHF=right heart failure; Gi=gastrointestinal.)

Data evaluation and model specification

For GBD 2017, data exclusions were limited. We outliered all VA data in those over 5 years old as the age patterns were unreliable and led to poor model performance in the under-5 age groups. We also excluded some data sources from the parent model where only a subset of sub-causes were specified (eg, congenital heart disease, neural tube defects, and other congenital anomalies) and the sum of the sub-causes clearly represented systematic underreporting of one of the sub-causes. Systematic underreporting was suspected when sex- and age-specific rates were more than an order of magnitude lower than neighbouring or comparable locations. Data sources for those locations were still included by default for sub-cause-specific models because underreporting of the total was not assumed to necessarily be associated with underreporting of all of the component conditions.

Tables S3 and S4, below, list the covariates used in CODEm models for total congenital birth defects and CHD, respectively. Covariates having a specified positive correlation with CHD mortality were maternal alcohol consumption, proportion of live births in women aged 35+, age-standardised diabetes prevalence, indoor air pollution, and reproductive age-standardised smoking prevalence. Covariates having a specified negative correlation with CHD mortality were measles vaccine coverage, education (years per capita), and legality of abortion. Directionality with log-transformed lag distributed income per capita (LN-LDI) and SDI was not prespecified. CODEm uses a train-test-test approach to model development. Only those covariates where the relationship with observed data (in-sample) was statistically significant at the p<0.05 level and in the specified direction. All retained models were ranked based on out-of-sample predictive validity for a first set of held-out data. Rankings were used to construct weighted ensembles of component models. Ensembles and component models were the ranked on a second set of held-out data. The top-ranked model was selected to generate the final estimates. There is no *a priori* requirement that the final model is an ensemble, but generally ensembles performed better than component models. This process was then repeated 30 times with different structured

holdout patterns to ensure stability of final estimates. Input data and model results are publicly available in the Cause of Death Visualization Tool (<u>http://vizhub.healthdata.org/cod</u>).

Covariate	Transformation	Level	Direction
Maternal alcohol consumption during pregnancy (proportion)	None	1	Positive
In-facility delivery (proportion)	None	1	Negative
Live births 35+ (proportion)	None	1	Positive
Folic acid unadjusted (μg)	None	1	Negative

Skilled birth attendance (proportion)	None	3	Negative
Live births 35+ (proportion)	None	3	Positive

CoDCorrect and calculation of years of life lost (YLLs)

As described above, after completion of all cause-specific mortality models, the results are summed and scaled to match total all-cause mortality for each age group, sex, location, and year. Scaling is performed hierarchically so the sum of congenital subcauses equals the total for congenital birth defects after the latter is scaled to the all-cause mortality envelope. YLLs are calculated as the number of deaths at a specific age multiplied by remaining life expectancy at the age of death. Remaining life expectancy is based on a global standard as described above.

Supplemental methods: Non-fatal health loss due to congenital heart disease

A flowchart illustrating the estimation process is shown in Figure S6.

Figure S6: Estimation flowchart for estimation of prevalence and YLDs due to congenital cardiovascular birth defects

This flowchart illustrates the input data, databases, results, and processes used to estimate non-fatal health loss due to congenital heart disease. Colour-coding corresponds to the domain of GBD estimation in which each component is classified. ASD=atrial septal defect. CSMR=cause-specific mortality rate. DALY=disability-adjusted life-year. EUROCAT=European surveillance of congenital anomalies. HAQ=Healthcare access and quality. ICBDSR=International clearinghouse for birth defects surveillance and research. LM-LDI=natural log-transformed lag-distributed income. NBDPN=National birth defects prevention network. VSD=ventricular septal defect. YLD=year of life lived with disability. YLL=year of life lost.

