Supplementary Figure 1. Density plots of polygenic scores for 1000Genomes participants vary according to methodological choices in constructing polygenic scores (height GIANT). For all plots, weights were derived from the GIANT height GWAS and color-coding is according to 1000Genomes major populations. From left to right, r^2 values used in clumping were varied ($r^2 = .2, .05$, .01). From top to bottom, the 1000Genomes major population(s) used for clumping were varied (ALL 1000Genomes, EUR, AFR, AMR, EAS, SAS). A and B correspond to the p-value threshold applied to the summary statistics to specify variant inclusion/exclusion. **A)** p_r =genome-wide significant variants (p<5x10⁻⁸); **B)** p_r = full genome variants (p</-1).

Supplementary Figure 2. Density plots of polygenic scores for 1000Genomes participants vary according to methodological choices in constructing polygenic scores (PGC PTSD). For all plots, weights were derived from the trans-ancestry Psychiatric Genomics Consortium post-traumatic stress disorder (PGC-PTSD) GWAS and color-coding is according to 1000Genomes major populations. From left to right, r^2 values used in clumping were varied ($r^2 = .2, .05, .01$). From top to bottom, the 1000Genomes major population(s) used for clumping were varied (ALL 1000Genomes, EUR, AFR, AMR, EAS, SAS). A and B correspond to the p-value threshold applied to the summary statistics to specify variant inclusion/exclusion. A) p_i =top variants (p<1x10⁻⁴); B) p_i = full genome variants (p</=1).

Supplementary Figure 3. Relationships between principal components (PCs) and population categories, for 1000Genomes participants. A) Five major 1000Genomes populations. B) Twenty-six sub-populations, ordered by major populations (1000Genomes standard abbreviations are used). Color denotes effect size (Cohen's d for each population as compared to all others).

Absolute value of correlations between PCs and PRSs, magnitude (grayscale) and significance (asterisks)

Supplementary Figure 4 Correlations between principal components (PCs) and polygenic scores for 1000Genomes participants, for four GWAS (height_{GIANT}, height_{UK_Biobank}, body mass index_{GIANT}, and schizophrenia_{PGC}). For each phenotype, rows correspond to a range of p-values thresholds used to construct polygenic scores. See Supplemental Table 3 for exact correlations and p-values.

1000Genomes populations

- African ancestry
- Americas ancestry
- East Asian ancestry
- European ancestry
- South Asian ancestry

Supplementary Figure 5. Scatterplots of principal components (PCs) and polygenic

scores for 1000Genomes participants. X-axis = scores on PC 1. Y-axis = polygenic risk score (PRS), using genome-wide significant variants to construct polygenic scores ($p_7=5x10^{-8}$).

Supplementary Figure 6. Flowchart of study inclusion for Part 1, per PRISMA example. *the first empirical polygenic scoring study (2009 Purcell et al.) did not appear in the search, apparently due to keyword mismatch issues.

Population	Total	Country
Chinese Dai in Xishuangbanna, China (CDX)	99	China
Han Chinese in Bejing, China (CHB)	106	China
Japanese in Tokyo, Japan (JPT)	105	Japan
Kinh in Ho Chi Minh City, Vietnam (KHV)	101	Vietnam
Southern Han Chinese, China (CHS)	112	China

Percent included	75.3	

Supplementary Table 1. 1000Genomes samples (from http://www.1000genomes.org/about on 8/12/14). ¹Removed due to missing height phenotype data; ²Removed due to combination of highly mixed country ancestry (impacting validity of height phenotype) and admixture of the 1000Genomes population (impacting variability in the polygenic scores for height); ³Removed due to the absence of a single European country of origin.