Input data

The GBD case definition of congenital anomalies includes any condition present at birth that is a result of abnormalities of embryonic development, excluding those that are directly the result of infections or substance abuse (eg, fetal alcohol syndrome, congenital syphilis) and excludes minor anomalies as they are defined by EUROCAT. Further, our GBD case definition includes only live births and excludes all terminations of pregnancy following prenatal diagnosis and stillbirths. Datasets for estimating CHD epidemiology were informed by three mechanisms: 1) systematic literature review for prevalence, excess mortality, and with-condition mortality, 2) congenital birth defects registries, and 3) hospital administrative data.

First, we conducted a systematic review of the available literature for all types of congenital anomalies by constructing search strings designed to capture information on the prevalence, associated mortality, and long-term health outcomes associated with each sub-category of congenital anomalies. Searches were limited to PubMed. The search was performed on September 13, 2016, with the following search string:

("Heart Defects, Congenital"[MeSH] OR "patent ductus arteriosus"[Title/Abstract] OR "Ebstein's anomaly"[Title/Abstract] OR "Ebstein anomaly"[Title/Abstract] OR "tetralogy of fallot"[Title/Abstract] OR "total anomalous pulmonary venous connection"[Title/Abstract] OR "total veins" [Title/Abstract] OR ("congenital" [Title/Abstract] AND (aorta [Title/Abstract] OR aortic[Title/Abstract] OR valve[Title/Abstract] OR conotruncal[Title/Abstract] OR "conotruncal"[Title/Abstract] OR "great vessels"[Title/Abstract] OR "great arteries"[Title/Abstract] OR "truncus" [Title/Abstract] OR ventricle [Title/Abstract] OR ventricular [Title/Abstract] OR septal[Title/Abstract] OR septum[Title/Abstract] OR tricuspid[Title/Abstract] OR mitral[Title/Abstract] OR pulmonary[Title/Abstract] OR endocardial[Title/Abstract] OR heart[Title/Abstract]) AND (transposition[Title/Abstract] OR atresia[Title/Abstract] OR stenosis[Title/Abstract] OR stenotic[Title/Abstract] OR stenosis[Title/Abstract] OR defect[Title/Abstract] OR insufficiency[Title/Abstract] OR single[Title/Abstract] OR hypoplastic[Title/Abstract]))) AND (mortality[Title/Abstract] OR survival[Title/Abstract] OR prevalen*[Title/Abstract] OR inciden*[Title/Abstract]) AND (2013/11/01[PDAT]:2016[PDAT]) NOT (hydroceph*[Title/Abstract] OR "Case Reports"[Publication Type] OR "Review"[Publication Type] OR "case report" [Title/Abstract] OR transplant* [Title/Abstract] OR polymorphism[Title/Abstract] OR "cat"[Title/Abstract] OR "dog" [Title/Abstract] OR "rabbit" [Title/Abstract] OR "mouse" [Title/Abstract] OR "mice" [Title/Abstract] OR "rat" [Title/Abstract] OR "porcine" [Title/Abstract] OR "novel" [Title] OR "single institution"[Title/Abstract])

A total of 2,083 titles and abstracts were screened, of which 88 were selected for full-text review to ensure the availability of required information and the representativeness of the reported population, and the exclusion of duplicate data also reported as part of the birth registry data inputs. A total of 27 sources were extracted. Data were identified primarily from scientific publications based on community-based cross-sectional and cohort studies and population-representative administrative datasets.

Second, we supplemented with birth prevalence data from congenital birth defects registries, including the European Surveillance of Congenital Anomalies (EUROCAT), International Clearinghouse for Birth Defects Surveillance and Research (ICBDSR), The World Atlas of Birth Defects which largely covers earlier years for countries reporting to ICBDSR, Birth Defects Registry of India (BDRI) from participating facilities, China Maternal and Child Health Surveillance (MCHS), and the ICD-coded National Birth Defects Prevention Network (NBDPN) for participating states in the USA. The Birth Defects Registry of India (BDRI) reports congenital anomalies from participating hospitals within India. Registry data from countries where GBD subnational analyses were completed were assigned to the most detailed location available in the dataset; if only national data were available, prevalence values were copied to each of the subnationals and sample sizes were weighted proportional to population.

Third, GBD 2017 incorporated administrative data from ICD-coded hospital discharges, outpatient visits, and insurance claims from USA MarketScan. These data were adjusted for overall inpatient utilisation as well as readmission rates, primary versus non-primary discharge code position, and inpatient-to-outpatient ratio as previously described.⁴ All adjustment factors were based on analysis of claims data sources.

Table S5below, along with Figures S2 and S3above, summarise the volume of data included in the final models.Each model's data and fit can be examined in the GBD online epi visualization tool(http://vizhub.healthdata.org/epi).

Model	Site-years (total)	Number of countries with data	Number of GBD regions with data (out of 21 regions)	Number of GBD super-regions with data (out of 7 super- regions)
Congenital heart (parent model)	1618	64	16	7
Single ventricle and single ventricle pathway heart defects	1332	48	16	7
Malformations of great vessels, valvular heart disease, and patent ductus arteriosus	921	40	14	6
Ventricular septal defect and atrial septal defect	1142	44	16	7
Complex congenital heart defects excluding single ventricle and single ventricle pathway	1344	45	15	6

Table S5: Prevalence dataset contents for each of the congenital heart defects non-fatal models

Data evaluation and model specification

Five separate DisMod-MR 2.1 models were developed for each of the CHD categories including 1) total congenital cardiovascular anomalies, 2) atrial septal defect and ventricular septal defect (ASD/VSD), 3) single ventricle and single ventricle pathway, 4) complex CHD excluding single ventricle defects, and 5) malformations of the great vessels including patent ductus arteriosus (PDA). DisMod-MR 2.1 is a compartmental model consisting of three states – susceptible, diseased, and dead – with state transitions determined by the rates of incidence, remission, excess mortality, and other-cause mortality.¹² DisMod-MR 2.1 synthesises all available data and covariates using differential equations with appropriate boundary conditions to generate internally consistent results for all disease parameters. The tool uses an offset log-normal model with nested random effects on GBD location and fixed effects on both location-specific covariates and study covariates denoting study characteristics causing deviation from a reference category (ie, crosswalks as described below).

The reference category for each model was ICD-coded registry data and literature data based on the judgement that the reporting in these sources was most likely to be complete. China MCHS and USA NBDPN were the only registries where data were ICD-coded. All other registries report only a subset of CHD in their statistical reports, although all specify which ICD codes or CHD lesions are included. To facilitate adjustment for this compositional bias, we generated a series of "dummy" extractions using NBDPN data that matched the subset of codes used in each of the other registries. MCHS data were tabulated by GBD collaborators in country according to the map in Table S2, so we did not have access to individual-level data to make similar extracts for it. All hospital and claims data for 20 years and older were excluded based on the observation from a number of different sources of an up to ten-fold decline in prevalence when transitioning from 15-19 years to 20-24 years, a difference we considered implausible. All other data were evaluated visually and, if considered implausible, were outliered. All data with a prevalence value of zero at birth were outliered; all those with prevalence of <3 per 1,000 for total congenital cardiovascular anomalies were identified with a study covariate to denote suspected underreporting; these data were identified with a second study covariate to denote suspected sampling error as well. Hospital data for under 1 year of age and for over 1 were identified with separate study covariates to allow for differential calculation of crosswalk coefficients. Claims data from MarketScan were crosswalked for all models except total congenital cardiovascular anomalies and single ventricle and single ventricle pathway – these crosswalks were tested but had no effect in the models.

For most of the severe congenital conditions, the mortality associated with the condition is highly dependent on access to adequate surgical interventions and other medical care during the first hours, weeks, and years of life. Location-level covariates were the same for all models – log-transformed lag-distributed income (LDI) per capita and Healthcare Access and Quality (HAQ) Index¹³ on excess mortality and maternal alcohol consumption on prevalence for all models. Incidence was set to zero for all congenital models, as congenital conditions occur at the time of birth and by definition there are no incident cases after birth. Remission was bounded to zero for all subcause models except ASD/VSD, where it was constrained to be between 0% and 20% per year until age 10 years based on the values that corresponded to observed spontaneous closure in longitudinal studies.^{14,15} Causespecific priors and slope priors were used to guide biologically plausible DisMod-MR 2.1 estimates of excess mortality and remission where applicable. Random effects limits were bounded to +/- 0.5 for all models except VSD/ASD, which was set to +/- 0.3. For a subset of conditions, a decreasing slope prior on excess mortality rate was applied to capture the highest risk of mortality from congenital conditions in the neonatal age groups and a subsequent decreasing risk of mortality from congenital conditions later in life. Excess mortality was set to zero after age 70 for all models in keeping with the GBD cause of death estimates for all congenital causes. Specific study-level covariates (i.e., crosswalks), value prior settings, and model performance statistics for each of the five models are described below.

We then used age- and sex-specific prevalence ratios derived from the MarketScan inpatient claims data to derive the proportion of the total CHD that is "other congenital cardiovascular disease." This proportion was applied to the total CHD model results and the sum of prevalence by age group, sex, year, and location of the other four categories was scaled with it to match the total prevalence of CHD. Model covariates and calculated coefficients for each are shown in Tables S6 through S10.

Assigning disease sequelae and calculation of years of life lived with disability (YLDs)

After scaling to match the total congenital cardiovascular anomalies, each model was paired with a set of mutually exclusive and collectively exhaustive sequelae which quantify the main outcomes of each. YLDs were calculated by multiplying the sequela-specific prevalence by corresponding GBD disability weights (DW) derived from population surveys of over 60,000 respondents.^{2,16} The proportions of each type of CHD with each type of sequela were derived using available information. To determine the distribution of health outcomes associated with the congenital causes, we extracted data from the same studies identified in the systematic review described above, this time focused on the long-term health outcomes of survivors in cohorts born with each type of congenital malformation. For conditions requiring surgical intervention shortly after birth to ensure survival, the health states included in the disability weight calculations correspond to the post-surgery outcomes

reported in cohorts of individuals born with these life-threatening congenital conditions. Where data were available on multiple cohorts, we pooled these cohorts together to calculate the proportion of individuals with each health state. Where data on the joint distribution of the long-term health outcomes were not available, we assumed independence of each long-term health outcome. Combined disability weights were calculated for all necessary combinations of existing disability weights.

Heart failure distribution was derived from the updated GBD 2017 heart failure analysis using the same approach of proportional allocation based on cause-specific mortality rate as previously described.¹⁷ Several scientific literature sources reported on the prevalence and severity of intellectual disability in congenital heart defect populations;¹⁸⁻²⁰ the asymptomatic proportion of ASD/VSD was derived from literature sources on the long-term outcomes of patients diagnosed with septal defects at birth.²¹⁻²³ All except those asymptomatic ASD/VSDs were also assigned a health state of "congenital heart disease," the DW for which was derived from analysis of the Medical Expenditure Panel Survey in the United States as previously described.⁴ Evidence for CHD-related disability universally was presented separately for each of intellectual disability and heart failure. We therefore assumed independence of the probability of each in calculating the proportion of CHD cases in each combination of health states (eg, mild heart failure + profound intellectual disability). Due to limited data availability, global pooled estimates of disability were applied to all locations and years, although the distribution was different for under 5 years and those older than 5 years. Combined disability weights were calculated in a multiplicative fashion as described above. Each unique combination of health states, including asymptomatic, represented a sequela of YLD calculation. YLDs were calculated as prevalence multiplied by DW for each sequela. YLDs for each sequela were then processed through a microsimulation framework to adjust for comorbidity across all GBD causes by location, age group, year, and sex.

Sequela	<5 years proportion	≥ 5 years proportion
Congenital heart disease due to malformations of great vessels, congenital valvular heart disease and PDA	0.646 (0.629 - 0.659)	0.972 (0.968 - 0.974)
